ARTS and SCIENCES.

SINES.

SINE, or *Right Sine*, in *Trigonometry*, a right line drawn from one extremity of an arc, perpendicular to the radius drawn from the other extremity: or, the sine is half the chord of twice the arc.

Thus the line AD (*Plate I. Trigonometry, fig. 4.*) which is half the chord, AB , of the double arc AEB , is the right sine; or, simply, the sine of the arc AE .

SINE, *Whole*, *Sinus totus*, is the sine of the quadrant HE , or of 90° ; that is, the whole sine is the same with the radius HC .

SINE, *Verse*, is a part, ED , of the whole sine or radius intercepted between the right sine AD and the arc AE .

It is demonstrated, 1. That, the right sine AD being perpendicular to the radius EC , all sines drawn to the same radius are parallel to each other.

2. Since the arc AE is the measure of the angle ACE , and AI the measure of the contiguous angle ACI , and the quadrant HE the measure of the right angle; AD is also the right sine, and ED the verse sine, of the angles ACE and ACI , and the whole sine is the sine of the right angle.

3. Two angles contiguous, as ACE and ACI , have the same sine.

4. The sines of obtuse angles are the same with those of their complements to two right angles: or the sine of any angle, and the sine of its supplement, are the same; or the sines of arcs less than 90° , serve equally for arcs as much greater than 90° ; *i. e.* the sines of 80° and 100° , of 60° and 120° , &c. are respectively equal.

5. All sines of similar arcs have the same ratio to their radii.

6. In every triangle the sides are as the sines of the opposite angles.

SINE-Complement, or *Cofine*, is the sine of an arc AE , which is the complement of another arc AH , to a quadrant.

Thus also the sine of the arc AH is called the *sine-complement* of the arc AE . And it is plain, that the *verse sine* and *cofine*, taken together, are equal to the radius.

The sine DE (*fig. 10.*) and the *verse sine* AE , being given in common measure, not in parts of the radius, to find the arc DA in degrees. Find the semidiameter AC : then in the triangle DEC , besides the right angle E , by the sides DE and DC we find the angle ECD (ACD), which shews the number of degrees in the arc DA ; the double of which is the arc DAD . This problem is of use in finding the segment of a circle. See **SEGMENT**.

Arithmetic of Sines is a term commonly employed to denote what is perhaps more properly called *analytical trigonometry*, being a modern branch of the analytical calculus, which we owe in a great measure to the celebrated Euler, though the principal geometrical theorem on which it is founded was first pointed out by Mayer, in a memoir published in the *Acta Petro.* for 1727; but the extension of the method, and a suitable mode of notation, are undoubtedly due to Euler.

The object of this branch of science is to exhibit the relations of the sines, cosines, tangents, cotangents, &c. of arcs, multiple arcs, &c.; and it is, without doubt, owing, in some measure, to the facilities this calculus has afforded, of expressing in a simple manner formulæ, which, without its aid, would have exceeded the powers of the human mind, that astronomy, which depends so much on these relations, has attained its present high degree of perfection.

In common arithmetic, our object is to combine together different simple numbers, by addition, multiplication, &c.;

*A.E.E.
F.23
1213
v.33

or to decompose them by the reverse operations of subtraction, division, or evolution; and the rules for all these cases are plain and direct, because the units of the several parts are equal and identical. But after we quit this species of calculation, we are no longer able to proceed with the same facility; the quantities we have to combine are only the representatives of others, and have no longer the same relation with each other; whatever we fix upon as an unit, it will not have to its representative the ratio of number to number, and consequently different modes of operation then become necessary. The first case of this kind occurs in the theory of logarithms, or, as it may be called, logarithmic arithmetic. Here, if we add two quantities together, *viz.* two logarithms, the sum thus obtained does not represent a quantity that is equal in value to the two quantities; because neither of the two original logarithms, nor that which is obtained by the addition of them, are quantities connected with our research, otherwise than as they are the representatives of certain numbers, whose relation or connection is sought; and the combinations, therefore, of these artificial numbers have not the same relation with each other as those they are taken to represent. If, for example, we have given the log. a , and wish to find the log. of $3a$, we cannot, as in simple arithmetic, call the latter $3 \log. a$, but $\log. 3 + \log. a$; so also, in trigonometry, if we have given the sine a , and wish from thence to find the sine $3a$, we can neither find it by multiplication, as in arithmetic; nor by addition, as in logarithms; but must proceed in a manner wholly different from either: and this process, (which we will now endeavour to illustrate) is what is here to be understood by the arithmetic of sines.

The notation used in this calculus is very simple, being as follows; *viz.* a being any angle, we denote

the sine of a , by $\sin. a$
 the cosine of a , by $\cos. a$
 the sine of $2a, 3a, \dots$ } by $\sin. 2a, \sin. 3a,$
 $4a, \dots n a,$ } $\sin. 4a, \dots \sin. n a$
 the cosine of $2a, 3a, \dots$ } by $\cos. 2a, \cos. 3a,$
 $4a, \dots n a,$ } $\cos. 4a, \dots \cos. n a$

In a similar manner,

the tangent of a is denoted by $\tan. a$
 the cotangent of a , by $\cot. a$
 the secant of a , by $\sec. a$
 the cosecant of a , by $\csc. a$
 the versed sine of a , by $\text{vers. } a$

And the several multiples of these in the same manner as above explained for the sines and cosines; thus the tangent, secant, cosecant, &c. of $2a, 3a, na, \dots$ are written $\tan. 2a, \sec. 3a, \csc. na, \dots$

Again, the powers of any of those lines are denoted by placing the index of the power over the name of the line; thus,

the square of the sine of a , by $\sin.^2 a$
 the cube of the cosine of a , by $\cos.^3 a$
 the cube of the tangent of a , by $\tan.^3 a$
 the n th power of the cotangent a , by $\cot.^n a$
 &c. &c. &c.

Having thus shewn the nature of the notation which is now universally adopted, it will not be amiss to say a few words relative to the value of the several trigonometrical lines, as the arc increases from 0 to the whole circumference; for though, in the more simple application of sines and cosines, as in the doctrine of plane trigonometry, we

have never to contemplate an arc greater than a semicircle; we have, in the more extended doctrine of sines, to consider angles of all possible magnitudes, and generally as functions of the arcs to which they correspond, or as general analytical expressions, whose values depend entirely on those of the arcs, and which may be of any magnitude. We have, therefore, frequently to treat of arcs, which it would be impossible to exhibit geometrically: and it is, therefore, of the highest importance to understand clearly the nature of the changes and variations which take place in the numerical values, and in the positions or signs of the different trigonometrical lines, while the arc increases from 0 to the whole circumference.

The value of these lines at certain determinate points, as at the 1st, 2d, 3d, and 4th quadrant, is absolutely necessary for laying the foundation of our analytical calculus; but with regard to the variation of position of those lines, which is analytically exhibited by a change of sign, we might dispense with it in this place, and depend wholly upon the deductions arising out of our general formulae: but as it is satisfactory to see the precise agreement between the analytical and geometrical mode of considering the subject, and as it will occupy but a few words, we shall trace the variation, both in sign and magnitude, of the sines and cosines through the first circumference, and afterwards shew the same from the analytical expressions. For this purpose, let $A B C D$ (*fig. 8.*) be a circle, having the several lines as exhibited in the figure, and suppose one of the extremities, as A , of an arc $A M$, to remain fixed, while the other extremity, M , passes successively over the circumference of the circle, through $C B D$, to A again.

Then, as the sine $M P$ continually recedes from A , till the point M arrives at B , and afterwards approaches towards A , on the other side of the diameter $A B$, till it is united with it again, it is evident that the sines of all arcs in the first semicircle have a different direction to those in the second, and we therefore consider the first as affirmative, or $+$, and the others as negative, or $-$.

It is also obvious that the sine $M P$ increases from 0, during the first quadrant $A C$, till at the end of it, it becomes equal to the radius; and that it decreases in the second quadrant to B , where it is again equal to zero. In the third quadrant it increases from B to D , where it is again equal to radius; but the signs being here negative throughout, it is equal to $- \text{rad.}$; after which it decreases till it arrives at A , where the sine is once more equal to 0.

In like manner, the cosine $O P$, being referred to the centre O , will become negative as often as it passes that point; and as this takes place both when the arc $A M$ becomes greater than $A C$, and when by its farther increase it is greater than $A B C D$, it is evident that the cosines of all arcs in the first and fourth quadrants are affirmative or $+$, and those of the second and third quadrants negative or $-$.

It is also obvious that the cosine $O P$ is equal to the radius, when the arc $A M$ is $= 0$, and that it continually decreases during the first quadrant $A C$; and at the end of it, becomes zero or 0. It then increases negatively during the second quadrant, and is at $B = - \text{rad.}$ It then decreases negatively in the third quadrant, and at D is again equal to zero. It then increases positively, till at A it is equal to radius, as before.

The same changes of sign will again obviously recur, both in the sine and cosine, if we suppose the radius $A M$ to pass a second, a third, &c. time over the circumference. We

SINES.

may, therefore, from what has been said, draw the following general conclusion. Let π be taken to represent the semi-circumference, and making rad. = 1; then,

$$\begin{aligned} \sin. 0\pi &= 0, & \sin. \frac{1}{2}\pi &= 1, & \sin. \pi &= 0, & \sin. \frac{3}{2}\pi &= -1, & \sin. 2\pi &= 0; \\ \cos. 0\pi &= 1, & \cos. \frac{1}{2}\pi &= 0, & \cos. \pi &= -1, & \cos. \frac{3}{2}\pi &= 0, & \cos. 2\pi &= 1. \end{aligned}$$

We may, on the same principles, demonstrate that

$$\begin{aligned} \tan. 0\pi &= 0, & \tan. \frac{1}{2}\pi &= \infty, & \tan. \pi &= 0, & \tan. \frac{3}{2}\pi &= \infty, & \tan. 2\pi &= 0; \\ \cot. 0\pi &= \infty, & \cot. \frac{1}{2}\pi &= 0, & \cot. \pi &= \infty, & \cot. \frac{3}{2}\pi &= 0, & \cot. 2\pi &= \infty; \\ \sec. 0\pi &= 1, & \sec. \frac{1}{2}\pi &= \infty, & \sec. \pi &= -1, & \sec. \frac{3}{2}\pi &= \infty, & \sec. 2\pi &= 1; \\ \operatorname{cosec}. 0\pi &= \infty, & \operatorname{cosec}. \frac{1}{2}\pi &= 1, & \operatorname{cosec}. \pi &= \infty, & \operatorname{cosec}. \frac{3}{2}\pi &= -1, & \operatorname{cosec}. 2\pi &= \infty. \end{aligned}$$

In addition to the preceding deductions, it may not be amiss to refer, in this place, to the relations subsisting between the different trigonometrical lines; but as these are mere simple analogies, which follow immediately from the

definitions themselves, it will, we presume, be deemed quite sufficient, if we exhibit them only, without going over the operations by which they are obtained. The most important of these are as follow, *viz.*

$$\begin{aligned} \sin. a &= \frac{\cos. a}{\cot. a} = \cos. a \cdot \tan. a = \sqrt{(1 - \cos.^2 a)} = \frac{1}{\sqrt{(1 + \cot.^2 a)}} = \frac{\tan. a}{\sqrt{(1 + \tan.^2 a)}} = \frac{1}{\operatorname{cosec}. a}; \\ \cos. a &= \frac{\sin. a}{\tan. a} = \sin. a \cdot \cot. a = \sqrt{(1 - \sin.^2 a)} = \frac{1}{\sqrt{(1 + \tan.^2 a)}} = \frac{\cot. a}{\sqrt{(1 + \cot.^2 a)}} = \frac{1}{\sec. a}. \end{aligned}$$

We may now establish our fundamental proposition, which, in words at length, may be stated thus.

Theorem.—The sine of the sum of two arcs is equal to the sum of the products of the sine of each, multiplied by the cosine of the other, divided by radius; or, according to our notation, in which we denote one arc by a , and the other by b , and make the radius = 1, it becomes

$$\sin. (a + b) = \sin. a \cdot \cos. b + \sin. b \cdot \cos. a.$$

Let AB (*fig. 9.*) represent the arc a , and AC the arc b ; BD and OD being the sine and cosine of the former, and AF and OF the sine and cosine of the latter; also BG the sine of the sum; we have to prove that

$$OA \cdot BG = BD \cdot OF + AF \cdot OD.$$

Draw DH parallel to OC, or perpendicular to BG; then the three right-angled triangles, HBD, ODE, OAF, are similar, and we have

$$AO : OF : BD : BH$$

$$\text{Also, } AO : OD : AF : DE \text{ or } HG.$$

Consequently,

$$OA \cdot BH + AO \cdot HG = BD \cdot OF + AF \cdot OD, \\ \text{or } OA \cdot BG = BD \cdot OF + AF \cdot OD.$$

And consequently, when the radius OA = 1, we have

$$\sin. (a + b) = \sin. a \cdot \cos. b + \sin. b \cdot \cos. a.$$

This one general formula would be sufficient for all our purpose, in establishing the doctrine of sines; but we prefer drawing also a second, as it follows immediately from the same principles as the above; *viz.*

$$\cos. (a + b) = \cos. a \cdot \cos. b - \sin. a \cdot \sin. b.$$

$$\text{For as } OA : AF :: BD : HD \text{ or } GE$$

$$OA : OF :: OD : OE;$$

therefore,

$$OA \cdot OE - OA \cdot GE = OF \cdot OD - AF \cdot BD, \\ \text{or } OA \cdot OG = OF \cdot OD - AF \cdot BD.$$

And when OA = radius = 1, this becomes

$$\cos. (a + b) = \cos. a \cdot \cos. b - \sin. a \cdot \sin. b.$$

If now we repeat these two, *viz.*

$$\begin{aligned} \sin. (a + b) &= \sin. a \cdot \cos. b + \sin. b \cdot \cos. a \\ \cos. (a + b) &= \cos. a \cdot \cos. b - \sin. a \cdot \sin. b; \end{aligned}$$

and multiply the first by $\cos. b$, and the second by $\sin. b$, and subtract the results, we shall have

$$\sin. (a + b) \cos. b - \cos. (a + b) \sin. b = \frac{\sin. a (\cos.^2 b + \sin.^2 b)}{\sin. a (\cos.^2 b + \sin.^2 b)};$$

or, since $\cos.^2 b + \sin.^2 b = 1$, this is

$$\sin. a = \sin. (a + b) \cdot \cos. b - \cos. (a + b) \sin. b.$$

If now we make $a + b = a'$, then $a = a' - b$, and we have $\sin. (a' - b) = \sin. a' \cos. b - \sin. b \cdot \cos. a'$, which is a third general formula.

Again, multiplying the first of the above formulæ by $\sin. b$, and the latter by $\cos. b$, and adding the results, we obtain

$$\sin. (a + b) \sin. b + \cos. (a + b) \cos. b = \frac{\cos. a (\cos.^2 b + \sin.^2 b)}{\cos. a (\cos.^2 b + \sin.^2 b)};$$

or, since $\cos.^2 b + \sin.^2 b = 1$,

$$\cos. a = \cos. (a + b) \cos. b + \sin. (a + b) \sin. b.$$

Or making $a + b = a'$, as above,

$$\cos. (a' - b) + \cos. a' \cos. b = \sin. a' \sin. b;$$

which is a fourth general formula.

In the two latter expressions we have used a' for a ; but it is obvious that this was merely for the sake of distinction, and that it is not necessary to retain it in our future operations.

These four formulæ being the foundation of the whole calculus of sines, we shall repeat them here in a connected order, whereby their analogy and relation will be more readily discovered; it will also be convenient for the sake of reference.

$$\begin{aligned} 1. \sin. (a + b) &= \sin. a \cdot \cos. b + \sin. b \cdot \cos. a \\ 2. \cos. (a + b) &= \cos. a \cdot \cos. b - \sin. a \cdot \sin. b \\ 3. \sin. (a - b) &= \sin. a \cdot \cos. b - \sin. b \cdot \cos. a \\ 4. \cos. (a - b) &= \cos. a \cdot \cos. b + \sin. a \cdot \sin. b \end{aligned} \quad (1).$$

Or they may be reduced to two, by means of the double sign \pm , thus:

1. $\text{fin. } (a \pm b) = \text{fin. } a \cdot \text{cof. } b \pm \text{fin. } b \cdot \text{cof. } a.$
2. $\text{cof. } (a \pm b) = \text{cof. } a \cdot \text{cof. } b \mp \text{fin. } a \cdot \text{fin. } b.$

In order to find similar formulæ for the tangents, cotangents, secants, cosecants, &c. we may put our second expression under the form,

$$\text{cof. } (a \pm b) = \left(1 \mp \frac{\text{fin. } a \cdot \text{fin. } b}{\text{cof. } a \cdot \text{cof. } b} \right) \text{cof. } a \cdot \text{cof. } b.$$

And if now we divide formula 1 by this, we have, by observing that $\frac{\text{fin. } a}{\text{cof. } a} = \tan. a,$

3. $\tan. (a \pm b) = \frac{\tan. a \pm \tan. b}{1 \mp \tan. a \cdot \tan. b}.$

4. $\cot. (a \pm b) = \frac{\cot. a \cdot \cot. b \mp 1}{\cot. b \pm \cot. a};$

the latter being obtained by dividing the second formula by the first.

Again, taking the reciprocal of formula 2, we have

$$\frac{1}{\text{cof. } (a \pm b)} = \frac{1}{1 \mp \tan. a \cdot \tan. b} \cdot \frac{1}{\text{cof. } a \cdot \text{cof. } b}; \text{ or,}$$

5. $\text{sec. } (a \pm b) = \frac{\text{sec. } a \cdot \text{sec. } b}{1 \mp \tan. a \cdot \tan. b}.$

6. $\text{cof. } (a \pm b) = \frac{\text{cosec. } a \cdot \text{cosec. } b}{\cot. b \pm \cot. a}.$

In like manner may be found,

7. $\text{cho. } (a \pm b) = \text{cho. } a \cdot \text{sup. cho. } b \pm \text{cho. } b \cdot \text{sup. cho. } a.$

8. $\text{verf. } (a \pm b) = \sqrt{\text{verf. } a \cdot \text{sup. verf. } b} \pm \sqrt{\text{verf. } b \cdot \text{sup. verf. } a}.$

The reader will find a different investigation of these properties under the article *Geometry of POSITION*.

Let us now see how far these general formulæ will indicate the changes of signs in the trigonometrical lines, as connected with the several different magnitudes of their respective arcs; a subject that we have already considered geometrically.

Let π denote the semicircle, and let the arc $a = \frac{1}{2}\pi$; then because $\text{fin. } \frac{1}{2}\pi = 1,$ and $\text{cof. } \frac{1}{2}\pi = 0,$ we have from

- Formula (1) $\text{fin. } (\frac{1}{2}\pi + b) = + \text{cof. } b.$
- (2) $\text{cof. } (\frac{1}{2}\pi + b) = - \text{fin. } b.$
- (3) $\text{fin. } (\frac{1}{2}\pi - b) = + \text{cof. } b.$
- (4) $\text{cof. } (\frac{1}{2}\pi - b) = + \text{fin. } b.$

Here we obtain the same results as before deduced; that is, it is obvious from these, that if we consider the sine and cosine of an arc less than a quadrant as positive quantities, the cosine of an arc greater than a quadrant, but less than a semicircle, will be negative, but its sine positive.

Again, let the arc $a = \pi$; then because $\text{fin. } \pi = 0,$ $\text{cof. } \pi = -1,$ we have

$$\begin{aligned} \text{fin. } (\pi + b) &= - \text{fin. } b; & \text{cof. } (\pi + b) &= - \text{cof. } b; \\ \text{fin. } (\pi - b) &= + \text{fin. } b; & \text{cof. } (\pi - b) &= - \text{cof. } b. \end{aligned}$$

Whence it follows, that the sines of angles greater than a semicircle, but less than a circle, have negative signs; while

those that are less than a semicircle are positive: whereas the cosines of angles equally above and below the semicircle have the same signs.

If now we assume the arc $a = \frac{3}{2}\pi$; then, because $\text{fin. } \frac{3}{2}\pi = -1,$ and $\text{cof. } \frac{3}{2}\pi = 0,$ we have

$$\begin{aligned} \text{fin. } (\frac{3}{2}\pi + b) &= - \text{cof. } b; & \text{cof. } (\frac{3}{2}\pi + b) &= + \text{fin. } b; \\ \text{fin. } (\frac{3}{2}\pi - b) &= - \text{cof. } b; & \text{cof. } (\frac{3}{2}\pi - b) &= - \text{fin. } b. \end{aligned}$$

Therefore, when the arc is comprehended between $\frac{3}{2}\pi, 2\pi,$ its cosine is positive, and its sine negative. These results have all been previously established geometrically; but they are here very readily extended to any arcs expressed by

$\frac{n}{2}\pi \pm b;$ n being any number whatever. These are all contained in the following general formulæ, *viz.*

$$\text{fin. } \left(\frac{4n+1}{2}\pi \pm b \right) = + \text{cof. } b.$$

$$\text{fin. } \left(\frac{4n+2}{2}\pi \pm b \right) = \mp \text{fin. } b.$$

$$\text{fin. } \left(\frac{4n+3}{2}\pi \pm b \right) = - \text{cof. } b.$$

$$\text{fin. } \left(\frac{4n+4}{2}\pi \pm b \right) = \pm \text{fin. } b.$$

$$\text{cof. } \left(\frac{4n+1}{2}\pi \pm b \right) = \mp \text{fin. } b.$$

$$\text{cof. } \left(\frac{4n+2}{2}\pi \pm b \right) = - \text{cof. } b.$$

$$\text{cof. } \left(\frac{4n+3}{2}\pi \pm b \right) = \pm \text{fin. } b.$$

$$\text{cof. } \left(\frac{4n+4}{2}\pi \pm b \right) = + \text{cof. } b.$$

Hence it follows, that there is an indefinite number of arcs that have the same sine and cosine, as also the same secant and tangent; the conditions of which latter are readily deduced from the above, by means of the formula

$$\tan. a = \frac{\text{cof. } a}{\text{fin. } a}, \quad \cot. a = \frac{\text{fin. } a}{\text{cof. } a}, \quad \text{sec. } a = \frac{1}{\text{cof. } a}, \quad \&c.$$

For since $\tan. a = \frac{\text{fin. } a}{\text{cof. } a},$ and $\cot. a = \frac{\text{cof. } a}{\text{fin. } a},$ it fol-

lows, that the tangent will be positive, while $\text{fin. } a$ and $\text{cof. } a$ have the same signs; and negative, when the signs are different; and the same also with the cotangents: these are, therefore, both positive in the first and third quadrants, and negative in the second and fourth. Also the tangent is infinite when the $\text{cof.} = 0,$ and cotangent infinite when

$\text{fin.} = 0.$ Again, since $\text{sec. } a = \frac{1}{\text{cof. } a},$ and $\text{cosec. } a = \frac{1}{\text{fin. } a},$

it follows that these lines have the same signs as the cof. and fin. respectively; and that the secant is infinite when $\text{cof.} = 0,$ and the cosecant infinite when $\text{fin.} = 0.$

Having thus shewn the relations between the several trigonometrical lines, their mutations and determinate values, under certain magnitudes of the arcs to which they appertain, we shall proceed in the next place to investigate some of the principal formulæ for the sines, cosines, &c. of multiple arcs.

SINES.

Of Multiple Arcs.

By referring to our formula (I), we have

$$\sin. (a + b) = \sin. a \cdot \text{cof. } b + \sin. b \cdot \text{cof. } a;$$

which, by writing $(n - 1) a$ for a , and a for b , becomes

$$\sin. n a = \sin. (n - 1) a \cdot \text{cof. } a + \text{cof. } (n - 1) a \cdot \sin. a.$$

By substituting in this formula for $\sin. (n - 1) a$, and $\text{cof. } (n - 1) a$, under the form

$$\begin{aligned} & \sin. \left\{ (n - 2) a + a \right\} \text{ and } \text{cof. } \left\{ (n - 1) a + a \right\}, \text{ we obtain} \\ \sin. n a = & \left\{ \sin. (n - 2) \cdot \text{cof. } a + \text{cof. } (n - 2) a \cdot \sin. a \right\} \text{cof. } a \\ & + \left\{ \text{cof. } (n - 2) a \cdot \text{cof. } a - \sin. (n - 2) a \cdot \sin. a \right\} \sin. a \end{aligned}$$

Substituting here again for $(n - 2) a$, under the form $(n - 3) a + a$, and observing that the second term of the first line is the same as the first of the second, we have

$$\begin{aligned} \sin. n a = & \left\{ \sin. (n - 3) a \cdot \text{cof. } a + \text{cof. } (n - 3) a \cdot \sin. a \right\} \text{cof.}^2 a \\ & + 2 \left\{ \text{cof. } (n - 3) a \cdot \text{cof. } a - \sin. (n - 3) a \cdot \sin. a \right\} \text{cof. } a \cdot \sin. a \\ & - \left\{ \sin. (n - 3) a \cdot \text{cof. } a + \text{cof. } (n - 3) a \cdot \sin. a \right\} \sin.{}^2 a \end{aligned}$$

$= \sin. (n - 3) a \cdot \text{cof.}^3 a + 3 \text{cof. } (n - 3) a \cdot \text{cof.}^2 a \cdot \sin. a - 3 \sin. (n - 3) a \text{cof. } a \cdot \sin.{}^2 a - \text{cof. } (n - 3) a \cdot \sin.{}^3 a$;
the last term of each of those lines being still the same as the first term of the following; and therefore, without pursuing the operation any farther, the law of continuation is obvious; *viz.* the several coefficients will be exactly those of the binomial; but the signs will be two *plus* and two *minus* alternately, whence generally

$$\sin. n a = \sin. (n - m) a \cdot \text{cof.}^m a + A \text{cof. } (n - m) a \cdot \text{cof.}^{m-1} a \sin. a - B \sin. (n - m) a \cdot \text{cof.}^{m-2} a \sin.{}^2 a - C \text{cof. } (n - m) a \text{cof.}^{m-3} a \cdot \sin.{}^3 a + \&c.$$

where A, B, C, &c. are the coefficients of $(1 + 1)^m$.

And exactly in the same manner, we find

$$\text{cof. } n a = \text{cof. } (n - m) a \cdot \text{cof.}^m a - A \sin. (n - m) a \text{cof.}^{m-1} a \sin. a - B \text{cof. } (n - m) a \cdot \text{cof.}^{m-2} a \cdot \sin.{}^2 a + C \sin. (n - m) a \cdot \text{cof.}^{m-3} a \cdot \sin.{}^3 a + \&c.$$

In these formulæ m is indeterminate, and may be assumed at pleasure; let us therefore take $m = n$, and we have

$$\sin. n a = A \text{cof.}^{n-1} a \cdot \sin. a - C \text{cof.}^{n-3} a \cdot \sin.{}^3 a + E \text{cof.}^{n-5} a \cdot \sin.{}^5 a - \&c. \quad (\text{II.})$$

and

$$\text{cof. } n a = \text{cof.}^n a - B \text{cof.}^{n-2} a \cdot \sin.{}^2 a + D \text{cof.}^{n-4} a \cdot \sin.{}^4 a - \&c. \quad (\text{III.})$$

where A, B, C, &c. represent the coefficients of $(1 + 1)^n$.

From these two general formulæ we readily deduce the following particular cases; *viz.*

1. $\sin. a = 1 \sin a$
2. $\sin. 2 a = 2 \text{cof. } a \cdot \sin. a$
3. $\sin. 3 a = 3 \text{cof.}^2 a \cdot \sin. a - \sin.{}^3 a$
4. $\sin. 4 a = 4 \text{cof.}^3 a \cdot \sin. a - 4 \text{cof. } a \sin.{}^3 a$
5. $\sin. 5 a = 5 \text{cof.}^4 a \cdot \sin. a - 10 \text{cof.}^2 a \sin.{}^3 a + \sin.{}^5 a$
- &c. = &c.

1. $\text{cof. } a = \text{cof. } a$
2. $\text{cof. } 2 a = \text{cof.}^2 a - \sin.{}^2 a$
3. $\text{cof. } 3 a = \text{cof.}^3 a - 3 \text{cof. } a \cdot \sin.{}^2 a$
4. $\text{cof. } 4 a = \text{cof.}^4 a - 6 \text{cof.}^2 a \cdot \sin.{}^2 a + \sin.{}^4 a$
5. $\text{cof. } 5 a = \text{cof.}^5 a - 10 \text{cof.}^3 a \cdot \sin.{}^2 a + 5 \text{cof. } a \cdot \sin.{}^4 a$
- &c. = &c.

These, it is obvious, may be continued at pleasure, the law of the coefficients being exhibited in the above general formulæ.

SINES.

In the formulæ of (II) and (III), the $\sin. a$ and $\cos. a$ both enter; but as $\sin.^2 a = 1 - \cos.^2 a$, we may, by substitution in the latter, express the $\cos. n a$ in terms of the $\cos. a$ only; but in the former, in consequence of the odd powers of the sine, we cannot exterminate either the $\sin. a$ or $\cos. a$ entirely; the simplest state of these formulæ, after the above substitution, is as follows; *viz.*

$$\sin. n a = \left\{ (2 \cos. a)^{n-1} - \frac{n-2}{1} (2 \cos. a)^{n-3} + \frac{(n-3)(n-4)}{1 \cdot 2} (2 \cos. a)^{n-5} \right. \\ \left. - \frac{(n-4)(n-5)(n-6)}{1 \cdot 2 \cdot 3} (2 \cos. a)^{n-7} + \&c. \right\} \sin. a \quad (\text{IV.})$$

$$\cos. n a = \frac{1}{2} \left\{ (2 \cos. a)^n - n (2 \cos. a)^{n-2} + \frac{n(n-3)}{1 \cdot 2} (2 \cos. a)^{n-4} \right. \\ \left. - \frac{n(n-4)(n-5)}{1 \cdot 2 \cdot 3} (2 \cos. a)^{n-6} + \&c. \right\} \quad (\text{V.})$$

From which the following particular cases are readily drawn, *viz.*

1. $\sin. a = 1 \sin. a$
2. $\sin. 2 a = 2 \cos. a \cdot \sin. a$
3. $\sin. 3 a = (4 \cos.^2 a - 1) \sin. a$
4. $\sin. 4 a = (8 \cos.^3 a - 4 \cos. a) \sin. a$
5. $\sin. 5 a = (16 \cos.^4 a - 12 \cos.^2 a + 1) \sin. a$
- &c. = &c.

1. $\cos. a = 1 \cos. a$
2. $\cos. 2 a = 2 \cos.^2 a - 1$
3. $\cos. 3 a = 4 \cos.^3 a - 3 \cos. a$
4. $\cos. 4 a = 8 \cos.^4 a - 8 \cos.^2 a + 1$
5. $\cos. 5 a = 16 \cos.^5 a - 20 \cos.^3 a + 3 \cos. a$
- &c. = &c.

If we refer again to our formula (I), *viz.*

$$\sin. (a + b) = \sin. a \cdot \cos. b + \sin. b \cdot \cos. a \\ \cos. (a + b) = \cos. a \cdot \cos. b - \sin. a \cdot \sin. b$$

we readily draw from these the following, *viz.*

$$\sin. (n + 1) a = \sin. n a \cdot \cos. a + \cos. n a \sin. a \\ \cos. (n + 1) a = \cos. n a \cdot \cos. a - \sin. n a \sin. a$$

Multiplying now the first by any indefinite quantity v , and adding it to the second, we obtain

$$\cos. (n + 1) a + v \sin. (n + 1) a \\ = \left\{ \begin{array}{l} (\cos. a + v \sin. a) \cos. n a \\ + (\cos. a - \frac{1}{v} \sin. a) v \sin. n a \end{array} \right.$$

Where, by taking for the indefinite quantity v , the particular value $\sqrt{-1}$, so that $v = -\frac{1}{v}$, these will become

$$\cos. (n + 1) a + v \sin. (n + 1) a = (\cos. a + v \sin. a) \cos. n a \\ (\cos. n a + v \sin. n a)$$

whence, making n successively = 1, 2, 3, &c. we obtain

$$\cos. 2 a + v \sin. 2 a = (\cos. a + v \sin. a)^2 \\ \cos. 3 a + v \sin. 3 a = (\cos. a + v \sin. a)^3 \\ \cos. 4 a + v \sin. 4 a = (\cos. a + v \sin. a)^4 \\ \cos. 5 a + v \sin. 5 a = (\cos. a + v \sin. a)^5 \\ \vdots \\ \cos. n a + v \sin. n a = (\cos. a + v \sin. a)^n \quad (\text{VI.})$$

If, instead of adding the two formulæ, after multiplying the first by v , we subtract the first from the second, we shall get

$$\cos. (n + 1) a - v \sin. (n + 1) a \\ = \left\{ \begin{array}{l} (\cos. a - v \sin. a) \cos. n a \\ - (\cos. a + \frac{1}{v} \sin. a) v \sin. n a \end{array} \right.$$

Where, by giving the same value, *viz.* $\sqrt{-1}$, to v , we have

$$\cos. (n + 1) a - v \sin. (n + 1) a \\ (\cos. a - v \sin. a) (\cos. n a - v \sin. n a)$$

and making again $n = 1, 2, 3,$ &c. we obtain

$$\cos. 2 a - v \sin. 2 a = (\cos. a - v \sin. a)^2 \\ \cos. 3 a - v \sin. 3 a = (\cos. a - v \sin. a)^3 \\ \cos. 4 a - v \sin. 4 a = (\cos. a - v \sin. a)^4 \\ \cos. 5 a - v \sin. 5 a = (\cos. a - v \sin. a)^5 \\ \vdots \\ \cos. n a - v \sin. n a = (\cos. a - v \sin. a)^n \quad (\text{VII.})$$

Whence by addition and subtraction, and establishing the value of v ,

$$\cos. n a = \frac{1}{2} \left\{ (\cos. a + \sqrt{-1} \cdot \sin. a)^n + (\cos. a - \sqrt{-1} \cdot \sin. a)^n \right\}$$

$$\sin. n a = \frac{1}{2 \sqrt{-1}} \left\{ (\cos. a + \sqrt{-1} \sin. a)^n - (\cos. a - \sqrt{-1} \sin. a)^n \right\}$$

If in these two formulæ we substitute $\cos. a = x$, $\sin. a = \sqrt{1 - x^2}$; then $\sqrt{-1} (\sin. a) = \sqrt{x^2 - 1}$, and we have

$$\cos. n a = \frac{1}{2} \left\{ (x + \sqrt{x^2 - 1})^n + (x - \sqrt{x^2 - 1})^n \right\}$$

$$\sin. n a = \frac{1}{2 \sqrt{-1}} \left\{ (x + \sqrt{x^2 - 1})^n - (x - \sqrt{x^2 - 1})^n \right\}$$

And assuming $x = y + \frac{1}{y}$, so that $x^2 - 1$ may be a complete square, or $\sqrt{x^2 - 1} = y - \frac{1}{y}$; these expressions reduce to

$$\cos. n a = \frac{1}{2} \left(y^n + \frac{1}{y^n} \right) \quad (\text{VIII.})$$

$$\sin. n a = \frac{1}{2 \sqrt{-1}} \left(y^n - \frac{1}{y^n} \right) \quad (\text{IX.})$$

From

SINES.

From which the following particular cases readily flow; which are the most elegant expressions we have for the sines and cosines of multiple arcs.

For a farther application of these formulæ to the doctrine of sines and cosines, see the article *Cotesian THEOREM*.

It may not be amiss to add, with regard to the history of the invention of these formulæ, that both the general and particular cases of the numbers (II) and (III) were first given by John Bernoulli, in the Leipzig Acts for 1701; those of numbers (IV) and (V) were published by Vieta, under the denomination *angular sections*; but he regarded them not as properties of sines and cosines, but as those of chords and their supplements, to which they are easily reduced. The other four formulæ, viz. (VI), (VII), (VIII), (IX), are all derived from a formula published by De Moivre in his "Miscellanea Analytica."

In order to investigate formulæ for the multiple tangents and cotangents, we may repeat here our formulæ (II) and (III); viz.

$$\begin{aligned} \sin. n a &= A \cos.^{n-1} a \sin. a - C \cos.^{n-3} a \sin.^3 a + E \cos.^{n-5} a \sin.^5 a - \&c. \\ \cos. n a &= \cos.^n a - B \cos.^{n-2} a \sin.^2 a + D \cos.^{n-4} a \sin.^4 a - \&c. \end{aligned}$$

where 1, A, B, C, &c. represent the coefficients of $(1 + 1)^n$.

Writing these under the form

$$\begin{aligned} \sin. n a &= \left\{ A \frac{\sin. a}{\cos. a} - C \frac{\sin.^3 a}{\cos.^3 a} + E \frac{\sin.^5 a}{\cos.^5 a} - \&c. \right\} \cos.^n a \\ \cos. n a &= \left\{ 1 - B \frac{\sin.^2 a}{\cos.^2 a} + D \frac{\sin.^4 a}{\cos.^4 a} - \&c. \right\} \cos.^n a \end{aligned}$$

and dividing the former by the latter, and observing that $\frac{\sin. a}{\cos. a} = \tan. a$; we have

$$\tan. a = \frac{A \tan. a - C \tan.^3 a + E \tan.^5 a - \&c.}{1 - B \tan.^2 a + D \tan.^4 a - \&c.} \quad (X.)$$

Or writing them under the form

$$\begin{aligned} \sin. n a &= \left\{ A \frac{\cos.^{n-1} a}{\sin.^{n-1} a} - C \frac{\cos.^{n-3} a}{\sin.^{n-3} a} + E \frac{\cos.^{n-5} a}{\sin.^{n-5} a} - \&c. \right\} \sin. n a \\ \cos. n a &= \left\{ \frac{\cos.^n a}{\sin.^n a} - B \frac{\cos.^{n-2} a}{\sin.^{n-2} a} + D \frac{\cos.^{n-4} a}{\sin.^{n-4} a} - \&c. \right\} \sin. n a \end{aligned}$$

and dividing the latter by the former, we have

$$\cot. n a = \frac{A \cot.^{n-1} a - C \cot.^{n-3} a + E \cot.^{n-5} a - \&c.}{\cot.^n a - B \cot.^{n-2} a + D \cot.^{n-4} a - \&c.} \quad (XI.)$$

From these we draw the following particular cases.

1. $\tan. a = \tan. a$	1. $\cot. a = \cot. a$
2. $\tan. 2 a = \frac{2 \tan. a}{1 - \tan.^2 a}$	2. $\cot. 2 a = \frac{\cot.^2 a - 1}{2 \cot. a}$
3. $\tan. 3 a = \frac{3 \tan. a - \tan.^3 a}{1 - 3 \tan.^2 a}$	3. $\cot. 3 a = \frac{\cot.^3 a - 3 \cot. a}{3 \cot.^2 a - 1}$
4. $\tan. 4 a = \frac{4 \tan. a - 4 \tan.^3 a}{1 - 6 \tan.^2 a + \tan.^4 a}$	4. $\cot. 4 a = \frac{\cot. 4 a - 6 \cot.^2 a + 1}{4 \cot.^3 a - 4 \cot. a}$
5. $\tan. 5 a = \frac{5 \tan. a - 10 \tan.^3 a + \tan.^5 a}{1 - 10 \tan.^2 a + 5 \tan.^4 a}$	5. $\cot. 5 a = \frac{\cot.^5 a - 10 \cot.^3 a + 5 \cot. a}{5 \cot.^4 a - 10 \cot.^2 a + 1}$
&c. = &c.	&c. = &c.

In order to obtain similar formulæ for the secants and cosecants, we must avail ourselves of the formulæ (IV) and (V), which may be written

$$\begin{aligned} \sin. n a &= \left\{ 2^{n-1} - \frac{n-2}{1} \cdot 2^{n-3} \frac{1}{\cos. a} + \frac{(n-3)(n-4)}{1 \cdot 2} \cdot 2^{n-5} \frac{1}{\cos.^3 a} - \&c. \right\} \cos.^{n-1} a \cdot \sin. a \\ \cos. n a &= \frac{1}{2} \left\{ 2^n - n \cdot 2^{n-2} \frac{1}{\cos.^2 a} + \frac{n(n-3)}{1 \cdot 2} \cdot 2^{n-4} \frac{1}{\cos.^4 a} - \&c. \right\} \cos.^n a \end{aligned}$$

SINES.

$$\text{or, } \sin. n a = \left\{ 2^{n-1} - \frac{n-2}{1} \cdot 2^{n-3} \sec.^2 a + \frac{(n-3)(n-4)}{1 \cdot 2} \cdot 2^{n-5} \sec.^4 a \right\} \frac{1}{\sec.^{n-1} a \cdot \text{cofec. } a}$$

$$\text{cof. } n a = \left\{ 2^{n-1} - n \cdot 2^{n-3} \sec.^2 a + \frac{n(n-3)}{1 \cdot 2} \cdot 2^{n-5} \sec.^4 a - \&c. \right\} \frac{1}{\sec.^n a}$$

The reciprocal of the latter gives,

$$\text{fec. } n a = \frac{\sec.^n a}{2^{n-1} - n \cdot 2^{n-3} \sec.^2 a + \frac{n(n-3)}{1 \cdot 2} \cdot 2^{n-5} \sec.^4 a - \&c.} \quad (\text{XII.})$$

And the reciprocal of the former,

$$\text{cofec. } n a = \frac{\sec.^{n-1} a \cdot \text{cofec. } a}{2^{n-1} - \frac{n-2}{1} \cdot 2^{n-3} \sec.^2 a + \frac{(n-3)(n-4)}{1 \cdot 2} \cdot 2^{n-5} \sec.^4 a - \&c.} \quad (\text{XIII.})$$

From these we draw the following particular cases :

1. $\text{fec. } a = \sec. a$	1. $\text{cofec. } a = \text{cofec. } a$
2. $\text{fec. } 2 a = \frac{\sec.^2 a}{2 - \sec.^2 a}$	2. $\text{cofec. } 2 a = \frac{\sec. a \cdot \text{cofec. } a}{2}$
3. $\text{fec. } 3 a = \frac{\sec.^3 a}{4 - 3 \sec.^2 a}$	3. $\text{cofec. } 3 a = \frac{\sec.^2 a \cdot \text{cofec. } a}{4 - \sec.^2 a}$
4. $\text{fec. } 4 a = \frac{\sec.^4 a}{8 - 8 \sec.^2 a + \sec.^4 a}$	4. $\text{cofec. } 4 a = \frac{\sec.^3 a \cdot \text{cofec. } a}{8 - 4 \sec.^2 a}$
5. $\text{fec. } 5 a = \frac{\sec.^5 a}{16 - 20 \sec.^2 a + 5 \sec.^4 a}$	5. $\text{cofec. } 5 a = \frac{\sec.^4 a \cdot \text{cofec. } a}{16 - 12 \sec.^2 a + \sec.^4 a}$
&c. = &c.	&c. = &c.

These latter formulæ have the same defect as those of the sines from which they are derived; *viz.* that both the secant and cofecant of the single arc enter in the general expression for the cofecant of the multiple arc.

We shall not investigate the formula for the multiple versed sine, but shall content ourselves with merely exhibiting the result, which is as follows :

$$\text{vers. } n a = n^2 \text{vers. } a - \frac{n-1}{2 \cdot 3} (A) \text{vers.}^2 a - \frac{n^2-2^2}{3 \cdot 5} (B) \text{vers.}^3 a - \frac{n^2-3^2}{4 \cdot 7} (C) \text{vers.}^4 a - \&c.$$

where A, B, C, &c. are the coefficients of the preceding terms.

A variety of other formulæ for multiple arcs might be here investigated, but our limits forbid a farther extension; those which we have given above are chiefly exhibited by means of the powers of the single arc; a few others, in the form of continued products, may be here enumerated, but we must not attempt their investigation.

Let π denote the semicircumference, and we shall have

$$\begin{aligned} \sin. n a &= 2^{n-1} \cdot \sin. a \cdot \sin. \left(\frac{\pi}{n} - a \right) \cdot \sin. \left(\frac{\pi}{n} + a \right) \cdot \sin. \left(\frac{2\pi}{n} - a \right) \cdot \sin. \left(\frac{2\pi}{n} + a \right) \cdot \sin. \left(\frac{3\pi}{n} - a \right) \\ &\quad \cdot \sin. \left(\frac{3\pi}{n} + a \right) \&c. \\ \text{cof. } n a &= 2^{n-1} \text{cof.} \left(\frac{n-1}{2n} \pi + a \right) \cdot \text{cof.} \left(\frac{n-1}{2n} \pi - a \right) \cdot \text{cof.} \left(\frac{n-3}{2n} \pi + a \right) \cdot \text{cof.} \left(\frac{n-3}{2n} \pi - a \right) \\ &\quad \cdot \text{cof.} \left(\frac{n-5}{2n} \pi + a \right) \cdot \text{cof.} \left(\frac{n-5}{2n} \pi - a \right) \&c. \\ \tan. n a &= \tan. a \cdot \tan. \left(\frac{\pi}{n} - a \right) \tan. \left(\frac{\pi}{n} + a \right) \tan. \left(\frac{2\pi}{n} - a \right) \tan. \left(\frac{2\pi}{n} + a \right) \tan. \left(\frac{3\pi}{n} - a \right) \\ &\quad \tan. \left(\frac{3\pi}{n} + a \right) \&c. \dots \tan. \left(\frac{n\pi}{2n} + a \right) \end{aligned}$$

To these we add the following, which are very simple; *viz.*

$$\sin. a + \sin. (a + b) + \sin. (a + 2b) + \sin. (a + 3b) + \&c. \text{ ad infinitum} = \frac{\text{cof.} (a - \frac{1}{2}b)}{2 \sin. \frac{1}{2}b}; \text{ and}$$

$$\sin. a + \sin. (a + b) + \sin. (a + 2b) + \&c. \sin. (a + n b) = \frac{\sin. (a + \frac{1}{2}b) \sin. \frac{1}{2} (n + 1) b}{\sin. \frac{1}{2}b}$$

$$\text{cof. } a + \text{cof.} (a + b) + \text{cof.} (a + 2b) + \text{cof.} (a + 3b) + \&c. \text{ ad infinitum} = - \frac{\sin. (a - \frac{1}{2}b)}{2 \sin. \frac{1}{2}b}$$

$$\text{cof. } a + \text{cof.} (a + b) + \text{cof.} (a + 2b) + \&c. \text{ cof.} (a + n b) = \frac{\text{cof.} (a + \frac{1}{2}n b) \sin. \frac{1}{2} (n + 1) b}{\sin. \frac{1}{2}b}$$

SINES.

Of the Powers of the Sines, Cofines, &c. of single Arcs.

In order to exhibit the powers of the sine, cofine, &c. of the single arcs, in terms of the sines and cofines of the multiple arcs, we may refer to our formulæ (VIII) and (IX), viz.

$$\left. \begin{aligned} 2 \text{ cof. } a &= y + \frac{1}{y} \\ 2 \text{ cof. } na &= y^n + \frac{1}{y^n} \end{aligned} \right\} \begin{aligned} (-1)^{\frac{1}{2}} \cdot 2 \text{ fin. } a &= y - \frac{1}{y} \\ (-1)^{\frac{1}{2}} \cdot 2 \text{ fin. } na &= y^n - \frac{1}{y^n} \end{aligned}$$

From the first of these we have $2^n \cdot \text{cof.}^n a = \left(y + \frac{1}{y}\right)^n = y^n + A y^{n-2} + B y^{n-4} + C y^{n-6} + \&c. \pm \frac{1}{y^{n-2}} + \frac{1}{y^n}$
 A, B, C, &c. representing the binomial coefficients; or, collecting the terms from each extreme,

$$2^n \text{ cof.}^n a = \left(y^n + \frac{1}{y^n}\right) + A \left(y^{n-2} + \frac{1}{y^{n-2}}\right) + B \left(y^{n-4} + \frac{1}{y^{n-4}}\right) + \&c. \text{ or,}$$

$$2^{n-1} \text{ cof.}^n a = \text{cof. } na + n \cdot \text{cof. } (n-2) a + \frac{n \cdot (n-1)}{1 \cdot 2} \text{ cof. } (n-4) a + \&c. \quad (\text{XIV.})$$

It is only necessary to observe here, that when n is even, the number of terms in the original expansion will be odd, and its middle term, into which no power of y enters, will form the last term of the latter series; and having, therefore, no cofine in it, it will be only one-half of the coefficient given in the general term.

Whence the following particular cases.

1. $\text{cof. } a = \text{cof. } a$
 2. $2 \text{ cof.}^2 a = \text{cof. } 2a + 1$
 3. $4 \text{ cof.}^3 a = \text{cof. } 3a + 3 \text{ cof. } a$
 4. $8 \text{ cof.}^4 a = \text{cof. } 4a + 4 \text{ cof. } 2a + 3$
 5. $16 \text{ cof.}^5 a = \text{cof. } 5a + 5 \text{ cof. } 3a + 10 \text{ cof. } a$
- &c. = &c.

For the sines, we have $(-1)^{\frac{n}{2}} \cdot 2^n \cdot \text{fin.}^n a = \left(y - \frac{1}{y}\right)^n = y^n - A y^{n-2} + B y^{n-4} - C y^{n-6} + \&c. \pm \frac{1}{y^n}$, the last sign being + when n is even, but - when n is odd. Collecting the terms from the two extremes, we have first, when n is even,

$$(-1)^{\frac{n}{2}} \cdot 2^n \cdot \text{fin.}^n a = \left(y^n + \frac{1}{y^n}\right) - A \left(y^{n-2} + \frac{1}{y^{n-2}}\right) + B \left(y^{n-4} + \frac{1}{y^{n-4}}\right) - \&c. \text{ or,}$$

$$(-1)^{\frac{n}{2}} \cdot 2^{n-1} \cdot \text{fin.}^n a = \text{cof. } na - n \text{ cof. } (n-2) a + \frac{n(n-1)}{1 \cdot 2} \text{ cof. } (n-4) a - \&c. \quad (\text{XV.})$$

Observing here the same as above in respect to n , an even number; and when n is odd,

$$(-1)^{\frac{n}{2}} \cdot 2^n \text{ fin.}^n a = \left(y^n - \frac{1}{y^n}\right) - A \left(y^{n-2} - \frac{1}{y^{n-2}}\right) + B \left(y^{n-4} - \frac{1}{y^{n-4}}\right) - \&c. \text{ or}$$

$$(-1)^{\frac{n-1}{2}} \cdot 2^{n-1} \cdot \text{fin.}^n a = \text{fin. } na - n \text{ fin. } (n-2) a + \frac{n(n-1)}{1 \cdot 2} \text{ fin. } (n-4) a - \&c. \quad (\text{XVI.})$$

Observing now the change of sign, which takes place in the imaginary coefficient $(-1)^{\frac{n}{2}}$ and $(-1)^{\frac{n-1}{2}}$, according as n is of the form $4m$, $4m+1$, $4m+2$, or $4m+3$, we draw from the above two formulæ the following particular results viz.

1. $1 \text{ fin. } a = + \text{fin. } a$
 2. $2 \text{ fin.}^2 a = - \text{cof. } 2a - 1$
 3. $4 \text{ fin.}^3 a = - \text{fin. } 3a + 3 \text{ fin. } a$
 4. $8 \text{ fin.}^4 a = + \text{cof. } 4a - 4 \text{ cof. } 2a + 3$
 5. $16 \text{ fin.}^5 a = + \text{fin. } 5a - 5 \text{ fin. } 3a + 10 \text{ fin. } a$
- &c. = &c.

We must now come to a conclusion of our investigations relative to the doctrine of sines; had our limits admitted of it, we might have carried them to a much greater extent, but the above will be sufficient for illustrating the principles of

the most important and useful transformations; and the following results, which would occupy too much space to develop, but which at the same time are too important to be passed over unnoticed, the reader will be able to deduce, with facility, from the formulæ drawn from our general expression, (No. I.) and many others equally curious may be seen in Cagnoli's "Traité de Trigonometrie;" vol. i. of Euler's "Analysis Infinitorum;" Bonnycastle's and Keith's Treatises of Trigonometry, &c. &c.

The formulæ to which we have above referred are the following.

Miscellaneous Formula of frequent Application in the Arithmetic of Sines.

1. $\text{fin. } a \cdot \text{cof. } b = \frac{1}{2} \text{ fin. } (a+b) + \frac{1}{2} \text{ fin. } (a-b)$
2. $\text{cof. } a \cdot \text{fin. } b = \frac{1}{2} \text{ fin. } (a+b) - \frac{1}{2} \text{ fin. } (a-b)$
3. $\text{fin. } a \cdot \text{fin. } b = \frac{1}{2} \text{ cof. } (a \cap b) - \frac{1}{2} \text{ cof. } (a + b)$

SINES.

4. $\text{cof. } a \cdot \text{cof. } b = \frac{1}{2} \text{cof. } (a + b) + \frac{1}{2} \text{cof. } (a \text{ } \text{ } b)$
5. $\text{fin. } a + \text{fin. } b = 2 \text{fin. } \frac{1}{2} (a + b) \cdot \text{cof. } \frac{1}{2} (a \text{ } \text{ } b)$
6. $\text{cof. } a + \text{cof. } b = 2 \text{cof. } \frac{1}{2} (a + b) \cdot \text{cof. } \frac{1}{2} (a \text{ } \text{ } b)$
7. $\tan. a + \tan. b = \frac{\text{fin. } (a + b)}{\text{cof. } a \cdot \text{cof. } b}$
8. $\cot. a + \cot. b = \frac{\text{fin. } (a + b)}{\text{fin. } a \cdot \text{fin. } b}$
9. $\text{fin. } a - \text{fin. } b = 2 \text{fin. } \frac{1}{2} (a - b) \cdot \text{cof. } \frac{1}{2} (a + b)$
10. $\text{cof. } a \text{ } \text{ } \text{cof. } b = 2 \text{fin. } \frac{1}{2} (a - b) \cdot \text{fin. } \frac{1}{2} (a + b)$
11. $\tan. a - \tan. b = \frac{\text{fin. } (a - b)}{\text{cof. } a \cdot \text{cof. } b}$
12. $\cot. a \text{ } \text{ } \cot. b = \frac{\text{fin. } (a - b)}{\text{fin. } a \cdot \text{fin. } b}$
13. $\frac{\text{fin. } (a + b)}{\text{fin. } (a - b)} = \frac{\tan. a + \tan. b}{\tan. a - \tan. b} = \frac{\cot. a + \cot. b}{\cot. a - \cot. b}$
14. $\frac{\text{cof. } (a + b)}{\text{cof. } (a \text{ } \text{ } b)} = \frac{\cot. b - \tan. a}{\cot. b + \tan. a} = \frac{\cot. a - \tan. b}{\cot. a + \tan. b}$
15. $\frac{\text{fin. } a + \text{fin. } b}{\text{fin. } a - \text{fin. } b} = \frac{\tan. \frac{1}{2} (a + b)}{\tan. \frac{1}{2} (a - b)}$
16. $\frac{\text{cof. } a + \text{cof. } b}{\text{cof. } a \text{ } \text{ } \text{cof. } b} = \frac{\cot. \frac{1}{2} (a + b)}{\tan. \frac{1}{2} (a - b)}$
17. $\text{fin. } (a - b) \text{fin. } (a + b) = \begin{cases} \text{fin.}^2 a - \text{fin.}^2 b, \text{ or} \\ \text{cof.}^2 a \text{ } \text{ } \text{cof.}^2 b \end{cases}$
18. $\text{cof. } (a \text{ } \text{ } b) \text{cof. } (a + b) = \text{cof.}^2 a - \text{fin.}^2 b$
19. $\frac{\text{fin. } (a - b) \text{fin. } (a + b)}{\text{cof.}^2 a \cdot \text{cof.}^2 b} = \tan.^2 a - \tan.^2 b$
20. $\frac{\text{fin. } (a - b) \text{fin. } (a + b)}{\text{fin.}^2 a \cdot \text{fin.}^2 b} = \cot.^2 a - \cot.^2 b$

If $a + b + c = 180^\circ$, then

21. $\tan. a \cdot \tan. b \cdot \tan. c = \tan. a + \tan. b + \tan. c$
22. $\text{fin. } a \cdot \text{fin. } b \cdot \text{fin. } c = \frac{1}{4} (\text{fin. } 2a + \text{fin. } 2b + \text{fin. } 2c)$

It only remains now to exhibit the method of expressing the sine, cosine, &c. of an arc, in terms of the arc itself; and reverſedly, to expreſs the arc in terms of its ſine, coſine, &c. This is performed with great facility, if we allow ourſelves to employ the principles of the doctrine of fluxions; but our object, in this place, is to perform the ſame by means of the *arithmetic of ſines* only.

For this purpoſe, let x repreſent any arc, then it is obvious that its ſine will be ſome function of this arc, and ſuch a function that it will change its ſign, without changing its magnitude, when the arc, without changing its magnitude changes its ſign, becauſe $\text{fin. } -x = -\text{fin. } x$; conſequently the development of the ſine in functions of the arc, will contain only the odd powers of that arc; if, therefore, we repreſent the coefficients of the odd powers of x by $A, B, C, \&c.$ we ſhall have, or may aſſume,

$$\text{fin. } x = Ax + Bx^3 + Cx^5 + Dx^7, \&c. \quad (\alpha)$$

And if z is another arc,

$$\text{fin. } z = Az + Bz^3 + Cz^5 + Dz^7 + \&c.$$

by ſubtraction,

$$\text{fin. } x - \text{fin. } z = A(x - z) + B(x^3 - z^3) + C(x^5 - z^5) + \&c.$$

but $\text{fin. } x - \text{fin. } z = 2 \text{fin. } \frac{1}{2} (x - z) \cdot \text{cof. } \frac{1}{2} (x + z),$

therefore
$$\frac{2 \text{fin. } \frac{1}{2} (x - z) \cdot \text{cof. } \frac{1}{2} (x + z)}{x - z} = \frac{A(x - z) + B(x^3 - z^3) + C(x^5 - z^5) + \&c.}{x - z}$$

Subſtituting now for $2 \text{fin. } \frac{1}{2} (x - z)$, its expanded value, by changing x , in the firſt ſeries, into $\frac{1}{2} (x - z)$, *viz.* $2 \text{fin. } \frac{1}{2} (x - z) = A(x - z) + \frac{1}{4} B(x - z)^3 + \frac{1}{16} C(x - z)^5 + \&c.$ and dividing both ſides by $(x - z)$, we have, by making, after the diviſion, $x = z,$

$$A \text{cof. } x = A + 3Bx^2 + 5Cx^4 + 7Dx^6 + \&c. \quad (\beta)$$

and conſequently,

$$A \text{cof. } z = A + 3Bz^2 + 5Cz^4 + 7Dz^6 + \&c.$$

Whence, by ſubtraction, and obſerving that

$$\text{cof. } x - \text{cof. } z = -2 \text{fin. } \frac{1}{2} (x + z) \text{fin. } \frac{1}{2} (x - z)$$

$$= -\text{fin. } \frac{1}{2} (x + z) \left\{ A(x - z) + B(x - z)^3 + C(x - z)^5 + \&c. \right\}$$

we ſhall have, after dividing both members by $x - z$, and then making $x = z,$

$$-A^2 \text{fin. } x = 2 \cdot 3 Bx + 4 \cdot 5 Cx^3 + 6 \cdot 7 Dx^5 + \&c.$$

But $\text{fin. } x = Ax + Bx^3 + Cx^5 + \&c.$

therefore

$$-A^2 \text{fin. } x = -A^3 x - A^2 Bx^3 - A^2 Cx^5 + \&c.$$

Whence, by equating the coefficients of the homologous terms, we have

$$2 \cdot 3 B = -A^3; \quad 4 \cdot 5 C = -A^2 B; \\ 6 \cdot 7 D = -A^2 C, \&c.$$

$$B = \frac{-A^3}{2 \cdot 3}; \quad C = \frac{A^5}{2 \cdot 3 \cdot 4 \cdot 5}; \quad D = -\frac{A^7}{2 \cdot 3 \cdot \dots \cdot 7}; \quad \&c.$$

ſo that

$$\text{fin. } x = Ax - \frac{A^3 x^3}{2 \cdot 3} + \frac{A^5 x^5}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{A^7 x^7}{2 \cdot 3 \cdot \dots \cdot 7} + \&c.$$

and it remains only to find the value of A ; which is readily drawn from the following conſideration; *viz.* if we divide both ſides of this equation by x , it becomes

$$\frac{\text{fin. } x}{x} = A - \frac{A^3 x^2}{2 \cdot 3} + \&c.$$

which ought to answer to every value of x ; but when x is indefinitely ſmall, $\text{fin. } x = x$, and therefore the firſt number of the equation = 1; and therefore the ſecond alſo equal 1, conſequently $A = 1$; and we have therefore

$$\text{fin. } x = x - \frac{x^3}{2 \cdot 3} + \frac{x^5}{2 \cdot 3 \cdot 4 \cdot 5} - \frac{x^7}{2 \cdot 3 \cdot \dots \cdot 7} + \&c. \quad (\text{XVII.})$$

and by ſubſtituting, in equation (β) , the above values of $A, B, C, \&c.$ we obtain

$$\text{cof. } x = 1 - \frac{x^2}{2} + \frac{x^4}{2 \cdot 3 \cdot 4} - \frac{x^6}{2 \cdot 3 \cdot \dots \cdot 6} + \&c. \quad (\text{XVIII.})$$

In order to expreſs the arc in terms of the ſine and coſine, let x and z be two arcs; let y be the ſine of the former, and u the ſine of the latter; and ſince, for the ſame reaſon as above, the expanded functions can contain only odd powers of y and u , we will ſuppoſe that

$$x = Ay + By^3 + Cy^5 + Dy^7 + \&c. \quad (\gamma)$$

$$z = Au + Bu^3 + Cu^5 + Du^7 + \&c.$$

and,

and, by subtraction, we have

$$x - z = A(y - u) + B(y^3 - u^3) + C(y^5 - u^5) + \&c.$$

Dividing here both sides by $y - u$, and after the division making $u = y$, it will become

$$\frac{x - z}{y - u} = A + 3By^2 + 5Cy^4 + 7Dy^6 + \&c. \quad (\delta)$$

In order to establish an identity, we must ascertain what the first member becomes, on the supposition of $u = y$, after dividing by $y - u$. Now

$$\frac{x - z}{y - u} = \frac{x - z}{\sin. x - \sin. z} = \frac{x - z}{2 \sin. \frac{1}{2}(x - z) \cos. \frac{1}{2}(x + z)}.$$

Substituting, in the latter denominator, for $2 \sin. \frac{1}{2}(x - z)$, its value, as exhibited in No. (XVII.), and dividing both its members by $x - z$; that fraction becomes

$$\left\{ 1 - \frac{1}{2 \cdot 3 \cdot 4} (x - z)^2 + \&c. \right\} \cos. \frac{1}{2}(x + z);$$

and if now we make $x = z$, we shall find the result will be

$$= \frac{1}{\cos. x}. \quad \text{Now}$$

$$\frac{1}{\cos. x} = \frac{1}{\sqrt{(1 - \sin.^2 x)}} = \frac{1}{\sqrt{(1 - y^2)}} = (1 - y^2)^{-\frac{1}{2}} \\ = 1 + \frac{y^2}{2} + \frac{1 \cdot 3}{2 \cdot 4} y^4 + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6} y^6 + \frac{1 \cdot 3 \cdot 5 \cdot 7}{2 \cdot 4 \cdot 6 \cdot 8} y^8 + \&c.$$

and consequently this series is identical with equation (δ), viz. with

$$A + 3By^2 + 5Cy^4 + 7Dy^6 + 9Ey^8 + \&c.$$

Comparing the homologous terms, we have

$$A = 1; B = \frac{1}{2 \cdot 3}; C = \frac{1 \cdot 3}{2 \cdot 4 \cdot 5}; D = \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 7}; \&c.$$

carrying, therefore, these values into the equation (γ), and substituting $\sin. x$ for y , we have

$$x = \sin. x + \frac{\sin.^3 x}{2 \cdot 3} + \frac{1 \cdot 3 \sin.^5 x}{2 \cdot 4 \cdot 5} + \frac{1 \cdot 3 \cdot 5 \sin.^7 x}{2 \cdot 4 \cdot 6 \cdot 7} + \&c. \quad (\text{XIX.})$$

and since the $\sin. x = \cos. \left(\frac{\pi}{2} - x\right)$, we have, by substituting this expression for $\sin. x$, in the above series,

$$x = \frac{\pi}{2} - \cos. x - \frac{\cos.^3 x}{2 \cdot 3} - \frac{1 \cdot 3 \cos.^5 x}{2 \cdot 4 \cdot 5} - \frac{1 \cdot 3 \cdot 5 \cos.^7 x}{2 \cdot 4 \cdot 6 \cdot 7}$$

- &c. (XX.) in which the arc is expressed in terms of its cosine.

In order to investigate a formula, which shall express the arc in terms of its tangent, it may be shewn, as before,

$$1. a = \sin. a + \frac{\sin.^2 a}{2 \cdot 3} A + \frac{3^2 \sin.^4 a}{4 \cdot 5} B + \frac{5^2 \sin.^6 a}{6 \cdot 7} C + \frac{7^2 \sin.^8 a}{8 \cdot 9} D + \&c.$$

where A, B, C, &c. are the preceding terms.

$$2. \sin. a = a - \frac{a^2}{2 \cdot 3} A + \frac{a^4}{4 \cdot 5} B - \frac{a^6}{6 \cdot 7} C + \frac{a^8}{8 \cdot 9} D - \&c.$$

$$3. a = 90^\circ - \cos. a - \frac{\cos.^3 a}{2 \cdot 3} - \frac{3 \cos.^5 a}{2 \cdot 4 \cdot 5} - \frac{3 \cdot 5 \cos.^7 a}{2 \cdot 4 \cdot 6 \cdot 7} - \&c.$$

$$4. \cos. a = 1 - \frac{a^2}{2} A - \frac{a^4}{3 \cdot 4} B - \frac{a^6}{5 \cdot 6} C - \frac{a^8}{7 \cdot 8} D - \&c.$$

for the sines, that only the odd powers of the tangent can enter into the expressions; assuming, therefore, x and z as two arcs, whose tangents are t and t' , we may assume

$$x = At + Bt^3 + Ct^5 + \&c. \quad (\epsilon)$$

$$z = At' + Bt'^3 + Ct'^5 + \&c.$$

and, by subtraction, we shall have

$$x - z = A(t - t') + B(t^3 - t'^3) + C(t^5 - t'^5) + \&c.$$

Dividing both members by $t - t'$, and afterwards making $t = t'$, we have

$$\frac{x - z}{t - t'} = A + 3Bt^2 + 5Ct^4 + 7Dt^6 + \&c. \quad (\theta)$$

Also, to establish an identity, we have

$$\frac{x - z}{t - t'} = \frac{x - z}{\tan. x - \tan. z} = \frac{(x - z) \sin. (x - z)}{\cos. x \cdot \cos. z} \\ = \frac{(x - z) \cos. x \cdot \cos. z}{\sin. (x - z)}.$$

$$\text{But } \sin. (x - z) = (x - z) - \frac{1}{2 \cdot 3} (x - z)^3 \\ + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5} (x - z)^5 - \&c.$$

If, therefore, we substitute this value for $\sin. (x - z)$, in the denominator of the latter fraction, it becomes, after dividing both members by $(x - z)$,

$$\frac{x - z}{t - t'} = \frac{\cos. x \cdot \cos. z}{1 - \frac{x - z}{2 \cdot 3} + \frac{(x - z)^4}{2 \cdot 3 \cdot 4 \cdot 5} - \&c.}$$

which, on the supposition we have made of $t = t'$; and, consequently, $x = z$, reduces to

$$\cos.^2 x = \frac{1}{\sec.^2 x} = \frac{1}{1 + \tan.^2 x} = \frac{1}{1 + t^2} = \\ 1 - t^2 + t^4 - t^6 + t^8 - \&c.$$

which is therefore identical with our equation (θ), viz.

$$A + 3Bt^2 + 5Ct^4 + 7Dt^6 + \&c.$$

whence, by comparing the coefficients of the like powers of t , we have

$$A = 1, B = -\frac{1}{2}, C = \frac{1}{3}, D = -\frac{1}{4}, \&c.$$

which values substituted in equation (ϵ), gives

$$x = \tan. x - \frac{1}{2} \tan.^3 x + \frac{1}{3} \tan.^5 x - \frac{1}{4} \tan.^7 x + \&c. \quad (\text{XXI.})$$

We shall now conclude this article by exhibiting, in a connected order, a few of the most important developments of angular functions; observing that A, B, C, &c. are the preceding terms.

SINES.

$$5. a = \tan. a - \frac{\tan.^3 a}{3} + \frac{\tan.^5 a}{5} - \frac{\tan.^7 a}{7} + \&c.$$

$$6. \tan. a = a + \frac{a^3}{3} + \frac{2a^5}{15} + \frac{17a^7}{315} + \frac{62a^9}{2835} + \&c.$$

$$7. a = \frac{1}{\cot. a} - \frac{1}{3 \cot.^3 a} + \frac{1}{5 \cot.^5 a} - \frac{1}{7 \cot.^7 a} + \&c.$$

$$8. \cot. a = \frac{1}{a} - \frac{a}{3} - \frac{a^3}{45} - \frac{2a^5}{945} - \frac{a^7}{4725} - \&c.$$

$$9. a = 90^\circ - \frac{1}{\sec. a} - \frac{1}{2 \cdot 3 \sec.^3 a} - \frac{3}{2 \cdot 4 \cdot 5 \sec.^5 a} - \&c.$$

$$10. \sec. a = \left\{ \frac{\sec. a - 1}{\sec. a} + \frac{\sec.^3 a - 1}{2 \cdot 3 \sec.^3 a} + \frac{3(\sec.^5 a - 1)}{2 \cdot 4 \cdot 5 \sec.^5 a} + \frac{3 \cdot 5(\sec.^7 a - 1)}{2 \cdot 4 \cdot 6 \cdot 7 \sec.^7 a} + \&c. \right\}$$

$$11. a = \frac{1}{\operatorname{cosec}. a} + \frac{1}{2 \cdot 3 \operatorname{cosec}.^3 a} + \frac{1 \cdot 3}{2 \cdot 4 \cdot 5 \operatorname{cosec}.^5 a} + \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6 \cdot 7 \operatorname{cosec}.^7 a} + \&c.$$

$$12. \operatorname{cosec}. a = \frac{1}{a} + \frac{a}{6} + \frac{7a^3}{360} + \frac{31a^5}{15120} + \frac{127a^7}{604800} + \&c.$$

$$13. a = 2 \sqrt{2 \operatorname{verf}. a} \left\{ 1 + \frac{\operatorname{verf}. a}{2^2 \cdot 3} + \frac{1 \cdot 3 \operatorname{verf}. a}{2^3 \cdot 4 \cdot 5} + \frac{1 \cdot 3 \cdot 5 \operatorname{verf}. a}{2^4 \cdot 4 \cdot 6 \cdot 7} + \&c. \right\}$$

$$14. \log. \sin. a = \log. a - \frac{1}{M} \left\{ \frac{a^2}{2 \cdot 3} + \frac{a^4}{2^2 \cdot 3 \cdot 5} + \frac{a^6}{3^2 \cdot 5 \cdot 7} + \&c. \right\}$$

$$15. \log. \operatorname{cosec}. a = \log. 1 - \frac{1}{M} \left\{ \frac{a^2}{2} + \frac{a^4}{3 \cdot 4} + \frac{a^6}{3^2 \cdot 5} + \&c. \right\}$$

$$16. \log. \tan. a = \log. a + \frac{1}{M} \left\{ \frac{a^2}{3} + \frac{7a^4}{2 \cdot 3^2 \cdot 5} + \frac{62a^6}{3^4 \cdot 5 \cdot 7} + \&c. \right\}$$

In all these series, as also throughout the entire article, we have supposed radius = 1; if in any case the radius r be required, it may be introduced by giving it such a power as will render the quantities on both sides of the equation of the same dimension with regard to the powers of its factors.

SINES, Cosines, &c. Figures of, are figures made by conceiving the circumference of a circle extended out in a right line, upon every point of which are erected perpendicular ordinates, equal to the sines, cosines, &c. of the corresponding arcs, and drawing a curve line through the extremities of all the ordinates, which is then the figure of the sines, cosines, &c.

It appears that these figures took their rise from the circumstance of the extension of the meridian line by Edward Wright, who computed that line by collecting the successive sums of the secants, which is the same thing as the area of the figures of the secants. This being made up of all the ordinates or secants by the construction of the figure, and in imitation of this, the figures of the other lines have been invented. By means of the figures of the secants, James Gregory shewed how the logarithmic tangents may be constructed in his "Exercitationes Geometricæ," 4to. 1668.

Construction of the Figures of the Sines, Cosines, &c.—Let $A D B$, &c. (Plate I. fig. 10.) be the circle, $A D$ an arc, $D E$ its sine, $C E$ its cosine, $A E$ the versed sine, $A F$ the tangent, $G H$ the cotangent, $C F$ the secant, and $C H$ the cosecant.

Draw a line aa (fig. 11.), equal to the whole circumference $A D G B A$ of the circle, upon which lay off also the length of several arcs, as of every ten degrees, from o at a ,

to 360° at the other end at a ; upon these points raise perpendicular ordinates upwards or downwards, according as the sine, cosine, &c. is affirmative or negative in that part of the circle; lastly, upon these set off the length of the sines, cosines, &c. corresponding to the arcs at those points, or circumference aa , drawing a curve line through the extremities of all these ordinates, which will be the figure of the sines, cosines, versed sines, tangents, cotangents, secants, and cosecants, as in figs. 11, 12, 13, 14, 15, 16, 17, where it may be observed, that the following curves are the same, namely, those of the sines and cosines, tangents and cotangents, and those of the secants and cosecants, only some of their parts a little differently placed.

It may be known when any of these lines, *viz.* the sines, cosines, &c. are positive or negative; that is, to be set upwards or downwards; by observing the following general rules for those lines, in the 1st, 2d, 3d, and 4th quadrants of the circle.

The sines	{	in the 1st and 2d	are affirmative,
		in the 2d and 4th	negative.
The cosines	{	in the 1st and 4th	affirmative,
		in the 2d and 3d	negative.
The tangents	{	in the 1st and 3d	affirmative,
		in the 2d and 4th	negative.
The cotangents	{	in the 1st and 3d	affirmative,
		in the 2d and 4th	negative.
The secants	{	in the 1st and 4th	affirmative,
		in the 2d and 3d	negative.

and all the versed sines are affirmative.

To find the Equation and Area of each of those Curves.—Draw an ordinate, *dc*, putting r = the radius $A C$ of the given

SINES.

given circle, $x = ad$, or AD any absciss or arc, and $y = de$, its ordinate, which will be either the sine DE = s , cosine CE = c , versed sine AE = v , tangent AF = t , cotangent GH = τ , secant CF = f , or cosecant CH = σ , according to the nature of the particular construction. Now, from the nature of the circle are obtained these following general equations, expressing the relations between the fluxions and the circular arc, and its sine, cosine, &c.

$$\dot{x} = \frac{r\dot{s}}{\sqrt{(r^2 - s^2)}} = \frac{-r\dot{c}}{\sqrt{(r^2 - c^2)}} = \frac{r\dot{v}}{\sqrt{(2rv - v^2)}}$$

$$= \frac{r^2\dot{t}}{r^2 + t^2} = \frac{-r^2\dot{\tau}}{r^2 + \tau^2} = \frac{r^2\dot{f}}{f\sqrt{(f^2 - r^2)}} = \frac{-r^2\dot{\sigma}}{\sigma\sqrt{(\sigma^2 - r^2)}}$$

and these also express the relation between the absciss and ordinates of the curves in question, each in the order in which it stands; where x is the common absciss to all of them, and the respective ordinates are s, c, v, t, τ, f , and σ ; and hence the area of any of these curves may be found as follows.

1. In the Figure of the Sines, (fig. 11.) Here $x = ad$, and $s =$ the ordinate de , and the equation of the curve, as

above, is $\dot{x} = \frac{r\dot{s}}{\sqrt{(r^2 - s^2)}}$. Hence the fluxion of the

area, or $s\dot{x} = \frac{rs\dot{s}}{\sqrt{(r^2 - s^2)}}$, the correct fluent of which is

$r^2 \mp r\sqrt{(r^2 - s^2)} = r^2 - rc = rv =$ the rectangle of radius and versed sine minus or plus, according as s is increasing or decreasing; which is a general expression for the area ade in the figure of sines. When $s = 0$, as at a , or b , this expression becomes 0, or $2r^2$; that is, 0 at a , and $2r^2$ at b ; that is, the whole area $acb = 2r^2$.

2. In the Figure of the Cosines, (fig. 12.) Here $x = ad$, and

$c = de$; and the equation of the curve is $\dot{x} = \frac{-r\dot{c}}{\sqrt{(r^2 - c^2)}}$;

hence the fluxion of the area = $c\dot{x} = \frac{-rc\dot{c}}{\sqrt{(r^2 - c^2)}}$; and

the correct fluent of this = $r\sqrt{(r^2 - c^2)} = sr$, the rectangle of the radius and sine for the general area adc . When $s = r$, or $c = 0$, this becomes $r^2 =$ area afc , whose absciss af is equal to a quadrant of the circumference; the same as the figure of the sines upon an equal absciss.

3. In the Figure of the versed Sines, (fig. 13.) Here $x = ad$, and $v = de$, and the equation of the curve is $\dot{x} =$

$\frac{r\dot{v}}{\sqrt{(2rv - v^2)}}$; hence the fluxion of the area is $v\dot{x} =$

$\frac{rv\dot{v}}{\sqrt{(2rv - v^2)}} = \frac{r\dot{v}\sqrt{v}}{\sqrt{(2r - v)}}$; and the fluent of this

is $rx - rs = r(x - s) =$ the general area in the figure of the versed sines. When ad is a quadrant, this becomes

$\frac{3.1416}{2} r^2 - r^2 =$ the area afg ; and when ad is a semi-

circle it becomes $3.1416 r^2$, the whole area of the figure of versed sines.

4. In the Figure of the Tangents, (fig. 14.) Here $x = ad$, and $t = de$; and the equation of the curve becomes $\dot{x} =$

$\frac{r^2\dot{t}}{r^2 + t^2}$; and hence the fluxion of the area is $t\dot{x} =$

$\frac{r^2 t \dot{t}}{r^2 + t^2}$; the correct fluent of which is $\frac{1}{2} r^2 \cdot \text{hyp. log.}$

$\frac{r^2 + t^2}{r^2} = r^2 \cdot \text{hyp. log.} \frac{\sqrt{(r^2 + t^2)}}{r} = r^2 \cdot \text{hyp. log.}$

$\frac{f}{r}$; and hence the figure of the tangents may be used for

the construction of the logarithmic secants; a property first pointed out by Gregory at the end of his "Exercit. Geometricæ."

When ad becomes the quadrant af , t being then infinite, this becomes infinite for the area afg ; and the same for the figure of cotangents, beginning at f , instead of a . See fig. 15.

5. Figure of the Secants, (fig. 16.) Here $x = ad$, and $f = de$; and the equation of the curves is $\dot{x} =$

$\frac{r^2\dot{f}}{f\sqrt{(f^2 - r^2)}}$, and the fluxion of the area is $f\dot{x} =$

$\frac{r^2\dot{f}f}{f\sqrt{(f^2 - r^2)}}$, the fluent of which is $r^2 \cdot \text{hyp. log.}$

$\frac{f + \sqrt{(f^2 - r^2)}}{r}$ for the general area ade ; which is

infinite when ad becomes equal to a quadrant. The same process answers for the cosecants, beginning at f instead of a . See fig. 17.

Hence the meridional parts in Mercator's chart may be calculated for any latitude AD or ad . For the meridional parts: arc of latitude :: the sum of the secants: the sum of as many radii, or :: area ade : $ad \times \text{rad. } ac$; or AD \times AC in fig. 10.

SINES, *Line of*, a line on the sector, Gunter's scale, &c. the description and use of which see under the articles SECTOR, and GUNTER'S Scale.

In estimating the quantity of sines, &c. we assume radius for unity; and determine the quantity of the sines, tangents, and secants, in fractions thereof. From Ptolemy's Almagest we learn, that the ancients divided the radius into 60 parts; which they called degrees, and thence determined the chords in minutes, seconds, and thirds; that is, in sexagesimal fractions of the radius, which they likewise used in the resolution of triangles.

The sines, or half chords, for aught that appears, were first used by the Saracens.

Regiomontanus, at first, with the ancients, divided the radius into sixty degrees, and determined the sines of the several degrees in decimal fractions of it. But he afterwards found it would be more commodious to assume radius for 1; and thus introduced the present method into trigonometry.

In the common tables of sines and tangents, the radius is conceived divided into 1000000 parts, beyond which we never go, in determining the quantity of the sines and tangents. Hence, as the side of an hexagon subtends the sixth part of a circle, and is equal to radius, the sine of 30° is half the radius, or 500000.

1. The sine AD being given (fig. 4.), to find the sine-complement. From the square of the radius AC subtract the square of the sine AD; the remainder will be the square of the sine-complement DC or AG: whence the square root being extracted, we have the sine-complement. E. gr. Supposing AC 1000000, and AD 500000, AG will be found 8660254, the sine of 60° .

2. The sine AD of the arc AE being given (fig. 18.), to find the

the sine of the half arc, or half of AB. Find the chord of the arc AB; for half of this is its sine. Thus supposing AG and AD, as in the preceding problem: we shall find the sine of half the arc AB, or the sine of 15°, = 2588190.

3. The sine DG of the arc DF being given, to find the sine DE of the double arc DB (fig. 19.) Since the angles at E and G are right angles, and the angle B is common to each triangle BCG and DEB, we shall have BC : CG :: BD : DE; wherefore CG being found by the first problem, and BD being double of DG, DE is found by the rule of proportion.

4. The sines FG and DE (fig. 20.) of the arcs FA and DA, whose difference DF is not greater than 45 minutes, being given, to find any intermediate sine, as IL. To the difference FD of the arcs, whose sines are given, the difference of the arc AI, whose sine is required, and AF, viz. IF, and the difference of the given sines DH, find a fourth proportional: this, added to the less given sine FG, the aggregate will be the sine required.

5. To find the sine of 45 degrees. Let HI (fig. 4.) be a quadrant of a circle; then will HCI be a right angle; consequently the triangle rectangular; therefore $HI^2 = HC^2 + CI^2 = 2 HC^2$; wherefore, since HC the whole sine is 10000000; if from $2 HC^2$, 200000000000000, be extracted the square root 14142136; we shall have the chord HI, whose half 7071068, is the sine of 45° required.

6. The side of a pentagon being given (see POLYGON), the sine of 36° may be easily found. For the sine of 36° is equal to half 11755706, i. e. = 5877853.

7. The sine of a minute, or 60", FG (fig. 20.) being given, to find the sine of one or more seconds MN. Since the arcs AM and AF are very small, AMF may be taken for a right line, without any sensible error in the decimal fractions of the radius, in which the sine is expressed; that is, the arcs AM and AF may be taken proportional to their chords. Wherefore, since MN is parallel to FG, we shall have AF : FG :: AM : MN; therefore, AF, FG, and AM, being given, MN is easily had.

SINES, to construct a canon of. The sines of 30°, 15°, 45°, and 36° (which we have already shewn how to find) being had; we can thence construct a canon of all the sines to every minute, or every second. For from the sine of 36° we find those of 18° 9' 4" 30", and 2° 15', by the second problem: the sines of 54° 72' 81° 85' 30", and 87° 45', &c. by the first problem.

Again, from the sine of 45°, find the sine of 22° 30' 11" 15', &c. From the sine of 30°, and the sine of 54°, find the sine of 12°. From the sine of 12°, find the sines of 6° 3' 1" 30' 45' 78" 84", &c. From the sine of 15°, find the sine of 7° 30' 3" 45', &c. till you have 120 sines succeeding each other orderly, at an interval of 44 minutes. Between these, find the intermediate sines by the fourth problem: thus will the canon be complete.

From the sine of an arc given, to find the tangent and secant. See TANGENT, SECANT, and sequel of this article.

To find the logarithm of a given sine, called the artificial sine, see LOGARITHM. Wolfii Element. Math. vol. i. p. 214, &c.

There are various other methods of constructing the triangular or trigonometrical canon. We shall here subjoin the following, as the most simple and easy. But it will be necessary to premise the three subsequent propositions.

1. The sine EF of an arc AE (fig. 21.) being given, to find its cosine CF, versed sine AF, tangent AT, cotangent

DH, secant CT, and cosecant CH. The cosine CF is evidently = $\sqrt{CE^2 - EF^2}$, and the versed sine = CE or CA - CF. And the triangles CFE, CAT, and CDH being similar, we shall have CF : FE :: CA : AT; or the tangent will be a fourth proportional to the cosine, the sine, and radius; and CF : CE (CA) :: CA : CT, whence the secant is a third proportional to the cosine and radius; and EF : CF :: CD : DH, or the cotangent is a fourth proportional to the sine, cosine, and radius; and EF : EC (CD) :: CD : DH, or the cosecant, is a third proportional to the sine and radius. Moreover, because AT : AC :: CD (AC) : DH, the rectangle of the tangent and cotangent is equal to the square of the radius, and, therefore, the tangent of half a right angle, being equal to its cotangent, is equal to the radius; and the cotangents of any two different arcs (represented by P and Q), are to one another inversely as their tangents; for tang. P × cotang. P = rad.² = tang. Q × cotang. Q: therefore cotang. P : cotang. Q :: tang. Q : tang. P, or cotang. P : tang. Q :: cotang. Q : tang. P.

2. If there be three equidifferent arcs AB, AC, AD, (fig. 22.) we shall have radius is the cosine of their common difference BC, or CD, as the sine CF of the mean, to half the sum of the sines BE + DG of the two extremes; and as radius to the sine of the common difference, so is the cosine of the mean to half the difference of the sines of the two extremes. For let BD be drawn, intersecting OC in m; also draw mn parallel to CF, and BH and mv parallel to AO. The arcs BC and CD being equal, OC is perpendicular to BD, and bisects it; and, therefore, Bm or Dm will be the sine of BC or DC, and Om its cosine. Moreover mn, being an arithmetical mean between the sines BE, DG, of the two extremes (because Bm = Dm) is, therefore, equal to half their sum, and Dv equal to half their difference. But the triangles OCF, Omn, and Dvm, being similar, we shall have OC : Om :: CF : mn,

$$\text{and } OC : Dm :: FO : Dv. \text{ Whence } mn = \frac{DG + BE}{2}$$

$$= \frac{Om \times CF}{OC}, \text{ and } Dv = \frac{DG - BE}{2} = \frac{Dm \times FO}{OC},$$

$$\text{and consequently } DG + BE = \frac{2Om \times CF}{OC}, \text{ and } DG$$

$$- BE = \frac{2Dm \times FO}{OC}. \text{ And, moreover, if the mean arc}$$

AC be 60°, OF its cosine will be = sine 30° = $\frac{1}{2}$ chord 60° = $\frac{1}{2}$ OC; consequently DG - BE will, in this case, be barely = Dm, and DG = Dm + BE. Hence it follows: 1. That if the sine of the mean of three equidifferent arcs (radius being unity) be multiplied by twice the cosine of the common difference, and the sine of either extreme be subtracted from the product, the remainder will be the sine of the other extreme. And, 2. The sine of any arc above 60° is equal to the sine of another arc, as much below 60°, together with the sine of its excess above 60°.

3. To find the sine of a very small arc, e. gr. of 15'. The chords of very small arcs being to each other nearly as the arcs themselves, we shall have $\frac{1}{15}$ th of the semiperiphery : $\frac{1}{15}$ th :: 360 : 384) :: .00818121, the chord of $\frac{1}{15}$ th : .008726624, the chord of $\frac{1}{10}$ th of the semiperiphery, or half a degree, whose half, or .004363312, is the sine of 15', very nearly; and, therefore, 15' : 1' :: .004363312 : .000290888, the sine of the arc of 1' nearly.

SINES.

Upon the foregoing principles the canon may be easily constructed. For, the sine of 1' being .0002908882, its square is .0000008461594, which subtracted from the square of the radius 1, leaves .9999991538406, whose square root .999999577 is the cosine of 1', or the sine of 89° 59'. Now having the sine and cosine of 1', the other sines may be found in the following manner. Let the cosine of 1' be called C, and we shall have by prop. 2. supra.

$$\begin{aligned}
 2 C \times \text{fine } 1' - \text{fine } 0' &= \text{fine } 2' = .0005817764 \\
 2 C \times \text{fine } 2' - \text{fine } 1' &= \text{fine } 3' = .0008726645 \\
 2 C \times \text{fine } 3' - \text{fine } 2' &= \text{fine } 4' = .0011635526 \\
 2 C \times \text{fine } 4' - \text{fine } 3' &= \text{fine } 5' = .0014544406 \\
 2 C \times \text{fine } 5' - \text{fine } 4' &= \text{fine } 6' = .0017453283, \text{ \&c.}
 \end{aligned}$$

Thus are the sines of 7', 8', 9', &c. successively derived from each other. The sines of every degree and minute, up to 60°, being thus found; those of above 60° will be had by addition only, by prop. 2. supra; and the sines being all known, the tangents and secants will likewise become known by prop. 1. supra. If all these numbers be multiplied by the radius of any table (radius being here supposed unity), we shall have the natural sines, tangents, &c. of such a table. It will be sufficient to compute the sine of every fifth minute only by the preceding method; because the sines of all the intermediate arcs may be had from them, by taking the proportional parts of the differences so near, as to give the first six places true in each number. *E. gr.* $2 C 5' \times \text{fine } 5' - \text{fine } 0' = \text{fine } 10'$; subtract the sine 5' from that of 10'; add $\frac{1}{2}$ th of the remainder to the sine 5', for the sine of 6', to which add the same $\frac{1}{3}$ th for the sine of 7', &c. to 10'. Again, $2 C 5' \times \text{fine } 10' - \text{fine } 5' = \text{fine } 15'$, &c. Simpson's Trigonometry, p. 10, &c. Robertson's Elem. Navig. book iii. § 2.

The tables now chiefly used in trigonometrical computations, exhibit the logarithms of those numbers, which express the lengths of the sines, tangents, &c. which, in order to distinguish them from the natural ones, are called logarithmic or artificial sines, tangents, &c. A table of this kind, the use of which often occurs in the course of this work, is here annexed. The sines, tangents, &c. of

any arc are easily found, by seeking the degree at the top, if the arc be less than 45°, and the minutes at the side, beginning from the top, and by seeking the degree, &c. at the bottom, if the arc be greater than 45°. If a given logarithmic sine, or tangent, falls between those in the tables, the corresponding degrees and minutes may be reckoned $\frac{1}{3}$, $\frac{1}{2}$, or $\frac{2}{3}$, &c. minutes more than those belonging to the nearest less logarithm in the tables, according as its difference from the given one is $\frac{1}{3}$, or $\frac{1}{2}$, or $\frac{2}{3}$, &c. of the difference between the logarithm next greater and next less than the given log. Or generally, as 60'' is to the difference between any two consecutive tabular sines; so is the number of seconds beyond the less tabular sine, to the proportional part that is to be added to it. Thus if it were required to find the sine of 1° 28' 45'':

Sine 1° 29' is	-	-	8.4130676
Sine 1° 28' is	-	-	8.4081614
Difference	-	-	49062

Then as 60'' : 49062 :: 45'' : 36796.

Therefore to	-	-	8.4081614
Add	-	-	36796
Sine 1° 28' 45'' is	-	-	8.4118410

And in the same manner may the tangent or cotangent of any angle be found to seconds. The secants and cosecants are not given in the table, but they are readily found as follows; *viz.* any cosecant is found by subtracting the sine from 20.0000000, and the secant by subtracting the cosine from 20.0000000. See Sherwin's Mathematical Tables, which contain both the natural and artificial sines, &c. and Gardiner's Tables of Logarithms, &c. in which the logarithms of the sines are computed to every second in the first seventy-two minutes of the quadrant. But the most correct English table at present extant is Dr. Hutton's, containing the logarithms of all numbers to 100000, and the natural and logarithmic sines, cosines, tangents, &c. to every minute of the quadrant.

SINES.

TABLE of Logarithmic Sines and Tangents to every Minute of the Quadrant.

Min.	0 Degree.				60
	Sine.	Cofine.	Tang.	Cotangent.	
0	0.0000000	10.0000000	0.0000000	Infinite.	60

	Cofine.	Sine.	Cotangent.	Tang.	

45 Degrees.

SINE of Incidence, in *Catoptrics* and *Dioptrics*, is used for the sine of the angle of incidence.

SINE of Reflection, in *Catoptrics*, is used for the sine of the angle of reflection.

SINE of Refraction, in *Dioptrics*, is used for the sine of the angle of refraction.

SINE *assensu capituli*, in *Law*, a writ that lies where a bishop, dean, prebendary, or master of an hospital, aliens the lands holden in right of his bishopric, deanery, house, &c. without the assent of the chapter or fraternity; in which case his successor shall have this writ.

SINE-CURES, are ecclesiastical benefices, without cure of souls. Their original was as follows: The rector (with proper consent) had a power to intitle a vicar in his church to officiate under him; and this was often done: and by this means, two persons were instituted to the same church and both to the cure of souls, and both did actually officiate. So that however the rectors of sine-cures, by having been long excused from residence, are in common opinion discharged from the cure of souls, (which is the reason of the name,) and however the cure is said in the law-books to be in them *habitualiter* only; yet in strictness, and with regard to their original institution, the cure is in them *actualiter*, as much as it is in the vicar. *Gibf.* 719. *Johnf.* 85.

That is to say, where they come in by institution; but if the rectory is a donative, the case is otherwise: for then coming in by donation, they have not the cure of souls committed to them. And these are most properly sine-cures, according to the genuine signification of the word. *Johnf.* 85.

No church where there is but one incumbent can properly be a sine-cure: and though the church being down, or the parish being become destitute of parishioners, the incumbent may be thereby necessarily acquitted from the actual performance of public duty, yet he is still under an obligation to do it, whenever a church shall be built, and there is a competent number of inhabitants; and, in the mean while, if the church be presentative, as most of such churches are, the incumbent is instituted into the cure of souls. Such benefices are rather depopulations than sine-cures; and it will be proper for the new incumbent to read the thirty-nine articles, and the liturgy, in the church-yard, &c. and to do whatever other incumbents usually do.

But a rectory, or portion of it, may properly be a sine-cure, if there be a vicar under the rector, endowed and charged with the cure; in which case it does not come within the statute of pluralities, 21 Hen. VIII. c. 13.

Here, therefore, no dispensation is necessary to hold the sine-cure with a former living; nor need the incumbent read the articles, or divine service, as required by 13 Eliz. c. 12. which extends only to a benefice with cure.

A sine-cure donative wants no institution and induction, but one presentative must have both, especially if it consist in glebe and tithes, and not in a portion of money; but the institution must not run in *curam animarum*, but in *rectoriam, sive portionem rectoria de A. B. &c.*

By the above-mentioned statute (21 Hen. VIII.) not only prebends, and rectories with vicarages endowed, but deaneries and archdeaconries are declared to be benefices *without cure*.

SINE DIE, in *Law*. When judgment is given against the plaintiff, he is said to be *in misericordia pro falso clamore suo*; and for the defendant, it is said, *eat inde sine die*; i. e. he is dismissed the court.

The phrase is also used in parliament, for the adjournment

ment of any debate, without fixing the day when it shall come on again; which is looked upon as a genteeler dismissal of the thing in question.

SINEER, in *Geography*, a town of Hindoostan, in Baglana; 3 miles W. of Junere.

SINEGAR CREEK, a river of Maryland, which runs into the Potomack, N. lat. $39^{\circ} 8'$. W. long. $77^{\circ} 33'$.

SINEMAHONING, a north-west branch of the river Susquehanna.

SINE PARI, in *Anatomy*, an epithet applied to the vena azygos, which latter is an equivalent expression derived from the Greek. It means the *single vein*; as there is only one in the body, and not a pair, as in general, consisting of a right and left vessel. See **VEIN**.

SINEPUMENT INLET, in *Geography*, a bay on the S.E. coast of Maryland. N. lat. $38^{\circ} 20'$.

SINERVAS, in *Ancient Geography*, a town of the Lesser Armenia, on the route from Satala to Melitene, between Carfagis and Analiba. It. of Anton.

SINES, in *Geography*, a sea-port town of Portugal, in Eltremadura, containing about 1400 inhabitants; 39 miles S. of Setuval. N. lat. $37^{\circ} 46'$. W. long. $8^{\circ} 51'$.

SINESCLA, a town of Asiatic Turkey, in the province of Diarbekir; 80 miles E. of Rabba.

SINEU, a town of the island of Majorea; 20 miles E. of Parma.

SINEW properly denotes what we call a *nerve*; though, in common speech, it is rather used for a *tendon*.

The Hebrews do not eat the sinew of the thighs of animals, in memory of the sinew of Jacob's thigh, which the angel touched. This abstinence is not commanded by the law, and some interpreters think that it is an act of voluntary devotion.

SINEW, in the *Manege*. To unfinew a horse, called in French *enerver*, is to cut the two tendons on the side of the head, about five inches under the eyes; which two join in one at the tip, or the end of the nose, in order to perform its motion. This tendon at the tip of the nose is likewise cut. We unfinew, in order to dry the head, and make it smaller.

SINEW-Shrunk, is said of a horse that is over-rid, and so worn down with fatigue, that he becomes gaunt-bellied, through a stiffness and contraction of the two sinews that are under his belly.

SINEW-Sprung, is a violent attain, or over-reach, in which a horse strikes the toe of his hinder feet against the sinew of the fore-legs.

SINF, in the *Materia Medica of the Ancients*, a word used to express the same as *agallochum*, or lignum aloes.

SIN-FONG, in *Geography*, a town of China, of the third rank, in Kiang-fi; 27 miles S. of Kan-cheou.

SING, a town of Dalmatia, built by the Turks, in opposition to Clissa. It was strongly fortified; and the Venetians, after taking this place in the year 1686, strengthened its fortifications, in order to secure it to themselves; 16 miles N. of Spalatro.—Also, a town of Corea; 153 miles S.S.E. of King-ki-tao. N. lat. $35^{\circ} 27'$. E. long. $127^{\circ} 49'$.—Also, a town of Corea; 25 miles S.E. of Long-Kouang.

SINGA, in *Ancient Geography*, a town of Syria, in the Comagene. Ptolemy.

SIN-GAN, in *Geography*, a city of China, of the first rank, and capital of the province of Chen-fi; next to Peking, one of the largest and most beautiful cities in the kingdom. Its walls are thick, very high, and four leagues in circumference; they are flanked with a great number of towers, and surrounded by a deep ditch. Some of its gates are magnificent and remarkably lofty. In this city is still

seen a palace where the ancient kings of Chen-fi resided, the extent of whose country, and the bravery of their people, once rendered them formidable to their neighbours. The houses are, according to the Chinese fashion, low and ill-constructed; and the furniture, on account of the scarcity of good artists, inferior to that in the southern provinces; porcelain being very rare, and the varnish coarse. The inhabitants are generally more robust, and brave, and better formed for enduring fatigue, and also of greater stature, than those of the other provinces. The principal Tartar forces destined for the defence of the northern part of the empire are garrisoned in this city, under a general of their own nation, who, with his soldiers, occupies a quarter of the city, separated from the rest by a wall. Bats of a singular species are found in the territories of Sin-gan; they are as large as domestic fowls, and the Chinese prefer their flesh to that of the most delicate chickens. This country also furnishes the ladies with a white paint, which they use for embellishing their complexions. It appears, by an inscription on a marble monument dug up here in 1625, that the Christian religion flourished in China from the year 636 to 782. This capital has 37 cities under its jurisdiction; six of the second class and 31 of the third. The Mandarins, who are numerous in this city, are mostly Tartars. N. lat: $35^{\circ} 14'$. E. long. $108^{\circ} 29'$. Grofier.—Also, a town of China, of the third rank, in Pe-tche-li; 22 miles E.N.E. of Pao-ting.

SINGANA, in *Botany*, Aubl. Guian. 574. Just. 257, altered by Aublet from the name *Singan Singa*, given by the blacks in Guiana to the fruit of this shrub. See **STERBECKIA**.

SINGANELLORE, in *Geography*, a town of Hindoostan, in Coimbetore; 5 miles E. of Coimbetore.

SINGAPETTY, a town of Hindoostan; 17 miles S.S.W. of Tinevelly.

SINGARA, **SINJER**, in *Ancient Geography*, an important town of Asia, in Mesopotamia, on the banks of the river Mygdonius. Dion Cassius says that it was taken by Trajan; and that it afterwards became a Roman colony, under the appellations of Aurelia and Septimia, which it bears on medals.

SINGARPETTY, in *Geography*, a town of Hindoostan, in Barramaul; 25 miles E.N.E. of Dairempoury.

SINGARPILLY, a town of Hindoostan, in Myfore; 23 miles E.S.E. of Chinna Balabaram.

SINGAS, **SINSJA**, in *Ancient Geography*, a river of Asia, which, according to Ptolemy, flowed from Pieria, the most northerly canton of Syria, and discharged itself into the Euphrates S.E. of Samofata, between Arudis and Porfica.

SINGBOON, in *Geography*, a circar of Hindoostan, of small extent, bounded N.E. and E. by Bengal, S. by Mohurbunge, W. and N.W. by Bahar.

SINGEAH, a town of Hindoostan, in Bahar; 10 miles N. of Hajypour. N. lat. $25^{\circ} 52'$. E. long. $85^{\circ} 24'$.

SINGECOLLAM, a town of Hindoostan; 10 miles S. of Tinevelly.

SINGECONDA, a town of Hindoostan, in the Carnatic; 25 miles N. of Ongole.

SINGEE, a town of Hindoostan, in Bahar; 24 miles S.S.E. of Durbungah. N. lat. $25^{\circ} 45'$. E. long. $86^{\circ} 21'$.

SINGERAM, a town of Hindoostan, in Goleonda; 15 miles S.E. of Hydrabad.

SINGERBILL, a town of Hindoostan, in Bengal; 30 miles N. of Cormillah.

SINGERS, in the *Jewish Antiquities*. See **CHANTOR**.

SINGERS in Lulli's operas. See **LULLI**.

SINGESECKEN, in *Geography*, a town of Norway,

in the province of Drontheim; 46 miles S.S.W. of Drontheim.

SINGFING, a town of America, in New York, on the river Hudson; 27 miles N. of New York. N. lat. $41^{\circ} 8'$. W. long. $73^{\circ} 53'$.

SINGHOLE, a town of Hindoostan, in Gurry Mundella; 36 miles N.N.W. of Gurrah.

SINGHORE, a town of Hindoostan, in Oude; 16 miles S.E. of Manickpour.

SINGHYA, a town of Hindoostan, in Bahar; 10 miles N. of Hajypour.

SINGILIEV, a town of Russia, in the government of Simbirsk, on the Volga; 24 miles S. of Simbirsk. N. lat. $54^{\circ} 1'$. E. long. $48^{\circ} 34'$.

SINGING, the act of making divers inflexions of the voice, agreeable to the ear, and corresponding to the notes of a song, or piece of melody.

The Greek musicians, says Dr. Smith in his Harmonics, p. 3. note *c*, rightly describe the difference between the manner of singing and that of talking. They considered two motions in the voice; the one continued, and used in talking; the other discrete, and used in singing. In the continued motion, the voice never rests at any certain pitch, but waves up and down by insensible degrees; and in the discrete motion it does the contrary, frequently resting or staying at certain places, and leaping from one to another by sensible intervals. Euclid's *Introductio Harmonica*, p. 2. In the former case, the vibrations of the air are continually accelerated and retarded by turns, and by very small degrees, and in the latter by large ones.

The first thing done, in learning to sing, is to raise a scale of notes, by tones and semitones, to an octave; and descend again by the same notes; and then to rise and fall by greater intervals, as a 3d, 4th, and 5th, and to do all this by notes of different pitch.

Then these notes are represented by lines and spaces, to which the syllables *fa, sol, la, mi*, are applied, and the pupil is taught to name each line and space by them; whence this practice is usually called *sol-fa-ing*. The nature, reason, defects, &c. of which, see under the article SOL-FA-ING.

For the history of singing, as a part of religious worship, see *Choral SERVICE*.

SINGING, *Proceffional*. It was about the year 386, during the persecution of the orthodox Christians by the empress Justina, mother to the then young emperor Valentinian II. that ecclesiastical music was introduced in favour of the Arians. "At this time," says St. Augustine, "it was first ordered that hymns and psalms should be sung after the manner of eastern nations, that the people might not languish and pine away with a tedious sorrow, and from that time to the present it is retained at Milan, and imitated by almost all the other congregations of the world."

Music is said by some of the fathers to have drawn the Gentiles frequently into the church through mere curiosity; who liked its ceremonies so well, that they were baptized before their departure. The generality of our parochial music is not likely to produce similar effects; being such as would sooner drive Christians with good ears *out* of the church, than draw Pagans *into* it.

About this time, during the contention between the orthodox Christians and the Arians, we find by Socrates the historian, (l. vi. c. 8.) that the heretics used to sing hymns, marching through the streets of Constantinople in procession, with which the vulgar were so much captivated, that the orthodox, under the direction of St. Chryostom, thought it necessary to follow the example which had been set them

by their greatest enemies. Proceffional singing had been long practised by the Pagans, but no mention is made of it among Christians before this period.

SINGING *in the Church by the primitive Christians*. With respect to the music that was first used by the Christians, or established in the church by the first emperors that were converted, as no specimens remain, it is difficult to determine of what kind it was. That some part of the sacred music of the apostles and their immediate successors, in Palestine and the adjacent countries, may have been such as was used by the Hebrews, particularly in chanting the psalms, is probable; but it is no less probable that the music of the hymns which were first received in the church, wherever Paganism had prevailed, resembled that which had been many ages used in the temple-worship of the Greeks and Romans. Of this, the verification of those hymns affords an indisputable proof, as it by no means resembles that of the psalms, or of any other Hebrew poetry. And examples may be found in all the breviaries, missals, and antiphonaries, ancient and modern, of every species of verification which has been practised by the Greek and Roman poets, particularly the lyric; such as the Alcmæian, Alcaic, Sapphic, &c.

St. Hilary, bishop of Poitiers, and St. Ambrose, are said to have been the first that composed hymns to be sung in the western churches. Both these fathers flourished about the middle of the fourth century; but Prudentius, a Christian poet, contemporary with Theodosius, who died in 395, was author of most of the hymns in the Roman breviary.

SINGING, *Celestial*. It seems as if the primitive Christians had had no conceptions more sublime of the employment of the blest in the celestial abode, than that they were eternally singing. The ancient hymn, "Te Deum laudamus," still retained in the church, appears to have furnished the poet Dante with a model of the 28th canto of his "Paradiso," where, under three different hierarchies, consisting each of three choirs or choruses, the heavenly host of cherubim and seraphim are singing perpetual hosannahs. Milton has assigned them the same employment:

————— Their golden harps they took:
Harps ever tun'd, that glittering by their side
Like quivers hung, and with preamble sweet
Of charming symphony they introduce
Their sacred song, and waken raptures high;
No voice exempt, no voice but well could join
Melodious part, such concord is in heaven.

Parad. Lost, book iii.

Orazio Benivoli composed, in the last century, a mass for the cessation of the plague at Rome, upon the same idea, for six choirs, of four parts each, the score consisting of twenty-four different parts: it was performed in St. Peter's church, of which he was maestro di capella, and the singers, amounting to more than two hundred, were arranged in different circles of the dome; the sixth choir occupying the summit of the cupola.

SINGING *in England by Madrigalists*. Choral compositions, madrigals, and songs in that style, always of many parts, being the only vocal music that was in favour with masters and their most powerful patrons, precluded all refinement in the performance: as fugues, canons, and full choruses, of which they chiefly consisted, are founded upon democratic principles, which admit of no sovereignty; and whatever good they contain, is equally distributed to all ranks in the musical state; the art of singing, therefore, in these times, further than was necessary to keep a performer in tune and time, must have been unknown: the possessor of the most exquisite voice had no more frequent opportunities

allowed

allowed of displaying it, than the most disagreeable; solo songs, anthems, and cantatas, being productions of later times. The penalty for the crime of playing a solo at the concert of ancient music was five guineas; but at this time, if instead of that sum being forfeited, five hundred had been offered to the individual who could perform such a feat, fewer candidates would have entered the lists than if the like premium had been offered for flying from Salisbury steeple over Old Sarum, without a balloon.

SINGING, Parochial. See PSALMODY. See also STERNHOLD and HOPKINS.

SINGING in Italy, during the 16th century. Zacconi, one of the best Italian writers on music of that period, in his "Prattica di Musica," published 1596, chiefly dwells, in the first book, on the superiority of the singing and fingers of his own time, over all that preceded them; and has a long chapter upon the manner of gracing and embellishing a melody, where he tells us, "Che stile si tenghi nel far di gorgia; dell' uso de i moderni *passaggi*, come si *fioriscino* le cantilene;" and speaks of *acconciature*, as the modern Italians do of *rifforamenti*, or graces. The divisions, however, into which he breaks passages, in order to *embellish* them, if adopted by an opera-singer of the present times, would be like a modern fine lady appearing at court in the furbelows and flounces of queen Elizabeth, or a fine gentleman in the peruke of sir Cloudesley Shovel.

SINGING in France, during the 17th century. See MERSENNUS, and ST. EVREMOND.

SINGING in England, previous to the reign of queen Anne.

Music at all times has been called in to the assistance of weak plays and unattractive actors in our national theatres; and incidental songs, and singing between the acts, have been found so alluring, that when there was no plan formed for exhibiting musical dramas, singers have been engaged at considerable salaries, expressly for that purpose.

Before the last century, the art of singing, indeed, seems to have been little cultivated among us, by either sex, beyond what concerned time and tune. The honourable Roger North, in his manuscript "Memoirs of Music," speaks of the younger Banister as an excellent singing-master; but the players, who sung Purcell's songs on the stage, seem to have had nothing but voice and action to recommend them: such as Bowen, Harris, Freeman, and Pate, among the men; and among the women, Mrs. Davies, Miss Shore, afterwards wife to Colley Cibber, Mrs. Cross, Miss Champion, and Mrs. Bracegirdle. It was, however, a powerful recommendation to a song, during the 17th century, to say that it had been performed at the playhouse. How different from modern times! Church music, by the gay and fastidious frequenters of the opera, before, as well as after it had been heard, is pronounced to be *old-fashioned*, and playhouse music *vulgar*. Till the reign of queen Anne, indeed, the gentlemen of the chapel royal were occasionally allowed to sing on the stage; but that princes thinking the practice indecent, prohibited its continuance. There are few instances of vocal performers, especially female, being brought on our stage, but by accident. The fear of seduction, profligacy, and the world's opinion, deters parents from educating their children with a view to a profession, which nothing but uncommon success and prudence can render honourable in the eyes of the most serious part of the nation. The generality of female singers, therefore, having every thing to learn after leisure for study is no longer in their power, usually remain ignorant of the principles of their art, and so totally dependent on a master, as to be obliged to perpetuate that apprenticeship, which ought to have been served before they let up for themselves.

VOL. XXXIII.

In 1763, the pasticcio burletta of "Love in a Village," and in 1765 "The Summer's Tale," and "The Maid of the Mill," betrayed us into a taste for Italian melody, which has been the model of most of our vocal composers in and out of the theatre ever since. The "Duenna," another favourite English pasticcio, in 1775, helped us on, and Dr. Arnold, Mr. Dibdin, and Mr. Shield, have very judiciously complied with the reigning taste, and imitated or adopted the opera style in all its vicissitudes. Linley of Bath, and Jackson of Exeter, in their elegies at least, have steadfastly adhered to a style of their own, which seems to have been formed upon the melodies of our best old English masters, and those of the last age, that were most worthy of being preserved.

Till the Italian opera was established in this country, little was expected of a singer besides voice and an ear. Indeed, long after that period, good taste in singing was so little diffused throughout the island, that the great and exquisite performers who came hither from the continent seem to have made but a small impression on their astonished hearers. Nicolini, Senesino, Bernacchi, Faustina, Cuzzoni, Farnelli, Caffarelli, Carestini, Conti, Monticelli, Mingotti, Elizi, Manzoli, Guarducci, and Guadagni, had no effect upon our national taste; and though a few individuals among the people of fashion, by private instructions from them, and by the best of all lessons, hearing them frequently perform in public, diminished the original sin of our native *brogue* and vulgar expression; yet as these pupils could be heard but by few, their power was local, and no more likely to have any general effect upon our national cantilena, than their learning French and Italian upon our general language. It is not difficult, however, to fix the era of a change in our vocal music, which seems to have remained stationary for near half a century. It was begun by the compositions and instructions of Dr. Arne, who endeavoured to refine our melody and singing, more from Italian than English models; and was greatly accelerated by the pasticcio English operas above mentioned, as well as by the instructions of Tedeschi, Cocchi, Vento, and Giardini, who were employed about this time to teach several of our playhouse singers. Tenducci's performance in Artaxerxes had a rapid effect upon the public taste, and stimulated to imitation all that were possessed of good ears and flexible voices. In later times, the scholars of Sacchini, Piozzi, Parsons, and others, with the public concerts, where the best compositions and most exquisite performances of all kinds were constantly heard, completed the revolution; and it may be with truth and certainty affirmed, that our taste and judgment in both, even at the playhouses, differ as much from those of twenty or thirty years ago, as the manners of a civilized people from those of savages.

SINGING of Birds. See SONG of Birds.

SINGINGING, in *Geography*, a small island in the East Indian sea, near the E. coast of the island of Nassau. S. lat. 3° 50'. E. long. 100° 2'.

SINGITICUS SINUS, in *Ancient Geography*, a gulf of Macedonia, in the Ægean sea.

SINGIVENDA, in *Geography*, a town of Hindoostan, in the Carnatic; 28 miles N.N.W. of Ongole.

SINGLE, among *Sportsmen*, the tail of any of the deer kind.

SINGLE Bond or Obligation, *simplex obligatio*, in *Law*, is a deed, by which the obligor obliges himself, his heirs, executors, and administrators, to pay a certain sum of money to another at a day appointed. See OBLIGATION.

SINGLE Cast, in *Husbandry*, a term used by farmers for that

that sort of sowing, that disperses the necessary quantity of corn at one bout.

SINGLE Echo, Fine, Position, Proposition, Rasters, Tenaille, and Voucher. See the substantives.

SINGLE-Horse Carts, in *Agriculture.* See **CART.**

SINGLES. See **PETTY Singles.**

SINGO, in *Geography,* a town of European Turkey, in the province of Macedonia, near mount Athos.

SINGON, an island near the coast of Sweden, at the entrance into the gulf of Finland. N. lat. $60^{\circ} 11'$. E. long. $18^{\circ} 20'$.

SINGOONMAW, a town of the Birman empire; 16 miles S. of Pegongmew.

SINGOR, a sea-port town of Asia, in the kingdom of Siam, on the coast of Malacca. N. lat. $6^{\circ} 40'$. E. long. $101^{\circ} 14'$.

SINGPINE, a town of Bengal; 25 miles S.E. of Natore.

SINGPOUR, a town of Bengal; 22 miles E.S.E. of Ramgur.—Also, a town of Bengal; 8 miles S.E. of Koonda.—Also, a town of Hindoostan, in the circar of Sohajepour; 8 miles S. of Sohajepour.

SINGRAMOW, a town of Hindoostan, in Oude; 24 miles S.S.E. of Sultanpour.

SINGRECOTTA, a town of Hindoostan, in the circar of Cicacole; 23 miles W. of Vizianagram.

SINGREMOM, a town of Hindoostan, in Allahabad; 23 miles N.N.E. of Gazypour.

SINGREPETTA, a town of Hindoostan, in the Carnatic; 15 miles S.E. of Trichinopoly.

SINGROWLA, a town of Hindoostan, in Allahabad, S.W. of Bahar.

SING-SING, a town of America, in the state of New York; 35 miles N. of New York.

SINGUAR, a town of Hindoostan, in Bahar; 14 miles E.N.E. of Hajypour.

SINGUE, a town of Hindoostan, in Bahar; 38 miles S. of Bahar.

SINGULAR NUMBER, in *Grammar,* the first manner of declining nouns, and conjugating verbs; used when we only speak of a single person or thing. See **NUMBER.**

SINGULAR History. See **HISTORY.**

SINGULAR Proposition. See **PROPOSITION.**

SINGULARIS, or **SINGLE,** in the *Manege,* a name given by the Romans to a horse, upon which a man rode, in their races, without a saddle, using only a cloth, like the Greeks, fastened with a surcingle, or else sitting upon the bare back.

SINGULATOR, among the Romans, a horseman who rode with one horse only.

SINGULTUS, in *Medicine,* a spasmodic affection of the diaphragm, which, from the sound which accompanies it, is commonly called *hiccup*; under which head see an ample account of this affection.

SINGUM, in *Geography,* a town of Hindoostan, in the Carnatic; 23 miles S.S.W. of Trichinopoly.

SINGUR, a town of Hindoostan, in Bahar; 35 miles S.E. of Gaybah.—Also, a town of Hindoostan, in Vissapour; 12 miles S. of Poonah.

SINGUS, in *Ancient Geography,* a town of Macedonia, in Chalcidic, on the Singitic gulf. Ptol.

SING-Y, in *Geography,* a town of China, of the third rank, in Quang-tong; 17 miles N. of Kao-tcheou.

SINHALA, in *Ancient Geography,* a name formerly given to the island of Ceylon, formed from the Sanscrit *Sinha,* a lion, and given to it on account of its being in-

habited by Sinhalas, or the offspring of a lion. See *Asiatic Researches,* vol. i. p. 48.

SIN-HIANG, in *Geography,* a town of China, of the third rank, in Ho-nan, on the river Ki; 12 miles S.W. of Oue-kiun.

SIN-HING, a small island near the coast of China, in the Eastern sea; 3 miles S. of Tfong-ming. N. lat. $31^{\circ} 32'$. E. long. 121° .—Also, a town of China, of the third rank, in Quang-tong; 27 miles S. of Tchao-king.—Also, a city of China, of the second rank, in Yun-nan. N. lat. $24^{\circ} 30'$. E. long. $102^{\circ} 23'$.

SIN-HO, a town of China, of the third rank, in Petchie-li; 15 miles S.W. of Kli.

SIN-HOA, a sea-port town of Cochinchina. N. lat. 17° . E. long. $88^{\circ} 14'$.—Also, a town of China, of the third rank, in Hou-quang, on the river Lo; 32 miles N.N.W. of Pao-king.

SIN-HOEI, a town of China, of the third rank, in Quang-tong; 40 miles N.W. of Macao.—Also, a town of China, of the third rank, in Quang-tong; 45 miles S.S.E. of Tchao-king.

SINIA, a river of Russia, which runs into the Oby, 52 miles N. of Berezov, N. lat. 65° . E. long. $66^{\circ} 14'$.

SINJAR, a town of Asiatic Turkey, in the province of Diarbekir; 140 miles S.E. of Diarbekir. N. lat. $36^{\circ} 17'$. E. long. $41^{\circ} 35'$.—Also, a range of mountains, in the province of Diarbekir; 70 miles S.E. of Diarbekir. On this range stood the fortrefs of Sangara, which was surrendered to the Persians by the pusillanimous successor of Julian, about eight or ten miles from Nisibis. This mountain is at present peopled by several tribes of that sect called Yezedi, who worship, or rather deprecate, the devil, from a notion that he possesses an unlimited power over mankind.

They are the descendants of those Arabs who followed the banners of Yezid, and fought against Hafein, in the battle of Kerbela; and Sheikh Ade, the founder of the sect, is interred near Mosul. They are said to adore the Supreme Being as the creator and benefactor of the human race, drink wine and other strong liquors, and circumcise like the Mahometans. They are the mortal enemies of the Turks, and have never been completely subdued. They lie in ambush behind the rising grounds, which skirt the road between Mosul and Merdin; and as travellers are obliged to pass a lonely wild, 20 furlongs in length, they are liable, if not numerously attended, to be murdered by these miscreants. Sinjar affords abundance of pasturage, and also a sufficient quantity of grain for the consumption of its savage inhabitants. In the year 341 a bloody battle was fought near this place, between the emperor Constantius and Sapor II., in which the former sustained a total defeat, and was driven by his victorious rival across the Euphrates.

SINIA STANITZ, a town of Russia, in the government of Irkutsk, on the Lena. N. lat. $61^{\circ} 15'$. E. long. $125^{\circ} 34'$.

SINICA, a town of America, in South Carolina, belonging to the Cherokee Indians, on the Keowe; 43 miles N.W. of Petersburg.

SINICAL QUADRANT. See **QUADRANT.**

SINIGAGLIA, in *Geography,* a sea-port town of Italy, in the duchy of Urbino, the see of a bishop, suffragan of Urbino, on the Adriatic, at the mouth of the river Nivola (anciently Senon), which separates the duchy of Urbino from the marquise of Ancona. It was anciently called "Sena Gallorum," denoting that it was built by the Gallic Senones, and became a Roman colony in the year of Rome 462. It has been several times destroyed, especially

by the Goths. It contains four churches and six convents, with about 6000 inhabitants. It is an unhealthy place, and water fit for drinking is scarce; 28 miles E.S.E. of Urbino.

SINJIAR. See SINJAR.

SIN-ING, a town of Corea; 25 miles E.S.E. of Long-Kouang.

SI-NING, a town of Corea; 8 miles N.E. of Sing-tcheou.—Also, a city of China, of the second rank, in Chen-fi. N. lat. $36^{\circ} 40'$. E. long. $101^{\circ} 24'$.—Also, a town of China, of the third rank, in Pe-tche-li; 25 miles N.W. of Yu-tcheou.—Also, a town of China, of the third rank, in Quang-tong; 15 miles S.W. of Te-king.

SINION, a river of China, which runs into the Kialing, 15 miles S. of Oei-tcheou.

SINIS COLONIA, in *Ancient Geography*, a town of Asia, in Lesser Armenia, near the Euphrates, according to Ammianus Marcellinus.

SINISCOLA, in *Geography*, a town of Sardinia, on the east coast. N. lat. $40^{\circ} 30'$. E. long. $10^{\circ} 1'$.

SINISI, a town of Naples, in Basilicata; 11 miles S.W. of Turfi.

SINISTER, something on, or towards the left hand.

Hence some derive the word finitser, a *finendo*, because the gods, by such auguries, permit us to proceed in our designs.

SINISTER is also used among us for unlucky; though, in the sacred rites of divination, the Romans used it in an opposite sense. Thus, *avis sinistra*, or a bird on the left hand, was esteemed a happy omen; whence, in the law of the Twelve Tables, *Ave sinistra populi magister esto*.

SINISTER, in *Heraldry*. The finitser side of an escutcheon is the side answering to the right hand of the person who looks at it.

SINISTER Chief and Base. See ESCUTCHEON.

SINISTER Bend. See BEND.

SINISTER Aspect, among *Astrologers*, is an appearance of two planets, happening according to the succession of the signs; as Saturn in Aries, and Mars in the same degree of Gemini.

SINISTRARI, a sect of ancient heretics, thus called, because they held the left hand in abhorrence, and made it a point of religion not to receive any thing with it.

What in us is a piece of civility, in them was a superstition. Balsamon observes, that they were likewise called Sabbatians and Novatians.

SINKBAZAR, in *Geography*, a town of Bengal; 15 miles S.S.W. of Rogonatpour.

SINKEL, a sea-port town of the island of Sumatra, near the west coast, on a river which runs into the sea. This town is a good mart for salt, iron, steel, and sometimes opium. N. lat. $2^{\circ} 8'$. E. long. 97° .

SINKING of the Earth. See ABSORPTIONS of the Earth.

SINKING Fund. See FUND.

SINKOO, in the *Materia Medica*, a name given by some authors to the lignum aloes, or agallochum, used in medicine.

SINKOUANG, in *Geography*, a town on the west coast of Sumatra. N. lat. $1^{\circ} 12'$. E. long. $98^{\circ} 13'$.

SIN-LO, a town of China, of the third rank, in Pe-tche-li, on the Chao river; 42 miles S.W. of Pao-ting.

SINN, a river of Germany, which runs into the Maine, with the Saal, near Gemunden, in the duchy of Wurzburg.—Also, a town of Asiatic Turkey, in the province of Diarbekir; 40 miles S.E. of Diarbekir.

SINNEMAHONING CREEK, a river of America, in

Pennsylvania, which runs into the west branch of the Susquehanna, N. lat. $41^{\circ} 17'$. W. long. 78° .

SINNERSHAUSEN, a town of Germany, in the county of Henneberg; 8 miles N.W. of Meinungen.

SINNET, aboard a Ship. See SENNET.

SIN-NGHAN, in *Geography*, a town of China, of the third rank, in Ho-nan; 17 miles W. of Ho-nan.

SIN-NHING, a town of China, of the third rank, in Hou-quang; 20 miles S.S.W. of Oukang.

SIN-NING, a town of China, of the third rank, in Quang-tong; 52 miles S. of Tchao-king.—Also, a town of China, of the third rank, in Se-tchuen; 17 miles E.S.E. of Ta.—Also, a city of China, of the second rank, in Quang-fi. N. lat. $22^{\circ} 34'$. E. long. $107^{\circ} 17'$.

SINNO, a river of Naples, which runs into the Adriatic, N. lat. 40° . E. long. $16^{\circ} 40'$. Near the mouth of the Sinno was Siris, probably the port of Heraclea; but at present there is nothing but an open road, where ships may lie to take in a cargo of corn, and other commodities, of which one is liquorice, a root that grows wild in great quantities along these swamps, and the sale of which is said to have produced 700*l.* a year to the duke of Corigliano. The banks of the Sinno are famous in Roman history for the victory gained by Pyrrhus over the consul Levinus, in the year of Rome 473. This is said to have been the first encounter of the Epirots with the Romans. The honour of the day was purchased by Pyrrhus at the expence of the flower of his army.

SINO, a town of Africa, on the Grain Coast; 30 miles S.E. of Sanguin.

SINOBO, or SINOPE, a sea-port town of Asiatic Turkey, in the sangiacat of Kiutaja, near the coast of the Black sea, on the isthmus of a peninsula, six miles in circumference, which terminates in a considerable cape, which has not above twelve feet of water. The antiquity of this town is traced to the time of the Argonauts, or at least to the time when the Cimmerians established themselves here; for being driven from their country by the Scythians, they came into Asia, over against the mouth of the Ister. Its first commencement, however, was feeble; but when it received a colony of Milesians, it rose to such a degree of power, that it founded other colonies on the coasts of the Euxine sea, whilst it possessed all the advantages of liberty. It was taken by Pharnaces, father of Mithridates, and made the capital of Pontus; and it became the birth-place of Mithridates. In the year B.C. 70, it was taken by the Romans under Lucullus, who restored its liberty. After experiencing a variety of calamities under the tyranny of Pharnaces, Julius Cæsar, having vanquished this prince, re-established Sinope, and sent hither a Roman colony. It established a new era in commemoration of this happy event, and inscribed on its monuments the title of "Colonia Julia Felix Sinope." This colony was sent to Sinope in the year of Rome 709. The town subsisted in a flourishing state under the Roman emperors. Its commerce, which was considerable, and the convenience of its ports, contributed alike to its opulence and its splendour. Strabo says that it was one of the most considerable towns of Asia. A particular worship was paid to Serapis at Sinope, and it also honoured Mercury as the god of commerce. Strabo and Pliny say, that Sinope, under the Roman emperors, comprised in Paphlagonia, formed a part of the government of Bithynia. Paphlagonia, however, was detached from Bithynia, and formed a particular province, about the reign of Constantine; but the town of Sinope was united with some other towns of Pontus, to form the province of Hellepont, in honour of Helena, the mother of Constantine.

tine. When the emperor Heraclius divided the East into several departments, the town of Sinope was included in that of Armenia. Christianity was received in this city towards the end of the third century. This place has two good harbours, and a dock-yard for building ships. Turks only reside within the walls; one of the fauxbourgs is inhabited by Greeks, with a metropolitan dependant on the patriarch of Constantinople. In the environs are some copper-mines. Diogenes, the cynic, was a native of Sinope, but he was buried at Corinth; 380 miles E. of Constantinople. N. lat. $41^{\circ} 6'$. E. long. 35° .

SINON, a river of Persia, in the province of Mazanderan, which runs into the Caspian sea, 5 miles E. of Fehrabad.

SINONGI, a town of Japan, in the island of Ximo; 20 miles S.W. of Sanga.

SI NON OMNES, in *Law*, a writ on affocation of justices, by which, if all in commission cannot meet at the day assigned, it is permitted that two or more of them may finish the business.

SINOOTS, in *Geography*, a town of Japan, in the island of Ximo; 20 miles E. of Taifero.

SINOPE, in *Ancient Geography*. See SINOB.

SINOPE, a river of Asia, in Paphlagonia, which runs near the town of Sinope.

SINOPER, or SINOPIS, in *Natural History*. See SINOPICA Terra.

SINOPICA TERRA, the name of a red earth, of the ochre-kind, called also *rubrica sinopica*, and by some authors *sinopis*.

It is a very close, compact, and weighty earth, of a fine glowing purple colour, but in some specimens much deeper than in others, and in some degenerates into paleness; but, even in its worst condition, the colour is very fine. It is of a pure texture, but not very hard, and of an even but dusty surface. It adheres firmly to the tongue, is perfectly fine and smooth to the touch, does not crumble easily between the fingers, and stains the hands. It melts very slowly in the mouth, and is perfectly pure and fine, and of a very austere astringent taste, and ferments very violently with aqua fortis. In the fire it acquires a great hardness, but does not change colour.

It was dug in Cappadocia, and carried for sale to the city Sinope, whence it had its name. It is now found in plenty in the New Jerseys, in America, and is called by the people there *blood-stone*, from its staining the hands to a blood-colour, and may probably be had in many other places; and this deserves thoroughly inquiring into, since there seems not one among the earths more worthy of notice. Its fine texture and body, with its high florid colour, must make it very valuable to painters, and its powerfully astringency equally so in medicine.

The ancients were well acquainted with it in fluxes and hæmorrhages, and experience shews it possesses the same virtues at this time. The deepest coloured is ever the most astringent. Hill's Hist. of Foss. p. 60.

SINOPLE, or SENOPLE, in *Heraldry*, denotes *vert*, or the green colour in armories; thus called by the ancient heralds: though Pliny and Isidore, by *color sinopicus*, or *sinople*, mean a brownish-red, such as that of our ruddle.

F. Menestrier derives the word from the Greek *prafina bopla*, *green armories*; by corruptedly retrenching the first syllable *pra*; which is no new thing among Oriental words, witness Salonica for Thessalonica.

Sinople is supposed to signify love, youth, beauty, rejoicing, and liberty: whence it is, that letters of grace,

abolition, legitimation, &c. are always to be sealed with green wax.

SINOPOLI, in *Geography*, a town of Naples, in Calabria Ultra; 5 miles S.W. of Oppido.

SINOTIUM, in *Ancient Geography*, a town of Illyria, in Dalmatia, and one of the fifty possessed by the Dalmatians. Strabo says, that it was reduced to ashes by Augustus.

SINOVIA. See SYNOVIA.

SIN-PING, in *Geography*, a town of China, of the third rank, in Yun-nan; 35 miles N. of Yuen-kiang.

SINSACATA, a town of South America, in the province of Cordova; 36 miles N. of Cordova.

SIN-SI, a town of Corea; 30 miles N.N.E. of Kingki-tao.

SINSJA, a river of Asia, which runs into the Euphrates, 33 miles S.E. of Semifat.

SINSILIN, a town of Persia, in the province of Ghilan; 23 miles W.N.W. of Reshd.

SINSIN, a town of Persia, in the province of Irak; 120 miles N. of Isfahan. See ZINJAN.

SINSO, a province of Africa, in the kingdom of Angola, north of Loanda.

SIN-TAI, a town of China, of the third rank, in Chan-tong; 37 miles S.E. of Tai-nghan.

SIN-TAI-TOUKA, a town of Chinese Tartary. N. lat. $41^{\circ} 16'$. E. long. $120^{\circ} 14'$.

SIN-TAN, a town of China, of the third rank, in Setchuen; 10 miles S.S.E. of Han.

SIN-TCHANG, a town of Corea; 45 miles E. of Haimen.—Also, a town of China, of the third rank, in Kiang-si; 37 miles W.S.W. of Choui-tcheou.—Also, a town of China, of the third rank, in Tche-kiang; 42 miles N.N.W. of Tai-tcheou.—Also, a city of China, of the second rank, in Yun-nan. N. lat. 29° . E. long. $103^{\circ} 29'$.

SIN-TCHEOU, a city of China, of the first rank, in Quang-si. N. lat. $33^{\circ} 26'$. E. long. $109^{\circ} 29'$.

SIN-TCHIM HOTUN, a city of Corea. N. lat. $42^{\circ} 57'$. E. long. $130^{\circ} 18'$.

SIN-TCHIN, a town of China, of the third rank, in Pe-tche-li; 32 miles N.E. of Pao-ting.—Also, a town of China, of the third rank, in Chan-tong; 30 miles N.W. of Tcin-tcheou.

SIN-TCHING, a town of China, of the third rank, in Kiang-si; 22 miles S.S.E. of Kien-tchang.—Also, a town of China, of the third rank, in Tche-kiang; 30 miles N.N.E. of Yen-tcheou.—Also, a town of China, of the third rank, in Setchuen; 17 miles E. of Xun.—Also, a town of China, of the third rank, in Ho-nan; 20 miles N. of Hiu-tcheou.

SIN-TCHU-AM, a town of Chinese Tartary. N. lat. $41^{\circ} 5'$. E. long. $120^{\circ} 54'$.

SIN-TCHUEN, a town of Corea; 48 miles S.W. of Hoang-tcheou.

SIN-TCIN, a town of China, of the third rank, in Hou-quang; 20 miles W.S.W. of Koue-yang.

SINTHUS, in *Ancient Geography*, a town of Macedonia, in the Amphaxitide, near the gulf Thermæus, according to Herodotus.—Also, one of the largest rivers which discharged themselves into the Erythræan sea. Arrian.—Also, one of the mouths of the Indus, according to Ptolemy.

SIN-TIEN, in *Geography*, a city of China, of the second rank, in Yun-nan. N. lat. $25^{\circ} 36'$. E. long. $102^{\circ} 54'$.

SIN-TIENTSE, a town of Chinese Tartary. N. lat. $41^{\circ} 16'$. E. long. $121^{\circ} 19'$.

SINTII, in *Ancient Geography*, the name of a people

who inhabited the isle of Lemnos, according to Homer. This name, however, probably belongs to the inhabitants of the town of Sindus, or Sinthus, near the Thermaic gulf.

SINTQUIPAQUE, in *Geography*, a town of Mexico, in the province of Guadalajara, on the Barania; 110 miles N.W. of Guadalajara.

SIN-TOU, a town of China, of the third rank, in Kiang-si, on the river Kan; 13 miles S. of Lin-kiang.—Also, a town of China, of the third rank, in Se-tchuen; 10 miles S. of Han.

SINTRA. See **CINTRA**.

SIN-TSAI, a town of China, of the third rank, in Honan, on the river Yu; 32 miles E.S.E. of Yun-hing.

SINTZHEIM, a town of the duchy of Baden; 13 miles S.S.E. of Heidelberg.

SINU. See **ZINU**.

SINUATUM FOLIUM, in *Botany*, a Sinuated Leaf, so called from *sinus*, a bay or creek, in allusion to its winding outline, or the broad, deep, rounded incisions of its margin. See **LEAF**.

SINUESSA, in *Ancient Geography*, a town of Italy, on the frontiers of Latium and Campania, near the marsh of Miltunes. It derived its name, according to Strabo, from the sinuosity of the coast, which at this place formed a small gulf. Some remains of it, as well as of its baths, the water of which was reputed to be excellent against sterility, still subsist. Sinuessā was a Roman colony, according to Livy.

SINUNIA, a town of Asia, in Parthia, according to Ptolemy.

SINUOSITY, a series of bends and turns in arches, or other irregular figures; sometimes jetting out, and sometimes falling in: such as described by the motion of a serpent, &c.

It is the sinuosity of the sea-coasts that forms bays, ports, capes, &c. Du Loir observes, that the course of the river Meander, creeping in a thousand agreeable sinuosities, served Dædalus as a model by which to form his labyrinth.

SINUOUS ULCERS. See **ULCER**.

SINUS, in *Anatomy*, a term applied to various cavities of the body. In the head we have the sinuses of the frontal, sphenoid, ethmoid, and maxillary bones; which are cavities of these bones communicating with the nose. (See **CRAanium** and **NOSE**.) The sinuses of the dura mater are the large veins of the brain. (See **BRAIN**, **NERVOUS System**, and **VEIN**.) The sinuses of the venæ and cavæ and pulmonary veins are the principal parts of the two auricles. (See **HEART**.) The sinus of the vena portarum is its trunk, just before it divides into the right and left branches. See **VEIN**.

SINUS, in *Surgery*, a small orifice leading down to an abscess.

SINUS Hipponensis, in *Ancient Geography*, the gulf of Bizerta, a gulf of Africa, formed by the promontory "Candidum" to the north-west, and the promontory "Apollinis" to the east.

SINUS Numidicus, the gulf of Stora, a gulf of Africa, formed to the west by the promontory "Tritum," and to the east by the promontory "Tapfus."

SIN-YAN, in *Geography*, a river of China, which runs into the Eastern sea, 17 miles E.N.E. of Yen-te-hing.

SIN-YANG, a town of Corea; 45 miles S. of Koang-tcheou.—Also, a city of China, of the second rank, in Honan. N. lat. 32° 12'. E. long. 113° 38'.

SIN-YE, a town of China, of the third rank, in Honan; 27 miles S.S.W. of Nan-yang.

SIN-YU, a town of China, of the third rank, in Kiang-si; 25 miles W.S.W. of Lin-kiang.

SINZIG. See **ZINZIG**.

SINZITA, in *Ancient Geography*, a town of Lesser Armenia, in the prefecture of Muriana. Ptolemy.

SIO, in *Geography*, a river of Hungary, which runs into the Sarand, near Simontornya.—Also, a river of Spain, which runs into the Segra, a little above Balaguer.—Also, a decayed town of Africa, on the coast of Zanguebar; 10 miles N.W. of Ampaça.

SIOCON, a town on the west coast of the island of Mindanao. N. lat. 7° 25'. E. long. 122° 12'.

SIOCOTTICLAY, a town of the island of Ceylon; 25 miles N.N.W. of Trincomaly.

SIODA, in *Ancient Geography*, a town of Albania, being one of those which Ptolemy places between the Cyrrhus and Albanus.

SIOE, in *Geography*, a small island of Denmark, near the W. coast of Langeland. N. lat. 54° 58'. E. long. 10° 42'.

SION, or **ZION**, in *Ancient Geography*, a mountain of Palestine, or of the land of Canaan, for an account of which, see **JERUSALEM**.

SION was also one of the names of mount Hermon, or rather of a chain of mountains, called mountains of Hermon, from mount Hermon, the principal of them. Of this mountain the Psalmist probably speaks in Ps. cxxviii. 3.—Also, a town of Palestine, in the tribe of Issachar, according to the book of Joshua.

SION, in *Geography*, a town of France, in the department of the Lower Loire; 9 miles W. of Chateaubriant.

SION, or **Sitten**, a town of Switzerland, and capital of the Vallais, situated on a river of the same name, which soon after runs into the Rhone. This is the see of a bishop, the most ancient in Switzerland, and said to have been originally founded at Martinach. The bishop, who styles himself count and vogt-governor of the Vallais, is elected by the chapter of the cathedral and the representatives of the tythings, and is a suffragan of the archbishop of Moutiers, in Savoy. It contains six churches, with some convents, a college, and three palaces of the bishop, standing one above another; 48 miles E. of Geneva. Sion is situated at the foot of three insulated rocks, that rise immediately from the plain. The highest, called Tourbillon, supports the ruins of the old episcopal palace, containing two or three untenanted apartments, in one of which are the portraits of the several bishops. On the second rock, denominated Valeria, are observed the remains of the old cathedral, and a few houses belonging to the canons. On Mayoria, the third rock, stands the episcopal palace, an ancient edifice of stone, built in 1547. Two apartments in this palace deserve attention. The first is that in which the diet assembles; and the other is the hall, in which the bishop holds his court, like the feudal lords of ancient times; at the further extremity is a raised seat, called a throne, surrounded by a wooden balustrade, and as an incitement to wisdom and impartiality, the figures of Justice and Solomon's judgment are coarsely painted upon the walls. Sion is an ancient town, and was formerly the capital of the Seduni, who inhabited this part of the country in the time of Julius Cæsar. Among several obliterated inscriptions, one is legible, in honour of the emperor Augustus, during his eleventh consulship. In this inscription the town is called "Civitas Sedunorum." N. lat. 46° 11'. E. long. 7° 9'. See **VALLAIS**.

SION College. See **COLLEGE**.

SIONDEIAR, in *Geography*, a town of Hindoostan, in the Carnatic; 25 miles N.W. of Ongole.

SIONDY,

SIONDY, a town of Hindoostan, in the Carnatic; 20 miles S. of Ongole.

SIONE, a river of America, which runs into lake Erie, N. lat. $42^{\circ} 22'$. W. long. $82^{\circ} 52'$.

SIONI, a town of Georgia, in the province of Carduel; 90 miles N.N.W. of Teflis.

SIOPE, a river of Brazil, which runs into the Atlantic, S. lat. $3^{\circ} 20'$. W. long. $40'$.

SIORING, a town of North Jutland; 4 miles N.W. of Titled.

SIOTO. See SCIOTO.

SIOTOSTA, a town of Sweden, in West Gothland; 49 miles E.S.E. of Gotheborg.

SIOUEN, a town of China, of the third rank, in Quang-tong; 32 miles S. of Louy.

SIOULE, a river of France, which runs into the Allier, two miles N. of St. Pourçain, in the department of the Allier.

SIOU-OUEN, a town of China, of the third rank, in Koei-tcheou; 15 miles N.N.W. of Koei-yang.

SIOUX, a river of Louifiana, which runs into the Mississippi, N. lat. $38^{\circ} 42'$. W. long. $93^{\circ} 17'$.

SIOUX, a denomination that distinguishes Indians of North America, who inhabit the territories about the rivers Mississippi and Missouri. The dread of this powerful nation is extended over all the other savage nations, from the confluence of the Mississippi and Missouri, to the Raven river on the former, and to the Snake Indians on the latter. Among these nations, however, the Sioux have many allies; but the Chippeways are an exception, as they have maintained with them a long contest; and, indeed, by means of their small lakes, water-courses, and impenetrable morasses and swamps, they bid defiance to the attacks of their neighbours. Of the Sioux nation there are different bands, that are distinguished among themselves. The first of these comprehends the Minowa Kantong, or Gens de Lac, who extend from the Prairie des Chiens to Le Prairie du François, 35 miles up the St. Peters. This band is again subdivided into four classes, under different chiefs. The first subdivision hunts on both sides of the Mississippi and its confluent streams, from the Prairie des Chiens to the river Du Bœuf. The second subdivision resides near the head of the lake Pepin, and hunts from the Rivière du Bœuf near to the river St. Croix. The third subdivision resides between the Rivière au Canon and the entrance of the St. Peters. Its principal hunting ground is on the St. Croix. The fourth subdivision is situated from the entrance of St. Peters to the Prairie des François; they have a village nine miles up the St. Peters, on the N. side. The band Minowa Kantong is reputed the bravest of all the Sioux. The second band of Sioux includes the Washpetong, or Gens des Feuilles, who inhabit the country from the Prairie des François near to Roche Blanche, on the St. Peters. They hunt on the St. Peters, and also in the Mississippi up Rum river, and sometimes follow the buffalo over the plains. The third band comprises the Sussitongs, who extend from the Roche Blanche to Lac de Gros Roche, on the river St. Peters. They are subdivided into the Cawrees and Sussitongs proper, both of whom hunt E. of the Mississippi, and up that river, as far as the Rivière de Corbeau. The fourth great band comprehends the Yanc-tongs, who are dispersed from the Montaignes de la Prairie, which extend from St. Peters to the Missouri, to the river De Moyen. These are subdivided into the Yanc-tongs of the north and those of the south. These are the most unsettled and erratic of all the Sioux; so that they are sometimes found on the borders of the Lower Red river, sometimes on the Missouri, and on those immense plains that lie be-

tween the two rivers. The fifth band includes the Titongs, who are dispersed on both sides of the Missouri. The sixth and smallest band of the Sioux includes the Washpetoute, who reside generally on the lands west of the Mississippi, between that river and the Missouri. They generally hunt on the head of the river De Moyen. These are represented as the most stupid and inactive of all the Sioux.

The Minowa Kantongs are the only Sioux who use canoes, and they are by far the most civilized; being the only Sioux who have ever built log huts, or cultivated any species of vegetables. This band is entirely armed with firearms. The Washpetong are a roving band; they leave the river St. Peters in April, and do not return from the plains until the middle of August. The Sussitongs of Roelic Blanche bear the character of being the most evil-disposed Indians on the river St. Peters. They likewise follow the buffalo in the spring and summer months. The Sussitongs of the Lac de Gros Roche bear the character of good hunters and brave warriors. The Yanc-tongs and Titongs are the most independent Indians; as they follow the buffalo where chance directs; clothing themselves with the skin, and making their lodges, bridles, and saddles of the same materials, the flesh of the animal furnishing them with food.

The claims of limits of the Sioux nation are allowed by all their neighbours to commence at the Prairie des Chiens, and to ascend the Mississippi, on both sides, to the Rivière de Corbeau, up the river to its source; from thence to the source of St. Peters; from thence to the Montaigne de la Prairie; from thence to the Missouri, down that river to the Mahas, bearing thence N.E. to the source of the river De Moyen; and from thence to the place of commencement. They also claim a large territory S. of the Missouri. The country E. of the Mississippi, from Rum river to the Rivière de Corbeau, is likewise in dispute between them and the Chippeways, and has been the scene of many sharp encounters for near 150 years past.

The Sioux are represented as the most warlike and independent nation of Indians within the boundaries of the United States, every passion being subservient to that of war; and their leaders feel themselves perfectly secure from any combination that can be made against them. Their guttural pronunciation, high cheek-bones, thin visages, and distinct manners, together with their own traditions, supported by the testimony of neighbouring nations, leave little room for doubt, that they have emigrated from the N.W. point of America, to which they had come from the narrow strait which in that quarter divides the two continents, and that they are descendants of a Tartarian tribe. Pike's Account of Expeditions to the Sources of the Mississippi, &c. Appendix to part 1.

SIPA, a town of Napaul; 98 miles N.E. of Catmandu.

SIPALAY, a town on the W. coast of the island of Negroes. N. lat. $9^{\circ} 43'$. E. long. $122^{\circ} 28'$.

SIPANEA, in *Botany*, Aubl. Guian. 147. t. 56, a name of Aublet's, whose origin or meaning does not appear. The plant is supposed by Jussieu to be a congener of *Mussaenda*; but Schreber more justly refers it to *VIRECTA*, Linn. Suppl. 17. See that article hereafter.

SIPARUNA, Aubl. Guian. 864. t. 333. Juss. 443, an unexplained name for a shrub of Guiana, whose generic characters are not sufficiently made out to allow of its being reduced by Jussieu to any of his natural orders; nor has Schreber admitted it into his *Genera Plantarum*. Aublet refers it to the *Monocia Decandria* of the Linnæan system.

Gen. Ch. Male, *Cal.* Perianth of one leaf, in four deep roundish segments. *Cor.* none. *Stam.* Filaments four, six, eight, or ten, inserted into a hairy receptacle; anthers of two cells. *Pist.* none.

Female, *Cal.* and *Cor.* as in the male. *Stam.* none. *Pist.* Germen superior, roundish; style oblong, striated; stigmas five, capillary. *Fruit* unknown.

1. *S. guianensis*.—Found on the borders of rivulets, in the quarter of Oyac, flowering in August. The stem is eight or ten feet high, slender, with long, slender, smooth, opposite branches; its wood white and brittle. *Leaves* elliptic-oblong, smooth, pointed, entire, about five inches in length, opposite, on short stalks. The flowers are axillary, green, very small, on short, somewhat racemose, stalks.

SIPAVEND, in *Geography*, a town of Persia, in the province of Mekran; 212 miles N.N.W. of Kidge.

SIPELER, a town of Hindoostan, in the circar of Condapilly; 24 miles S. of Masulipatam.

SIPGICON-COUTEN, a town of Chinese Tartary, in the country of Hami. N. lat. 40° 10'. E. long. 95° 42'.

SIPHAC, a name used by some authors for the peritomeum.

SIPHANTO, in *Geography*, an island of the Archipelago, N. of Argentiera, and very close to it. In former times this island was flourishing under the name of "Siphnos," and it was even reckoned the richest of the Archipelago, on account of the gold and silver-mines which had there been discovered, and of which the tenth alone furnished the temple of Apollo at Delphos with the richest treasure that had been seen. These mines reflect dishonour on the memory of the Siphnians, whilst they enriched them; for their opulence produced such a corruption of morals and duplicity of character, which became so common and so characteristic of them, that they served, throughout all Greece, as a term of comparison, when it was required to paint discredited morals or perfidy of conduct. At this day, the treasures concealed within the bosom of the earth are unknown; and the discovery of them remains to become a source of riches to an island, which, though less impoverished than some others, exhibits in a degree the picture of misery common to all these countries. Besides the mines of gold and silver which Siphanto afforded, it has some that are very abundant in lead, iron, and load-stone. Its mountains also contain quarries of very beautiful marble, and the residents speak of a species of very soft stone, with which they made vases that were conveyed throughout all Greece, but are not known in our days; so that the island of Siphanto would still be the richest of the Archipelago, if it ceased to be subject to a government which crushes it with an iron hand. It is also one of the most agreeable and most cheerful; the air is pure and wholesome; the plains are adorned with a variety of dress, which it owes to easy labour; and the excellent quality of their productions is another precious favour of nature. Salt, cotton, figs, oil, wax, and a few other commodities of less importance, compose the crops and the trade of the island: but both might be much augmented by industry, if it were encouraged. Fine cotton-cloths, straw-hats, &c. are manufactured here. The inhabitants are mild and hospitable; the women are beautiful; but their dress disguises their charms. This island has no harbour, except for small vessels. The most considerable place, which is called Scrai, is built on steep rocks, which leave below the town only a small cave, where boats can anchor, because if they were surpris'd here by a northerly wind, they would soon be dashed to pieces on the coast; those of the country are hastily drawn on

shore as soon as they are unloaded. Siphanto contains five villages, and about 5000 inhabitants. N. lat. 36° 59'. E. long. 24° 56'.

SIPHILIS, from *σιφλος*, *filthy*, in *Surgery*, the venereal disease. See LUES *Veneræ*.

SIPHITA, a word used by Paracelsus, and his followers, with the addition of *parva* and *magna*, for two disorders. The *siphita parva* signifies the *chorea sancti Viti*, or *St. Vitus's dance*; and the *siphita magna*, walking in time of sleep.

SIPHNIUS LAPIS, in the *Natural History* of the ancients, a substance found in great plenty in the island Siphnos, (*Siphanto*), in the *Ægean* sea. It was dug up in large masses in the neighbourhood of the sea; and when fresh, might be cut or worked into any sorts of vessels, by reason of its softness; but when afterwards burnt and oiled over, became black and solid, and fit for any service: and the vessels made of it bore the fire very well. The same substance is still found in many parts of Europe, and called *lapis lebitum*, and applied to the same use. It is no other than the steatites, or our soap-rock.

SIPHON, or *ΣΥΦΩΝ*, in *Hydraulics*, a crooked tube, one leg or branch of which is longer than the other; used in the raising of fluids, emptying of vessels, and in various hydrostatical experiments.

The word in the original Greek, *σιφών*, signifies simply *tube*, whence some apply it to common tubes or pipes. Wolfius particularly describes two vessels under the name of siphons: the one cylindrical in the middle, and conical at the two extremes; the other globular in the middle, with two narrow tubes fitted to it axis-wise: both serving to take up a quantity of water, &c. and to retain it when up.

But the most useful and celebrated siphon is that which follows: a crooked tube ABC (*Plate XV. Hydraulics, fig. 1.*) is provided of such a length, and with such an angle, or so bent at the vertex, as that when the orifice A is placed on an horizontal plane, the height of AB may not exceed thirty-two or thirty-three feet. For common uses, a foot or half a foot high suffices. If, now, the left arm, AB, be immersed in water, or any other liquid, and the air be sucked out of it by the aperture C, till the liquor follow; the liquor will continue to flow out of the vessel, through the tube BC, as long as the aperture A is under the surface of the liquor.

Note, instead of sucking out the air, the event will be the same, if the siphon be at first filled with the fluid, and the aperture C lopped with the finger, till the aperture A be immersed.

The truth of the phenomenon is known by abundance of experiments; nor is the reason of part of it far to seek. In sucking, the air in the tube is rarefied, and the equilibrium destroyed; consequently the water must be raised into the taller leg AB, by the preponderating pressure of the atmosphere.

The siphon being thus filled, the atmosphere presses equally on each extremity, so as to sustain an equal quantity of water in each leg; but the air not being able to sustain all the water in the longer leg, and being more than able to sustain that in the shorter leg; with the excess of force, therefore, it will raise new water into the shorter leg; and this new water cannot make its way, but by protruding the first before it: by this means is the water continually driven out at the longer leg, as it is continually raised by the shorter.

The cause of the siphon's running may be otherwise explained in the following manner: the air which passes into the vessel ABCD (*fig. 2.*), represented by the column

K L, sustains the column of water, L D, in the short leg of the siphon, pressing against that air with its perpendicular height D F; whilst the column of air M S, pressing upwards against the whole of the long or issuing leg D S, which acts according to the height D C, must yield and suffer the water to run out, as long as the leg D S is longer, or rather perpendicularly higher, than D G. For since K and M are supposed to be at the top of the atmosphere, the columns K L and M S are equal in height and pressure, (for the height of L above S is of no account with respect to the whole height of the atmosphere,) as long as M S is acted upon by the descending water D S, whose height is from D to S, (*e. g.* fifteen inches,) an height superior to that of the column D G, (*e. g.* seven inches,) supported by the column of air K L, the column M S must yield to the water issuing out at S; and however the surface of the water, E F, descends, the column K L, by its pressure, will always overcome the resistance of the column M S, because it has a less height of water to sustain than M S has. If the mouth of the issuing leg had been at T, the water would hang *in equilibrio*, filling both legs of the siphon, when the water is come down in the upper vessel to I H T; because then the two columns of air, K L and M S, will be acted against by an equal height of water in the legs of the siphon; but if you raise the issuing end of the siphon (now supposed at T) up to the level of *v* V above I H, the water will run back up from V to D, and so out at H in the upper vessel; because then the column M S, having only the height V D to sustain, will be acted against with less force than the column K L, which is pressed against by the whole height, D H, superior to V D. Since, therefore, the pressure of the air is the cause of the water being pushed up into the siphon, and the difference of its pressure (as one column is acted against by the water in the short leg more weakly than another column of air is acted upon by the water in the long leg) is the cause of its running continually from one vessel into another, when once set a-going; it follows, that the bend, D, of the upper part of the siphon must not be above thirty-two feet higher than the water in the upper vessel, because the air cannot sustain a column of water, whose height exceeds thirty-two feet.

Mercury will run in a siphon in the same manner as water; but in this case, the bend of the siphon must not be more than $30\frac{2}{3}$ inches above the stagnant mercury in the upper vessel; because, as it is about fourteen times specifically heavier than water, it will be lifted up by the pressure of air but the fourteenth part of the height to which the water is lifted. Defag. Exp. Phil. vol. ii. sect. 8.

But some authors assert, that the water continues to flow through the siphon, even when placed under a receiver, and the air exhausted from it.

Some will have it, that there is still air enough left in the evacuated receiver, to raise the water to an inch or two. But as both mercury and water are found to fall entirely out of the Toricellian tube, *in vacuo*; the pressure of the thin remaining air there can never be the cause of the ascent, both of mercury and water, in the shorter leg of the siphon. Hence, as the height of the siphon is limited to thirty-two feet; for this only reason, that air cannot raise water higher; some have questioned whether or not we are in the right in rejecting Hero's method of carrying water, by means of a siphon, over the tops of mountains, into an opposite valley. For Hero only orders the apertures of the siphon to be stopped, and water to be poured through a funnel into the angle or meeting of the legs, till the siphon be full; when, shutting the aperture in the angle, and opening the other two, the water, he says, will continue to

flow. Now, if there only need air for the first rise of the water into the legs, not for the continuation of the motion, it were possible to raise the water much higher than the height of the atmosphere would carry it.

Wolfius (*Elem. Mathes. tom. ii. p. 348. ed. 1733.*) expressly says, that this proposed artifice of Hero is very justly rejected; because air is necessary not only for the elevation of the water in the shorter leg, but for the continuance of its motion; and he adds, that this method was unsuccessfully tried, where the height was greater than thirty-two feet.

Defaguliers also observes, that in a crane or siphon, such as that proposed by Hero, of about forty feet high, the water, instead of running from the upper vessel into the lower, as it would do if the height of the short leg were much under thirty-two feet, will in the two legs fall back to the height of thirty-two feet, above the respective vessels, where it will hang; the air not being able to sustain the water above these heights, and consequently drive it up over the bend.

In an experiment of this kind, the water in the legs of the siphon, unless it be purged of its air, will not rest at a height of quite thirty feet above the water in the vessels, because air will extricate itself out of the water, and getting above the water in the legs, presses it downwards, so that its height will be less to balance the pressure of the atmosphere. However, this is certain, that a siphon of a particular kind, once set a running, will persist in its motion, though removed into the most perfect vacuum our air-pumps will make: or, if the lower orifice of a full siphon be shut, and the whole be thus placed in a receiver, with a contrivance for opening the orifice when the air is exhausted; the water will be all emptied out of the vessel, as if it had been in the open air.

This fact has been sufficiently ascertained by many approved hydrostatical writers.

Defaguliers informs us, that he made the experiment, both with water and mercury; for having filled a siphon, recurved at the extremities of its legs, successively with those liquors, and suspended it by a slip-wire in the receiver of an air-pump, over two small jars containing mercury to unequal heights, (and water, when water was used in the siphon,) he exhausted the air out of the receiver, and then letting down the siphon, so that its two ends went into the liquor in the jars, the liquor ran from the higher into the lower vessel. He also made an experiment in the open air, where the mercury ran through a siphon, whose bend was more than thirty-one inches above the lower orifice of the short leg of the siphon. But neither of these experiments affords a just objection against the doctrine advanced in the preceding part of this article, *viz.* that the air is the cause of the discharge of liquors from one vessel into another by means of siphons; for its running *in vacuo* was only owing to the attraction of cohesion, which acts for a small height; because the experiment will not succeed *in vacuo*, if the siphon used for mercury has its bend six inches higher than the orifice of the short leg, and if the bend of the siphon for water be two or three feet high; neither will the last-mentioned experiment with mercury in the open air answer, if the bend of the siphon be forty inches high: and in all the experiments, the bores of the siphons must be very small. Exp. Phil. ubi supra, p. 168.

The figure of the siphon may be varied at pleasure (see *figs. 3, 4, 5.*), provided only the orifice C be below the level of the surface of the water to be drawn up; but still the farther it is distant from it, the faster will the fluid be carried off. And if, in the course of the flux, the orifice A

be drawn out of the fluid, all the liquor in the siphon will go out at the lower orifice C; that in the leg C B dragging, as it were, that in the shorter leg A B after it.

If a filled siphon be so disposed, as that both orifices, A and C, be in the same horizontal line, the fluid will remain pendant in each leg, how unequal soever the length of the legs may be. Fluids, therefore, in siphons, seem, as it were, to form one continued body; so that the heavier part, descending like a chain, pulls the lighter after it.

Lastly, it must be observed, that the water will flow out, even through a siphon that is interrupted, by having the legs A D and F C joined (fig. 5.) together, by a much bigger tube full of air.

The siphon Wirtembergicus is a very extraordinary machine of this kind, performing divers things which the common siphon will not reach. *E. gr.* In this, though the legs be in the same level, yet the water rises up the one, and descends through the other; the water rises, even though the aperture of the less leg be only half immersed in water; the siphon has its effect after continuing dry a long time; either of the apertures being open, the other remaining shut for a whole day, and then opened, the waters flow out as usual. Lastly, the water rises and falls indifferently through either leg.

Muschenbroeck, in accounting for the operation of this siphon, observes, no discharge could be made by it, unless the water applied to either leg cause the one to be shorter, and the other longer by its own weight. *Introd. ad Phil. Nat. tom. ii. p. 853. ed. 4to. 1762.*

The project of this siphon was laid by Jordanus Pelletier, and executed at the expence of prince Frederic Charles, administrator of Wirtemberg, by his mathematician Shachard, who made each branch twenty feet long, and set them eighteen feet apart; the description of it was published by Reifelius, the duke's physician.

This gave occasion to M. Papin to invent another, that did the same things, described in the Philosophical Transactions; and which Reifelius, in another paper in the Transactions, ingenuously owns to be the very same with that of Wirtemberg. Its structure will appear from its figure, which is represented *Plate XV. Hydraulics, fig. 6.*

SIPHONANTHUS, in *Botany*, from *σινωον*, a tube, and *ανθος*, a flower, because of the long tube of the corolla. Ammann, the author of the genus, in the Petersburg Transactions, for 1736, called it *Siphonanthemum*.—*Linn. Gen. 53. Schreb. 70. Willd. Sp. Pl. v. 1. 606. Mart. Mill. Dict. v. 4. Juss. 132. Lamarck Illustr. t. 79.—*Class and order, *Tetrandria Monogynia*. *Nat. Ord. Borraginæ affine, Juss.*

Gen. Ch. Cal. Perianth inferior, of one leaf, large, in five deep permanent segments. *Cor.* of one petal, funnel-shaped; tube thread-shaped, very slender, many times longer than the calyx; limb in four deep spreading segments, smaller than the calyx. *Stam.* Filaments four, longer than the limb of the corolla; anthers oblong, triangular. *Pist.* Germen superior, four-cleft, very short; style thread-shaped, the length of the stamens, recurved at the extremity; stigma simple. *Peric.* Berries four, roundish, within the spreading calyx. *Seeds* solitary, roundish.

Eff. Ch. Corolla of one petal, funnel-shaped, very long, inferior. Berries four, with solitary seeds.

1. *S. indica*. Indian Pipe-flower. *Linn. Sp. Pl. 159. Willd. n. 1. Poiret in Lam. Dict. v. 7. 200.* ("Siphonanthemum falicis folio, flore flavescente; *Amm. Act. Petrop. ann. 1736, 214. t. 15.*" *Lysimachii* species; *Pis. et Bont. Ind. Or. 159?*)—Native of the East Indies? We have seen no specimen, but the figures and descriptions

of this plant represent it as having an herbaceous, simple, leafy stem. *Leaves* alternate, or partly opposite; sometimes three in a whorl, sessile, lanceolate, acute, wavy, entire. *Flower-stalks* axillary and terminal, much shorter than the leaves, three-cleft. *Flowers* thrice as long as their stalks, yellowish.

Willdenow has separated Lamarck's fig. 2. as a distinct species, by the name of *S. angustifolia*; but Lamarck himself in his *Illustr. p. 318*, gives that figure as perhaps only a better representation of the original species. The difference indeed between the stigmas of the two figures is too great to be probable. We should think, with this author, that the figure in Bontius might rather belong to some *Volkameria* or *Clerodendrum*, were it not spoken of as a pot-herb. After all, who can be certain, that the history of *Siphonanthus* is not altogether a blunder, and that the original plant itself is not a *Volkameria*, *Clerodendrum*, or *Ovicida*? *O. mitis*, a species very little known to botanists in general, bears a considerable resemblance to it, though the inflorescence differs materially from what is described in *Siphonanthus*.

SIPHONIA, from *σινωον*, a pipe, alluding to the uses made of the resinous exudation of this tree, so well known under the appellation of elastic gum, or *caoutchouc*.—*Schreb. Gen. 656. Willd. Sp. Pl. v. 4. 567. Mart. Mill. Dict. v. 4. Lamarck Illustr. t. 790. (Hevea; Aubl. Guian. 871.)—*Class and order, *Monocelia Monadelphia*. *Nat. Ord. Tricocca, Linn. Euphorbia, Juss.*

Gen. Ch. Male, Cal. Perianth of one leaf, bell-shaped, rather globose, cut half way down into five erect, acute teeth, reflexed at the margins. *Cor.* none. *Stam.* Filaments united into a column, shorter than the calyx; anthers five, nearly ovate, attached to the column below its summit.

Female, Cal. Perianth inferior, of one leaf, bell-shaped, somewhat turbinate, with five acute, spreading, recurved deciduous teeth, the circular base only being permanent. *Cor.* none. *Pist.* Germen superior, globose, somewhat conical, shorter than the calyx; style none; stigmas three, thickish, depressed, two-lobed. *Peric.* Capsule large, three-lobed, depressed, hollowed out at the base, woody, very hard, of three cells, invested with a fibrous bark; each cell with two elastic valves. *Seeds* one, two, or three, nearly ovate, with a brittle spotted shell.

Eff. Ch. Male, Calyx bell-shaped, five-cleft. *Corolla* none. *Filament* columnar, with five anthers.

Female, Calyx bell-shaped, five-cleft. *Corolla* none. *Stigmas* three, sessile. *Capsule* of three lobes, with elastic valves.

1. *S. elastica*. Elastic-gum Tree. *Martin n. 1. (S. Cahuchu; Richard. Willd. n. 1. Jatropha? elastica; Linn. Suppl. 422. Hevea guianensis; Aubl. Guian. 871. t. 335. "Pao feringa; Mem. de l'Acad. des Sc. for 1751. t. 20, bad.)—*Native of Brazil, and the forests of Guiana, bearing fruit in April and May. A tree, whose trunk rises to the height of 50 or 60 feet, with a thin grey bark, and a soft white wood; the branches spreading widely in every direction. *Leaves* towards the ends of the branches, alternate, but crowded, and spreading in a circular order round the branch, on long stalks, ternate; leaflets elliptical, obtuse, entire, or minutely undulated, smooth, reticulated with veins; paler beneath; each about three inches long, and one wide, on a partial stalk about half an inch in length. *Common footstalks* rather longer than the leaflets, round, singly downy. The flowers we have not seen, but they are said to be small, downy, as well as their stalks; the male ones numerous, racemose; the female solitary, at

the end of each cluster. *Fruit* the size of a chestnut in its shell, green, smooth, of three large ovate lobes, the valves bursting elastically, like those of a *Jatropha*. Aublet says the *nuts* are very good and wholesome. The trunk of the tree, when wounded, discharges a milky fluid, which being collected, either in a mass, or by smearing it over lumps of clay, sticks, &c. dries into any shape that is wanted, and becomes the elastic gum, or Indian rubber, so useful to artists for effacing at pleasure the marks of a black-lead pencil. (See CAOUTCHOUC.) We beg leave to correct a slight botanical inaccuracy in that article; for the *Hevea* and the *Jatropha elastica* are precisely the same plants. There is indeed, in the Linnæan herbarium, besides the original specimen, marked with this last name, another from Mutis, which that learned botanist judged to be a distinct species, though affording, as some other trees do, a similar gum. The *leaflets* in this specimen are larger, more acute at each end, and destitute of partial stalks. The *calyx* is nearly half an inch long. The younger Linnæus, in his *Supplementum*, 422, promised to publish something at a future time respecting the various trees that yield an elastic gum, of the same utility as the *Caoutchouc*; but he did not live to execute his design. His reference to the Mem. de l'Académie for 1751, with a censure of the figure, appears to be copied from Aublet.

SIPIAS, in *Geography*, a town of Mingrelia, situated on a river which runs into the Black sea; 100 miles W.N.W. of Teflis.

SIPING, a town of China, of the third rank, in the province of Ho-nan; 30 miles N.N.W. of Yun-hing.

SIPONIMA, in *Botany*. See CIPONIMA, and SYMLOCOS.

SIPSEY, in *Geography*, a river of the state of Georgia, which runs into the Tombigh, N. lat. 32° 22'. W. long. 87° 51'.

SIPTACE, in *Natural History*, the name given by the ancients to a beautiful bird, of which they were very fond, and which was often kept in their houses. Some have conjectured this to be the goldfinch, from the fine yellow they describe about it; but Pliny plainly makes it the parrot; he tells us, among other things, that it imitated the human voice the best of all birds.

SIPUCA, in *Geography*, a town of Peru, in the diocese of La Plata; 60 miles E. of Plata.

SIPUNCULUS, or TUBE-WORM, in *Vermiology*, a genus of the Vermes Intestina class and order, of which the generic character is as follows: Body round, elongated; mouth cylindrical at the end, and narrower than the body; the aperture at the side of the body, and veruciform. There are only two

Species.

* **NIDUS.** The body of this species is covered with a close skin, and globular at the lower end. It is described and figured by Pennant, Barbut, and Martin. It inhabits European seas, under stones; and is about eight inches long. The body is conic, and broader on the fore-part; the mouth is much slenderer than the body, and armed with fleshy, three-pointed papillæ; the aperture is near the upper extremity.

SACCATUS. Body covered with a loose skin, and rounded at the lower end. It inhabits the American and Indian seas. It is shaped like the nidus, except in being enclosed as it were in a loose bag, and in not having the lower end globular.

SIR, or **SIRR,** in *Geography*, a river which rises in the

mountains of Tartary, about 160 miles W. of Cashgar, and runs into the lake of Aral, in N. lat. 45° 10'.

SIR Biby's Island, a small island in Hudson's bay. N. lat. 61° 55'. W. long. 93° 40'.

SIR Charles Hardy's Island, an island in the Southern Pacific ocean, discovered by captain Carteret in 1767. Its extent is considerable, and it appears to be flat, green, and pleasant. S. lat. 4° 38'. E. long. 134° 6'.

SIR Charles Hardy's Islands, a cluster of small islands in the South Pacific ocean, discovered by captain Cook in 1770. S. lat. 11° 55'. W. long. 217°.

SIR Thomas Hay's Point, a cape on the N.W. coast of Portland, one of Queen Charlotte's islands, in the South Pacific ocean. S. lat. 10° 42'. E. long. 165° 14'.

SIR William James's Island. See *St. Sufanna*.

SIR Henry Martin's Island, an island in the Pacific ocean, about 16 leagues in circumference; discovered by lieutenant Hergest, commander of the *Dædalus* store-ship, in the year 1792. The country seemed to be highly cultivated, and was fully inhabited by a civil and friendly race of people, readily inclined to supply whatever refreshments their country afforded. Mr. Hergest's company were induced to entertain this opinion from the hospitable reception they experienced, on landing, from the chiefs, and upwards of 1500 of the natives, who were assembled on the shores of the harbour. On their return to the ship, they found the same harmony subsisting there with the Indians, who had carried off and sold a supply of vegetables and some figs. It is called by the natives Noohëva. S. lat. 8° 51'. E. long. 220°.

SIR Charles Saunders's Island, or *Tapooamānoo*, an island in the Southern Pacific ocean, discovered by captain Wallis in the year 1767. The island is about six miles in length, and has a mountain of considerable height in the centre, which appeared to be fertile. The inhabitants did not appear to be numerous. S. lat. 17° 28'. W. long. 150° 40'.

SIR Thomas Roe's Welcome, a large bay in the north part of Hudson's bay.

SIRA, a name by which some of the chemical writers have called orpiment.

SIRACAUSTUM, a name given by Mesue to a medicine he recommends in acute diseases.

SIRACUSA, in *Geography*. See SYRACUSA.

SIRADIA, a town of the duchy of Warsaw, late capital of a palatinate of Poland, of the same name, situated on the Warta; 100 miles N.N.W. of Cracow. N. lat. 51° 31'. E. long. 18° 45'.

SIRÆUM, a word used by some to express a sweet decoction, whether given in that form, or first inspissated into a sort of rob by evaporation.

SIRAF, in *Geography*, a town of Persia, in the province of Laristan, on the N. coast of the Persian gulf, inhabited by Arabians from the opposite shores; 30 miles S.W. of Lar. N. lat. 26° 44'. E. long. 53° 50'.

SIRAGUAY, a town on the W. coast of the island of Mindanao. N. lat. 7° 15'. E. long. 112° 9'.

SIRAJEPOUR, a town of Hindoostan, in Allahabad; 10 miles E. of Corah. N. lat. 26° 9'. E. long. 80° 58'.

SIRAITINA, a town of Russia, in the country of the Cossacks; 56 miles S. of Arkadinikaia.

SIRAN, a town of France, in the department of the Herault; 15 miles S.W. of St. Pons.

SIRANCAPE, a river of Africa, which runs into the Indian sea, S. lat. 13° 4'.—Also, a town of Africa, in the country of Mozambique, at the mouth of the river of the same name. S. lat. 13° 4'.

SIRANI,

SIRANI, GIOVANNI ANDREA, in *Biography*, a painter of the school of Guido Rheni. He was born at Bologna in 1610, and was a favourite disciple of his master, whose style he imitated with great success. After the death of Guido, he was employed to finish many of his works, left incomplete in different churches, at Bologna; particularly the large picture of St. Brunone, in the Certosini. He usually painted upon a large scale, and with a free pencil, but in general his manner is too strong and dark, like that of Caravaggio. He died in 1670, at the age of 60.

SIRANI, ELIZABETTA, was the daughter of Giovanni Andrea Sirani, and born at Bologna in 1638. She learned the rudiments of the art from her father, but endeavoured to imitate the best style of Guido. At so early a period as her fifteenth year, she had acquired considerable renown for her performances. Her first public work was painted when she was only seventeen. In general she wrought upon a large scale, and in a most finished manner; with a rich and natural tone of colour. Her compositions are tasteful, and the airs of her heads graceful, and noble in character. Her portraits have greatly the air of nature, with an unaffected character of expression and action.

Unhappily, whilst in the enjoyment of the renown justly due to her inestimable talents and amiable qualities, and which had been acquired by unceasing assiduity, her brilliant career was interrupted by poison; by whom administered is not exactly known, though it is supposed by her servant. This melancholy event happened in 1664, when she had only attained her twenty-sixth year; yet such had been her industry, that she had produced, according to Malvasia, from a register of her own keeping, 150 works: the most admired of which were painted for the churches and palaces at Bologna. They are elsewhere scarce.

SIRAN-LOSA, in *Geography*, a lake of Thibet, about 18 miles in circumference, which communicates with lake Tenckiri by means of a river called also "Siran-lofa;" 18 miles W. of lake Tenckiri.

SIRA-OULOSO, a town of Thibet; 15 miles E. of Hami.

SIRAT, AL, in the *Mahometan Theology*, the name of a bridge, which is situated in the midst of hell, finer than a hair and sharper than the edge of a sword; over which those who are admitted into paradise, and who take the right-hand way, and those who are destined to hell-fire, and take the left, are supposed to pass. On account of its form, it is conceived to be very difficult for any one to stand upon it; and therefore most of the Motazalites reject it as a fable, though the orthodox believe it on the authority of their prophet, by whom it is affirmed; and who has likewise declared, that in order to add to the difficulty of this passage, the bridge is beset on each side with briars and hooked thorns, which will, however, be no impediment to the good, for they shall pass with wonderful ease and swiftness, like lightning or the wind, Mohammed and his Moslems leading the way; whereas the wicked, obstructed by the slipperiness and extreme narrowness of the path, the entangling of the thorns, and the extinction of the light, which directed the former to paradise, will soon miss their footing, and fall down headlong into hell, which is gaping beneath them. Koran, c. 18.

SIRATIK, in *Geography*, one of the Foulah states in Africa, next in order to the principal, which lies within Sierra Leona, and of which Teambo is the capital. It borders on the south of the Senegal river, and on the Jaloffs.

SIRAVAN, a town of Persia, in the province of Chuzistan; 48 miles N.N.E. of Susfer.

SIRE, a title of honour in France, now given to the king only, as a mark of sovereignty. In all placets and petitions, epistles, discourses, &c. to the king, he is addressed under the title of *sire*.

Some derive the word from the Latin *herus*, *master*: of which opinion seems Budæus, who, in speaking to king Francis I., always called him *here*, q. d. *master*, or *sire*; others derive it from the Greek *κυριος*, *lord*; of which opinion is Pasquier, who adds, that the ancient Franks gave the same title to God, calling him *beau sire Dieu*: others fetch the word from the Syriac, and maintain it was first given to the merchants who traded in Syria: Menage will have it come from *senior*, *elder*; whence *seigneur*, then *seignor*, and *sire*.

SIRE was likewise anciently used in the same sense with *sieur* and *seigneur*, and applied to barons, gentlemen, and citizens.

SIRÉ, in *Geography*, a province of Abyssinia, about 25 miles broad, and not much more in length, reckoned as part of Tigré. It lost the rank of a province, and was united to Tigré, on account of the misbehaviour of its governor Kasmeti Claudius, in an expedition against the Shangalla, in the reign of Yafous the Great. It is separated from Samen by the river Tacazzé, and reaches from Axum to this river.—Also, a town situated on the brink of a very steep, narrow valley, through which a road lies that is almost impassable. In the midst of the valley runs a brook, bordered with palm-trees. The town of Siré is larger than that of Axum; it is in form of a half-crown fronting the plain, but its greatest breadth is at the west end. All the houses are of clay, and thatched; the roofs are in form of cones, as indeed are all in Abyssinia. Siré is famous for a manufacture of coarse cotton cloths, which pass for current money through all the province of Tigré, and are valued at a drachm, the tenth part of a wakea of gold, or near the value of an imperial dollar each; their breadth is $1\frac{1}{2}$ yard. Besides these, beads, needles, cohol, and incense, at times only, are considered as money. Although Siré is situated in one of the finest countries in the world, it is very subject to putrid fevers of the worst kind, which sweep away 2 number of people daily. N. lat. $14^{\circ} 4' 35''$. E. long. $38^{\circ} 0' 15''$. Bruce's Travels, vol. iii.

SIREN, *σειρην*, in *Antiquity*, *Mermaid*, a name given to a kind of fabulous beings, represented by the moderns as sea-monsters, with women's faces and fishes' tails; but by the ancient poets, &c. as having the upper part human, and the lower like birds; and decked with a plunage of various colours. There are antique representations of them still subsisting, under both these forms. They are said to have been the daughters of Ocean and Amphitrite, and to form a beautiful part of Homer's machinery in the *Odyssey*. Hyginus places their birth among the consequences of the rape of Proserpine. And Ovid makes them daughters of the river Achelous, and one of the Mules.

The three sirens are called *Parthenope*, *Lygea*, and *Lrucosia*. Homer only makes mention of two sirens, and some others reckon five. Virgil places them on rocks, where vessels are in danger of splitting. Pliny makes them inhabit the promontory of Minerva, near the island Caprea. Others fix them in Sicily, near Cape Pelorus.

Claudian says, they inhabited harmonious rocks; that they were charming monsters; and that sailors were wrecked on their rocks without regret, and even expired in raptures: *Dulce malum in pelago siren*.

Pausanias tells us, that the sirens, by the persuasion of Juno, challenged the Muses to a trial of skill in singing; and these, having vanquished them, plucked the golden

feathers from the wings of the sirens, and formed them into crowns, with which they adorned their own heads. This description is, doubtless, founded on a literal explication of the fable, that the sirens were women who inhabited the shores of Sicily; and who, by all the allurements of pleasure, stopped passengers, and made them forget their course.

The name, according to Bochart, who derives it from the Phœnician language, implies a *song-strefs*: and hence, it is probable, that in ancient times there might have been excellent singers, but of corrupt morals, on the coast of Sicily, who, by seducing voyagers, gave rise to this fable. The Argonauts are said to have been diverted from the enchantment of their songs, by the superior strains of Orpheus: Ulysses, however, had great difficulty in securing himself from seduction. Circe prepares him for the conflict, by the picture and precepts described in the *Odyss.* lib. xii. ver. 51.

Some interpreters of the ancient fables will have the number and names of the three sirens to have been taken from the triple pleasure of the senses, wine, love, and music, which are the three most powerful means of seducing men; and hence, so many exhortations to avoid the siren's fatal song.

Probably it was hence that the Greeks fetched their etymology of siren, viz. from *σειρα*, a chain; as if there was no getting free of their enticement.

Others, who do not look for so much mystery in the fable, maintain that the sirens were nothing but certain straits in the sea, where the waves whirling furiously around, seized and swallowed up vessels that approached them too near.

Lastly, others hold the sirens to have been certain shores and promontories, where the winds, by the various reverberations and echoes, cause a kind of harmony that surpriseth and stops passengers. This, probably, might be the origin of the sirens' song, and the occasion of giving the name of sirens to these rocks.

The learned Mr. Bryant says, that the sirens were Cuthite and Canaanitish priests, who had founded temples in Sicily, which were rendered infamous on account of the women who officiated. They were much addicted to cruel rites, so that the shores upon which they resided are described as covered with the bones of men, destroyed by their artifice. *Virgil, Æneid*, lib. i. v. 864.

The ancients represent their songs as so fatally winning, that nobody could withstand their sweetness: all werefoothed with it; though their life was the purchase of the gratification. See *Homer's Odyss.* M. v. 39.

Mr. Bryant observes, that the story of the sirens relates to those people, who with their music used to entice strangers into the purlieus of their temples, and then put them to death. Nor was it music only with which persons were seduced to follow them; the female part of their choirs were maintained for a twofold purpose, both on account of their voices and their beauty. They were accordingly very liberal of their favours, and by these means enticed sea-faring persons, who paid dear for their entertainment. *Analysis of Ancient Mythol.* vol. ii. p. 17, &c.

SIREN, in *Ichthyology*, a name given by Artedi to the sea-monster often described by authors, but either not existing at all, or not so like man as their description makes it. Artedi supposes it to constitute a peculiar genus of the plagiuri or cetaceous fishes. The characters he gives of it are these: it has no pinnated tail; the head, neck, and breast, down to the navel, represent those of the human species; there are only two fins on the whole body, and those stand on the breast.

Bartholin, in his *History of Curiosities*, describes such a fish as this under the name of *Syrene*, and Barchewitz under the name of *homo marinus*. See MERMAID, SEA-Calf, SEA-Cow, and SEA-MAN.

SIREN, in *Natural History*, a genus of the class and order Amphibia Reptilia, of which the generic character is, Body two-footed, tailed, naked; the feet are placed in the manner of arms, and furnished with claws. There is only a single species mentioned by Gmelin, but Dr. Shaw notices three

Species.

LACERTINA. Body eel-shaped; branchiæ ramified. This species stands eminently distinguished in the list of animals, by the ambiguity of its characters, which are such as to have induced the great Linnæus to institute it for a new order of Amphibia, under the title of MEANTES. The genus with which the siren has the nearest affinity is the *lacerta*, or lizard; which see. It resembles the larva, or first state of a lacerta; and it is even still doubtful whether it may not really be such: yet it has never been observed in any other state, having two feet only, without any appearance of a hind pair. The feet are also furnished with claws, whereas the larvæ of the lacertæ are observed to be without claws; the mouth has several rows of small teeth; the body is eel-shaped, but slightly flattened beneath, marked on the sides by several wrinkles, and slightly compressed towards the extremity of the tail, which is edged with a kind of soft skin, or adipose fin; on each side the neck are three ramified branchial processes, resembling, but on a larger scale, those belonging to the larvæ of water-newts, and at the base are the openings into the gills; the eyes are very small, and blue. The general colour of the animal is a deep or blackish-brown, scattered over, especially on the sides, with numerous minute whitish specks. It is frequently found of the length of two feet, or even more. It is a native of North America, and more particularly of South Carolina, where it is not uncommon in muddy and swampy places, living generally under water, but sometimes appearing on dry land. It has a kind of squeaking or singing voice; hence it was distinguished by the name of siren. This curious animal was first discovered and described by Dr. Garden, who resided many years in Carolina, and who gave the utmost attention to the science of natural history, which he enriched by many highly interesting observations, and by the discovery of many new facts. The doctor communicated specimens of the siren to Linnæus, with particulars relative to its history and manners. The great Swedish naturalist, in his letter to Dr. Garden on this subject, declares that nothing had ever exercised his thoughts so much, nor was there any thing he so much desired to know, as the real nature of so extraordinary an animal. Mr. Hunter has given an anatomical description of the siren in the 56th vol. of the *Philosophical Transactions*, to which the reader is referred.

The siren, if thrown on the ground with any degree of violence, will sometimes break in two or three pieces; and in this particular it resembles the *Anguis fragilis*, or slow-worm. It may also be observed, that though in some respects it resembles the larva of the lizard, yet no lizard, of which it may be supposed the larva, has ever yet been discovered in those parts of Carolina where it is most frequent. The species to which it seems most allied is the *Lacerta tegui* in of Linnæus, which is a native of South America.

ANGUINE; Four-footed siren, with eel-shaped body, and ramified branchiæ. This has been denominated the Proteus anguinus by some naturalists, and by others the Austrian siren. This animal is found in a very singular situation,

being an inhabitant of the celebrated romantic lake Zirknitz, in the duchy of Carniola, in Aultria. From this lake the water regularly retires during the summer, by numerous subterranean outlets at the bottom; leaving the ground dry, and fit for pasture, as well as for various kinds of hunting, and other amusements: but in the month of October it again returns with great force, springing out of the passages before mentioned, from a vast depth, till the lake is completely filled. It is situated in a valley, surrounded by rocky and woody mountains, in which are vast caverns, and it is principally supplied by eight rivulets running into it from the adjoining mountainous region. See Phil. Transf. vol. xvi.

This species of firen is extremely rare, and is found in the spring, and towards the decline of summer, in some particular parts of the above-mentioned lake, and measures from ten to twelve or thirteen inches in length, and about three quarters of an inch in diameter. It is entirely of a pale rose-colour, or even nearly white, except the three pair of ramified branchial fins on each side the neck, which are of a bright red or carmine-colour. Its general shape is that of an eel; the body being cylindrical till towards the end of the tail, where it becomes flat, and is attenuated, both above and below, into a kind of fatty fin, scarcely distinguishable from the rest of the tail; the skin is very smooth and even; the head is of a somewhat depressed form, with a lengthened, obtuse, and widish snout, and it has no external eyes; the mouth is moderately wide, and furnished with a row of very minute teeth; the legs are three quarters of an inch long, and the feet of the fore-legs are furnished with three toes, without claws; the feet of the hind-legs have only two toes. The motions of this animal, when taken out of the water, are, in general, extremely slow and languid; as is also the case when kept in a vessel of water; but in its native lake, it is sometimes observed to swim briskly, waving its body in a serpentine direction, not unlike that of a leech. The Anguine firen is figured and very accurately described by Laurenti, in his work entitled "Specimen Medicum, exhibens Synopsis Reptilium." The real nature of the animal is not completely ascertained; some imagining it to be the larva of some species of lizard, while others contend that it is a perfect animal *sui generis*. It is evidently of a predacious nature, feeding on the smaller kind of aquatic animals; since one of them, which was kept alive in a vessel of water, was observed to discharge from its stomach several small shells of the genus *Helix*; and in the stomach of one, which was dissected, were found the head and bones of a small fish. Its voice is a strong hiss, much louder than might be expected from the size of the animal.

Dr. Schreibers, who has most diligently investigated the nature and anatomy of this animal, says, "there can be no doubt that it bears a great affinity to the *S. lacertina*, having both gills and lungs; and therefore it leaves us in equal uncertainty as to its being a perfect animal in itself, or the larva of another animal." It is, however, remarkable, that notwithstanding the most careful researches during many years, and the frequent fishing which takes place in the lakes and caverns of the neighbouring country, at all seasons of the year, no animal has hitherto been found of which it can possibly be supposed the larva."

PISCIFORMIS; Ferruginous-brown firen, spotted with black, with finely ramified branchiæ, tetradaçtylous fore and pentadaçtylous hind-feet. This animal, in the Naturalist's Miscellany, is denominated *Gyrinus Mexicanus*, or Mexican tadpole. According to the description given in that work, it is a native of Mexico, and, if only the larva of some large American lizard, is scarcely a less singular

and curious animal than the firen. In its general appearance it bears some resemblance to the larva of the *Rana paradoxa*, but is furnished with gills, opening externally in the manner of a fish; the openings are very large, and the external flap is continued from the sides of the head across the throat beneath, so as completely to insulate the head from the breast; the gills themselves consist of four semi-circular bony or cartilaginous arches, which are denticulated or serrated on their internal or concave part, like those of fishes; on the opercula, or external flaps, are situated three very large and elegant branchial fins, or ramified parts, divided and subdivided into a vast number of slender or capillary processes. In these particulars it resembles the *S. lacertina*, except that in the latter animal the external opening to the gills is very small; the mouth is furnished in front with a row of extremely minute teeth; the tongue is large, smooth, and rounded at the tip; the rictus, or gape, when the mouth is closed, appears considerably wider than it really is, owing to a lateral fulcus proceeding from each corner to some distance; the feet are entirely destitute of webs, and they are furnished with rather weak claws; the front feet have four toes, and those behind five. Independently of the general colour of the animal, the whole skin, when minutely examined, appears to be scattered over with very minute white specks, resembling those on the surface of the *S. lacertina*. The sides of the body are marked by several strong rugæ or furrows, and an impressed lateral line or fulcus is continued from the gills to the tail.

SIREN is also a name given by Mousset, and other authors, to a species of bee; of which they distinguish two kinds, a larger and a smaller. These differ greatly from the common bee, in that they live solitary, and never unite into swarms, or build nests, or make combs.

SIRET, in *Geography*, a town of the province of Bukovina; 85 miles N.W. of Jassi.—Also, a river of Moldavia, which runs into the Danube; 4 miles S. of Galacz.

SIREX, or *Tailed Wasp*, in *Entomology*, a genus of insects of the order Hymenoptera, of which the generic character is, Mouth with a thick, horny, truncate, short, denticulate mandible; four feelers, the hind ones longer, and thicker upwards; antennæ filiform, of more than twenty equal articulations; the sting is exerted, ferrate and stiff; the abdomen is sessile, terminating in a point; wings lanceolate, incumbent, the lower ones shorter.

The larvæ of this genus are six-footed, soft, cylindrical; the head rounded; they perforate wood, and frequently eat their way into the bowels of other insects, and their larvæ, living upon them till they have utterly consumed their entrails; the pupa is folliculate: the perfect insect lives on the nectar of flowers. There are about twenty-six

Species.

* *GIGAS*. The abdomen of this species is yellow at the base and tip; the body is black-blue. This is the largest species in the whole genus: it surpasses a hornet in size, and is principally observed in the neighbourhood of pines and other cone-bearing trees: it is of a black colour, with the eyes, the base, and lower half of the abdomen, of a bright orange-yellow; the thorax is villose, and the wings of a transparent yellowish-brown; the sting, or terminal tube, is very conspicuous. The larva, which measures about an inch and a quarter in length, is of a yellowish-white colour, and inhabits decayed firs and pines; at first view it bears some resemblance to the larvæ of the beetle tribe, but is thinner in proportion, and furnished, at the tip of the abdomen, with a short black spine or process. It changes to a chrysalis in the month of July; first enveloping itself in a slight silken

web of a whitish colour. The chrysalis is of a lengthened shape, with the antennæ, legs, and terminal tube or process, very distinctly characterized. If the change to chrysalis takes place, as it sometimes does, in summer, the fly proceeds from it in the space of about three weeks; but if at the close of autumn, the animal continues a chrysalis the whole winter, emerging in the following spring. The male insect is considerably smaller than the female, and may be farther distinguished by the want of the caudal tube or process, so conspicuous in the female insect: the tip of the abdomen is also of a black colour. The eggs, which are deposited by the female in the decayed parts of the trees already mentioned, are very small, and of a lengthened oval shape, with pointed extremities.

PSYLLIUS. Abdomen yellow at the base and before the tip; the body is black. It inhabits different European countries, and is half the size of the last. The antennæ and legs are yellow, and the thighs black; the head is black, with a yellow spot on each side, behind the eyes; certain segments of the abdomen yellow.

COLUMBA. This is an American species, and is distinguished by its black body, marked by testaceous bands. The specific character is as follows: thorax villous, ferruginous; abdomen black, the sides are spotted with yellow; the antennæ are short and black, ferruginous at the base; the abdomen beneath is black, with a yellow streak; the projection is short, acute, ferrate, yellow tipped with black; the legs are yellow; hind-thighs black.

MAGUS. Black, thorax villous; tip of the antennæ, lateral spots on the abdomen, shanks, and base of the tarsi, are white. It is of the size of the *S. gigas*, and is found in many parts of Saxony. The abdomen beneath is white in the middle; the wings are dusky.

NIGRICORNIS. Thorax villous, blueish-black; abdomen ferruginous, blue at the base. It is found in North America. The head is shining blue-black; the antennæ are black; the legs are piceous; thighs yellow; sting pitchy.

FLAVICORNIS. Thorax villous, black, immaculate; four bands on the abdomen, antennæ, and legs, yellow. It is found at Labrador, in America. The head is black; the upper part of some of the segments is yellow; the appendage ferrate, yellow; the sting is black.

FUSCICORNIS. Thorax villous, black; abdomen with eight yellow bands; the antennæ are black; the legs are yellow. This, which is of the size of the *gigas*, inhabits Saxony. The wings are subtestaceous; the sting is black, with a yellow sheath; the horn of the abdomen is subulate, yellow tip with black; the thighs are black.

* **SPECTRUM.** The abdomen of this species is black; the thorax is villous, with a yellow stripe before the wings. It is found in this country, and in many other parts of Europe. The antennæ are black or yellow, and the legs are yellow.

* **JUVENCUS.** The abdomen is blueish-black; the thorax villous, immaculate. This also is a native of England and other European countries. The antennæ are black or yellow; the legs are yellow.

PHANTOMA. Abdomen above yellow, with black belts; the head and legs are yellow. It inhabits Germany. The mouth is black; the thorax yellowish before, beneath black; the abdomen beneath is black.

CYANUS. This is of a shining blue colour; the legs are yellow. It inhabits North America. The antennæ are black; the thorax subvillous; the wings are hyaline.

ALBICORNIS. Black; head with a white spot on each side; the antennæ are white in the middle. It is a native of North America. The antennæ are black at the tip; the

abdomen with a white dot on each side on the last segment but one; the legs are black; the shanks and ends of the tarsi are white.

NIGRITA. This is of a black-blue, immaculate; the hind-legs are compressed. It is a native of Saxony, and is of the same size as the *S. mariscus*, hereafter to be noticed.

* **CAMELUS.** The abdomen is black, the sides spotted with white; the thorax smooth. This is found in England and other European countries.

EMARGINATUS. Black; thorax emarginate before, and pale at the sides; the fore-legs are rufous. It inhabits Germany. The antennæ are black; the head is black, with a pale spot on each side; the sides of the thorax are slightly ferrate. The four front legs are rufous; the shanks are tipped with black; the hind ones are black; the thighs rufous.

DROMEDARIUS. Abdomen black, rufous in the middle, with a white dot on each side. The shanks are pale at the base. It is chiefly found at Kiel, and resembles the *S. camelus*. The head is black, with two white lines; the thorax is black, with a white dot before the wings; some of the segments of the abdomen are black, some rufous, one black, with a white spot on each side, and one is altogether black.

PACCA. Abdomen black, two of the segments are rufous, the rest dotted with white. This also is found at Kiel, and is the size of the *S. camelus*. The antennæ are black, a little thicker towards the tip; the thorax is villous and black, with two minute white spots on the fore margin; the horn of the abdomen yellowish, sting rufous; legs compressed, black.

SIMILIS. Black; first segment of the abdomen at the base and second rufous, the rest with five yellow spots. It inhabits the Cape of Good Hope. The head is black; the orbits yellow; antennæ ferruginous; the base and tip black; the thorax black, with a yellow dot on each side; the legs are rufous, the thighs black; the tail is pointed, without any projection.

VESPERTILIO. Black; abdomen ferruginous, the base is black. This is a small insect, and is found in divers parts of Germany. The antennæ are black, with a whitish ring; the tail is black beneath, without the appendage; the upper wings are white, with a broad brown patch before the tip, and white marginal dots; the legs are black, tip of the thighs and base of the shanks white.

MARISCUS. Of this species the abdomen is testaceous, the two last segments are black; the thorax villous. This is found in divers parts of Europe. Antennæ yellow; head with a yellow callous dot behind the eyes; the abdomen beneath is black, spotted with yellow; it has no sting.

TROGLODYTA. Smooth, black; abdomen with seven yellow dots, and two bands. It inhabits Saxony. The legs are yellow; the thighs black.

NOCTILIA. This is of a black-blue colour; the antennæ are black; the thorax is villous; the abdomen testaceous in the middle. It inhabits several parts of Germany, and is about the size of the *S. mariscus*. Thorax blue; abdomen blue at the base and tip; wings yellowish; legs yellow; hind ones compressed, black, the thighs yellow.

COMPRESSA. Black; abdomen compressed, ferruginous; the first and last segments are black. It inhabits Barbary, and is very small. Legs white; thighs black; hind ones black; the shanks are compressed, black, with two yellow dots, and three bands.

* **PYGMÆUS.** Abdomen compressed, black, with two yellow dots and three bands. It is a native of this country, and of other parts of Europe. This is one of the smallest of the European species, being, according to Linnæus, about the

the size of a gnat, with a black abdomen, marked by three yellow bands, the middle of which is interrupted. It is found in Sweden.

MACILENTUS. Black; abdomen compressed, yellow at the sides. It inhabits Barbary, and resembles the next. The head is black, with two yellow dots between the eyes; the thorax black, with a yellow dot, and a larger one beneath; the abdomen is yellow at the sides, and projecting into two bands on the back; the wings are hyaline; the rib black beyond the middle; the legs are black; the fore-thighs are yellowish.

* **TABIDUS.** Black; sides of the abdomen dotted with yellow; fore-shanks testaceous. It inhabits England, and a specimen is in Sir Joseph Banks's museum.

SIRGAI-SOUSAI-PO, in *Geography*, a town of Chinese Tartary. N. lat. $42^{\circ} 15'$. E. long. $117^{\circ} 50'$.

SIRGIAN, SERJAN, or Kerman, the ancient *Carmana*, a city of Persia, which at a former period rivalled the proudest cities of the empire; and its situation, in the direct road from the northern provinces of Persia and Bucharia to Gombroon, then the great emporium of the India trade, contributed to the increase of its opulence and prosperity. It has, however, suffered much from destructive wars, domestic and foreign, and from the plunder of an exasperated and licentious army. After having been courageously defended, in 1794, by Lutf Ali Khan, it was betrayed into the hands of his rival Aga Mohamed Khan, by Nujuf Kooly Khan, one of his treacherous adherents. The city was abandoned for nearly three months to the rapacity of the soldiers, the walls and public buildings were levelled with the ground, great numbers of the inhabitants were put to death, and 30,000 of them were exiled into the distant provinces of the empire: nor will it probably ever recover from the effects of this dreadful calamity. The present fortifications inclose but a small portion of the ancient city, which is quite deserted, and in a most ruinous condition. It is situated on the western side of an extensive plain, so close to the mountains as to be completely commanded by two of them. The walls are high, and built of mud, with 19 or 20 positions in each face, and a dry ditch, 20 yards wide and 10 deep. It has four gates, and the ark or citadel, where the governor resides, is on the S. side of the fort. Its present population is not more than 20,000 souls, of which some few are Guebres; there are also Armenians, Jews, and Hindoos in the place. Its trade is still very considerable; and it is celebrated for its manufacture of shawls, match-locks, and carpets, which are chiefly exported to Khorassan and the northern provinces, and returned in drugs, skins from Bockhares, furs, silk, steel, and copper. These articles, as well as pistachio nuts, carpets, rose-buds for preserves, and bullion, are sent to India, whence are imported, tin, lead, iron, chintz, wrought silk, spices, indigo, mastic, gold brocade, china and glass-ware, broad-cloth, hard-ware, &c. The bazar is well supplied with articles of every description, and in one part neatly arched with a fine blue stone, procured in the adjoining mountains. There are nine caravanseras within the walls, and many inferior ones both within and without. N. lat. $29^{\circ} 30'$. E. long. $56^{\circ} 50'$.

SIRGOULIN, a town of Chinese Tartary. N. lat. $41^{\circ} 53'$. E. long. $119^{\circ} 14'$.

SIRGUNE, a river of Prussia, which runs into the Frisch Haff, below Elbing.

SIRHIND, a circar of Hindoostan, between the soubah of Delhi and Lahore, bounded on the N. by Thibet, on the E. by the Jumnah, which separates it from Schaurunpour,

on the S. by the circar of Nardeck, and on the W. by Moultan and the province of Jallindar.—Also, a town of Hindoostan, and capital of the above-mentioned circar, N. of Delhi, supposed by some to be built on the spot where the battle was fought between Alexander and Porus. Justinian is said to have had silk from hence: it is an ancient city, but, like most of the Indian cities, has greatly declined: between it and Delhi are extensive plains, within which are situated the towns of Panniput and Carnawl, famous for great battles, both in ancient and modern times; 140 miles S.E. of Lahore. N. lat. $30^{\circ} 41' 30''$. E. long. $76^{\circ} 6'$.

SIRHUD, literally meaning a boundary, and metaphorically applied to a cold region, a district of Persia, comprehending most of the mountainous part of the province of Fars, extending from the latitude of Kazaroon to that of the town of Yezdekhast, situated on the bed of what appears to have been formerly a river, which separates this province from Irak. The plains which here intersect the mountains seldom exceed eight or ten miles in breadth, but vary in length from 15 to 100. They are in general fertile, and afford abundance of pasturage; neither are they so deficient in water as some have supposed. It is the want of population and of encouragement to industry that retards their improvement.

SIRI, among the Romans, were subterranean caves or vaults, in which wheat could be kept sound and fresh for fifty years.

SIRI, VITTORIO, in *Biography*, a writer in politics and history, was born at Parma about the year 1607: he was educated for the study of theology, and took the habit of the Benedictine order, in the monastery of St. John, and there began to publish a work entitled "*Mercurio Politico*," by which he acquired some temporary celebrity. Fifteen volumes of this work appeared successively, containing an account of the public events from 1635 to 1655. After this he added to it "*Memoriæ Reconditæ*," in eight vols. which going back to 1601 come to 1640. The author not only records facts, but endeavours to investigate causes in the secret negotiations of cabinets, and to give the documents confirming his narrative. Of these pieces, a great number is to be found in his publications, communicated by popes' nuncios and the ambassadors of different crowned heads, and especially by the ministers of Louis XIV. Through the influence of cardinal Mazarin, he was invited by that monarch to Paris, and presented to a secular abbey, on which occasion he quitted his religious habit for that of an ecclesiastic. He assumed to himself the title of counsellor, almoner, and historiographer to his most Christian majesty, and he spent all the latter years of his life at Paris, where he died in the year 1685, at the age of 78. He is characterized by biographers as a man without any fixed principles, who had a venal pen, which was always ready to justify and defend any cause, provided he was liberally paid for his services; yet the opportunities he possessed of gaining information from authentic sources, and the number of original documents published by him, have given a marked value to his works as materials for the history of his time. The circumstances of his being a foreigner, and writing in Italian voluminous publications little read in France, are said by Le Clerc to have induced him to speak more freely of Louis XIII., his brother and ministers, than the French writers have done. The first four volumes of his "*Memoriæ Reconditæ*" are extremely rare. A translation into the French language, of the most important parts of all his works, has been published in several volumes by M. Requier. Siri is said also to have written under a feigned name some pieces respecting the war of Montferrat.

SIRI, in *Geography*, a mountain of Thibet; 36 miles N.E. of Taringafong.

SIRI, or *Dsiri*, a town of Thibet; 45 miles E. of Taringafong.

SIRIA, or SIRJA, a town of Syria, in the pachalic of Aleppo; 70 miles S.E. of Aleppo.

SIRIAGULLY, a town of Mocaumpour; 20 miles S.S.W. of Mocaumpour.

SIRIAN, a sea-port town of Pegu, on the river Appoo; and whilst it remained in possession of the Portuguese, a place of great trade. Before their time it had a king of its own: it is now frequented by French, English, and Dutch; 72 miles S. of Pegu. N. lat. $16^{\circ} 54'$. E. long. $96^{\circ} 50'$.

SIRIASIS, in *Medicine*, from *σῖγος*, a cavity, a disease of children, so named by the older writers, in consequence of an accompanying depression of the fontanelle, but which in fact appears to have been an inflammation of the brain and its membranes; and accordingly Dr. Cullen ranks it as synonymous with *phrenitis*. It is very indistinctly described, and in some respects resembles hydrocephalus. Aëtius, indeed, expressly asserts that it is an inflammation of the brain and its membranes; but the only symptoms which he enumerates, are hollowness of the finciput and of the eyes, ardent fever, paleness, dry skin, and total loss of appetite. See Aëtius, *Tetrab. i. Serm. iv. cap. 13.* Forest. *Obf. Med. lib. xxviii. cap. 82.* Sennert. *Pract. lib. i. part. i. cap. 20.*

SIRIBOA, in *Botany*, Rumph. *Amboin. v. 5. 340. t. 117.* *Piper Siriboa*, Linn. *Sp. Pl. 51*, is a kind of long pepper, reckoned one of the kinds of Betle, and used for chewing with the *Areca*, or Betle nut, on account of its gratefully aromatic; and not too pungent, flavour. See PIPER.

SIRICA, in *Geography*, a town of Tripoli; 120 miles S. of Mesurada.

SIRICIUS, *Pope*, in *Biography*, was a native of Rome, and succeeded to the pontifical throne in 384. There are extant several letters of this pope, which are accounted his first decretals. In his first epistle, in answer to some questions proposed by Himerius, bishop of Tarragona, are many curious particulars of the ecclesiastical discipline observed at that period. He was a warm opposer of the Priscillianists and Jovinians, and in one of his letters relative to the latter, an example appears of the ancient manner in which the apostolic see passed its judgments: Siricius acquainted the church of Milan that he had condemned Jovinian and his followers, with the consent and advice of the priests, deacons, and all the clergy. In another of his letters, a cogent testimony is given of the reverence paid by the ancient popes to the decision of councils: it is addressed to some bishops respecting the heresy of one Bonofus, who was accused of asserting that the Virgin Mary had children after the birth of Christ. The pontiff replies, that the synod of Capua having ordained that the prelates in the vicinity of Bonofus should take cognizance of his cause, it did not belong to him to enter into the dispute. Siricius had the satisfaction of seeing ended the long continued schism of Antioch, the bishop of which, Flavianus, had occupied the see for a number of years, without being acknowledged by the Egyptian bishops. Through the mediation of John Chrysofom, a reconciliation was effected, and Flavianus was acknowledged by the pope, who died soon after in 398, leaving behind him a very respectable character.

SIRICON PLUMBI, a name given by some chemical writers to calcined lead, or the grey powder made of lead by a slight calcination in an open fire.

SIRINAGUR, SRINAGOR, or *Cashmere*, in *Geography*. See CASHMERE.

SIRINAGUR, or *Srinagur*, a town of Thibet, capital of a district in Alucknundra, or Alacananda, a branch of the Ganges, which has its source in the snowy mountains of Thibet, the position of which, according to Capt. John Guthrie, who visited it in 1789, is 85 miles from Coadwar Gaut, through the hills, and 60 colles from Hurdwar, up the Ganges to the E.N.E., ascertained by a compass and perambulator. Mr. Daniel, who visited it in the same year, gives the same idea of its geographical position. It is situated in an exceeding deep and very narrow valley, formed by mount Sewalick, the northern boundary of Hindoostan on one side, and the vast ridge of snowy mountains of Himmaleh, or Imaus, on the other. Mr. Daniel was much struck with the magnificence of the scenery of this valley, in which the thermometer rose, in the shade, to 100° , though in crossing the mountain of Sewalick, it stood at $58\frac{1}{2}^{\circ}$. We shall here subjoin some further particulars on this subject, with which we are furnished by a narrative of a survey for the purpose of discovering the sources of the Ganges, by Capt. Raper, communicated to the society at Calcutta. This survey was ordered by the supreme government of Bengal in 1807, and at the recommendation of Lieut. Col. Colebrooke, executed by Lieut. Webb, accompanied by Capt. Raper and Capt. Hearsay. The party commenced their tour at Hurdwar, an inconsiderable town of one street, in N. lat. $29^{\circ} 57' 9''$. E. long. $78^{\circ} 8' 30''$, April 1st, 1808. On the 13th of May they arrived at Srinagur, in N. lat. $30^{\circ} 10' 52''$. E. long. $78^{\circ} 43'$. The town is situated on the S. bank of the Alacananda, in the centre of a valley, which is about four miles in length, running nearly in the direction of E.N.E. to W.S.W., and about two miles in its greatest breadth. It extends along the banks of the river, and forms, in shape, a small segment of a circle, of which the stream constitutes the chord. The principal street runs through the city, about four furlongs in length, and contains the grand bazar. The houses are in general two stories high, constructed of large stones, with a shelving slated roof of shingles. The lower apartments are allotted for shops and merchandize, the upper for the accommodation of the families. The rigid uniformity of the buildings, both in structure and materials, shews what little advancement has been made in architecture, at the same time that it detracts from the beauty of the place. A narrow projecting verandah, or balcony, forms the only apparent difference in the houses of the higher class of inhabitants; and such a system of equality prevails, that one might suppose it the effect of design, or of a cautious fear to manifest an increase of wealth, by an ostentatious display in their outward appearance. Even those of the two chiefs by no means convey the idea of mansions appropriated to the residence of men to whom was committed the government of a province. When this capital was visited by Col. Hardwicke, in the year 1796, it was under the government of a raja, to whom it had hereditarily descended through many generations, and might then be supposed to be in its most flourishing state; yet its appearance did not indicate opulence or splendour; but since that period, many natural and fortuitous causes have combined to reduce it to a lower state of poverty and insignificance. The encroachments annually made by the Alacananda, on the houses contiguous to the river, the earthquake of 1803, which shook every building from its foundation, and the Gur'hali invasion at the close of the same year, devolved such an accumulation of evils on this devoted capital, that one might have inclined to conclude that it would not survive its native princes,

princes. Every house and every street, not excepting the palace of the raja, exhibited marks of dilapidation. Many of the inhabitants expressed their sorrow and regret on account of the events that had occurred, and spoke of their former sovereign with great tokens of feeling. Under its Gure'hali rulers the city is not likely to recover from this forlorn condition; for all classes of people complain much of the peculation of the chiefs, and of the injustice, with the want of method, that attends all their proceedings. The inhabitants are composed chiefly of the descendants of emigrants from the Dooab, Rohileund, and Audh. The Hindoos form the greatest proportion: the number of Mussulman families not exceeding sixty or seventy. Most of these are petty shopkeepers, who, to gain a scanty subsistence, are forced to enter into various speculations; and a piece of silk or a ser of onions may be procured at the same shop. The principal persons are the agents of great banking houses at Najibabad and in the Dooab, who are employed in the sale and exchange of merchandize and coins. They reside here only eight months in the year; quitting the hills, and returning to their houses, at the commencement of the rainy season. The traffic in silver and specie forms one of the most profitable branches of commerce, and is carried on to a considerable amount. Bullion and coins are imported, for the purpose of being converted into temashas, the currency of the hills; and as a constant coinage of them is kept up at the mint, the supplies are furnished by the Serrafs, who receive a premium, agreeable to the quality of the silver, amounting to one and a half, or two *per cent.* on the Farrakabad or Bareli rupee. The temasha is a small uneven silver coin, four of which pass for the nominal rupee of the hills; and five for the Farrakabad or Bareli. Spanish dollars also find their way hither, and are converted into the same currency. The inferior coin is a small piece, ten tacas of which are equal to one temasha.

The other articles of speculation consist in the produce of the hills, and imports from Bootan. The former are *bhang* (hemp); a coarse cloth, or sort of canvas, manufactured from it, called *bhangela*; lead, copper, drugs, gums, wool, and a species of flannel made from it called *pan'bi*; from Bootan are received chairs or cow-tails, musk in pods, saffron, borax, salt, drugs of different kinds, and a few shawls, which come by that route from Cashmere. Among the drugs is one called *nirbisi*, or zedoary. Hawks are also brought down from the hills. In exchange for the above, the following articles are supplied from the low countries. Coarse cotton and woollen cloths, silk, spices, Lahore salt, sugar and tobacco. On all these goods a greater or less duty is levied at Sirinagur, amounting, on an average, to one ana in the rupee, or about eight and a third *per cent.*; and additional duties are collected at different posts, in their transit through the country.

The territories which formerly belonged to the raja of Sirinagur, are now divided into 84 *perganahs*, included in three *pat'his*, or divisions, over each of which is appointed a military governor, who has the same jurisdiction in his own district.

In the year 1803 an army of 8000 or 10,000 men was sent from Nepal, to execute a project which had been long formed at the court of Nepal, *viz.* that of invading the territories of the raja of Sirinagur, and extending their possessions to Cashmere. The troops of the raja amounted to 15,000 or 20,000 men, principally mercenaries, who endeavoured to shun an engagement: the death of their chief secured the conquest of the whole country to the Gure'halis.

On taking a view of Sirinagur from a height, it has the appearance of a double valley; one situated on a level with

the river, the other on its banks, elevated about forty or fifty feet, and extending along the base of the mountain. The lower one, in which the city stands, has apparently been formed by the receding of the Alacananda from the fourth shore; and although the period be too remote to ascertain the fact, the appearance of the ridge or bank, marking the concavity, would incline one to suppose that such has been the case; and that, in its present progressive inclination, it is gradually returning to its former channel. From the bottom of the upper valley, to the city, is a space of three or four furlongs, laid out in small fields and inclosures, with a few mango trees, thinly scattered among them. Opposite to the city, the Alacananda divides into two or three streams, which reunite about one mile below. On one of the small islands are the ruins of buildings, which were formerly connected with the city. The aspect of the surrounding mountains is very barren; here and there a solitary tree may be seen; but the general features betray a rocky and unfriendly soil, and the little vegetation that is produced on them is soon parched up and dried. On the opposite side of the river, several hamlets are seen, situated along the foot of the hills, with which a communication is open, by a *jhula* to the W. and a ferry boat to the E. of the city. One of the largest of these villages is called *Rani Hat't*, containing a temple sacred to raja Iswara, at whose shrine some rites are performed, in imitation of the mysteries observed in the temple of the Cyprian goddess. It is inhabited chiefly by dancing women; and the ceremony of initiation to this society consists in anointing the head with oil, taken from the lamp placed before the altar; by which act they make a formal abjuration of their parents and kindred, devoting their future lives to prostitution. A short distance beyond it is a *Mat'h* or *sane* of Rallea Devi, the god of love; whose shafts, if we may believe the reports and complaints of his numerous votaries, are tainted with a fatal and pernicious poison: indeed, his wounds appear to be so generally diffused, that four-fifths of the inhabitants are supposed to labour under the effects of them, and the calamity is heightened by their ignorance of proper remedies to check their progress. Asiatic Researches, vol. xi.

SIRINAGUR, a town of Bengal; 20 miles N.N.E. of Calcutta. N. lat. 23° 7'. E. long. 88° 48'.

SIRIS, SIRO, or *Sinno*, in *Ancient Geography*, a river of Italy, near the *Acinis*, in Lucania. See *SINNO*.

SIRIS, a very ancient town of Italy, in Lucania, said by Strabo to have been founded by Trojans, and eminent for its college of priests skilled in cabalistic lore. It was situated at the mouth of a river of the same name, now called *Sinno* (which see), and became a dependance of Heraclea, to which the principal inhabitants of Siris were obliged to remove. When the Ionians took possession of this city, they changed its name into that of Policram. In process of time, the Tarentines drove the inhabitants from Siris, and having sent a colony into this country, they built Heraclea at a small distance from Siris. Strabo distinguishes these two towns; but Pliny (l. iii. c. 10.) says that they were the same under different names. The adjacent country was called *Siritis*, or *Sirentina*.—Also, a town of Pæonia, in Thrace.

SIRISHEK, in *Geography*, a town of Persia, in Khorassan; 30 miles S.S.W. of Herat.

SIRIUM, in *Botany*. See *SANTALUM*.

SIRIUS, σ_{1210} , in *Astronomy*, the *Dog-star*, a very bright star of the first magnitude, in the mouth of the constellation *Canis Major*, or the Great Dog.

This, indeed, is the brightest of all the stars in our firmament, and, therefore, probably, says Dr. Maskelyne, the late

astronomer royal, in a paper recommending the discovery of its parallax, *Phil. Trans.* vol. li. p. 889, the nearest to us of them all. Some, however, suppose Arcturus to be the nearest.

The Arabs call it *Afchere, Elschere, Scera*; the Greeks, *Sirius*; and the Latins, *Canicula*, or *Canis cadens*. See *CANICULA*.

SIRIUS, in *Geography*, an island in the South Pacific ocean, discovered and so called by lieutenant Ball, in 1790; it is about 18 miles in circumference. S. lat. 10° 52'. E. long. 162° 30'.

SIRMAN, *MAD.*, in *Biography*, a celebrated performer on the violin, who had her musical education in a conservatorio at Venice. Her maiden name was Maddalena Lombardini. She was a favourite élève of Tartini, and it was for her that he drew up his little tract on the use of the bow on the violin, in the form of a letter, "Arte dell' Arco."

After quitting the conservatorio, she married a German of the name of Sirman, and came to England in 1773; when her performance of Tartini's compositions on the violin was justly and universally admired. But in the operas of "Sofonisba" by Vento, and the "Cid" by Sacchini, she unadvisedly undertook the second woman's part on the stage, as a singer; but having been first woman so long upon the violin, she degraded herself by assuming a character, in which, though not deficient in voice or taste, she had no claim to superiority.

SIRMARKS, in *Ship-Building*, the different stations marked on the moulds where the respective bevellings are to be applied, as the lower firmark, floor-firmark, &c.

SIRMIONE, in *Geography*, a peninsula of Italy, about seven miles from the Lago di Garda, anciently celebrated under the name of Benanus, and always esteemed one of the grand ornaments of Italy. From *Peschiera* (which see), Sirmione appears as an island; so low and so narrow is the bank that unites it to the main land. Its entrance is defended, and indeed totally covered, by an old castle, with its battlements and high antique tower in the centre, in the form of a Gothic fortification. The promontory spreads behind the town, and rises into a hill, entirely covered with olives; which hill may be said to have two summits, as there is a gentle descent between them. On the nearest is a church and hermitage, now uninhabited and neglected. On the farthest, in the midst of an olive grove, stand the walls of an old building, said to be a Roman bath; and near it is a vault, called the grotto of Catullus. The extremity of this promontory is covered with arched ways, towers, and subterranean passages, supposed by the inhabitants to be Roman, but bearing, in fact, a strong resemblance to Gothic ruins. At all events, Catullus undoubtedly inhabited this spot, and preferred it, at a certain period, to every other region. He has expressed his attachment to it in some beautiful lines.

" Peninsularum Sirmio, insularumque
Ocelle, quascunque in liquentibus stagnis
Marique vasto fert uterque Neptunus:
Quam te libenter, quamque lætus inviso."

Catull. 32.

He could not, in fact, have chosen a more delightful retreat. In the centre of a magnificent lake, surrounded with scenery of the greatest variety and majesty, apparently secluded from the world, yet beholding from his garden the villas of his Veronese friends, he might have enjoyed alternately the pleasures of retirement and society; and daily, without the sacrifice of all his connexions, which Horace seemed inclined to make, in a moment of despondency, be-

held the grandeur and agitation of the ocean, without its terrors and immensity. Besides, the soil is fertile, and its surface varied; sometimes shelving in a gentle declivity, at other times breaking in craggy magnificence, and thus furnishing every requisite for delightful walks and luxurious baths; while the views vary at every step, presenting rich coasts or barren mountains, sometimes confined to the cultivated scenes of the neighbouring shore, and at other times bewildered and lost in the windings of the lake, and the recesses of the Alps. In short, more convenience and more beauty are seldom united; and such a peninsula is, as Catullus enthusiastically observes, scarcely to be matched in all the wide range of the world of waters.

SIRMIUM, or *SIRMICH*, a town of Slavonia, where the emperor Probus was born and killed. It is now in ruins, though the see of a bishop, founded, it is said, in the reign of Trajan. In the year 270, the emperor Claudius died here of the plague; 40 miles N.W. of Belgrade.

SIRMOND, *JAMES*, in *Biography*, a theologian of considerable note, born at Riom in 1559, was the son of a magistrate in that city. He was educated at a college of the Jesuits, which society he entered in 1576. Being sent to Paris, he taught in a college there, and at the same time pursued his studies with so much success, that he acquired a perfect knowledge of the learned languages, and formed a style in the latter, which, it is said, has rarely been excelled, either with respect to its strength or purity. He obtained so high a character for erudition, that he was summoned to Rome, in 1590, by Aquaviva, general of the order, to take upon him the office of his secretary. This office he held 16 years with high honour, and, in the mean time, he made use of all the advantages of the situation for the study of antiquities. He cultivated the acquaintance of all the great men of that period, among whom were Bellarmine, Barberini, and Baronio. To the latter he rendered important services in the composition of his Annals, especially by furnishing him with memorials relating to the Grecian history, translated into the Latin language. He returned to Paris in 1608, and resided four years in the house of the Jesuits, during which he edited several works of antiquity. He also entered into the controversy occasioned by Richer's famous treatise concerning the ecclesiastical and civil powers, in which he appeared as a partizan of the court of Rome. In 1612 he was employed in the labour of making a collection of the French councils; but this work did not cause him to intermit his publication of ancient writings; and a year seldom passed without sending one of them to the press, with learned commentaries. He was chosen rector of the Jesuits' college in Paris, in the year 1617, continuing to occupy himself as an editor and writer of original works. Pope Urban VIII. invited Sirmond to Rome, but Lewis XIII. would not consent to lose so eminent a scholar from his capital; and in 1637 he chose father Sirmond as his confessor. In this situation he conducted himself so as to merit the esteem of the king and his court. He rarely asked any favours for his relations; but he conferred an important benefit on his native place, by obtaining the revocation of an edict, which had transferred the board of finances of Auvergne from Riom to Clermont. When he quitted the court, he continued his literary occupations, which he pursued to a very advanced age. Huet, who, when a very young man, was introduced to Sirmond, then 90 years of age, found him inactive in body, but alert and vigorous with regard to his understanding and mental powers. He has described him as possessed of uncommon courtesy and elegance of manners, like one who had been long conversant with important public business.

ness. He died in 1651, at the age of 92. He was editor chiefly of the authors of the middle ages, the MSS. of which he discovered among the libraries at Rome, and other places. Those of his own composition were, in a great part, controversial. One, entitled "Censura de suburbicariis Regionibus," which related to the suburbicarian churches under the jurisdiction of the Roman pontiff, impugned the opinions of Godfrey and Saumaise. He had a dispute with Peter Aurelius respecting the second canon of the council of Orange, which was conducted on both sides with much acrimony. He was attacked with great bitterness, on account of a dissertation which he wrote, to prove that St. Denis the Arcopagite was a different person from St. Denis of France; but all fair judges of the subject admitted the validity of his arguments. He was less successful in a controversy respecting predestination, by which he became involved in hostility with the Jansenists. He never brought out, at first, all he knew on the subject, but made a reserve of some arguments for replication. His works were published collectively at Paris, in five volumes folio, 1696.

SIRNAME. See SURNAME.

SIROCC, or SIROCCO, a south-east wind of Sicily, particularly at Palermo, attended with an uncommon degree of heat, and singularly relaxing and oppressive in its effects. The blast of it is represented as resembling burning steam from the mouth of an oven: the whole atmosphere, during its continuance, seems to be in a flame. Its effect is described by Brydone like that of one of the subterranean sweating stoves at Naples; but it was much hotter. In a few minutes, those who are exposed to it find every fibre relaxed in a most inconceivable manner, and the pores opened to such a degree, that they expect immediately to be thrown into a most profuse sweat. At this time the thermometer, which stood in a room only at 73, rose immediately in the open air to 110, and soon after to 112. The air was thick and heavy, but the barometer was little affected, having fallen only about a line. The sun did not appear during the whole day; otherwise the heat, says Mr. Brydone, must have been insupportable; and on that side that was exposed to the wind, it could not be borne without difficulty for a few minutes. Upon exposing pomatum to it, the heat of the wind melted it as if it had been laid before the fire. This wind is more or less violent, and of longer or shorter duration at different times: however, it seldom lasts more than 36 or 40 hours, so that the walls of the houses are not warmed throughout, or else it is apprehended that it would be insupportable. Whilst it lasts, the people of the country confine themselves within; their windows and doors are shut close, to prevent the external air from entering; and where window-shutters are wanting, they hang up wet blankets on the inside of the window. The servants are constantly employed in sprinkling water through all the apartments, in order to preserve the air in as temperate a state as possible; and for this purpose, each house in the city of Palermo is provided with a fountain. By these means the people of fashion suffer very little from this wind, except the strict confinement to which it obliges them. Notwithstanding the scorching heat of the sirocco, it has never been known to produce any epidemical disorders, or to do any injury to the health of the people. They feel, indeed, very weak and relaxed after it; but a few hours of the Tramontane, or north wind, which generally succeeds it, soon braces them up again, and restores them to their former state. However, in Naples, and some other parts of Italy, where its violence is not to be compared with that of Palermo, it is often attended with putrid disorders, and

seldom fails to produce almost a general dejection of spirits. But there the sirocco lasts for many days, and even for weeks; so that, as its effects are different, it probably proceeds from a different cause. Some have supposed that this is the same wind with that which is so dreadful in the sandy deserts of Africa, where it sometimes proves mortal in the space of half an hour; but that in its passage over the sea, it is cooled and deprived of its tremendous influence, before it reaches Sicily. If this were true, we might expect to find it most violent on that side of the island that lies nearest to Africa, which is not the case; though it is possible, that its heat may be again increased by its passage across the island to Palermo, near the most northern part: and besides, this city is almost surrounded by very high mountains, the ravines and valleys betwixt which are entirely parched up and burning hot at this summer season of the year. These likewise contain springs of warm water, the steams of which may increase the heat, and at the same time soften the air, so as to disarm it of its noxious qualities. It is a practice too, at this season, to burn heath and brush-wood on the mountains, which must still add to the heat of the air.

SIROD, in *Geography*, a town of France, in the department of the Jura; 3 miles S.S.W. of Nozeroy.

SIRO-DEVA, a name of the Hindoo deity *Siva*; which see.

SIRONG, in *Geography*. See SERONGE.

SIROTE, a town of Bootan; 60 miles S.E. of Tafafudon. N. lat. 27° 18'. E. long. 90° 25'.

SIROWY, a circar of Hindoostan, in Agimere, lying on each side of the river Puddar, bounded N. by Jondpour, E. by Mewat, S. by Oudipour, and W. by sandy deserts. The chief towns are Sirowy and Jalour.

SIRPY, a town of Hindoostan, in the Myfore; 30 miles S.E. of Chittledroog.

SIRR. See SIR.

SIRSA, a town of Bengal; 30 miles S.E. of Ghidore.

SIRVENT, or VASIR, a town of Charafm; 60 miles S.E. of Urghenz.

SIRUN, a town of Persia, in the province of Segestan, or Seistan; 40 miles E. of Zareng.

SIRUPA, a town of New Mexico, in the province of Hiaqui; 80 miles N.E. of Riochico.

SIRZESZYN, a town of Lithuania, on the Dnieper; 50 miles N.E. of Mozyr.

SIS, a town of Asiatic Turkey, in the government of Sivas; 24 miles S. of Tocat.—Also, a town of Asiatic Turkey, in Caramania; 150 miles E.S.E. of Cogni.

SISAL. See SICAL.

SISALO, in *Ancient Geography*, a town of Spain, upon the route from Emerita to Saragolla, in passing by Lusitania, between Mirobriga and Corcuvium, according to the Itinerary of Antonine.

SISAN, a town of Asia, in the confines of Cilicia.

SISAPO, *Almaden*, a town of Spain, in Bætica, towards the east. Supposing it to be the same with Almaden, it yielded, in the time of the Romans, a mine of quicksilver, in high estimation, the produce and revenues of which were of great importance to the republic.

SISAPONE, the same with the former, a town of Spain, in the Tarragonensis, towards the confines of Bætica, which belonged to the Oresoni, according to Ptolemy.

SISAR, a river of Africa, in Mauritania Tingitana, between the towns of Chubar and that of Jerfeth, according to Ptolemy.

SISARA PALUS, the lake of Sifara, a lake of Africa, being the southern part of the lake Hipponibis, mentioned by Ptolemy.

SISARACA, a town of Spain, in the Tarragonensis, belonging to the Murbogi. Ptolemy.

SISARIS, *Mansourah*, a river in the eastern part of Mauritania Cæsariensis. Its mouth was five leagues N.E. of that of the river Nafava.

SISARMES, in *Ancient Armour*. See **GISARMES**.

SISARUM, in *Botany*, the Skirret, an eatable root, now out of use with us, though cultivated in the days of Gerard and Parkinson. Its flavour is said to be aromatic, with a sweetness not acceptable to every body, and of a flatulent, or indigestible, quality. See **SIUM**.

SISAURANUM, in *Ancient Geography*, a famous town of Persia, at the distance of two journeys from Dara and three miles from Rabdian, according to Procopius. This town was taken and razed by the emperor Justinian.

SISCAR, in *Geography*, a town of Spain, in Arragon; 19 miles E.N.E. of Balbaitro.

SISCO, a town of the island of Corfica; 6 miles N. of Bastia.

SISECKE, a river of Germany, in the county of Mark, which runs into the Lippe, a little below Lunen.

SISIBOU, or **SISSIBOU**, a town of Nova Scotia, on the W. coast; 25 miles S.S.E. of Annapolis.

SISINILLA, a town of the island of Cuba; 12 miles E.N.E. of Trinidad.

SISKIN, in *Ornithology*. See **SPINUS**.

SISNOVIA, in *Geography*, a town of Itria; 3 miles S.E. of Pedena.

SISOGUICHI, a town of Mexico, in the province of Biscay; 140 miles W. of Parral.

SISOLSK, **UST**, a town of Russia, at the confluence of the rivers Vim and Vithegda, in the province of Ulting; 120 miles N.E. of Ulting. N. lat. 61° 55'. E. long. 49° 40'.

SISON, in *Botany, a name adopted from Dioscorides, whose *σισων*, as he tells us, "is a little seed, produced in Syria, resembling parsley, oblong, black, and of a hot taste. Many of these seeds grow together at the tops of the stalks." There can be little doubt that this description applies to one of the umbelliferous order, but to what precise species or genus, can scarcely be guessed; nor did Dr. Sibthorp, when he examined the famous manuscript of Dioscorides at Vienna, find any thing to guide him respecting this point.—Linn. Gen. 139. Schreb. 188. Willd. Sp. Pl. v. 1. 1436. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 315. Prodr. Fl. Græc. Sibth. v. 1. 195. Ait. Hort. Kew. v. 2. 145. Pursh 194. Juss. 221.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellatae*, Linn. *Umbelliferae*, Juss.*

Gen. Ch. *General Umbel* of fewer than six unequal rays; *partial* of fewer than ten unequal rays. *General involucrem* of about four unequal leaves; *partial* similar to it. *Perianth* scarcely discernible. *Cor.* *Universal* uniform; all the flowers fertile; *partial* equal, of five lanceolate, inflexed, flattish petals. *Stam.* Filaments five, capillary, the length of the corolla; anthers simple. *Pist.* Germen inferior, nearly ovate; styles two, reflexed; stigmas obtuse. *Peric.* Fruit ovate, striated, separating into two parts. *Seeds* two, ovate, convex and striated on one side, flat on the other.

Eff. Ch. Flowers uniform, all fertile. *General* and *partial involucrem* each of few leaves. Fruit ovate, striated. Petals lanceolate, inflexed.

1. *S. Amomum*. Hedge Honewort, or Ballard Stone-parsley. Linn. Sp. Pl. 362. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 954. Jacq. Hort. Vind. v. 3. 13. t. 17. (*Petrofelinum macedonicum* Fuchsii; Ger. Em. 1016.)—Leaves pinnate. Umbels erect, of about four rays.—Native of England, Germany, the south of France, and the neighbour-

hood of the Bithynian Olympus. With us it chiefly occurs in moist shady places, where the soil is marly or chalky, flowering in August. The root is spindle-shaped, annual or biennial. *Stem* two or three feet high, branched, widely spreading, leafy, striated, smooth. *Leaves* dark green, smooth, finely pinnate, with a terminal lobed leaflet; the upper ones more compound or divided; all sharply serrated and cut. *Umbels* numerous, terminal, solitary, erect when in flower, white, but small and inconspicuous. *Fruit* roundish-ovate. *Seeds* aromatic and pungent when ripe. In a green state, their scent, like that of the whole herb, when bruised, is peculiarly nauseous, somewhat like *Coriander*, but even worse. These seeds have been known in the European Pharmacopæas by the name of *Amomum*, no one knowing what was the true *Amomum*; and have been celebrated as diuretic, useful in the stone and gravel, &c.; but they are now out of use, probably with no loss to the patient.

2. *S. fegetum*. Corn Honewort. Linn. Sp. Pl. 362. Willd. n. 2. Fl. Brit. n. 2. Engl. Bot. t. 228. Jacq. Hort. Vind. v. 2. 63. t. 134. (*Selinum filifolium*; Ger. Em. 1018. *Sium terrestre*, seu *fegetale*; Morif. sect. 9. t. 5. f. 6.)—Leaves pinnate; leaflets roundish, numerous. Umbels drooping, shapeless.—Native of England and Switzerland, but rare, chiefly in moist low fields, on a calcareous soil, flowering in August. Scarcely any body but a curious botanist would observe this little plant, which appears like a starved specimen of many a more common kind. The numerous crowded leaflets, imbricated, in a manner, before they expand, and the straggling, drooping, little umbels, are peculiar. The flowers, and their anthers, are tinged with purple.

3. *S. canadense*. Three-leaved Canadian Honewort. Linn. Sp. Pl. 363. Willd. n. 3. Ait. n. 3. (*Chærophyllum canadense*; Pursh 195. *Myrrhis canadensis*; Riv. Pentap. Irr. t. 54. *M. canadensis trilobata*; Morif. sect. 9. t. 11. f. 4.)—Leaves ternate. *General involucrem* wanting. *Seeds* elliptic-oblong.—Common in the woods of North America, from Canada to Virginia, flowering in July. *Pursh*. *Root* perennial, of many tapering fibres. *Stem* two feet high, branched, round, smooth, leafy. *Leaflets* smooth, broad, acute, doubly and sharply serrated; the lateral ones, of the lower leaves, often deeply divided, and their intermediate one sometimes three-lobed. *Umbels* slender, unequal, destitute of a general involucrem, and with very small partial ones, but otherwise having the genuine habit of this genus, and no character of *Chærophyllum*. *Fruit* elliptic-oblong, strongly ribbed, smooth, crowned with the small, conical, converging styles.

4. *S. Ammi*. Fennel-leaved Honewort. Linn. Sp. Pl. 363. Willd. n. 4. Jacq. Hort. Vind. v. 2. 95. t. 200. (*Ammi*; Camer. Epit. 522. Matth. Valgr. v. 2. 120. Riv. Pentap. Irr. 91. *A. perpusillum*; Lob. Ic. 725. Ger. Em. 1037.)—Leaves triply pinnate; the radical ones with linear segments; the upper setaceous.—Native of Portugal, Italy, and Egypt. A slender, annual, smooth plant, about a foot high, with an aromatic parsley-like smell. Segments of the leaves alternate, or ternate, acute. *General umbels* of five or more rays, with an unequal, somewhat leafy, *involucrem*; *partial* of numerous short rays; their *involucral leaves* linear, minutely fringed. Jacquin says his plant had neither general nor *partial involucrem*. *Flowers* white. *Germen* in the original Linnæan specimen, from Clifford's garden, ovate, minutely granulated, of which mark we find no account. The ripe seeds are described by Jacquin and Rivinus as ovate.

5. *S. pusillum*. Dwarf Honewort. Michaux Boreal-Amer. v. 1. 168. Pursh n. 1. (*Daucus divaricatus*; Walt.

Walt. Carol. 114, according to Pursh.)—"Leaves twice-ternate, many-cleft. Partial umbels of three to five flowers. Seeds roughish." In dry sandy fields in Carolina, flowering in April and May. *Root* annual. *Pursh.*

6. *S. trifoliatum*. Three-leaved Carolina Honewort. Michaux, *ibid.* Pursh n. 2.—"Leaves all ternate; leaflets toothed; the lower ones oval, with two or three lobes; upper oval-lanceolate. Umbel terminal, stalked, solitary. Seeds roundish."—Found by Michaux in North Carolina.

7. *S. marginatum*. White-edged Honewort. Michaux, *ibid.* Pursh n. 3.—"Leaves pinnate; the upper ones quinque; leaflets all fertile, lanceolate, entire, bordered with white. General and partial involucre wanting."—In wet meadows, from Virginia to Carolina, flowering in July and August. Perennial. *Pursh.*

8. *S. falsum*. Salt Honewort. Linn. Sp. 181. Willd. n. 7. ("Peucedanum redivivum; Pallas Act. Petrop. 1779. v. 2. 252. t. 8. f. 1—3.")—Leaves radical, doubly pinnate; leaflets digitate, somewhat whorled. Stem leafless, panicled, with numerous umbels.—In dry, muddy, salt plains about the Wolga; gathered by Pallas, whose specimen is before us. The *root* is perennial. *Leaves* all radical, appearing in the spring, stalked, spreading, three inches long, doubly compound, the *leaflets* crowded as if whorled, in many smooth, oblong, brittle-pointed segments, all together resembling some feathery sort of *Conserva*. *Stem* appearing after the leaves are gone, twelve or eighteen inches high, slender, round, smooth, bearing in August a panicle, alternately compounded, of slender spreading *umbels*, each of from three to five rays. At the base of each branch is a sharp membranous-bordered leaf, or *bractea*. *Partial umbels* of five or six capillary rays. *General involucre* of two or three small membranous leaves; *partial* like it, but smaller. *Flowers* white. *Germen* ovate. *Fruit* more oblong, smooth, obscurely ribbed. Some of the *flowers* in each partial umbel do indeed appear to be abortive, whence perhaps Pallas referred this curious species to *Peucedanum*; but we find no traces of a wing to the seeds, to confirm that measure.

9. *S. crinitum*. Capillary-leaved Honewort. Willd. n. 8. "Pallas Act. Petrop. 1779. v. 2. 250. t. 7."—"Radical leaves triply pinnate: those of the stem bipinnate; leaflets brittle-shaped. General involucre of many doubly pinnate leaves."—Native of Siberia. *Pallas*. We have not seen the plate cited, but the *involucre* is described as doubly compound and setaceous.

Two British Linnæan species, the *inundatum* and *verticillatum*, are removed, in the Flora Britannica, from the present genus; the former to HYDROCOTYLE, and the latter to SIUM; see those articles. We are as confident of the propriety of this alteration, as it is possible to be on any question regarding the genera of umbelliferous plants. *Sison* itself is considered, by some botanists, as a doubtful genus, and is reduced to *Sium* by Lamarek in his Dictionary, v. 1. 404.

Sison Syriacum, a name given by some authors to the ammi, or bishop's weed, a plant whose seeds were once much used in medicine.

SISSA, in *Geography*, a town of the duchy of Parma; 11 miles N.N.W. of Parma.

SISSACH, a town of Switzerland, in the canton of Bâle; 13 miles S.E. of Bâle.

SISSAN, a town of Itria; 3 miles E.N.E. of Pola.

SISSYPTIEPTERIS, in *Botany*, a name used by Pliny, and some others of the old authors, for the pimpinella, or burnet.

SISSONNE, in *Geography*, a town of France, in the department of the Aisne, and chief place of a canton, in the

district of Laon; 10 miles E. of Laon. The place contains 1105, and the canton 10,327 inhabitants, on a territory of 337½ kilometres, in 20 communes.

SISSOPOLI. See SIZEBOLI.

SISSUER, a town of Hindoostan, in Oude; 24 miles E.S.E. of Manickpour.

SISTAN, or SEGESTAN. See SEISTAN.

SISTER, a female born of the same parents.

SISTER-Blocks, in *Block-Making*, are blocks made of ash, similar to two single blocks, and turned out of a solid piece, about two inches long, one above the other: between the blocks is a score for a middle-feizing; a round head is turned at each end, and hollowed underneath, to contain the end-feizings: along the sides, through which the pins are driven, is a groove, large enough to receive part of the top-mast shroud, in which it is seized. In these blocks receive the lifts, and reef-tackle pendants of the top-sail-yards.

SISTERON, in *Geography*, a town of France, and principal place of a district, in the department of the Lower Alps, situated on the Durance, with a small castle on a rock; and before the revolution the see of a bishop, suffragan of Aix; 15 miles N.W. of Digne. The place contains 3891, and the canton 7070 inhabitants, on a territory of 230 kilometres, in 9 communes. N. lat. 44° 11'. E. long. 6° 1'.

SISTERS, two small islands in the Red sea. N. lat. 10° 30'. E. long. 39° 15'.—Also, two very small islands near the coast of Sumatra, covered with wood, lying in S. lat. 5° 0½'. E. long. 106° 12'; nearly N. and S. from each other, and surrounded by a reef of coral rocks; the whole circumference of which is about four or five miles.

SISTERSDORF. See ZISTERSDORF.

SISTOTREMA, in *Botany*, a genus of *Fungi*, of which several species are described, and some figured, in Albertini and Schweiniz's very learned work, entitled *Conspicuum Fungorum in Lusatia superioris agro Niskiensi crescentium*, p. 260—264. We, however, find there no generic character. The plants seem most akin to HYDNUM; see that article. The name appears to be compounded of *συσω* and *τετραμα*, alluding to the regular rows of pores; but if so, it ought to be *Systotrema*.

SISTOVA, or SZISTO, in *Geography*, a town of European Turkey, in Bulgaria, on the right bank of the Danube; 25 miles E. of Nicopoli. N. lat. 43° 45'. E. long. 24° 44'.

SISTROID Angle. See ANGLE.

SISTRUM, a sacred musical instrument with the ancient Egyptians; and one that is still used by the Abyssinians in religious ceremonies.

Spon describes it of an oval form, made in manner of a racket, with three sticks traversing it breadthwise, which, playing freely by the agitation or beating of the instrument, yielded a kind of sound, which, to the ancients, seemed melodious. The upper part was adorned with three figures; that of a cat with a human face in the middle, the head of Isis on the right side, and the head of Nephthys on the left. The representation which we have given in the *Plate of Music* was drawn from an ancient sistrum preserved in the library of St. Genevieve at Paris. It has been disputed by the abbé Winekelman, whether the sistrum was of very high antiquity in Egypt, because it did not appear in the hands of such Egyptian statues as he had seen at Rome; but as there is one in the hand of a very ancient statue of Isis, which doctor Pococke brought into England from Egypt, it puts that point of musical history out of all dispute. The sistrum appears in the *Isiac Table*; and Apuleius makes an old Greek invoke an Egyptian priest "by the stars in the firmament; by the infernal divinities; by the elements which

which compose the universe; by the silence of the night; by the sanctuary in the temple of Coptos; by the increase of the Nile; by the mysteries of Memphis; and by the sitrum of Pharos." By Pharos, an Egyptian island, was here figuratively meant, all Egypt.

Mr. Malcolm takes the sitrum to have been no better than a kind of rattle. Jer. Bosius has an express treatise on the sitrum, intitled, "Isiacus de Sitro."

Osefius observes, that the sitrum is found represented on several medals; and also on talismans. Osiris, on some medals, is painted with the head of a dog, and with a sitrum in his hand.

SISUPALA, in *Hindoo Mythology*, is the name of a malignant personage, into whose body an insolent celestial was doomed to be re-born on earth, as an expiation of his offence. He was slain by Krishna.

SISY-*sur-Ourcq*, in *Geography*. See LIZY-*sur-Ourcq*.

SISYMBRIUM, in *Botany*, Σισυμβριον of the Greeks, at least the Σ. ἕλερον of Dioscorides is probably included under our present genus. His first species, celebrated for its fragrance, has been supposed Wild Thyme, and by some our *Mentha hirsuta*, which last has also occasionally a very sweet smell. De Theis seems not to have been aware of this; nor might the plant in question find a place in garlands dedicated to Venus, so much on account of its odour, as of its warm and cordial properties.—Linn. Gen. 338 Schreb. 441. Willd. Sp. Pl. v. 3. 489. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 700. Prodr. Fl. Græc. Sibth. v. 2. 18. Ait. Hort. Kew. v. 4. 111. Pursh 440. Jull. 239. Lamarck Dict. v. 7. 201. Illustr. t. 565.—Class and order, *Tetradynamia Siliquosa*. Nat. Ord. *Siliquosa*, Linn. *Crucifera*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of four lanceolate-linear, spreading, coloured, deciduous leaves. *Cor.* cruciform, of four oblong spreading petals, often less than the calyx with very small claws. *Stam.* Filaments six, longer than the calyx, of which the two opposite ones are rather the shortest; anthers simple. *Pist.* Germen oblong-thread-shaped; style scarcely any; stigma obtuse. *Peric.* Pod long, incurved, gibbous, round, with two cells and two straight valves, which are rather shorter than the partition. *Seeds* numerous, small.

Ell. Ch. Pod bursting, with nearly straight valves. Calyx and corolla spreading.

A copious genus, tolerably natural as to habit, but not very distinctly defined; of which the 14th edition of Linn. Syst. Veg. contains twenty-nine species, and Willdenow's Sp. Pl. fifty-three. Nine of them are found wild in Britain. We shall describe all the latter, and give a general view of the five sections, into which the whole genus is divided by Linnaeus. Mr. Brown, in his very ingenious attempt at reforming the genera of the class *Tetradynamia*, in Ait. Hort. Kew. has separated some species, principally of the first section, into a genus called *Nasturtium*, and he has referred two of the British ones to *SINAPIS*, (see that article,) and one to *BRASSICA*. Respecting these very species, there has heretofore been a difference of opinion among botanists, as will appear when we come to speak of them in order. The whole genus is herbaceous, either annual or perennial, with alternate leaves, various, and sometimes inconstant, in shape and division mostly smooth. The flowers are almost invariably yellow; though always white in the first species.

SECT. 1. *Pods declining, short.* Eleven species in Willdenow.

S. Nasturtium. Common Water-cress. Linn. Sp. Pl. 916. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 855.

Curt. Lond. fasc. 6. t. 44. Woodv. Med. Bot. t. 48. Fl. Dan. t. 690. (*Nasturtium officinale*; Br. in Ait. Hort. Kew. v. 4. 110. *N. aquaticum*, five *Crataegium*; Ger. Em. 257.)—Pods declining. Leaves pinnate; leaflets roundish-heart-shaped.—In clear rivulets and springs throughout Europe, from Sweden to Greece, as well as in North America; and, according to Mr. Pursh, on the high mountains of the island of Dominica. It is perennial, flowering in June and July. No British plant is in such popular request as a salad; the young leaves having a pleasantly warm pungent flavour, and being supposed, like scurvy-grass, to purify the blood. The stems are branched, angular and leafy, floating by the help of their foliage, sending down long, white, fibrous roots, and terminating in ascending corymbose tufts, of numerous, white, purplish-tinted flowers, succeeded by long clusters of short, gibbous, recurved, stalked pods. The leaves are smooth, of a dark shining green, consisting of five or seven leaflets, the terminal one largest. There can be little doubt of this being Σισυμβριον ἕλερον of Dioscorides. The modern Greeks call it νεροάδδαμον; a word synonymous with Water-cress.

S. sylvestre. Creeping Water Rocket. Linn. Sp. Pl. 916. Willd. n. 2. Fl. Brit. n. 2. Engl. Bot. t. 2324. Curt. Lond. fasc. 3. t. 41. (*Nasturtium sylvestre*; Br. in Ait. Hort. Kew. v. 4. 110. *Eruca aquatica*; Ger. Em. 248. *Brachiolobos sylvestris*; Allion. Pedem. v. 1. 278. t. 56. f. 2.)—Pods declining. Leaves pinnate; leaflets lanceolate, deeply ferrated or cut.—Native of gravelly waste ground, in marshy places, or near rivers, flowering from June to September, in several parts of England, as well as in Germany, Switzerland, and France. Dr. Sibthorp observed it on mount Hæmus. The root creeps so extensively, that the pods are mostly abortive. Stems erect, leafy, angular, zig-zag, roughish, somewhat panicled. Leaves smooth; the leaflets of the lower ones decurrent, variously toothed; of the upper narrower, more slightly cut or ferrated. Flowers of a golden yellow; their clusters after flowering elongated and zig-zag.

Willdenow supposes *S. lippizense*, Jacq. Ic. Rar. t. 505, to be a variety of this, with more entire leaflets; but it is drawn with a fibrous, not creeping, root.

S. terrestre. Annual Water Rocket. Curt. Lond. fasc. 5. t. 49. Fl. Brit. n. 3. Engl. Bot. t. 1747. (*S. palustre*; Willd. n. 3. Pollich v. 2. 230. Pursh n. 2. *S. amphibium* α; Hudf. 296. *Nasturtium terrestre*; Br. in Ait. Hort. Kew. v. 4. 110. *Raphanus aquaticus*, foliis in profundas lacinias divisis; Bauh. Prodr. 38.)—Pods declining, turgid. Leaves pinnatifid, unequally toothed. Root simply fibrous. Petals scarcely so long as the calyx.—Found in watery places, about the sides of ditches, in the north of Europe, as well as America. Very plentiful about London, flowering from June to September.—The root is annual, sometimes branching at the top, but not creeping. Stem a foot high, nearly upright, branched, leafy, furrowed, smooth. Leaves lyrate, unequally toothed. Flowers numerous, yellow, small and inconspicuous, succeeded by short, turgid, erect pods, whose partial stalks are widely extended.

S. amphibium. Great Water Rocket, or Radish. Linn. Sp. Pl. 917. Willd. n. 4. Fl. Brit. n. 4. Engl. Bot. t. 1840. Pursh n. 3. Fl. Dan. t. 984. (*S. amphibium* β; Hudf. 296, and γ, 297. *Nasturtium amphibium*; Br. in Ait. Hort. Kew. v. 4. 110. *Raphanus aquaticus* alter; Bauh. Prodr. 38. *R. aquaticus*; Ger. Em. 240.)—Pods declining, on longish partial stalks. Leaves oblong, pinnatifid or ferrated. Petals longer than the calyx.—Not rare in the rivers and ditches of America, and the north of Europe;

SISYMBRIUM.

Europe; frequent in England, flowering copiously in July and August. In running streams it grows to a great size, with long floating stems, throwing out abundance of white fibrous radicles, and bearing, under water, deeply pectinated leaves. On the neighbouring banks it is found smaller, with broader, and merely serrated, foliage. The primary roots are perennial, long, perpendicular, not creeping. The leaves which grow out of the water are more or less oblong, jagged, clasping the stem with their dilated base; the radical ones stalked. Flowers yellow, not very bright. Pods short and small, often abortive. This seems to be the plant which Chateaubriand observed in Suffolk, and of which he has given so extravagant an account in his travels; as if the works of the Creator were not, of themselves, sufficiently admirable, without bombast or exaggeration.

S. tanacetifolium. Tanly-leaved Wild-rocket. Linn. Sp. Pl. 916. Willd. n. 6. Ait. n. 12. (Eruca, n. 460; Hall. Hist. v. 1. 200. E. tanacetifolio; Morif. sect. 3. t. 6. f. 19. E. fruticoso, con foglie di tanaceto, indiana; Zanon. It. 86. t. 33.)—Leaves pinnate; leaflets lanceolate, cut or deeply serrated; hoary beneath; the ultimate ones confluent. Pods erect, somewhat club-shaped.—Native of thickets and groves, on the loftiest alps of Savoy and Switzerland, but esteemed one of the rarest plants of those countries. We gathered it in seed on mount Cenis, August 13, 1787. Miller is said to have cultivated this *Sisymbrium* in 1731, and we believe it is still to be met with in curious collections. The root is perennial. Stem two or three feet high, clothed with very handsome spreading leaves, finely downy and hoary beneath, and often besprinkled with minute starry hairs on their upper surface. Flowers of a golden yellow, numerous, in terminal corymbs, growing out into long, lax clusters of smooth, erect, obtuse pods, half an inch or more in length, tapering at their base; their partial stalks about the same length, ascending obliquely.

S. tenuifolium. Wall Wild-rocket. Linn. Sp. Pl. 917. Willd. n. 9. Fl. Brit. n. 5. Engl. Bot. t. 525. (*Brassica muralis*; Hudf. 290. Curt. Lond. fasc. 3. t. 38. *Sinapis tenuifolia*; Br. in Ait. H. Kew. v. 4. 128. *Sinapi erucæ folio*; Bauh. Pin. 99. Tourn. Inst. 227. *S. tertium*; Matth. Valgr. v. 1. 516. *Eruca sylvestris*; Ger. Em. 246.)—Pods erect, somewhat beaked. Leaves smooth, pinnatifid or bipinnatifid, nearly entire; the uppermost undivided.—Native of old walls and rubbish, in England, Germany, Switzerland, and France, as well as about Constantinople, flowering from July to October. The root is perennial. Plant bushy, smooth, somewhat glaucous. Leaves acute, variously sinuated and pinnatifid; their segments lanceolate. Flowers large, lemon-coloured, strongly scented. Pods distant, tipped with the slightly elongated style.

S. sagittatum. Arrow-leaved Wild-rocket. Willd. n. 10. (*S. molle*; Jacq. Coll. v. 1. 68. Ic. Rar. t. 122. *Nasturtium sagittatum*; Br. in Ait. H. Kew. v. 4. 111.)—Downy. Leaves oblong, with shallow teeth; the radical ones hastate; the rest clasping the stem with their arrow-shaped base.—Native of Siberia. Sent to Kew, by Pallas, in 1780. The root is spindle-shaped, perennial. Whole plant clothed with soft, depressed, somewhat stellated down. Leaves bluntish, bearing some resemblance to those of Shepherd's Purse. Flowers yellow, succeeded by long clusters of drooping downy pods.

SECT. 2. Pods often axillary, nearly sessile. Five species.

S. polyceratum. Dandelion-leaved Wild-rocket. Linn. Sp. Pl. 918. Willd. n. 13. Ait. n. 11. Prodr. Fl. Græc. n. 1535. Jacq. Hort. Vind. v. 1. 34. t. 79. (*Iris alter*; Matth. Valgr. v. 1. 524. *Erysimum alterum italicum*; Ger. Emac. 254.)—Pods axillary, aggregate, awl-

shaped, nearly sessile. Leaves wavy or toothed.—Native of Switzerland, France, Italy, and Greece. Dr. Sibthorp found it, very common, throughout the last-mentioned country and the islands of the Archipelago, in waste ground, court-yards, and about villages, as Dioscorides reports of his *εγυσιμπος*, which therefore the Oxford professor judged this plant to be; perhaps rightly; but the description of the Greek author, particularly the yellow flowers, and the terminal pods, answer better to our *Erysimum officinale* (*Sisymbrium officinale*, Br. in Ait. H. Kew. n. 1.), which is also a Greek plant. The present *Sisymbrium*, a mean and ill-looking weed, is perfectly naturalized about Bury, in Suffolk, and might be taken for a native British plant, had we not the authority of sir T. G. Cullum, for its having escaped, many years since, from the botanic garden of the Rev. Mr. Laurence of that town. The root is annual. Stems branched, decumbent, leafy, smooth, gradually elongated after flowering. Leaves about an inch long, on short stalks, simple, somewhat hastate, slightly toothed or wavy, smooth. Flowers small, white, axillary, on short stalks, two or three together. Pods rather curved, an inch long, uneven, smooth, with a zig-zag furrow along each side.

S. torulosum. Rough-podded Wild-rocket. Desfont. Atlant. v. 2. 84. t. 159. Willd. n. 16. Sm. Fl. Græc. Sibth. t. 632, unpublished.—Pods racemose, sessile, awl-shaped, hairy. Stem diffuse. Leaves lanceolate, toothed.—Native of uncultivated fields, in Tunis, and the isle of Cyprus. An annual, branched, nearly prostrate herb, very like the last in general appearance, but the leaves are longer, truly lanceolate, and regularly toothed. Flowers terminal, densely corymbose, white, their stalk lengthening out into a long cluster, or rather spike, of crowded, sessile, spreading, rugged, hairy pods, each about an inch in length.

SECT. 3. Stem for the most part naked. Eight species.

S. murale. Sand Wild-rocket. Linn. Sp. Pl. 918. Willd. n. 17. Dickf. Dr. Pl. 12. Engl. Bot. t. 1090. Fl. Brit. 1401. (*Eruca viminea*, *iberidis folio*, luteo flore; Barrel. Ic. t. 131. *Sinapis muralis*; Br. in Ait. H. Kew. v. 4. 128.)—Pods erect. Stem spreading, short, roughish. Leaves lanceolate, deeply serrated.—Native of France, Italy, and the isle of Thanet, in waste sandy ground, flowering in autumn. Root truly annual. Stems branching, diffuse, often very short, leafy, round, more or less rough with deflexed hairs. Leaves of a grass green, tapering at the base into long footstalks; their margin deeply and irregularly serrated. Flowers smaller than those of *S. tenuifolium*, their corymbs becoming long loose clusters of erect, cylindrical, smooth pods, on spreading, hairy stalks. *S. Erucastrum*, Gouan Illustr. t. 20, is precisely this plant, not a variety.

S. monense. Dwarf Sea Wild-rocket. Linn. Sp. Pl. ed. 1. 658. Fl. Brit. n. 6. Engl. Bot. t. 962. Willd. n. 18. Lightf. Scot. 353. t. 15. f. 1. (*Brassica monensis*; Hudf. 291. Br. in Ait. H. Kew. v. 4. 124. *Eruca monensis laciniata*, flore luteo majore; Dill. Elth. 135. t. 111. f. 135.)—Pods nearly erect, quadrangular, with a long beak. Leaves pinnatifid, slightly hairy. Stems simple, almost naked, smooth.—Native of the sandy shores of Bute, Arran, and the west of Scotland, as well as of Cumberland, and the isles of Walney, Anglesea, and Man. Root thick, woody, and perennial. Stems several, a span high, leafy at the bottom only. Leaves almost all radical, numerous, stalked, rather fleshy and glaucous; their segments deep, tolerably uniform, either entire, or with broad incisions. Flowers large, numerous, lemon-coloured, corymbose, succeeded by a long cluster of smooth, obscurely quadrangular, upright, stalked, long-beaked pods. Calyx
lefs

less spreading than in most of the species, its leaves hairy at the tips. *Petals* veined.—We have been led to doubt whether Gerard's plant from Provence, described in the second edition of Sp. Pl. and preserved in the Linnæan herbarium, be the same with our's; because its *flowers* are smaller, and the veins of their *petals* scarcely discernible, though in our's very strong. It may nevertheless be a mere variety. We find in its young *Pods* plain indications of the remarkable lanceolate beak, half the length of the *pod* itself, so striking in our *S. monense*, and figured, as well as described, in English Botany. Willdenow was misled by Villars to consider Gerard's as the same with the following.

S. repandum. Wavy-leaved Wild-rocket. Willd. n. 19. (*S. monense*; Villars Dauph. v. 3. 350. t. 39, the synonyms mostly, if not entirely, wrong.)—*Pods* nearly erect, compressed, uneven, with a short quadrangular beak. Leaves with wavy teeth, smooth. Stems simple, smooth, quite naked.—Native of the mountains of Dauphiny; our specimen is from Villars himself, and proves, notwithstanding his assertion, very distinct from the plant of Gerard, mentioned under our preceding species, as well as from British specimens of that species. We have no means of knowing exactly how far the author is correct in Tournefort's synonym; but the phrase *radice crassâ* answers admirably to Gerard's specimen, and not to that of Villars. The *root* of the latter is long and tapering, divided, but not very thick, at the crown, where it bears several simple tufts of stalked, oblong, or obovate, bluntish leaves, about an inch only in length, always quite smooth; their margins either wavy, or more or less deeply toothed. *Stems* solitary, four or five inches high, quite leafless, simple, round and smooth, each bearing from four to nine large corymbose flowers, of a fine yellow. *Calyx* smooth, slightly spreading, a little coloured. *Pods* slightly spreading, rather longer than the last as to their valvular part, measuring from one and a half to two inches; but the beak is hardly two lines, instead of three-quarters of an inch, long, by which the plants are clearly distinguished. Willdenow rightly describes the *valves* of the present, which are unequally bunched out by the seeds, as marked with an elevated line, that makes them seem quadrangular; but they are much less really so than in *S. monense*, whose *Pods* few botanists appear to have seen.

S. vimineum. Rushy-stalked Wild-rocket. Linn. Sp. Pl. 919. Willd. n. 21. (*Eruca pumila*, burfæ pastoris folio; Bocc. Sic. 19. t. 10. f. 2. *E. minimo flore*, monfeliensis; Bauh. Hist. v. 2. 862; the leaves, as the author observes, too sharp.)—*Pods* erect, compressed, with a short quadrangular beak. Stems widely spreading, leafy at the base. Leaves smooth, obovate; toothed or pinnatifid. *Petals* erect, scarcely exceeding the calyx.—Native of Sicily and the south of France. A hardy annual, which we have had for near twenty years, springing up spontaneously, in a garden, so that it merits a place in Mr. Aiton's work, though of no attractive aspect, to procure it general notice. The *root* is small and fibrous. *Stems* several, branching at the very base only, from three to eight inches long, widely spreading or decumbent, simply racemose, round, slender, smooth. *Leaves* numerous, about the bottom of each stem, stalked, from one to two or three inches long, very obtuse; either simply obovate, entire, and partly wavy, or pinnatifid in a lyrate manner, sometimes rather deeply. *Flowers* extremely small, with a tawny and purplish tinge, succeeded by a long cluster of distant *Pods*, hardly an inch long, smooth, slightly unequal in their surface, each valve marked with a slender elevated line. This species, though very distinct, is so much akin to the last, that their characters are difficult to define. The *calyx* and *corolla* of the

present hardly answer indeed to the idea of a *Sisymbrium*, but rather to that of *Arabis*.

SECT. 4. *Leaves pinnate, or deeply pinnatifid*. Twenty species.

S. Sophia. Flix-weed. Linn. Sp. Pl. 920. Willd. n. 29. Fl. Brit. n. 7. Engl. Bot. t. 963. Mart. Rult. t. 57. Fl. Dan. t. 528. Pursh n. 4. (*Sophia chirurgorum*; Ger. Em. 1068. Lob. Ic. 738.)—Leaves doubly pinnate, with decurrent segments, a little hairy. *Petals* smaller than the calyx.—Native of waste ground, rubbish, and banks throughout Europe, from Sweden to Greece, flowering in summer. Mr. Pursh speaks of it as occurring by road-sides in Virginia, but rarely. We presume the seeds may have been imported from England. The *root* is annual. *Stem* about two feet high, erect, copiously clothed with finely divided spreading leaves, whose ultimate divisions are rather pinnatifid than pinnate. *Flowers* pale yellow, very small and inconspicuous, densely corymbose, succeeded by long clusters of slender, upright, torulose *Pods*, on slender, spreading, partial stalks, their valves separating and spreading from the base, somewhat like a *Cardamine*. The herb has been thought useful in fluxes.

S. millefolium. Mill-foil-leaved Wild-rocket. Willd. n. 28. Ait. n. 14. (*Sinapis millefolia*; Jacq. Coll. v. 1. 41. Ic. Rar. t. 127.)—Leaves triply pinnate, downy and hoary. *Petals* larger than the calyx.—Native of the Canary islands, from whence Mr. Masson brought it in 1779. This is a perennial, shrubby, greenhouse plant, flowering from May to September. Though like the last in general aspect, the leaves are more compound and hoary, with usually more rounded segments or leaflets; and the flowers are much more conspicuous, on account of their spreading yellow petals, double the length of the calyx.

S. Irio. London Wild-rocket. Linn. Sp. Pl. 921. Willd. n. 36. Fl. Brit. n. 8. Engl. Bot. t. 1631. Curt. Lond. fac. 5. t. 48. Jacq. Austr. t. 322. (*Erysimum latifolium majus glabrum*; Bauh. Pin. 101. Monf. sect. 3. t. 3. f. 3, at the bottom. *Irio lævis apulus*, erucæ folio; Column. Ecphr. 264. t. 265.)—Leaves runcinate, toothed, naked. *Stem* smooth. *Pods* erect, very long, thread-shaped.—Native of cultivated ground throughout Europe. Very common about London, where it was supposed by the sapient advocates of spontaneous generation, to have been generated in consequence of the great fire, in 1666. If, therefore, we confide in the bold assertion on the Monument, or the inscription on the fat boy at Pye-corner, this plant ought to be a cure for popery, or "the sin of gluttony," or for both. However this may be, the *root* is annual, the whole herb, except the upper flower-stalks and calyx occasionally, is invariably smooth, with an acrid flavour, like mustard. *Stem* erect, about two feet high, round, leafy, slightly zigzag, mostly branched. *Leaves* none of them truly pinnate, but deeply pinnatifid, with spreading or reflexed oblong lobes, most toothed at their upper or fore edge. *Flowers* corymbose, numerous, small, yellow; their petals spreading, longer than the calyx. *Pods* an inch and a half long, very slender, on partial stalks, about a quarter of an inch in length, all together composing a long lax cluster. *Stigma* sessile.

S. Loefelii. Loefel's Wild-rocket. Linn. Sp. Pl. 921. Willd. n. 38. Jacq. Austr. t. 324. (*Turritis Loefelii*; Br. in Ait. Hort. Kew. v. 4. 109. *Erysimum hirsutum*, filiquis erucæ; Loef. Prussl. 69. t. 14. *Rapistrum montanum*, irionis folio, macroleptoceron; Column. Ecphr. 266. t. 268.)—Leaves runcinate, toothed, hairy. *Stem* rough with deflexed bristles. *Pods* erect, thread-shaped, on long spreading stalks.—Native of Prussia, Austria, France,

SISYMBRIUM.

France, Italy, and Greece. More branched than the last, from which it differs in having the stem clothed with deflexed hairs, found more sparingly on the flower-stalks, which latter agree in length and slenderness with those of *S. Irio*. Nor do the leaves differ much in shape from that plant, though distinguished by their hairiness. The length and slenderness of the pods, in the Linnæan specimen, likewise accord with *Irio*; but in one from Jacquin they are shorter, as expressed in his plate. The stigma is sessile. There are, in the Linnæan and Banksian collections, specimens from Jacquin, of what he, at one time, seems to have confounded with his *S. Columnæ*, Fl. Austr. t. 323, as mentioned in Prodr. Fl. Græc. v. 2. 21. These specimens appear a smoothish variety of *S. Loefelii*, and bring this species very near to *Irio*. We now no longer feel any scruple respecting Columnæ's t. 268, cited indeed by Linnæus and Willdenow for *S. Loefelii*, though heedlessly by the latter for *S. Columnæ* also, after Jacquin, and though the hairs on the same do not point downward.

S. orientale. Oriental Wild-rocket. Linn. Sp. Pl. 921. Willd. n. 40. Ait. n. 40. Prodr. Fl. Græc. n. 1540. (*S. Columnæ*; Jacq. Austr. t. 323. Ait. n. 3.)—Leaves runcinate, downy. Stem without bristles. Pods erect, thread-shaped, on short, thick, spreading stalks.—Native of the Levant. Dr. Sibthorp had a wild specimen from Zante. According to Jacquin, this species also grows in Austria. The root is annual. Habit of the plant not unlike the two last, but the whole herbage is more or less densely clothed with fine close pubescence, and the partial stalks, supporting the pods, are much shorter and thicker than in either. The leaves of all three are pinnatifid, not pinnate: the upper ones are more lanceolate and entire in *S. orientale*, than in the others.

S. obtusangulum. Blunt-lobed Wild-rocket. Willd. n. 39. Schleich. Cat. 48. (Eruca, n. 459; Hall. Hist. v. 1. 199, excluding all the synonyms, except the following. *E. inodora*; Bauh. Hist. v. 2. 862.)—Leaves pinnate or pinnatifid, lyrate, with obtuse, deeply-toothed lobes. Stem rough with deflexed hairs. Pods erect, on long spreading stalks.—Native of various parts of Switzerland. We have specimens gathered by the late Mr. Davall near Aigle; where Haller indicates his variety γ , having larger and yellow flowers. We dare not answer for all his varieties, any more than for his very incorrect mass of synonyms, but our's is surely the plant of Schleicher and Willdenow. The root is annual. Stem two feet high, leafy, somewhat angular, clothed with more minute deflexed hairs than *S. Loefelii*. Leaves well compared by Haller to those of Common Ragwort, *Senecio Jacobææ*, as to their general aspect. They are often pinnate, not merely pinnatifid; their leaflets, or lobes, nearly uniform, remarkably blunt, most toothed backward. Flowers numerous, large, densely corymbose, on long stalks. Calyx hairy, spreading, as well as the petals.

S. catholicum. Notch-leaved Wild-rocket. Linn. Mant. 93. Willd. n. 43.—Leaves pinnate; leaflets elliptic-oblong, cut or serrated, smooth. Stem branched, spreading. Pods erect, on long spreading stalks.—Native of Spain and Portugal, to which the specific name alludes; but this is particularly unfortunate, for we have the same plant from Barbary. The root is woody, and apparently perennial. Stem bushy, not a foot high, leafy. Leaves stalked, smooth, fleshy, of about six or seven, opposite or alternate, leaflets, sharply serrated, and sometimes elegantly cut or pinnatifid, tapering at their base, each an inch long, more or less. Flowers yellow, half the size of *S. tenuifolium*, and situated like them on corymbose, finally racemose, long, terminal stalks. Linnæus, in his herbarium, has confounded a Stock-

holm specimen of this last-mentioned, in which the segments of the leaves happen to be jagged, with his real *catholicum*.

SECT. 5. Leaves oblong, scarcely divided. Nine species.
S. barbareæ. Plantain-leaved Wild-rocket. Linn. Sp. Pl. 921. Willd. n. 41. (*S. orientale*, *barbareæ* facie, *plantaginifolia*; Tourn. Cor. 16.)—Leaves simple; the upper ones ovate, toothed, elongated and clasping the stem at their base; radical ones somewhat heart-shaped, entire.—Native of the Levant. Linnæus had an incomplete specimen of this very rare plant from professor Burmann. Its general appearance is very like *Erysimum Barbareæ*. The whole herb is smooth, and said to be infipid. Stem stout, branched, angular and furrowed, leafy. Upper leaves gradually smaller, and more toothed. Flowers small, yellow, terminal, corymbose, rather numerous. We have ventured to remove this species from the last section, as the leaves cannot even be termed pinnatifid.

S. strictissimum. Spear-leaved Wild-rocket. Linn. Sp. Pl. 922. Willd. n. 46. Ait. n. 15. Prodr. Fl. Græc. n. 1542. Jacq. Austr. t. 194. (*Arabis a quibusdam dicta planta*; Camer. Epit. 342.)—Leaves ovato-lanceolate, toothed, downy, stalked. Corymbs panicle. Pods ascending.—Native of open, dry, mountainous situations, in Germany, Switzerland, and Italy. A hardy perennial, long known in our botanic gardens, flowering from June to August. The stems are a yard high, erect, round, or slightly angular, wand-like, clothed copiously with taper-pointed leaves, two or three inches long, dark-green, chiefly downy beneath, occasionally entire. Flowers very abundant and showy, of a golden yellow, in roundish, simple or compound, corymbose heads, on long stalks, collected at the upper part of the stem, into a dense oblong panicle. Pods racemose, two inches or more in length, slender, smooth, thread-shaped, two-edged, with a thick, nearly sessile, stigma.

S. hispanicum. Spanish Wild-rocket. Jacq. Coll. v. 1. 69. Ic. Rar. t. 124. Willd. n. 48.—Leaves lanceolate, sessile, smooth, with tooth-like serratures. Stem branched, spreading. Corymbs racemose. Pods close-pressed.—Native of Spain. Biennial; flowering in May and June, after being protected in the stove at Vienna through the winter. The whole herb is perfectly smooth, a foot and a half high. Leaves one or two inches long, bright green, rarely quite entire. Flowers deep yellow, smaller than the last, succeeded by long close clusters of crowded or imbricated pods, an inch in length.

S. integrifolium. Linear Siberian Wild-rocket. Linn. Sp. Pl. 922. Willd. n. 51. (*S. n. 38*; Gmel. Sib. v. 3. 270. t. 63.)—Leaves linear, entire. Flower-stalks hairy, glandular, and viscid. Pods spreading.—In mountainous sandy parts of Siberia. Gmelin. The root is slender, woody, supposed by Willdenow to be annual; but of this there is no certain account. Stem sometimes erect, sometimes procumbent, always hairy and glutinous, round, leafy, more or less branched. Leaves an inch and a half long, narrow, fleshy, obtuse, channelled, stalked, described by Gmelin as smooth, which they may perhaps usually be, but in his specimens before us they are clothed with longish scattered hairs. Flowers much larger than he delineates them, corymbose, purple or yellow, calyx hairy. Pods an inch long, linear, rather ascending, besprinkled, like their stalks, with prominent glands. Stigma very nearly sessile.

S. indicum. Indian Wild-rocket. Linn. Sp. Pl. 917. Mant. 93. Willd. n. 52. Burm. Ind. 140.—Leaves ovato-lanceolate, stalked, serrated, smooth; the lower ones somewhat lyrate. Stem zigzag, branched, spreading. Pods spreading, curved upwards.—Native of the East Indies. The

The Malay name on the Linnæan specimen is *Sasavi Sibina*, given by Burmann *Sesuri-china*. He describes the leaves as lyrate, of which we trace some indications on the specimen, and doubt not the lower ones are so. Linnæus has described this same specimen twice, not adverting to his *Sp. Pl.*, when he wrote the *Maniffa*; but both are sufficiently correct. The plant is annual, unknown in our gardens. Its affinity to *S. hispanicum*, induces us, with Willdenow, to place it in this section, rather than in the first, to which Linnæus first referred it; but not having seen the lower leaves, we cannot be positive. The stem is slender, smooth, and leafy. Flowers small, white, succeeded by long clusters of pods, each pod hardly an inch in length, nearly cylindrical, obscurely quadrangular, curved upwards, supported by a horizontal stalk, a quarter of an inch long. Stigma elevated on a short style. The pods have not the short turgid aspect proper to the first section of the genus, but accord precisely with the plants ranged in several of the latter sections, whose pods have more or less of a quadrangular shape, though two of the angles are often merely indicated by an elevated line along each valve.

Whoever shall take the trouble of tracing our remarks through this genus, and examining the other species, which, for brevity's sake, we have passed over, will see how much is still wanting towards a correct generic distribution of the whole order. Mr. Brown's, in *Hort. Kew.*, is, notwithstanding, an able and useful attempt at a reform, of which we may say more hereafter under the article TETRADYNAMIA. See also SILIQUOSÆ and SILICULOSÆ.

Sisymbrium, among the Romans, was one of the ingredients, of which the nuptial garlands were composed.

SISYMBRIUM, in *Gardening*, contains a plant of the hardy herbaceous kind, of which the species cultivated is the common water-crefs (*S. nasturtium*).

Method of Culture.—This may be effected by parting the roots, or by seed. In the first method, while the plants are young, a quantity of slips should be made with root-fibres to them, and be planted out immediately in a shallow, trickling, watery situation, when they will readily strike roots, feed, and increase themselves.

The seed should be collected during the summer season, and sown in the same places; or, which is better, the plants, with the ripened seeds upon them, be thrown into them, where they will strike root, and shed their seeds for future increase.

These plants are in much esteem as winter and spring salad herbs.

SISYMBRIUM *Nasturtium*, *Water-Cresses*, in the *Materia Medica*. The leaves of the water-creffes have a moderately pungent taste, and emit a quick penetrating smell, like that of mustard-seed, but much weaker. Their pungent matter is taken up both by watery and spirituous menstrua, and accompanies the aqueous juice, which issues copiously upon expression: it is very volatile, so as to arise, in great part, in distillation, with rectified spirit, as well as with water, and almost totally to exhale in drying the leaves, or inspissating by the gentlest heat to the consistence of an extract, either the expressed juice, or the watery or spirituous tinctures. Both the inspissated juice, and the watery extract, discover to the taste a saline impregnation, and in keeping throw up crystalline efflorescences to the surface. On distilling considerable quantities of the herb with water, a small proportion of a subtile, volatile, very pungent oil is obtained.

Water-creffes obtain a place in the materia medica for their antiscorbutic qualities, which have been long very generally acknowledged by physicians. They are also sup-

posed to purify the blood and humours, and to open visceral obstructions; they are nearly allied to scurvy-grafs, but are more mild and pleasant, and for this reason are frequently eaten as salad. In the pharmacopeias the juice of this plant is directed with that of scurvy-grafs and Seville oranges; and Dr. Cullen has remarked, that the addition of acids renders the juices of the plantæ siliquosæ most certainly effectual, by determining them more powerfully to an acceftent fermentation. Lewis Mat. Med. Woodville Med. Bot.

SISYMBRIUM is also a name used to express the wild water-mint. See MINT.

SISYRA, among the *Ancients*, a woolly skin used for a covering to beds.

SISYRINCHIUM, in *Botany*, from *συσ*, a bag, and *ῥιγχος*, a snout, the name of a bulb, mentioned by Pliny amongst other bulbs, under various Greek denominations. He relates, after Theophrastus, book vii. chap. 13. that it is remarkable for increasing, during winter, in the lower part, which in spring becomes contracted, and the upper part is then eatable. Nobody has ascertained the real *συσῤῥιχιον* of Theophrastus or Pliny. Botanists have applied this appellation according to their fancy, without even pretending to ascertain whether it alludes to the fondness of swine for the root, or to any resemblance in its figure to their snout. The *Sisyrrinchium* of Columna, *Ecpbr.* 328. t. 327, is *Ixia Bulbocodium*, in whose minute bulb that fanciful author traces such a resemblance. That of Bauhin and Tournefort is *Iris Sisyrrinchium* of Linnæus, a common Greek plant, whose bulb increases at its summit, and is eatable. The name is now retained for a modern genus, of the same natural order indeed, but otherwise having nothing in common with the plant of the ancients.—Linn. Gen. 465. Schreb. 450. Willd. Sp. Pl. v. 3. 577. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 135. Gawler (Ker) in Sims and Kou. Ann. of Bot. v. 1. 246. Pursh 31. Cavan. Diff. 344. Juss. 57. Lamarck Illustr. t. 569. (Bermudiana; Tourn. t. 208. Gærtn. t. 11.)—Class and order, *Monadelphia Triandria*. (*Gynandria Triandria*, Linn.) Nat. Ord. *Enfate*, Linn. *Irides*, Juss.

Gen. Ch. *Common Sheath* two-edged, of two compressed, pointed valves; *partial* ones several, lanceolate, concave, obtuse, inferior, single-flowered. Perianth none. *Cor.* superior, of six nearly equal, flattish, obovate, minutely pointed petals, spreading in their upper half; the three alternate exterior ones a little the broadest. *Stam.* Filaments three, united half way up, or more, into an obscurely triangular tube, shorter than the corolla, their extremities spreading; anthers incumbent, roundish. *Pistl.* Germen inferior to the corolla, obovate; style triangular, the length of the tube; stigmas three, erect, scarcely tumid, undivided, notched. *Peric.* Capsule obovate, rounded, with three slight angles, of three cells, and three valves; the partitions from the centre of each valve. *Seeds* numerous, roundish, inserted in two rows, into each of the partitions.

Ess. Ch. *Common sheath* of two or more leaves. Calyx none. Petals six, nearly equal, flat. Style one. Capsule of three cells, inferior.

1. *S. latifolium*. Broad-leaved Sisyrrinchium. Swartz Prodr. 17. Ait. n. 1. (*S. palmifolium*; Cavan. Diff. 348. t. 191. f. 1. *Moræa plicata*; Willd. Sp. Pl. v. 1. 243. *M. palmifolia*; Jacq. Ic. Rar. t. 227. Coll. v. 3. 192. *Marica plicata*; Curt. Mag. t. 655. Bermudiana palmæ folio, radice bulbosâ; Plum. Ic. 35. t. 46. f. 2.)—Stalk round. Sheath many-flowered. Leaves lanceolate, plaited. Native of the West Indies. Cultivated by Miller in 1737. It requires the heat of a stove, flowering from June

SISYRINCHIUM.

June to August. The *root* is an ovate bulb, with numerous, very thick and fleshy, fibres. *Leaves* radical, stalked, erect, from one to two feet long, taper-pointed, smooth, dark-green, with many longitudinal parallel ribs and plaits. *Stalk* solitary, taller than the leaves, very smooth and round, bent obliquely, and horizontally at the top, where it bears several white, inodorous, short-lived *flowers*, hardly an inch broad, accompanied by one small erect leaf. *Antbers* yellow. Linnæus unaccountably confounded this with his true *S. palmifolium*, hereafter described.

2. *S. elegans*. Yellow Green-spotted Sisyrrinchium. Willd. n. 1. (Moræa elegans; Jacq. Hort. Schoenbr. v. 1. 6. t. 12.)—*Stalk* round, simple, sheathed, single-flowered, shorter than the solitary, linear, decumbent, radical leaf. *Petals* oblong, acute.—Native of the Cape of Good Hope; flowering in a greenhouse in May. *Bulbs* the size of hazel-nuts, each bearing a long, narrow, decumbent, ribbed, green leaf, and an erect *stalk*, about a span high, clothed with many large, alternate, sheathing, rather tumid, *bractæas*. The solitary terminal *flower* is full two inches broad, of a bright yellow; the disk of each of the three outer *petals* marked with a broad green spot, highly ornamental. This and the following have not the true compressed bivalve *sheath* of the genus.

3. *S. collinum*. Tawny Sisyrrinchium. Cavan. Dill. 346. Willd. n. 2. Redout. Liliac. t. 250. (Moræa collina; Thunb. Moræa n. 13. Prodr. 11. Jacq. Ic. Rar. t. 226.)—*Stalk* round, sheathed, somewhat branched, shorter than its linear, pointed, ascending leaf. *Petals* oblong, acute. Plentiful on hills at the Cape of Good Hope. Taller than the last, with a branched *stalk*, bearing about three *flowers*, either of a tawny blush-colour, or pale buff, unspotted. The *leaf*, which grows from the lower part of the stalk, stands erect, its point drooping over the uppermost flower.

4. *S. grandiflorum*. Large-flowered Sisyrrinchium. Cavan. Dill. 346. t. 192. f. 2. Willd. n. 3.—*Stalk* round, simple, leafy. *Sheath* with about three flowers. *Petals* obtuse, pointless. *Leaves* lanceolate, plaited. Native of Peru. *Bulb* ovate, an inch long, with capillary fibres. *Stem* a foot high, jointed, bearing three or four stalked *leaves*, from three to ten inches in length. *Flowers* an inch and a half broad, with obovate *petals*, yellow in the dried specimen. Column of the *stamens* measuring near an inch. *Cavanilles*.

5. *S. Bermudiana*. Iris-leaved Sisyrrinchium. Linn. Sp. Pl. 1353, β. Willd. n. 4. Ait. n. 2. Cavan. Dill. 346. t. 192. f. 1. Mill. Illustr. t. 73. Redout. Liliac. t. 149. (*S. iridioides*; Curt. Mag. t. 94. Bermudiana iridis folio, radice fibrosa; Dill. Elth. 48. t. 41. f. 48.)—*Stalk* two-edged, branched, leafy. *Sheath* shorter than its four flowers. *Petals* pointed. *Leaves* sword-shaped.—Native of the Bermuda islands. Common in our stoves or greenhouses since the time of Dillenius, flowering in summer. The *root* is fibrous, perennial. *Plant* erect, about a foot high, smooth, with a narrow compressed *stem* and *leaves*. *Flowers* numerous, an inch wide, dark blue, pale green in the centre, on slender partial stalks.

6. *S. anceps*. Narrow-leaved Sisyrrinchium. Cavan. Dill. 345. t. 190. f. 2. Willd. n. 5. Ait. n. 3. Pursh n. 2. (*S. Bermudiana*; Linn. Sp. Pl. 1353, α. *S. gramineum*; Curt. Mag. t. 464. Redout. Liliac. t. 282. Bermudiana graminea, flore minore cæruleo; Dill. Elth. 49. t. 41. f. 49.)—*Stalk* two edged, winged, unbranched, nearly leafless. *Sheath* unequal, longer than its four flowers. *Petals* pointed. *Leaves* sword-shaped.—Native of North America. On dry hills and grass-plats; from Canada to Carolina, flowering in July and August. *Pursh*.

Hardy in our gardens, but seldom preserved, the *flowers* being so much smaller and less conspicuous than the former. The whole *plant* is about half the size of that species, of a grassy aspect; the *root* crowned with numerous fibres, from the decayed foliage of former seasons.

7. *S. mucronatum*. Pointed-sheathed Sisyrrinchium. Michaux Boreal-Amer. v. 2. 33. Pursh n. 1.—*Stalk* unbranched, somewhat fetaceous as well as the leaves. *Sheath* coloured; one valve ending in a long point. In wet meadows of short grass, in Pennsylvania and Virginia, flowering in June and July. Perennial. *Flowers* of a beautiful blue, smaller than the last. *Pursh*. The lower part of the *leaves* and the *sheaths* are purple. *Micbaux*.

8. *S. micranthum*. Small-flowered Sisyrrinchium. Cavan. Dill. 345. t. 191. f. 2. Willd. n. 6.—*Stalk* two-edged, branched, leafy. *Sheath* about equal to its two or three flowers. *Petals* linear, pointed. *Leaves* channelled.—Gathered by Joseph de Jussieu in Peru.—*Root* fibrous. Whole *plant* but three inches high. *Leaves* several, linear, pointed, concave or channelled, sheathing, shorter than the item. *Sheath* somewhat unequal. *Flowers* very small, on capillary stalks.

9. *S. californicum*. Yellow Unbranched Sisyrrinchium. Ait. n. 4. (Marica californica; Ker in Curt. Mag. t. 983.)—*Stalk* two-edged, winged, unbranched. *Petals* obovate, pointless. *Leaves* linear-sword-shaped.—Discovered on the coast of California, by Mr. Archibald Menzies, who brought seeds to England, in 1796. It proves a hardy greenhouse perennial plant, flowering in summer and autumn, and readily propagated, either by seed or parting the roots, which, like those of perhaps all the indubitable species of this genus, unfortunately for the origin of its name, are fibrous. The *stalk* is about two feet high, being taller than the *leaves*, though nearly the same breadth, and bears but one tuft of numerous *flowers*, from a close *sheath*, one of whose valves rises somewhat above them. The *corolla*, *stamens*, and *style*, are of an uniform bright yellow. Mr. Ker remarks, that the *filaments* are combined in their lower part only.

10. *S. convolutum*. Yellow Branched Sisyrrinchium. Redout. Liliac. t. 47.—*Stalk* two-edged, branched, leafy. *Petals* ovate, scarcely pointed. *Leaves* linear-sword-shaped.—Said to be a native of the Cape of Good Hope, but for this M. Redouté had no certain authority. It was sent from Italy to the Paris gardens, and we should not be greatly surpris'd, if future enquiries should prove it of American origin. There seems very little difference between this species and the last, except its more humble growth, and the *stem* being divided or branched, and leafy. Redouté has erroneously defined the latter as round, which is corrected in his fifth volume, at t. 275. The name alludes to the rolling in of the *petals* as they fade, which is also the case in *californicum*, and many, if not all, of the other species.

11. *S. tenuifolium*. Yellow Slender-leaved Sisyrrinchium. Redout. Liliac. t. 275.—*Stalk* compressed, branched, spreading. *Petals* ovate, acute. *Leaves* linear-awl-shaped. *Germs* hispid.—Communicated to the Paris garden by M. Zea, a celebrated Spanish botanist; so that we presume the plant to be a native of Mexico or Peru, though nothing has been made known as to its origin. This species agrees with the last in its yellow *flowers*, which however appear to be rather more numerous, sometimes six, in each *sheath*. The *stem* and *leaves* are much more slender, and hardly so tall; the former twice-branched, in a spreading manner, the *branches* curved upwards, with an erect leaf or two at each subdivision. The *germen* is remarkable

for being rough with little glandular hairs, which fall off as the capsule ripens. These have not been noticed in any other species.

12. *S. ixioides*. White New Zealand Sifyrinchium. Forst. Prodr. 61. (Ferraria ixioides; Willd. Sp. Pl. v. 3. 582. *Morea* ixioides; Thunb. *Moræa* n. 7.)—Stalk triangular, branched. Leaves linear, with cartilaginous edges. Outer petals half the size of the inner.—Gathered in New Zealand, by Forster, whose specimens are before us. The root is woody, furnished with very long, tough, zigzag fibres. Stalks a span high, nearly leafless, branched in the upper part. Leaves shorter than the stalks, erect, flat, linear, a quarter of an inch wide, strongly striated, with a pale cartilaginous edge, but not sword-shaped, as they have no prominence or rib in the middle; their bases are sheathing, or equitant. Partial flower-stalks rigid, widely spreading, two, three, or four together, with very small lanceolate sheaths at their origin. Flowers about half an inch broad, white, their three outer petals somewhat coloured, if we may judge from the dried specimen. Germen smooth. The specimens Thunberg saw were taller than our's. The inequality of the petals probably led Willdenow to make this plant a *Ferraria*; but it wants the genuine character of that genus, the jagged and curled corolla, and has altogether the habit of a true *Sifyrinchium*.

13. *S. palmifolium*. Palm-leaved Sifyrinchium. Linn. Mant. 122, excluding the synonym. Willd. n. 7. Ait. n. 5? (*Moræa palmifolia*; Thunb. *Moræa* n. 6.)—Stalk two-edged, winged, densely corymbose at the summit. Leaves sword-shaped, strongly ribbed.—Gathered in Brasil, by father Panegai, who sent it, with many other new plants, to professor Arduino of Padua, by whom they were transmitted to Linnæus. The present has all the appearance of a true *Sifyrinchium*, with a fibrous perennial root. The stem is two feet high, erect, unbranched, naked, with two opposite leafy wings. Leaves equitant, erect, shorter than the stem, three-quarters of an inch wide, having about five principal ribs in the middle part, and a few finer ones towards the edges. Flowers very numerous, in a dense, corymbose, compound, terminal panicle, two or three inches high, accompanied by one erect ribbed leaf, about the same height. Bractæas and sheaths near an inch long, ovate, pointed, striated, concave, membranous at the edges. Flowers apparently pale, with numerous dark or purplish veins; their partial stalks longer than the sheaths. Germen roundish, smooth. We are unable to account for the flowers having been termed *spiked*, unless Thunberg has confounded any thing else with this rare species. Linnæus says the style is three-cleft more than half way down.

14. *S. striatum*. Yellow Striated Sifyrinchium. Sm. Ic. Pi&t. t. 9. Willd. n. 8. Ait. n. 6. Redout. Liliac. t. 66. (*S. fipicatum*; Cavan. Ic. v. 2. 2. t. 104. *Morea* fertata; Jacq. Hort. Schoenbr. v. 1. 6. t. 11. *Marica* striata; Ker in Curt. Mag. t. 701.)—Stem much branched, leafy, compressed, winged, many-flowered. Flowers fasciculated, with a simple sheath to each.—Native of Mexico; a hardy perennial in our gardens, propagating itself spontaneously by seed. The root is fibrous, tufted. Stems several, two or three feet high, accompanied by copious, equitant, sword-shaped, striated, glaucous leaves, edged with purple, and tinged with saffron-colour at their base. Flowers very numerous, inodorous, forming tufts along the branches, as if whorled, each tuft accompanied by a large concave simple bractæa, and each of the numerous partial stalks attended by a simple membranous sheath. Corolla above an inch wide, expanding in sunshine only, when the flowers make a handsome appearance, lasting in

succession through most part of the summer. Petals obtuse with a point, slightly cohering at the base, into the form of a bell, yellow and more or less spotted within; their upper part widely spreading, pale yellow above, striated with purple veins beneath. Germen roundish, smooth. Capsule the size of a black currant, gibbous. It will be perceived that the sheaths of this species do not exactly answer to the generic character, yet nothing can be a more genuine *Sifyrinchium*. Much has been done to discriminate the genera of this order, and great improvements have been made, but much is still wanting.

SISYRINCHIUM, in Gardening, contains plants of the flowery perennial kind, of which the species cultivated are, the Iris-leaved sifyrinchium (*S. bermudiana*); and the narrow-leaved sifyrinchium (*S. anceps*).

It is observed, that the leaves, stalks, and flowers of the first sort are three times as large as in the second, and the sheath incloses six or seven flowers; whereas the second has rarely more than two, and these expand only for a short time in the morning, while, in the former, they continue open the whole day.

Method of Culture.—These plants may be increased by seeds and parting the roots: in the former method, the seeds of the first sort should be sown in the autumn, as soon as they become ripe, on a border which has an eastern aspect, in drills at three or four inches distance, covering them about half an inch with fine mould; they should afterwards be kept clean from weeds with care. They succeed best in a loamy soil in a shady situation, and where the ground has not been manured. But in the latter sort the seeds should be sown in pots, in order that they be protected in the greenhouse, or by some other means.

The first kind affords ornament in the large open borders and clumps of pleasure-grounds, and the latter among other green-house plants of the same growth.

SISZEK, in Geography, a town of Croatia, at the conflux of the rivers Save and Kulpa, fortified with a wall and moat; captured by the Turks in 1593, and burned by them in 1594, but rebuilt by the Hungarians; 48 miles S. of Varasdin. N. lat. 45° 38'. E. long. 16° 44'.

SIT, an island in the Adriatic. N. lat. 4° 14'. E. long. 15° 24'.

SITA, in Hindoo Mythology, is a celebrated incarnation of the goddess Lakshmi, celestial consort of Vishnu, in his avatara, or descent in the form of Rama. In the language of Hindoo fable, she was his *fakti*, or energy; and numberless poems have been written in honour of her beauty, merits, and deeds. She is one of the most popular goddesses of the Hindoo Pantheon, and is indeed one of the most virtuous and interesting characters in their puranic or heroic legends. Her history and that of her lord forms the subject of the Ramayana, which epic poem, like the Iliad, is grounded on a rape. (See RAMAYANA.) As noticed in that article, and RAVENA, the carrying off, by the treachery of the tyrant of that name, the virtuous spouse of Rama, roused that hero to the mighty deeds necessary for her rescue from the hands of her powerful persecutor, and celebrated in the fine poem of Valmiki; and, as noticed above, in numberless others of secondary and minor fame.

The outline of Sita's history is this. The childless raja Janaka, (see JANAKA,) having duly propitiated the gods, was led to the benevolent adoption of a female child about five years old, found inclosed in a box by a Brahman in a field. She was called Sita, from *sit* or *set*, meaning a furrow or field; and Janeki, after her adoptive father. Sita, however, means also *fair*, and may be thence derived, and is in this sense, of denoting beauty, given also to Parvati and Sarafwati, consorts

forts of the other two divine persons of the Hindoo triad. She proved to be an incarnation of Lakshmi, as before noticed; and on attaining maturity was won by Rama, in a contest of archery with many sovereigns, ambitious of obtaining a prize of such incomparable beauty. This story, as it is related in the Ramayana, reminds us of the unyielding bow of Ulysses; as none but Rama had power to accomplish the required and ordained feat; which was piercing the eye of a fish whirling on a pin fixed on a high pole; and not looking at the mark, but at its reflection in a vessel of oil placed on the ground. The ten-headed-twenty-handed tyrant Ravana had previously failed. See RAVENA.

Burning with the rage of disappointed desire, the tyrant carried her off; and having been in his power, her purity might be possibly suspected; she therefore plunged into the flames, where, defended by Pavaka, the regent of fire, her incomcombustibility attested her innocence. She was of course triumphantly restored to her overjoyed husband. In the Ramayana she is described as "endued with youth, beauty, goodness, sweetness, and prudence; an inseparable attendant on her lord, as the light on the moon; the beloved spouse of Rama, dear as his own soul; formed by divine illusion, amiable, and adorned with every charm;" and always held forth as an example of conjugal faith and affection.

While confined on the island of Lanka, or Ceylon, (see those articles,) and persecuted by the address of its tyrannical sovereign, the anguish and lamentation of Sita are copious subjects of hyperbole for Hindoo poets. Travellers are still shewn a lake or pool, called Sita-koonda, said to have originated in the floods of tears shed by the captive beauty. This extravaganza was not lost on our early missionaries and travellers. Ceylon being with them the garden of Eden, they find Adam's peak, Adam's bridge, &c. called Rama's by the natives. Eve personates Sita, in respect to this pool. Sir John Mandeville notices it in his quaint way. Describing Ceylon, he has fair scope for his poetical exuberance. "In that isle is a gret mountayne, and in mydd place of the mount is a gret lake in a full fayre pleyne, and there is gret plentie of watre. And thei of the contrie feyn that Adam and Eve wepten upon that mount 100 zeer, when they weren dryven out of Paradys. And that watre thei feyn is of here teres; for soe much watre they wepten that made the forefede lake." Sir John died in 1372. See MANDEVILLE.

A beautiful tree, called Afoka by Sanscrit botanists, bears a mythological reference to the above fable of Sita. She was confined in a grove of those trees, whose name is derived from grief, or lamentation. It is hence, perhaps, also sacred to the god of tears, or the avenging Siva. (See SIVA.) Afoka, indeed, rather from its privative initial, denotes the absence of grief, equivalent to grief-dispeller; thus named possibly from its beauty, so greatly admired by a poetical and tasteful people.

A numerous sect of Hindoos adore Sita as Lakshmi herself. It is a branch of the sect of Ramanuj. (See that article, and SECTS of Hindoos, for an account of their peculiarities.) Under the article SAKTI will be found farther thereon. She is said to have borne Rama two sons, Kushi and Lava, who were great orators and minstrels; but they are seldom heard of, except in legends immediately relating to their family.

In our article RAMA we have noticed a Peruvian festival, called Ramafitza, which, as well as in name (Rama-Sita), remind us of usages still common among Hindoos. Those disposed to lay stress on etymological coincidences, may, perhaps, here also find the source of the much disputed sense of the word *Parasiti*. (See Potter's *Archæol. Græc.* b. ii.

c. iii.) This was the name of an order of men among the Greeks, whose office seems originally to have been the gathering from the husbandmen the corn allotted for public sacrifices. Para and Sita are names, in fact, of all the three principal Hindoo goddesses, Lakshmi, Parvati, and Saraswati (see those articles, and PARA,) and may be said to mean *first* and *fairest*, as well as *first field* or *fruits*. To all these, corn and other first-fruits of the field are appropriate offerings; the gathering and care of which might give the priests the name of Parasiti. The common appropriation of these tithes to their own uses would naturally in time degrade them and their name in the estimation of their flock, who, detecting the impostures of priestcraft, brought them to their proper level in the sense of the thence derived word Parasite. See that article.

SITACA, or SITACE, in *Ancient Geography*, a large and well-peopled town of Asia, in the Perside, near Babylon, and 15 stadia from the Tigris, according to Xenophon. This town was situated nearly at an equal distance from the Tigris and the Euphrates, N.W. of Seleucia.

SITACAS, a river of Asia, in the Perside, which runs into the Persian gulf, about 800 stadia beyond the mount Areon, according to Nearchus.

SITALA, in *Geography*, a river of Mexico, which runs into the Pacific ocean, N. lat. 17° 38'. W. long. 101° 40'.

SITANG, a river of Hindoostan, one of the branches of the river called Pegu, which runs into the bay of Bengal.

SITANTA, the name of a fabulous mountain, in which is described the terrestrial abode of the god Indra, the Hindoo regent of the firmament. (See INDRA.) In the Hindoo Pantheon, the wonderful mountain Meru is described from the Puranas. (See MERU.) On one of its three peaks is Kailasa, the Olympus of Siva; and on another is the Swerga, or paradise of Indra. But his terrestrial abode is on Sitanta, a part probably of Meru; and it may be amusing to see in what the delights of Hindoo gods are supposed, by their sacred writers, to consist. Sitanta is "skirted by a most delightful country, well watered, and enlivened by the harmonious noise of the black bee and frogs. There, among immense caves, is the Kridavana, or place of dalliance of Mahendra; where knowledge and the completion of our wishes are fully acknowledged. There is the great forest of the Pariyateka-tree of the king of the gods, known through the three worlds; and the whole world sings his praise from the Veda. Such is the place of dalliance of him with a thousand eyes, or Indra. In this charming grove of Sakra, or Indra, the gods, the danavas, the snakes, yakshas, rakshas, guhyas or kuveras, gandharvas, live happy; as well as numerous tribes of Uplara, fond of sport." P. 270. The Gandharvas are celestial female choristers.

The abode of Vishnu is usually called *Vaikontha*; which see, and SWERGA.

SITAWACA, in *Geography*, a town of the island of Ceylon; 44 miles S.S.W. of Candy.

SITCA, a Russian settlement on the N.W. coast of America, somewhat S. of Cadiack, or Kadiak, in the interior of that deep bay to which Vancouver gave the name of Norfolk's found. The savages in this quarter are of a more lively and ferocious character than those of Cadiack. Instead of dozing on the ridges of their houses, they sing and dance perpetually; and are both brave and expert in the use of fire-arms, with which they are supplied by the American traders, who occasionally resort to that coast. They killed five or six of M. Lifsansky's men, in a gallant defence of a kind of rude fort, from which that commander chose to expel them, that the agents of the Russian Company might occupy the spot as a factory. After cannonading it all day,

it was found next morning that the natives had deserted it in the night; and when M. Lifsansky went to take possession, he was not a little shocked "to find, as in a second massacre of innocents, numbers of young children lying together murdered! left their cries, if they had been carried along with them, might have led to a discovery of the flight of their cruel parents;—a number of dogs had been butchered for the same reason." They burn their dead, and massacre their prisoners. They are extremely muscular and hardy; and apparently quite insensible to pain. One lad, who frequently visited the navigators, and stole whatever he could lay his hands on, was at last threatened with the scourge, but absolutely laughed at the menace,—and continued his derision and gaiety when under the most rigorous discipline that a Russian flagellator could apply. They are great beaux withal;—paint their faces of various colours, and work up their hair with a red paste, and then powder it in a magnificent manner with the fine white down of the sea-ducks. Their country is obviously volcanic. M. Lifsansky climbed up the highest mountain on the coast, which Vancouver distinguished by the name of Mount Edgcombe, and found the summit formed into a huge crater, nearly two miles in circuit, and about three hundred feet deep. It was partly filled with snow; and there is no tradition of the volcano having been seen in a state of activity. The height he estimated at no less than 8000 feet.

We shall here subjoin, from the work now before us, some account of the other settlement called *Cadiack*. This is a large barren island, at the eastern extremity of the Aleutian chain; inhabited by about 4000 of the most filthy and stupid savages of which we have any where an account. They are almost all covered over with itch and ulcers; and are extremely indolent and torpid. "Their favourite recreation," says M. Lifsansky, "after sleeping, is to sit on the roofs of their houses, or on the beach, for hours together, looking at the sea, and observing a profound silence, for they never converse; and I am persuaded," adds the worthy Muscovite, "that the simplicity of their character exceeds that of any other people." Their great passion is for snuff and amber; and their chief occupation catching whales,—on the blubber of which they fatten luxuriously, in a favourable season. They have a strange superstition, which leads them to believe that the possession of the dead bodies of any old or famous fishers contributes essentially to their good luck; and accordingly shew considerable sagacity in hunting them up in the caverns and other secret places where they have been flowed by their relations. Some, says M. Lifsansky, have actually accumulated a treasury of not fewer than twenty such corpses.

M. Lifsansky observes, that the volcanic energy seems to be more entire in this than in any other region of the world. In the neighbourhood of Oonalashka, which is situated about the centre of the Aleutian chain, a new island, nearly twenty miles in circumference, has been formed within these twenty years. The following is the account of it, which M. Lifsansky collected from eye-witnesses at Cadiack.

"In the evening of the 26th, while I was alone, writing the memorandums of my journal, a Russian introduced himself, who had resided on the island of Oonalashka, when a new island started up in its vicinity. I had heard of this phenomenon, and was therefore desirous to learn what he knew respecting it. He said, that about the middle of April 1797, a small island was seen where no island had been seen before. That the first intimation of its appearance had been brought by some Aleutians to Captain's Harbour, who, returning from fishing, observed a great smoke issuing out of the sea; that this was the smoke of the volcano, which was then gra-

dually rising above the surface of the sea, and which in May, 1798, burst forth with a blaze, that was distinctly seen from a settlement called Macooshino, on the island of Oonalashka, at the distance of no less than forty miles in the north-west. This new island is tolerably high, and about twenty miles in circumference. It has been remarked, that it has not increased in size since the year 1799; and that no alteration has taken place in its appearance, except that some of the highest points have been thrown down by violent eruptions." See Lifsansky's Voyage round the World, in the Years 1803, 4, 5, and 6, performed by Order of His Imperial Majesty Alexander I. Emperor of Russia, &c. 4to. London, 1814.

SITCHEVSK, a town of Russia, in the government of Smolensk; 96 miles E.N.E. of Smolensk. N. lat. 55° 34'. E. long. 34° 44'.

SI-TCHUA, a town of the kingdom of Corea; 33 miles N. of Han-tcheou.

SI-TCHUEN, a town of China, of the third rank, in Ho-nan; 55 miles W. of Nan-yang.

SI TE *fecerit securum*, in *Law*, a species of original writ, called peremptory, which directs the sheriff to cause the defendant to appear in court, without any option given him, provided the plaintiff gives the sheriff security effectually to prosecute his claim. This writ is in use, where nothing is specifically demanded, but only satisfaction in general; to obtain which, and minister complete redress, the intervention of some judicature is necessary. Such are writs of trespass, or on the case, in which no debt, or other specific thing, is sued for in certain, but only damages to be assessed by a jury. See PRÆCIPE.

SITE, or SCITE, *Situs*, denotes the situation of a house, messuage, &c. And sometimes the ground-plot, or spot of earth on which it stands.

SITES of *Homefalls, Yards*, &c. the situations proper for them in different cases. These are very various, according to the nature and kind of the farms for which they are designed, as whether they are those of the sheep, the grazing, the dairying, the hay and grass, or those of the mixed, arable, and grass fort. In each kind there is a great number of different suitable requisites to be provided, which must, in a great measure, depend upon the site itself. See FARM-YARD, and YARD.

SITE, *Situs*, in *Logic*, one of the predicaments, declaring a subject to be so and so placed.

SITENSKOI, in *Geography*, a town of Russia, in the government of Novgorod, near the Ilmen; 20 miles W.S.W. of Kretzei.

SITHA, a town of Hindoostan, in Guzerat; 75 miles N.N.E. of Junagur.

SITHCUNDMAN, in our *Old Writers*, one whose province it was to lead the men of a town or parish. Leg. Inc. cap. 56.

Dugdale says, that in Warwickshire the hundreds were formerly called *sythesoca*, and that *sithesocundman*, and *sithcundman*, was the chief officer within such a division, *i. e.* the high-constable of the hundred.

SITHE. See SCYTHIE.

SITHESOCA, in our *Old Writers*, is used to denote the district now called a *hundred*. The word is Saxon, signifying a *franchise*, or *liberty*.

SITHON, in *Ancient Geography*, a mountain of Thrace.—Also, an island of the Ægean sea.

SITHONIA, a part of Thrace, on the Toronæan gulf, in which were the towns of Torone, Galepfus, Sarmyles, Meczyberie, and Olymbe.

SITHONII,

SITHONII, a people of Thrace, near the Euxine sea, among whom Orpheus was born.

SITIA, a town of Spain, which had a voice in the assembly of Cordova.

SITICINES, among the Romans, persons who founded a kind of trumpet, having a very mournful tone, at the burying of the dead.

SITJES, in *Geography*, a town of Spain, in the province of Catalonia; 12 miles S.W. of Barcelona.

SITIFIS, in *Ancient Geography*, a town of Mauritania Cæsariensis, which became the capital of one of the Mauritanias, to which it gave name. See **SITIPHA**.

SITIGNAK, in *Geography*, one of the Fox islands, in the North Pacific ocean. N. lat. 53° 30'. E. long. 117° 14'.

SITINACUR, a town of Hindoostan, in Tellingana; 6 miles N. of Indelavoy.

SITIPHA, or **SITIFI Colonia, Settaf**, in *Ancient Geography*, a town of Africa, and the metropolis of Mauritania Sitifensis. It was situated in the interior of the country towards the S.E. of Saldæ.

SITIOGOGUS, a river of Asia, in the Perside, which ran into the Persian gulf.

SITODIUM, in *Botany*, Gærtn. v. 1. 344. t. 71, 72, a name originally applied to the genus affording the celebrated bread-fruit, by sir Joseph Banks and Dr. Solander, and derived from *σιτος*, bread, food, or provision. This name has given way to **ARTOCARPUS**; see that article, and **RADERMACHIA**.

SITOMAGUM, or **SITOMAGUS**, in *Ancient Geography*, a town of the isle of Albion, in the country of the Iceni, between Cambretonium and Venta Icenorum, according to Antonine's Itinerary.

SITON, a town of Greece, in Thessaly.

SITONÆ, *Σιτωναι*, among the Athenians, officers appointed to lay in corn for the use of the city, for which purpose the *ταμιας τῆς διοικησεως*, or the public treasurer, was to furnish them with as much money as they had occasion for. Potter, *Archæol. Græc. lib. i. cap. 15. tom. i. p. 83.*

SITONE, in *Ancient Geography*, a town of Macedonia, in the vicinity of mount Athos.

SITONES, the name of one of the three principal classes of people who inhabited Scandinavia, beyond mount Savos, and bounded by the sea to the west and the south.

SITOPHYLAX, *Σιτοφυλαξ*, formed from *σιτος*, corn, and *φυλαξ*, keeper, in *Antiquity*, an Athenian magistrate, who had the superintendance of the corn; and was to take care that nobody bought more than was necessary for the provision of his family.

By the Attic laws, particular persons were prohibited buying more than fifty measures of wheat a man; of those measures, we mean, called *φορμαι*, and the sitophylax was to look to the observation of this law. It was a capital crime to prevaricate in it.

There were fifteen of these sitophylaces; ten for the city, and five for the Piræus.

SITORE, in *Geography*, a town of Hindoostan, in the province of Tinevelly; 10 miles N. of Palamcotta.

SITPOUR, a town of Hindoostan, in the subah of Moultan, on the Indus; 30 miles N.W. of Moultan.

SITRIGALLY, a town of Hindoostan, in Myfore; 34 miles N.N.E. of Chitteldroog.

SITTA, the *Nuthatch*, in *Ornithology*, a genus of birds of the order Picæ, of which the generic character is, Bill tubulate, roundish, straight, entire; the upper mandible is a little longer, compressed, and angular at the tip; tongue jagged, short, horny at the tip; the nostrils are small, co-

vered with bristles; the feet are formed for walking; the hind-toe is long. Gmelin reckons twelve

Species.

* **EUROPEÆ**; European Nuthatch. Cinereous, beneath reddish; the tail-feathers black; the four lateral ones beneath are tipped with white. It weighs nearly an ounce; its length is five inches; the bill is strong and straight, and about three-quarters of an inch long; the upper mandible is black, the lower white; the irides hazel; the crown of the head, back, and coverts of the wings, are of a fine bluish-grey; a black stroke passes over the eye from the mouth; the cheeks and chin are white; the breast and belly are of a dull orange-colour; the quill-feathers are dusky; the wings underneath are marked with two spots, one white, at the root of the exterior quills, the other black, at the joint of the bastard-wing; the tail consists of twelve feathers, the two middle are grey, the two exterior feathers tipped with grey, then succeeds a transverse spot, beneath that the rest is black; the legs are of a pale yellow; the back toe very strong, and the claws large. Such is Mr. Pennant's description of the European nuthatch, who adds, that "this bird runs up and down the bodies of trees like the woodpecker tribe, and feeds not only on insects but on nuts, of which it lays up a considerable quantity, as winter provision, in the hollows of trees. It breeds likewise in the hollows of trees; and if the entrance be too large, it stops up part of it with clay, leaving only room enough for admission. In autumn it begins a chattering noise, being silent the greater part of the year. This bird makes its nest of dead leaves, mostly of the oak, which it heaps together without much order. It lays six or seven eggs, which are white, spotted with rust colour, so exactly like those of the great titmouse, that it is almost impossible to distinguish them. No persecution will force this little bird from its habitation, when sitting: it defends its nest to the last extremity, strikes the invader with its bill and wings, and makes a hissing noise; and after every effort of defence, will suffer itself to be taken in hand, rather than quit its post."

"The nuthatch," says colonel Montague, in his Ornithological Dictionary, "is more expert in climbing than the woodpecker; for it runs in all directions up and down a tree, whereas the other is never observed to descend: the stiff tail of those birds support them in the act of climbing and hacking. The flexible tail of the nuthatch gives it no such advantage, nor does it seem to want it; for its most favourite position, when breaking a nut, is with the head downwards. In autumn it is no uncommon thing to find, in the crevices of the bark of an old tree, a great many broken nut-shells, the work of this bird, who repeatedly returns to the same spot for this purpose. When it has fixed the nut firmly in a chink, it turns on all sides, in order to strike it with the most advantage. This, with the common hazel-nut, is a work of some labour; but it breaks the filberd with ease. In defect of such food, insects and their larvæ are sought after among the moss on trees, and old thatched buildings. It is commonly met with about orchards, and is sometimes seen, in the eider season, picking the seeds from the refuse of the pressed apples. The note is various: in the spring it has a remarkably loud shrill whistle, which ceases after incubation; in autumn is a double reiterated cry." There is a variety, called the little nuthatch, which is much smaller than the common nuthatch, and of a more noisy disposition. It resides in similar situations, and is equally solitary; associating only with its mate, and attacking any other it may happen to see.

CANADENSIS;

CANADENSIS; Canada Nuthatch. Cinereous, beneath pale rufous; eye-lids white. This is of the size of the European species; the bill is blackish; crown of the head, hind part of the neck, and shoulders, black; the back and rump are of a light grey; over each eye is a white line; the cheeks are white; larger quill-feathers dusky, with grey edges; breast and belly pure white; the two middle tail-feathers are grey, the rest black, with a white spot at the tip; the vent is ferruginous, and the legs are brown. It is, as its specific name imports, a native of Canada, and extends its journeys as far south as New York. Mr. Pennant makes it a mere variety of the European nuthatch; but by Linnæus and Latham it is regarded as a distinct species.

CAROLINENSIS; Black-headed Nuthatch. Cinereous, beneath whitish; lower part of the belly reddish; head and neck above black; lateral tail-feathers white, varied with black. It is a native of the temperate parts of America, and of the island of Jamaica.

JAMAICENSIS; Jamaica Nuthatch. Cinereous, beneath white; crown black; lateral tail-feathers blackish, tipped with transverse white lines. This has been described by Sir Hans Sloane in his Natural History of Jamaica. It is of the size of the common nuthatch, the length being five inches and a half; the bill nearly an inch long, and black; the head is large, with a black crown. It is, as its specific name imports, a native of the island of Jamaica. It is also found in many parts of South America, feeding on insects, and having the character of a stupid bird, easily suffering itself to be taken. From the size of its head, it is known in Jamaica by the name of loggerhead. There is a variety much less.

PUSILA; Small Nuthatch. Cinereous, beneath dirty white; the head is brown, with a dirty white spot behind; the lateral tail-feathers are black. It inhabits North America, and is said to be found in Carolina throughout the whole year.

MAJOR; Great Nuthatch. Grey, beneath whitish; the chin is white; the quill and tail-feathers brown, edged with orange. This is described by Sir Hans Sloane in the History of Jamaica; it is seven inches and a half long; the bill is thickest in the middle, and curved at the end; the head and back are grey; the under parts are whitish; the wings and tail are brown, with orange edges. It is a native of Jamaica, and feeds on worms, insects, &c.

NÆVIA; Spotted Nuthatch. Above it is of a lead-colour, beneath glaucous; the chin is white; the wing-coverts are spotted with white. This bird is described by Edwards under the title of wall-creeper of Surinam, who says, the bill is long in proportion, straight, somewhat compressed sideways, a little hooked at the point, and of a dusky brownish colour; the head, the hinder side of the neck, back, rump, tail, and wings, are of a dark blueish-lead colour; all the covert-feathers on the upper side of the wings are tipped with white; the insides of the quills and under side of the tail-feathers are ash-coloured, lighter than they are above; the throat is white; the breast, belly, thighs, and coverts beneath the tail, are of a blueish-ash colour, lighter than the upper side of the bird; from the throat, as far as the legs, the breast is marked with white lines, drawn down the middle of each feather, which end in points; the legs and feet are of a dusky brown colour. The length of this bird is about six inches. It is, as its trivial name imports, a native of Surinam.

SURINAMENSIS; Surinam Nuthatch. Reddish-chestnut, beneath it is of a dirty white; middle of the back white; wings and tail black; wing and tail-coverts tipped, and

secondary quill-feathers edged, with white. This is a very small species, not much more than three inches in length; the bill is of a dusky brown, and a little curved; the hind-head and neck are marked with oblong black spots. It is, as its specific name imports, a native of Surinam.

CAFFRA; Cape Nuthatch. Body beneath is yellow, above yellow, varied with black; the legs are black. It inhabits the Cape of Good Hope. This was described by Sparmann, and is by him said to be nine inches in length, with a straight blueish-black bill; the front, hind part of the neck, and back, mixed with brown and yellow; cheeks, neck, breast, and under parts, are of a dusky yellow, as are also the edges and tips of the wing-feathers; the tail is dusky black, beneath olive; the two middle feathers longer than the rest; the legs are black.

SINENSIS; Chinese Nuthatch. The specific character of this, according to Gmelin, is, that the lower eye-lid is purple. But Dr. Shaw denominates it the ferruginous nuthatch, with black head and neck, white breast and abdomen, a red spot behind the eye, and another white one. This bird is described by Latham as something larger than the goldfinch; the bill and head are black; the back is of a deep blueish-ferruginous; the throat, breast, and belly, are white, but the throat is encompassed by a black band, descending from the sides of the head, which is black and crested; near the eye is a small scarlet spot, succeeded by a large white one; the rump is yellow; the tail blackish, with a white tip; the bill and legs are black. It is, as its name denotes, a native of China, where it is said to be much esteemed on account of the elegance of its colours, and is a frequent ornament on Chinese papers. "It appears," says Dr. Shaw, "to be much allied to the *Lanius jocosus*, or red-vented shrike, and may perhaps prove, on future investigation, to be no other than the same bird."

LONGIROSTRA; Long-billed Nuthatch. Blueish, beneath pale rufous; primary quill-feathers tipped with brown; the lores are black. This species is described by Dr. Latham, and is said to measure nine inches; the bill is above an inch long, and black, but the base is pale or whitish; the crown of the head and whole upper parts of the bird are of a pale blueish-grey, but the cheeks and forehead are white, and a black streak passes through each eye, along the sides of the neck; the wings are tipped with brown, and the under parts of the bird are pale tawny; the legs are of a pale brown. It inhabits Batavia.

CHLONIS; Green Nuthatch. Above green, beneath white; the tail is black, tipped with yellowish; the bill is longer than the head, and blackish towards the tip; quill-feathers brown, outer edge greenish, yellowish in the middle, forming a yellowish band on the wings; the rump is yellowish, and the tail short. It is a native of the Cape of Good Hope, and is of the size of the Surinam nuthatch.

SITTACENE, in *Ancient Geography*, a country of Asia, in Assyria, near Susiana. Ptolemy.

SITTACENI, the name of those people of Asiatic Sarmatia, who inhabited the vicinity of the Palus Mæotis.

SITTART, in *Geography*, a town of France, in the department of the Roer; 12 miles S. of Ruremond.

SITTEBERIS, in *Ancient Geography*, a town of India, on this side of the Ganges. Ptolemy.

SITTENBACH, ALT, in *Geography*, a town of Bavaria, in the territory of Nuremberg; 3 miles W. of Herfbruck.

SITTENBACH, Kirch, a town of Bavaria, in the territory of Nuremberg; 5 miles N. of Herfbruck.

SITTENSEN,

SITTENSEN, a town of Germany, in the duchy of Verden; 18 miles N.E. of Rottenburg.

SITTER, a river of Switzerland, which rises in the canton of Appenzell, and joins the Thur, 9 miles W. of St. Gal.

SITTICHENBACH, a town of Saxony; 6 miles N.W. of Querfurt.

SITTICOTE, a town of Hindoostan, in Dowlatabad; 30 miles S. of Renapur.

SITTINGBOURNE, a post and fair-town in a parish of the same name, hundred of Milton, and county of Kent, England, is situated on the high road from London to Canterbury, at the distance of 40 miles S.E. from the metropolis, and 13 miles N.E. by E. from Maidstone. This place is of considerable antiquity, and derives its name, by corruption, from the Saxon word "Sædingburna," which signifies the village by the bourne or stream. Henry V. was entertained here, on his triumphant return from France, by John Northwood, esq. of Northwood, in a style of magnificence befitting the royal dignity. Queen Elizabeth incorporated this town by charter, and conferred upon it the privileges of a weekly market and fairs, first in the 16th year of her reign, and again in her 41st year. By the latter deed, the corporation was constituted by the style of the mayor and jurats, and was invested with the right of sending two members to parliament. These privileges, however, never seem to have been exercised; and even the market was dropped in a few years; but the fairs are still kept on Whitmonday and the two following days, and on the 10th of October and the four following days.

Sittingbourne chiefly forms one wide street on the high road, which here descends towards the east. The principal support of its inhabitants arises from the custom of travellers who pass through it. The inns are numerous, and some of them equal in magnificence to any provincial inn in the kingdom. The church is a spacious structure, divided into a nave and two aisles, a chancel, two chapels, and a tower, which rises at the west end. The whole has been rebuilt, with the exception of the tower, since the year 1762, when it was destroyed by fire. By that catastrophe, most of the monuments perished; and such of them as were preserved, were so capriciously removed, that few of them cover the remains of the persons they were intended to commemorate. The most curious monument remaining is one in the north, or Bayford chapel, which consists of a table-slab of Bethersden marble, placed under an obtusely pointed arch, ornamented with quatrefoil compartments, displaying heads, shields, fleur-de-lis, &c. and having, in the recess behind it, the emaciated figure of a female in a winding-sheet.

Sittingbourne parish is of small extent, and contains, according to the parliamentary returns of 1811, 239 houses, and 1362 inhabitants. Lewis Theobald, who published two editions of Shakspeare's plays, with notes, in 1733 and 1740, was a native of this parish.

At Bayford, to the north of Sittingbourne, are some remains of an ancient intrenchment, said to have been formed by king Alfred, when he came hither to repel the incursions of the Danes, in the year 893. This place was afterwards the site of a castle, which, in the time of Edward I., was the baronial seat of Robert de Nottingham, as appears from various deeds still extant, bearing date "Apud castellum suum de Bayford apud Goodneston." Hausted's History of Kent, vol. vi. Svo. edit. 1798. Beauties of England and Wales, vol. vii. by E. W. Brayley, 1806.

SITTUKERA, a town of Hindoostan, in the soubah of Moultan; 15 miles from Shawanaz.

SITUA, in *Ancient Geography*, a town of Asia, in Paphlagonia.

SITUS, in *Geometry* and *Algebra*, denotes the situation of lines, surfaces, &c.

Wolfius gives us some things in geometry, which are not deduced from the common analysis; particularly, matters depending on the situs of lines and figures. M. Leibnitz has even invented a particular kind of analysis thereon, called *calculus situs*.

SITZENBERG, in *Geography*, a town of Austria; 10 miles W.S.W. of Tulin.

SITZKOI, a town of Russia, in the government of Olonetz; 12 miles E.S.E. of Ladeinoepole.

SIVA, in *Ancient Geography*, a town of Cappadocia, in the prefecture of Cilicia. Ptolemy.

SIVA, in *Hindoo Mythology*, is a personification of one of the three great powers of the deity. Siva is usually deemed the third person in the Hindoo triad, and to represent the *destructive* energy. A detailed account of this important personage would extend itself to a history of the whole Hindoo Pantheon; for he appears in such a variety of forms, and on so many occasions, that scarcely a step can be taken in any department whatever of eastern science, art, or subject of literature, without encountering Siva in some of his varied characters. Under the articles SAIVA and VAISHNAVA we have stated, that the whole race of Hindoos are divided into those two classes, denoting the worship of Siva, or of Vishnu; Brahma, the first or creative power, having no worshippers, or temples. Of this curious fact, see under SARASWATI, the name of his consort. These two comprehensive classes are also called Saiva-bakht, and Vishnu-bakht. See *SECTS of Hindoos*.

As the *destructive* energy of the deity, Siva is most usually seen; but destruction being used in the sense of renovation, the character of Siva is that of the renovator, or recreator; associating him in character with Brahma, the producing or creative power. See *VEDANTA*.

We will try to exhibit, at one view, the variety of relations in which this and the other two members of the Hindoo triad appear; whether they be introduced mythologically, metaphysically, or philosophically. All three are symbols of the sun, as he is typical of that great light, as the theologians express it, "whence all proceeded, and to which all must return." See *O'M*.

Brahma	Power	Creation	Matter	The past	Earth.
Vishnu	Wisdom	Preservation	Space	The present	Water.
Siva	Justice	Destruction	Time	The future	Fire.

But these characters, or attributes, are not exclusively applicable to the three powers, as indicated above. They coalesce and participate, more or less, in several. An attempt has been made to shew in what degree, more particularly, they represent their material forms of earth, water, and fire: thus,

Brahma and Siva are Fire, in which Vishnu	} does not participate, or participates but remotely.
Vishnu and Brahma are Earth, in which Siva	
Siva and Vishnu are Water, in which Brahma	

As well as affinities, these powers have opposing properties; contests of persons, in mythological language, and in that of the mystics, attractions, and love.

The contests of these powers, or persons, their quarrels and reconciliations, yield fine occasions for poetical exuberance. The preservative and regenerative powers, being in constant action, are feigned to have defended on earth innumerable times, in divers places, for the instruction and benefit, including the salutary punishment, of mankind.

The wives and children of these powers have also, like their lords and parents, descended and assumed a variety of forms on earth, for similar purposes. The history of these endless incarnations affords ample scope for the imagination; and they are worked up by the poets, with wonderful fertility of genius and pomp of language, into a variety of sublime descriptions, interspersed with theological and moral texts, that at length were received as inspired productions, and have become the standard of divine truth. See PURANA, the title of a series of mythological poems, or rather of poems on every subject, under the similitude of mythological adventure.

The wives or consorts of these mythological personages are mentioned above. All the Hindoo deities are mated in fable, and their spouses are their powers or active energies, and are called their *Sakti*. See that article.

The Hindoo deities have also vehicles assigned for the conveyance of themselves and wives. These are called *vahan*. The *vahan* of Siva is a bull, called Nandi. They have likewise peculiar symbols or attributes: those that more particularly designate Siva, his *fakti*, or any thing connected with them, are the Linga, or phallus, and the Trifula, or trident. The phallic emblem denotes his presiding over generation; reminding us of the Jupiter Genitor of western mythologists, with whom sir William Jones identifies the Siva of the East.

There is yet another attribute of Mahadeva, (a name of Siva,) by which he is too visibly distinguished in the drawings and temples of Bengal. To *destroy*, according to the Vedantists of India, the Sufis of Persia, and many philosophers of our European schools, is only to *generate and reproduce* in another form. Hence the god of *destruction* presides over *generation*; as a symbol of which he rides on a *white bull*. Can we doubt that the loves and feasts of Jupiter Genitor, (not forgetting the white bull of Europa,) and his extraordinary title of *Lapis*, for which no satisfactory reason is commonly given, have a connection with the Indian philosophy and mythology?

The Jupiter Marinus, or Neptune of the Romans, resembles Mahadeva in his generative character; especially as the Hindoo god is the husband of Parvati, whose relation to the *waters* is evidently marked, by her image being restored to them at the conclusion of the great festival called Durgotava. She is known to have attributes exactly similar to those of Venus Marina, whose birth from the sea-foam, and splendid rise from the couch in which she had been cradled, have offered so many charming subjects for ancient and modern poetry. Diss. on the Gods of Greece, Italy, and India. Asiat. Ref. vol. i.

Another writer, Mr. Paterfon, in the eighth volume of the same work, offers a passage descriptive of the character and attributes of Siva. "To Siva," he says, "are given three eyes, probably to denote his view of the three divisions of time; the past, the present, and the future. A crescent on his forehead, portrays the measure of time by the phases of the moon; a serpent forms a necklace to denote the measure of time by years; a second necklace, formed of human skulls, marks the lapse and revolutions of ages, and the extinction and succession of the generations of mankind. He holds a trident, to shew that the great attributes are in him allembled and united; in another is a kind of rattle, shaped like an hour-glass, and I am inclined to think that it was at first intended as such, since it agrees with the character of the deity; and a sand *gheri* is mentioned in the Sastra as a mode of measuring time. In the hieroglyphic of Maha Pralaya, or grand consummation of all things, when time itself shall be no more,

he is represented as trodden under foot by Mahakala, or eternity." In this character he is called Kalanteka.

An anonymous writer (Edinburgh Review, N^o XXXIV. p. 316.) has offered some points of comparison between the Osiris of Egypt, the Bacchus of Greece, and the Siva of India, that will serve to illustrate our observations on the latter. "Osiris was adored in Egypt, and Bacchus in Greece, under the emblem of the phallus. It is under the same emblem that he is still venerated in Hindoostan, and Phallus is one of his names in the dictionary of Amara Singha. The bull was sacred to him in Egypt. Plutarch assures us that several nations of Greece depict Bacchus with a bull's head; and that when he is invoked by the women of Elis, they pray him to hasten to their relief on the feet of a bull. In India he is often seen mounted on a bull; hence one of his Sanscrit names, Vrishadwaja, signifying, whose ensign is a bull. Plutarch informs us, that 'Nilum patrem ac servatorem suæ regionis, ac defluxum Osiridis nominant.' The Ganges, in like manner, is fabled by the Hindoos to flow from the tresses of Siva; hence another of his names, Gangadhara, the supporter of the Ganges. We conceive, by the way, that Scaliger and Selden are mistaken in supposing that Siris, the Egyptian name of the Nile, is synonymous with Osiris. Siris seems to us the Sanscrit word Saras, a river in general, or *the river*, from its imputed superiority. Isis is the consort of Osiris; Isa that of Iswara, or Siva. (See ISA.) The attributes of the goddesses might be shewn to correspond as precisely as those of their lords. The attendants of Iswara resemble in their frantic demeanour the furious Bacchantes of the god of Naxos. It is remarkable, that many of the appellations by which the Greeks distinguish Bacchus, are also used by the Hindoos; but instead of applying them to Baghesa himself, the latter give them to his son, whilst both nations have their legends to account for them. Thus, the Greeks named Bacchus, Dimeter, having two mothers; the Hindoos call Skanda, the son of Baghesa, Divimatri, with the same signification. (See SKANDA.) Pyrgines, born from fire, and its equivalent in Sanscrit, Agniya, are respectively Greek and Indian appellatives of Bacchus and Skanda. The title of Thriambus, we are told by Diodorus, was assumed by the Greek deity, in his triumph after the conquest of India. Tryambo, in like manner, is one of the most common appellations of the Indian Bacchus, but we are not aware of its signification." See TRIAMBO.

We will subjoin what is given in the same article, as descriptive of Siva, under his name of Iswara, taken from a copious treatise in the Imperial library at Paris, entitled Hyasiras, but the MS. did not specify from what Purana it was extracted. The Matsya Purana exhibits a full code of similar instructions for the guidance of artists in portraying the various deities of the Hindoo Pantheon. (See PURANA.) We premise that the name Iswara means *powerful*; a character denoted by many hands, in the way that many heads denote sapience.

Iswara.—Let the arms, shoulders, and thighs of Iswara be brawny and muscular; his colour that of the beams of the crescent which decorates his brow; his long hair must be knotted in many convolutions; his shoulders covered by a tiger's skin; his ten arms ornamented with bracelets of snakes; pendants hang from his ears: a sword, a club, a trident, and other weapons, are perceived in his hands. When he appears in the character of the vanquisher of Tripura, during the conflagration of the city, he has sixteen arms. (See TRIPURA.) In the character of Yogeswara, his aspect must be terrific. See YOGESWARA.

Images and pictures of Siva, which, in his various characters,

ters, are very common, represent him under a great many forms, which our limits will not allow us to enumerate.

In some pictures he is seen four, six, eight, or ten, and as far as sixteen-handed; and in one character with five faces, thence called *Panchamuki*, which see; in sitting, standing, and dancing attitudes. His attributes are nearly similar to those of his fakti Parvati. Representations of him, or of his family or sect, are distinguished by the Linga, or cone, the Trifida, or trident, the Pasha, or cord of punishment, (see *PASHA*); the third eye, and collar of skulls, peculiar to him, his consort, or family; the moon and Ganga in his hair; a hand drum, shaped like an hour-glass, and called, both in Sanscrit and Greek, *dindima*, and hence probably the name of Dindimia, and other similar names given to the Grecian *queen of heaven*; and Dindymos, a fabulous mountain consecrated by the Argonauts to the *mother of the gods*; titles as well of the consort of the Indian Siva as of the Grecian Jupiter. An antelope, named Sasin, is sometimes seen in Siva's hand, supposed to have some lunar allusion. (See *SASIN*.) These are his most common attributes. Sometimes he is joined to his fakti, denoting then a mystical reunion of the powers of nature.

The fable of Bramah losing one of his heads has not hitherto been explained. It may probably mean that Bramah, or matter, undergoes curtailment by the destructive energy of fire, or Siva. Bramah had once five heads; he has now only four. Perhaps the older cosmogonies may have assigned five elements to the compeponcy of matter, which a subsequent theory, promulgated by a Saiva, reduced to four. From such speculations originate the fables of mythology. Saying that Siva is Brahma, may mean, that as renovator of forms, he is the recreator; matter being by some theories eternal; and creation, as we term it, being merely a periodical reorganization. (See *KALPA*.) He is the parent and the offspring of Vishnu. This is said according with the theory or sect, or the philosophy or religion, of the relator. (See *SECTS of Hindoos*.) Philosophically, it may mean that fire, or heat, is the *source* of water by its evaporating power, and the *effect* of humidity, through the process of fermentation; either terrestrial, or by aerial combination. Vishnu, it will be recollected, is a personification of humidity, and we may thus discern why Siva and Vishnu may be mythologically parent and offspring. In the article *SRADHA* an invocation to fire is given, from the funeral ceremonies of the Hindoos, denoting its renovating property. "Fire! thou was lighted by him; may he therefore be reproduced by thee."

As the patron of astronomy, Siva is the Uranus of the East. He is said to guide the motions of the planet Jupiter, named by the Hindoos *VRIHASPATI*; see that article. He has been already noticed as the sun, though that luminary, or its regent Surya, is more strikingly assignable to a relationship with Vishnu.

As destructive fire, that powerful changer of forms, Siva is, in a philosophical view, more immediately considered. Of him in this character, the cone or linga, it is said, is his symbol; being the form naturally assumed by flame; and the inverted cone, as the figure of water naturally descending, is symbolical of Vishnu. A triangle, with its apex upward or downward, is therefore, being conical, the symbol of these important deities, in their primary characters of fire and water. Sometimes these are seen combined, and are then mystically contemplated as the re-union of nature's elements.

The sectaries of these powers, the conservative and the changing, respectively uphold the supremacy of that worshipped severally by each. Siva being more immediately

fire, and Vishnu water, the philosophical contests for supremacy, which have, it is related, been carried to the sad length of theological war, on the parts of the adherents of these different doctrines, may remind one of those controversies, happily extending no farther, carried on in Europe by the parties at length denominated Vulcanists and Neptunists. The difference is, that in Europe the causes of the world's destruction by the deluge, and in India, the mode of its reformation at the period called kalpa, after a pralaya, or disorganization, is the point in dispute between their respective Saivas and Vaishnavas; or, in other words, the Vulcanists and Neptunists. Another instance, consonant to an European distinction, may be here noticed. It is said that individuals of the sect of Saiva are of a more reserved or serious cast than those of the Vaishnava sect. Gloomy individuals are more disposed to the reverent contemplation of the destructive and avenging attributes of the god of justice; or in other words, is it that those who adopt such adoration are thence gloomy and dark? Those, on the other hand, who contemplate and adore the deity in his attributes of preservation and mercy, are of a more cheerful turn. Thus the Saivas are the Calvinists, the Vaishnavas or Baudhas the Lutherans of India.

Siva, as the consort of Kali, is named Kal or Kala, supposed to be time; for *kal*, in Sanscrit and other languages of India, means both yesterday and to-morrow: it means also *black*; and in this character Siva, as well as his fakti, is painted of that colour, though under other forms, and usually, white is the colour of Siva. The contemplation of the distinctions of day and night; of the light and dark divisions of the month, a notation of time especially and superstitiously attended to in Hindoo ceremonials; of the six months' day and six months' night of the gods (occasioned by the obliquity of the sun's path); and, lastly, the contrast of the visible creation with eternal night; are supposed by a writer in the Asiatic Researches (Mr. Paterfon,) to have suggested the idea of painting Kal white and Kali black. When, however, he appears as Kal, he is sometimes, as above noticed, also black.

To Siva, in his various forms, several plants are esteemed sacred, and are of course nourished by his sectaries; chiefly, it may be presumed, by women, by the aged, or by Brahmans. A shrub named *Afoka*, is one supposed to be pleasing to Siva. It is described in the fourth volume of the Asiatic Researches, art. 17, by sir W. Jones, who says, that the vegetable world scarcely exhibits a richer sight than an *afoka* tree in full bloom: it is about as high as an ordinary cherry-tree. He expresses a hope that its Sanscrit name may be retained by botanists, as it perpetually occurs in the old Indian poems, and in treatises on religious rites. It is planted near Siva's temples, and his worshippers look for efficacy from bathing on a particular day in some holy stream, and drinking water with buds of the *afoka* floating in it. The name means *grief*, or lamentation, and is derived by mythologists from the grief of Sita, when confined in a grove of it on Ceylon, by the tyrant Ravana. *Sami* is the name of another shrub sacred to Siva, connected with which a great deal of enthusiastic extravagance might be pointed out. It may be remarked, that in their selection of holy vegetables, the Brahmans have shewed considerable taste by sanctifying those of the most lovely sorts.

One of the Sanscrit appellations of Siva is the god with a thousand names. These are given at length in the Padma Purana; and the sixty-ninth chapter of the Siva Purana is allotted to their enumeration. We proposed making a selection of some of them in this article; but it has already been enlarged to its utmost allowable extent.

For a further account of Siva and his family, we refer to several articles that have occurred in this work, and particularly to KAMA, LOTOS, MATRI, PATRA, PHILOSOPHY of the Hindoos, SECTS of Hindoos, SAGNIKA, SANKYA, and VEDANTA.

To this article reference is made from Parvati, of which indeed this may be considered as a continuation, and several errors of the press occurring in the latter, we take this opportunity of pointing them out correctively.—In col. 3, line 6, for *cap*, read *cup*; col. 4, l. 35, for *beauty's*, read *brevity's*; col. 5, l. 2, for *Karlikya*, read *Kartikya*; col. 5, l. 9 from the bottom, for *central is*, read *central eye is*.

SIVAN, in *Chronology*, the third month of the Jewish ecclesiastical year, answering to part of our May and June.

SIVAS, in *Geography*, a very large and populous town of Asiatic Turkey, and capital of a government, to which it gives name, the residence of a pacha; anciently called "Schalle." It is very well watered by the river: Cassal-mack, and several fountains and many clear streams, which run through it. It is seated on the W. side of a very fertile valley, which is almost surrounded by lofty mountains, having no opening except where the river runs in and out, through a very narrow channel between two steep hills. Here are two stone bridges at the distance of about a mile from each other. Corn in great abundance grows in this valley, but here is not much fruit, excepting plums, apples, and pears; but of garden vegetables there is plenty. In the middle of the town are some very extensive gardens; and on an artificial hill is an old castle, now tumbling into ruins. The houses in general have a very ordinary appearance, though the neighbourhood furnishes plenty of good materials for building; a great quantity of unsquared timber being employed to support an immense weight of stone and clay, with which the houses are covered. The inhabitants appear to enjoy much liberty; nor are the women confined, as in some large cities to the eastward. According to Mr. Jackson's account in his "Journey from India," Sivas is nearly as large as Liverpool, contains as many houses, and is fully as populous. Although most of the private houses are indifferent structures, many of the public buildings are elegant, and some of the monuments very lofty. In the year 1394 this city was taken by Bajazet, and soon after by Tamerlane, who destroyed the town and made a terrible slaughter of the inhabitants. N. lat. 38° 15'. E. long. 37°.

SIVATA, in *Ancient Geography*, a town of Asia, in Galatia. Ptolemy.

SIVEH, in *Geography*, a town of Persia, in the province of Mekran, on the Nehenk; 110 miles N.N.E. of Kidge.

SIUEN-TCHEOU, a city of China, of the first rank, in Fo-kien. N. lat. 24° 55'. E. long. 118° 29'.

SIVERIE. See SEVERIA.

SIVERS, HENRY JACOB, in *Biography*, was born at Lubec in 1709. At the age of 17 he took his degree, as master of arts, at Rosstock, and having become soon after a teacher in that seat of learning, he published, in 1730, a thesis, "De Fide Salvifica," by which he became advantageously known to the literary world. It was, in fact, an answer to a book written by Dr. Eric Pontoppidan, entitled "The Bright Mirror of Faith, in which are displayed the Marks of the Children of God." Soon after he stood candidate for the ministry at Lubec; and, on being licensed, he acquired so much popularity, that the churches were crowded wherever he preached. In 1734 he made a tour to Denmark and Sweden, to collect objects for a museum of natural history which he began to form, and settling in the latter, he was invited to be one of the pastors of the

German congregation at Norkoeeping; after this he was ordained by bishop Berzelius, and in 1746 was made one of the court chaplains. In 1747 he obtained the office of pastor of Trynerym from count Horn, and in the following year he died, in the 50th year of his age. He was a man of considerable learning, and possessed a very fine library. He had likewise accumulated a numerous collection of antiquities, natural productions, and various curiosities of art; but in 1737 he had been obliged to sell to count Charles Gyllenberg the half of his minerals, and a fine cabinet of Roman coins, which the count afterwards bequeathed to the academy of Lund. He carried on an extensive correspondence with the celebrated Linnæus, and in 1731 was elected a member of the Academy of Sciences at Berlin. He left behind him a large number of MSS., and he is said to have published more than a hundred different pieces, the titles of many of which are given in the Gen. Biog.

SIVIDURG, in *Geography*, a town of Hindooitan, in Myfore; 10 miles E. of Anantpour.

SIUM, in *Botany*, an old Latin name, *σιου* of Dioscorides, of whose etymology nothing plausible has occurred to us, except the opinion of De Theis, who deduces the word from the Celtic *siw*, water:—the plant thus called by Dioscorides, and every other writer, being an aquatic, of a small stature, succulent, and aromatic, with parsley-like leaves, as described in his work. Such is the *Sium* of modern botanists, as to most of its species; but their medicinal qualities do not well answer to the report of this old writer, the root especially being esteemed highly dangerous, like the generality of umbelliferous plants, that grow in water; nor should we trust to the herbage, either "recent or boiled, to break down and expel *calculi*, to promote urine or child-birth, or to cure the dysentery."—Linn. Gen. 138. Schreb. 188. Willd. Sp. Pl. v. 1. 1431. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 312. Prodr. Fl. Græc. Sibth. v. 1. 194. Ait. Hort. Kew. v. 2. 144. Pursh 194. Juss. 222. Lamarck Illustr. t. 197. Gærtn. t. 23.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellata*, Linn. *Umbellifera*, Juss.

Gen. Ch. *General Umbel* various in different species; *partial* spreading, flat. *General Involucrum* reflexed, of numerous lanceolate leaves, shorter than the umbel; *partial* of many small linear leaves. *Perianth* scarcely discernible. *Cor.* *Universal* uniform; flowers all fertile; *partial* of five equal petals, rendered heart-shaped by their inflexed points. *Stam.* Filaments five, simple; anthers simple. *Pist.* Germen minute, inferior; styles two, reflexed; stigmas obtuse. *Peric.* Fruit roundish-ovate, compressed, small, striated, separable into two parts. *Seeds* two, nearly ovate, convex and striated on the outer side, flat on the other.

Eff. Ch. Fruit nearly ovate, compressed, striated. *General* and *partial involucrum* of many leaves. Petals heart-shaped, uniform.

1. *S. filifolium*. Thread-leaved Water-parsnep. Thunb. Prodr. 50. Willd. n. 1. ("Conium tenuifolium; Vahl Symb. v. 3. 49.")—"Radical and stem-leaves simple, thread-shaped. Involucrum elongated."—Native of the Cape of Good Hope. We know nothing further about this species.

2. *S. latifolium*. Broad-leaved Water-parsnep. Linn. Sp. Pl. 361. Willd. n. 2. Fl. Brit. n. 1. Engl. Bot. t. 204. Fl. Dan. t. 246. Jacq. Austr. t. 66. (Sium; Rivin. Pentap. Irr. t. 78. *S. majus latifolium*; Ger. Em. 256.)—Leaves pinnate; leaflets oblong-lanceolate, equally serrated.—Native of rivulets, ditches, and watery ground, in the north of Europe; rather common in England, flowering in July and August. *Root* perennial, of many long, thick, whorled fibres, from the lower joints of the stem, by which

which the plant in some degree creeps along the muddy bottoms of pools and ditches. *Stem* erect, angular, hollow, leafy, smooth, scarcely branched. *Leaves* alternate, of about three pair of oblong, sessile, smooth leaflets, besides a terminal, stalked, rather longer one; all acute, neatly serrated, varying in breadth; those under water are liable to be finely divided. *Umbels* large, flattish, white, erect, solitary, terminal and lateral. *Involucral leaves* widely spreading, lanceolate, white-edged, sometimes lobed, often serrated. *Calyx* of five small teeth. *Petals* sometimes slightly unequal in size, as is nearly universal in this tribe. The whole *herb* is acrid, and the *roots* especially are reckoned poisonous. This species does not appear to be a native of Greece, nor to have been known to Dioscorides.

3. *S. angustifolium*. Narrow-leaved Water-parsnep. Linn. Sp. Pl. 1672. Willd. n. 3. Fl. Brit. n. 2. Engl. Bot. t. 139. Prodr. Fl. Græc. n. 674. Jacq. Austr. t. 67. (*S. nodiflorum*; Fl. Dan. t. 247. *S. erectum*; Hudf. ed. 1. 103. *S. minus*; Rivin. Pentap. Irr. t. 79. *S. majus angustifolium*; Ger. Em. 256.)—Leaves pinnate; leaflets irregularly lobed and serrated. *Umbels* stalked, opposite to the leaves. *Stem* erect.—Native of rivulets and ditches in Germany, England, France, and the south of Europe. Dr. Sibthorp found it in Greece; and it is more common with us than the preceding, flowering about July or August. The perennial *root* creeps to a considerable extent. The *herb* is of a smaller more delicate habit than the last, and known by the more unequal incisions of its *leaves*, at least the upper ones. The *leaflets* of the radical foliage are somewhat heart-shaped, their edges regularly serrated, and the lower pair distant from the next. *Umbels* solitary, each on a lateral stalk, shorter than the opposite leaf. *Leaves* of the general *involucrum* drooping, often cut or pinnatifid, often entire. *Calyx* of five hardly visible teeth.

4. *S. nodiflorum*. Procumbent Water-parsnep. Linn. Sp. Pl. 361. Willd. n. 4. Fl. Brit. n. 3. Engl. Bot. t. 639. Prodr. Fl. Græc. n. 675. Woodv. Med. Bot. t. 182. (*S. aquaticum repens et procumbens, ad alas floridum*; Morif. sect. 9. t. 5. f. 3.)—Leaves pinnate; leaflets ovate, equally serrated. *Umbels* sessile, opposite to the leaves. *Stem* procumbent.—Frequent in ditches and rivulets, throughout Europe, from Sweden to Greece, flowering in summer. Dr. Sibthorp observing this species abundantly in all the waters of the last-mentioned country, concludes it, with great probability, to be the real *σιον* of Dioscorides, as answering well to his description, and being called *νεροσίλων*, or water-parsley, by the modern Greeks. The *root* is perennial and creeping. *Stems* procumbent or floating, branched, bearing a nearly sessile greenish-white *umbel*, opposite to each leaf. The *leaflets* are somewhat heart-shaped at the base, acute, neatly and equally serrated, from five to nine in each leaf; the terminal one occasionally confluent with the next. *General involucrum* of one leaf, and often wanting; *partial* of several ovate ones. *Calyx* scarcely perceptible. The qualities of this species are probably milder than the two former, inasmuch that three large spoonfuls, mixed with milk, have been given twice a day, to cure cutaneous disorders; and this answers to the account given by Dioscorides, better than any thing we know of the rest of the genus.

5. *S. repens*. Creeping Water-parsnep. Linn. Suppl. 181. Willd. n. 5. Fl. Brit. n. 4. Engl. Bot. t. 1431. Jacq. Austr. t. 260.—Leaves pinnate; leaflets roundish, with deep tooth-like segments. *Umbels* stalked, opposite to the leaves. *Stem* creeping.—Native of moist pastures, and watery turfy bogs, in Bohemia, Austria, Scotland, and England, flowering from June to August. This is a much

smaller plant than the last, growing on wet ground, but not floating in water. The *stems* are quite prostrate, throwing out many radicles. *Leaflets* fewer, with broad notches, not fine serratures. *Umbels* more stalked, and whiter. *General involucrum*, as well as the *partial*, of several ribbed leaves. *Calyx* obsolete.

6. *S. Sifarum*. Skirret. Linn. Sp. Pl. 361. Willd. n. 6. Ait. n. 5. (*Sifarum*; Ger. Em. 1026. *Sifer primum*; Matth. Valgr. v. 1. 402. *Sju sjin, vulgò Nisji, &c.*; Kæmpf. Am. Exot. 818. t. 819. See Dryandr. in Tr. of Linn. Soc. v. 2. 228.)—Lower leaves pinnate; upper ternate; all sharply serrated. *Umbels* terminal.—Native of China. Cultivated, time out of mind, in Europe, for the sake of its perennial, fleshy, oblong, esculent roots, formerly reputed to possess an exciting quality. This notion perhaps originated with the Chinese; and that knavish nation seems, as Mr. Dryander first remarked, to have imposed upon the Japanese with these roots, for the true Ginseng of Tartary, or *Panax quinquefolia* of Linnæus, which latter seems to be *S. Nisji* of Thunberg. One may be as efficacious as the other, nor would a practitioner, of any description, now perhaps confide in either. The *herb* of the Skirret is twelve or eighteen inches high, erect, branched, leafy. Lower leaves of five or seven leaflets; upper of three; all copiously, neatly, and sharply serrated; the lowermost serratures often much the largest, or deepest, and somewhat spreading. *Umbels* at the tops of the branches, white, rather small, with few or no leaves in the general *involucrum*, but several linear or setaceous ones in the *partial*.—*Sium Nisji*, Linn. Sp. Pl. 361, having been entirely adopted from Kæmpfer's figure of the present, that species falls to the ground; nor is it entitled to rank even as a variety, though marked as such by Willdenow.

7. *S. rigidius*. Virginian Water-parsnep. Linn. Sp. Pl. 362. Willd. n. 7. Ait. n. 6. Pursh n. 1. (*Oenanthe maxima virginiana, pæoniæ fœminæ foliis*; Morif. sect. 9. t. 7. f. 1.)—Leaves pinnate; leaflets lanceolate, very nearly entire.—In wet meadows, from Pennsylvania to Virginia, flowering in July and August. *Flowers* small. This and the following, *S. lineare*, are considered as very poisonous plants, especially to horned cattle, and every farmer who knows their bad qualities is busily employed to destroy them." *Pursh*. The *roots*, and general habit, of this species bear considerable resemblance to the last; but the *leaflets* are more numerous, narrower, tapering at each end, and either quite entire, or with two or three broad notches only, here and there, in the lower *leaves*. The *umbels* are thrice the size of *S. Sifarum*, but, like them, are accompanied by only a slight general *involucrum*, nor are the *partial* ones much more considerable.

8. *S. lineare*. Linear Water-parsnep. Michaux Boreal-Amer. v. 1. 167. Pursh n. 2. (*S. suave*; Walter Carol. 115.)—"Leaves pinnate, leaflets elongated, linear, or slightly lanceolate, rather distantly serrated. *General involucrum* of few leaves; *partial* of many linear ones. *Umbel* with short rays."—In wet meadows, and by the sides of ditches, from Canada to Pennsylvania, flowering in July; perennial. *Pursh*.

9. *S. longifolium*. Long-leaved Water-parsnep. Pursh n. 3.—"Leaves pinnate; leaflets of the lower ones very long, linear, falcate, sparingly toothed. *Stem* slightly leafy; naked above. *Umbels* usually in pairs, with scarcely any *involucrum*."—In the ditches and bogs of New Jersey, flowering in August.—Very slender, perennial. *Pursh*.

10. *S. japonicum*. Japanese Water-parsnep. Thunb. Jap. 118. Willd. n. 8.—Leaves pinnate; leaflets of the lower ones oblong or ovate, variously cut; of the upper lanceolate,

lanccolate, entire. Umbels terminal.—Native of Japan, flowering in June. The inhabitants call it *Saiko*, or *Mits Suba Seri*. The stem is erect, zig-zag, branched at the upper part. Leaves smooth, the lower ones very large, with spreading variously shaped leaflets, which are either ovate or oblong, undivided or cut; the upper leaves minute. Umbels terminating the branches. Thunb.

11. *S. Falcaria*. Decurrent Water-parfneq. Linn. Sp. Pl. 362. Willd. n. 9. Ait. n. 7. Prodr. Fl. Græc. n. 676. Jacq. Austr. t. 257. (S. n. 782; Hall. Hist. v. 1. 347. Falcaria; Rivin. Pentap. Irr. t. 48. Eryngium montanum; Ger. Em. 1164. Ammi perenne repens, &c.; Morif. sect. 9. t. 8. f. 1.)—Leaflets linear, decurrent, confluent, finely serrated.—Native of Germany, Flanders, Switzerland, France, Greece, and Asia Minor; a hardy perennial, kept chiefly in botanic gardens, flowering in July and August. The root is long and cylindrical, white, friable when dried, said to resemble Eryngo in its sweetish, aromatic, rather acrid, flavour. Herb rigid, smooth, two or three feet high. Stem round, leafy, much branched, terminating in numerous slender umbels of many rays, with small white flowers. The general and partial involueral leaves are numerous, long, and very narrow. The radical leaves have long stalks; the rest shorter more sheathing ones; all are rigid, smooth, ternate in the first instance; the middle leaflet ternate; the lateral ones binate; the external edge of each lateral leaflet strongly decurrent.

12. *S. verticillatum*. Whorled Water-parfneq. Fl. Brit. n. 5. Roth. Germ. v. 2. p. 1. 336. (Sifon verticillatum; Linn. Sp. Pl. 363. Willd. Sp. Pl. v. 1. 1437. Ait. Hort. Kew. v. 2. 146. Lightf. Scot. 1096. t. 35. Engl. Bot. t. 395. Oenanthe millefolii palustris foliis; Morif. sect. 9. t. 7. f. 10. Daucus pratensis; Dalech. Hist. 718.)—Leaflets in numerous, capillary, whorl-like segments.—Native of wet salt-marshes. Plentiful in the western parts of Scotland and Wales; found at Killarney, and in the county of Kerry, Ireland, in 1805, by Mr. J. T. Mackay. It is also reported to grow in France, the Pyrenées, and some parts of Germany. Dr. Roth had, unknown to us, forestalled us in transferring this curious species to *Sium*, before the publication of Flor. Brit. though he had never seen a specimen. Of the propriety of this alteration we have no doubt, the umbels being of numerous rays, with many leaves in their general as well as partial involueral, and the petals heart-shaped. The plant is perennial, flowering in July and August. Root of several fleshy tapering knobs. Stem eighteen inches high, erect, smooth, scarcely branched, and slightly leafy. Leaves numerous, chiefly radical, pinnate, of many pairs of deeply-cut, radiating, plumose leaflets, spreading, so as to seem whorled. Petals white, uniform, and nearly equal. Involueral leaves deflexed, ovate; five or six to the general umbel, more to each partial one. Calyx hardly visible. Fruit roundish-ovate, compressed.

13. *S. grandiflorum*. Large-flowered Cape Water-parfneq. Thunb. Prodr. 50. Willd. n. 10.—“Leaves doubly pinnate; leaflets roundish, with tooth-like segments.”—Found by Thunberg, at the Cape of Good Hope.

14. *S. paniculatum*. Panicked Cape Water-parfneq.—Thunb. Prodr. 51. Willd. n. 11.—“Leaves doubly pinnate; leaflets linear, pinnatifid.”—From the same country.

15. *S. patulum*. Diffuse Cape Water-parfneq. Thunb. Prodr. 51. Willd. n. 12.—“Leaves doubly pinnate; leaflets three-cleft. Branches diffuse.”—From the same country.

16. *S. gracum*. Greek Water-parfneq. Linn. Sp. Pl. 362. Willd. n. 13. (Ligusticum græcum, apii folio; Tourn. Cor. 23.)—“Leaves doubly pinnate; leaflets lanceolate, serrated; the uppermost confluent.”—Native of Greece, according to Tournesort; but we have met with nothing referrible to this species among Dr. Sibthorp’s specimens, drawings, or catalogues, nor have we seen any specimen of the authentic plant. Willdenow, from whom we have taken the specific character, says the flowers are yellow.

17. *S. decumbens*. Decumbent Water-parfneq. Thunb. Japon. 118. Willd. n. 14.—“Leaves doubly pinnate; leaflets three-cleft. Stem decumbent.”—Gathered by Thunberg in Japan, where it is known by the name of *Jingsfaku*, and flowers in March. The stem is small, decumbent. Leaves radical, on long stalks, smooth. Umbel terminal, scarcely compound. Seeds ovate, obtuse, striated, smooth, crowned with the permanent styles. Thunberg.—By the description, we suspect this may be more properly a species of *Hydrocotyle*, but without seeing a specimen, we dare not determine.

18. *S. ficulum*. Sicilian Water-parfneq. Linn. Sp. Pl. 362. Willd. n. 15. Ait. n. 8. Jacq. Hort. Viend. v. 2. 62. t. 133. (Daucus siciliano, con foglie di pastinaca; Zanon. It. 78. t. 30.)—Leaves strongly serrated, doubly pinnate; the lower and uppermost ternate. Umbels terminal, stalked; partial ones very unequal.—Native of Sicily. A hardy perennial, flowering in July and August. The stem is variously branched, erect, leafy, about two feet high, round, solid, smooth. Leaves smooth and shining; their leaflets more or less ovate, acute, copiously, deeply, and acutely serrated, sessile. General and partial involueral of many linear deflexed leaves. Flowers yellow; in some of the partial umbels very few, perhaps solitary. Germen oblong. The genus of this species is rather doubtful, if we attend to its habit; and yet we know not how, by the characters, to refer it elsewhere.

19. *S. asperum*. Rough Cape Water-parfneq. Thunb. Prodr. 51. Willd. n. 16.—“Leaves triply pinnate. General and partial flower-stalks rough.”—Found by Thunberg at the Cape, as well as the two following. We have no information concerning any of them, besides what his *Prodromus* affords.

20. *S. hispidum*. Hispid Cape Water-parfneq. Thunb. Prodr. 51. Willd. n. 17.—“Leaves triply pinnate. Foot-stalks and flower-stalks rough.”

21. *S. villosum*. Villous Cape Water-parfneq. Thunb. Prodr. 51. Willd. n. 18.—“Leaves triply pinnatifid; segments ovate, deeply serrated, villous.”

SIUM, in *Gardening*, contains a plant of the hardy, herbaceous, esculent kind, of which the species cultivated is the skirret (*S. fitarum*).

This plant was formerly much cultivated for the roots, which were eaten boiled and stewed with butter, pepper, and salt; or rolled in flour and fried; or else cold, with oil and vinegar, being first prepared by boiling.

Method of Culture.—It may be raised either by seeds or slips from the roots, but the first is the best method, as in the latter mode the roots are apt to become sticky: the seeds should be sown about the beginning of April, either in broadcast over the surface, or in drills, the ground being previously well dug to a good depth; light and rather moist land being chosen for the purpose. The plants mostly appear in five or six weeks, and when they can be sufficiently distinguished by their leaves, the ground should be well hoed over, in the same manner as for carrots, the plants being properly thinned out to the distance of five

or six inches. The hoeing should be repeated as often as necessary, in dry weather. And in the autumn, when the leaves begin to decay, the roots will be fit for use, and will continue to till the spring.

But in the offset method, the old plants should be dug up in the spring before they begin to shoot, the side shoots being then slipped off with an eye or bud to each, planting them in rows a foot apart, and four or five inches distant in the rows: they should afterwards be cultivated as the others.

These roots are prepared, as has been seen, by boiling, and eaten in the same manner as above, or as carrots and parsneps. They are wholesome, but not held in such request as formerly was the case.

SIUM Nodiflorum, Procrumbent Water-parsnep, in the *Materia Medica*. This plant has been omitted by the London College, in the last edition of its Pharmacopeia, and not, it is thought, without reason, as its pretensions even to the character of an antiscorbutic require confirmation.

SIUMPOUR, in *Geography*, a town of Hindoostan, in Bahar; 25 miles E.S.E. of Doefa.

SIUN, a river of China, which runs into the Han river, near Siun-yam, in Chen-si.

SIUNDO, a town of Sweden, in the province of Nyland; 25 miles W. of Helsingfors.

SIUNISONG, a town of Corea, near the sea; 38 miles W.N.W. of Hoang-teheou.

SIUN-YAM, a town of China, of the third rank, in Chen-si; 20 miles E.N.E. of Hing-ngan.

SIUPH, in *Ancient Geography*, a town of Egypt, in the Saitic nome; the native place of king Amasis, according to Herodotus.

SIUR, a port of Africa Propria, in the gulf of Numidia, between the Lesser Collops, and near the promontory of Hippus, according to Ptolemy.

SIVRAY, in *Geography*. See *CIVRAY*.

SIVREY-fur-Meuse, a town of France, in the department of the Meuse; 3 miles W. of Verdun.

SIUT, *SIOUT*, or, as it is often called, *Affiut*, a town or city of Upper Egypt, and now the most considerable. This character formerly belonged to Girgê, which is still a place of note, but the character of pre-eminence belongs to *Affiut*. It is situated within land a few miles W. of the Nile, on an artificial eminence. The site of this ancient city seems to have been either Antopolis, as Pococke thinks, or more probably, as Strabo intimates, Lycopolis. It is a large, populous, and well-built town; and the manner in which the water is conducted round it is worthy of notice. A canal, dug probably from an early period, parallel to the Nile, in this part of the country washes the foot of the mountains which are near to *Affiut*, and having surrounded that city, and the adjacent villages, descends again into the river. The water, however, is not admitted into it except at a certain period of its increase, and then it overflows all the surrounding lands, and *Affiut* only communicates with the Nile by a road artificially raised above the common level, which leads down to the port where the boats resort, and are laden and discharged; and also by two bridges, the one leading to this road, and the other towards the mountains. This city has increased in population within a few years by the good government of Soliman Bey, who has also adorned it by planting many trees. *Affiut* was formerly known to the Arabic writers by the name of "Haut-e-Sultan," the king's fish, or fish-pond. The reason of the appellation is not ascertained, probably it took its rise from its having been appointed to

supply the king's table with fish. In the mountain above *Affiut* are several remarkable caverns, very spacious, and adorned with hieroglyphics and emblematical figures. Some appear to have been sepulchral, as they contain fragments of the jars, in which were deposited not only the ibis, but cats, dogs, and other animals, whether considered as sacred, or slain to attend their master or mistresses in the other world. In one of these caverns, besides the entrance, there are three chambers hewn in the rock, which is free-stone, one sixty feet by thirty; another, sixty by twenty-six; a third, twenty-six by twenty-five. Further up the mountains there are caverns more spacious even than these. Other cavities have been made by removing the stone for the purposes of building; but they have been afterwards appropriated to various purposes; some for sepulture, as we may conclude from the jars, curiously stopped with bitumen, and others either for religious retirement in a Christian age, or for summer retreats, as they are exposed to the north, and very cool.

Large quantities of fine flax are cultivated in the vicinity of Siout: this commodity and wheat are transported from Upper to Lower Egypt. Salt and other articles are brought in return. From Mecca, by way of Colfeir, are imported Indian goods; and the European articles of broad-cloth, tin, &c. are here rarely seen. The Soudan caravans form a chief support of *Affiut*, which serves to them as a midway station. They assembled in their way to Sennaar, here, and at Manfalout, under the protection of a bey: they then passed nearly south-west into the sandy desert of Libya, to El-wah, the Oasis Magna of antiquity, and so into the great desert of Selima. *Affiut* is regarded as the capital of Middle Egypt, and its population exceeds that of all the towns to the south of Cairo. Mr. Browne inclines to estimate the inhabitants at no less than 25,000. The "sen-jiak," or bey of Saïd, divides the year of his office between *Affiut* and Girgê: the internal government consists of the cadi, assisted by other civil officers; and five cahefs, mostly appointed by Soliman Bey, constantly reside there. It is the seat of a Coptic bishop, but the Copts are not very numerous; the people being chiefly Mahometans. Provisions are considerably cheaper at *Affiut* than at Cairo. Manfalout is at no great distance from *Affiut*: this is a city of considerable extent and population. Between these two cities stands Ben-Ali, a populous town. These three places constitute, with Girgê, the chief marts of the trade of Upper Egypt; 162 miles S. of Cairo. N. lat. 27° 25'. E. long. 31° 38'. Savary. Browne. Sonnini.

SIVENS, in *Medicine*. See *SIBBENS*.

SIWA, *SIWAH*, *Siouab*, or *See-awab*, in *Geography*, a town of Africa, in the country of Tripoli, on the frontiers of Egypt, supposed by some to be the ancient Mareotis, and by others to be the Siropum of Ptolemy. According to Mr. Browne, this place answers to the description given of the Oasis (see *OASIS*), as being a small fertile spot, surrounded on all sides by desert land. A path, encompassed with date-trees, leads to the town, which gives name to the district. About two miles from this place, after passing along some shady paths between the gardens, Mr. Browne arrived at what were called the ruins, or "birbé;" and was surprised to find himself near a building of undoubted antiquity, and which he has particularly described. It is situated in N. lat. 29° 12'. E. long. 26° 35'. This edifice consisted of a single apartment, built of massy stones, of the same kind with those which compose the pyramids, and covered originally with six large and solid blocks, that reach from one wall to the other; 32 feet long in the clear, about 18 high, and 15 wide. A gate, at one extremity, forms
the

the principal entrance, and two doors also near that extremity open opposite to each other. The other end is quite ruinous, but there is reason to believe that the whole building has never been much larger than it now is. On the exterior of the walls there is no sculpture, nor is there any appearance of another edifice having been attached to it. In the interior are three rows of emblematical figures, apparently designed to represent a procession; and the space between them is filled with hieroglyphic characters: the soffit is also adorned in the same manner; five of the six stones remain entire, but the other has fallen within, and thus the connection is broken. The sculpture is sufficiently distinguishable; and even the colours in some places remain. The soil around seems to indicate that other buildings have formerly existed near this place. In a rock not far distant there are apartments, which have the appearance of places of sepulture. Although they are without ornament or inscription, they seem to have been hewn with some labour. They appear to have been all opened, but no circumstances point out with certainty the uses to which they have been applied. Nevertheless here are many parts of human skulls, and other bones, with fragments of skin, and even of hair, attached to them. All of them appear to have undergone the action of fire; but whether they are the remains of bodies repositied there by a people accustomed to burn the dead, or whether they have been burned in this their detached state by the present inhabitants, it is now difficult to determine. Yet the size of the catacombs would induce one to conclude, that they were designed for bodies in an un mutilated state; the proportions being twelve feet in length, six in width, and about six in height. The number of these caverns may amount to thirty or more.

The Oasis, which contains the town of Siwa, is stated by Mr. Browne to be about six miles long, and four and a half or five wide. Mr. Horneman, who visited this country since Mr. Browne, says, that the principal and fertile territory of Siwah is 50 miles in circumference; but unless there be a mistake in numbers, 50 being inserted instead of 15, which is not improbable, he differs from all others; unless indeed we suppose, that he included the whole district within the surrounding mountains, without considering that between these and the Oasis are extensive plains of barren sand. A large proportion of the space in which Siwa is situated is filled with date-trees, and there are also pomegranates, figs and olives, apricots and plantains; and the gardens are remarkably flourishing. They cultivate a considerable quantity of rice, of a reddish hue, and different from that of the Delta. The remainder of the cultivable land furnishes wheat enough for the consumption of the inhabitants. Here is abundance of water, both salt and fresh; but the springs which furnish the latter are mostly tepid; and such is the nature of the water, air, and other circumstances, that strangers are often affected with agues and malignant fevers. It is observed by the natives concerning one of the springs, which rises near the building above described, that it is sometimes cold and sometimes warm.

The complexion of the people in this district is generally darker than that of the Egyptians; and their dialect is also different. They are not in the habitual use either of coffee or tobacco. The dress of the lower class is very simple, as they are almost naked; and the costume of the inhabitants, as far as it could be discerned, approached nearer to that of the Arabs of the desert than those of the Egyptians or Moors. Their clothing consists of a shirt of white cotton, with large sleeves, and reaching to the feet, a red Tunis cap, without a turban, and shoes of the same colour. Some earthen ware made by themselves, and a few mats, form the

chief part of their household furniture; none but those of the richer class being furnished with copper utensils. They occasionally purchase a few slaves from the Murzouk caravan. Their remaining wants are supplied from Cairo or Alexandria, whither they transport their dates, both in a dry state, and beaten into a mass, which when good resemble in some degree a sweet-meat. They eat no large quantity of animal food, and bread of the kind known to us is uncommon. Flat cakes, without leaven, kneaded and then half baked, form part of their nourishment. The remainder consists of thin sheets of paste, fried in the oil of the palm-tree, rice, milk, dates, &c. They drink, in large quantities, the liquor extracted from the date-tree, which has often the power of inebriating. Their domestic animals are the hairy sheep and goat of Egypt, the ass, and a very small number of oxen and camels. The women are veiled, as in Egypt. After the rains, the ground in the neighbourhood of Siwa is covered with salt for many weeks. Browne's Travels.

SIWA, in *Mythology*, a goddess of the Germans, represented in her statue naked, with her hair falling down behind as far as her knees, and holding in one hand a bunch of grapes, and in the other an apple. She is taken for Venus, or for the goddess of health. Others take her for a rural divinity, the Pomona of Lusatia.

SIWALON, in *Geography*, a rock in the East Indian sea, near the north coast of Java. S. lat. 6° 36'. E. long. 110° 49'.

SIXAIN, SIXTH, *Sextagena*, in *War*, an ancient order of battle, in which six battalions being ranged in one line, the second and fifth were made to advance, to form the vanguard; the first and sixth to retire, to form the rear-guard; the third and fourth remaining on the spot, to form the corps, or body of the battle.

The word is French, signifying the same thing.

SIX-CLERKS, officers in chancery of great account, next in degree below the twelve masters; whose business is to enrol commissions, pardons, patents, warrants, &c. which pass the great seal, and to transact and file all proceedings by bill, answer, &c.

They were anciently *clerici*, and forfeited their places, if they married; but when the constitution of the court began to alter, a law was made to permit them to marry. (Stat. 14 & 15 Hen. VIII. cap. 8.) They are also solicitors for parties in suits depending in the court of chancery.

Under them are six deputies and sixty clerks, who, with the under clerks, do the business of the office.

SIX-FOUR, in *Geography*, a town of France, in the department of the Var; 9 miles S.W. of Toulon.

SIXHINDEMEN. See SYXIHINDEMEN.

SIX-ISLANDS, in *Geography*, small islands in the East Indian sea. S. lat. 6° 37'. E. long. 71° 26'.

SIX-MEN FORT, a fort of the island of Barbadoes; 1 mile N. of Speight's Town.

SIX-MEN'S Bay, a bay on the north-west coast of the island of Barbadoes.

SIX-MILE BRIDGE, a post-town of the county of Limerick, Ireland; 6 miles S. of that city, on the road to Cork, and 102 miles S.W. from Dublin. There is another town of the same name west of Limerick, on the road to Ennis, and in the county of Clare, which is 102 $\frac{3}{4}$ miles W.S.W. from Dublin. The latter town is on the river Gearna or Owgarne, (*i. e.* Owin Gearn, river Gearna,) which falls into the Shannon, where Bunnatty castle stood; and had some ecclesiastical buildings in former days.

SIX-MILE Creek, a small stream in the state of New York, that enters the head of Canoga lake at Ithaca. A part

part of the creek is in the north-east part of Tioga county, where it furnishes excellent mill-seats. Its course is seventeen miles.

SIX-MILE CROFS, a fair-town of the county of Tyrone, Ireland, where there is a church. It is 7 miles S.E. from Omagh.

SIX-MILE WATER, a river of the county of Antrim, Ireland, which rises in Agnew's hill, near Larne, and running south-west, falls into Lough Neagh, below the town of Antrim. The valley of this river, containing several villages, is a fine specimen of the beauty and cultivation of the county, to which the frequent white-thorn hedges contribute not a little; shewing, as the plains about Antrim are approached, the increasing richness of the soil, by their superior size and vigour. Dubourdieu's Antrim.

SIX-NATIONS, a confederacy of American Indians, so called by the British and Americans, and by the French Iroquois. They are Mohawks, Oneidas, Onondagas, Senecas, Cayugas, and Tuscaroras. In the American war they took part with Great Britain, and in 1770 they were totally defeated by the troops of Congress. Many of them have removed to Canada; and in 1796 they amounted to 4058 persons. In this year a society of Friends or Quakers raised a fund, towards promoting the civilization and comforts of these poor people.

SIXT, a town of France, in the department of the Ille and Vilaine; 6 miles N. of Redon.

SIXTH, *SESTA*, Ital., *Sixte*, Fr., in *Music*, the second of the two imperfect concords, called by the Greeks Hexachordon, because its interval is formed of six sounds, or five diatonic degrees. The sixth is only a natural consonance by combination; for in the order of concords there is no simple and direct sixth.

To consider sixths by their intervals, there are four different sorts; two consonant, and two dissonant. The consonant are, first, the *minor* sixth, composed of three tones, and two major semitones; as E C: its ratio is 5 to 8. Secondly, the *major* sixth, composed of four tones, and a semitone major; as G E: its ratio is 3 to 5.

The dissonant sixths are the extreme flat, and the extreme sharp sixths; as B b and G *, called by the French the superfluous sixth; and C * and A b. Neither of these intervals can be used in melody, and only the first in harmony.

Dr. Pepusch has given eight examples of the allowable use of the sixth in two parts; and Rousseau has given a list of seven chords, in which sixths are employed. These are, first, the simple chord of the sixth to the third of a key, when that third is the supposed base, instead of its fundamental. This kind of chord, which is the common chord to the third below the base, may be given likewise to the second and the sharp seventh of a key. The second use of the sixth is with the fourth, which is still a perfect concord to the fifth below the base. The third use of the sixth is in the chord of the $\frac{6}{3}$, which is the chord of the seventh to the fifth below the base, with a sharp third. The fourth use of the sixth is in the chord or harmony of the $\frac{6}{4}$, which is the chord of the seventh to the minor third below the base. This harmony is usually given to the fourth of a key.

The fifth use of the sixth is in what Rameau calls *le double emploi*, or double use of the $\frac{6}{4}$; when either of these intervals may be regarded as the discord. If the fifth is made a discord by the sixth, it must be resolved by *descending* on a concord; but if, as before a close, the sixth is regarded as

the discord, it must be resolved by *ascending* to another fifth, while the fifth remains for a fourth to the next base. See *DOUBLE EMPLOI*, and *RESOLUTION*.

The sixth use of the sixth is that of the major sixth and false fifth, which is the chord of the extreme flat seventh to the second of a minor key, in which the false fifth is taken, instead of the fourth.

Lastly, the seventh use of the sixth is in the chord of the extreme sharp sixth, used only to the sixth of a minor key; as D * to F b, when the base descends to E, the fifth of the key, with a sharp third. This is an original chord, which cannot be inverted. All these chords will be given in notation on the music plates, in the rules for accompaniment, or thorough-bass. The major sixth is nine semitones or half notes above the base; the minor sixth, eight.

The sixths major and minor, being inversions of the thirds in composition and accompaniment, may, in two parts, move in succession upwards and downwards at pleasure. It has, in a regular descent, a solemn and melancholy effect, more pleasing than in a regular ascent. In composition and accompaniment, this concord is accompanied by the $\frac{3}{2}$, or by its octave and a third, or by two thirds. In thorough-bass, doubling the sixth or third, when the movement is not very rapid, enriches the chord and the harmony more than the eighth.

SIXTH, in the *Military Art*. See *SIXAIN*.

SIXTH PAIR OF NERVES. See *NERVE*.

SIXTH RATES. See *RATE*.

SIXTUS I., pope, in *Biography*, was by birth a Roman, and succeeded Alexander I. about the year 119. Very little is known concerning him; and though there are two decretals ascribed to him, they are generally regarded as forgeries. He died in the year 128, and has been ranked among the martyrs by the church of Rome, though it is not at all ascertained that he actually ended his life by martyrdom.

SIXTUS II., pope, was a deacon of the Roman church at the time he was elected to the pontificate, in the year 257, or, according to some authors, in 260. At the request of Dionysius, bishop of Alexandria, he put an end to a dispute commenced between his predecessor, Stephen, and St. Cyprian, concerning baptism administered by heretics. A persecution was at this time raging against the Christians in consequence of a rescript of the emperor Valerian, directing that search should be made for all bishops, priests, and deacons, in order to be put to death. Sixtus was one of the first victims, being beheaded after he had occupied the papal chair almost a year.

SIXTUS III., pope, a Roman, was long regarded as one of the principal ornaments of the church of Rome. In 418 he was a favourer and protector of the Pelagians; but when their opinions were condemned by Zosimus, he was one of the first who pronounced an anathema against them, and made a public declaration of his orthodoxy. He was raised to the pontifical throne in 432, on the death of Celestine. It was about this period that the Eastern churches were divided concerning the condemnation of Nestorius; Cyril, with the Egyptian bishops, maintaining the justice of that act; while John of Antioch, and other Oriental bishops, refused to concur in it. By the exertions of Sixtus the parties were reconciled. The Illyrian bishops made an attempt in the pontificate of Sixtus to free themselves from the papal jurisdiction, but they were induced by his letters to renounce their purpose. The munificence of this pontiff was displayed in various repairs and rich decorations of churches in

Rome. He died in 440, after a reign of eight years, and his name has been enrolled among those of the saints of the holy Roman see.

SIXTUS IV., pope, who assumed the name of Sixtus, instead of Francis della Rovere, was descended from a family of the same name in Savona, in the state of Genoa. He was born in 1414, and at an early age entered into the Franciscan order. He studied in the universities of Pavia and Bologna, and having taken the degrees of doctor of philosophy and theology, he gave public lectures in several of the principal cities of Italy, and acquired great reputation for learning. Having passed through some honourable offices in his order, he was at length raised to the head of it as general; and becoming known to cardinal Bessarion, through his recommendation, and that of cardinal Gonzaga, he was promoted by pope Paul II., in 1467, to the purple, by the title of St. Peter ad Vincula. On the death of the pope, in 1471, he was raised to the pontifical chair; but on his coronation a tumult was excited that had nearly proved fatal to him. Escaping from the hands of the mob, he attempted to form a league among the Christian princes against the Turks, who had made themselves masters of Bosnia, Iltria, and great part of Dalmatia, and threatened Italy. With this view he sent some of his most distinguished cardinals as his legates to different courts, with instructions to endeavour to compose the disputes existing between the several sovereigns; but, as usual in such cases, with small effect. He procured to be fitted out an allied fleet of galleys, which recovered Smyrna from the Turks, but he did little besides. He was more successful at home, in an attempt to expel a number of petty tyrants who had seized upon the cities belonging to the church, and governed them as independent sovereigns. With the aid of Ferdinand, king of Naples, he effectually cleared the ecclesiastical states of these usurpers, and thereby almost doubled his revenue. The year 1475 was that of the Jubilee, which was celebrated with great magnificence by Sixtus, and was dignified by an unusual assemblage of crowned heads, though the resort of pilgrims in general was less than on former occasions.

This pontiff carried the vice of nepotism to as great a degree as any of his predecessors, and it was one of his first objects to make a splendid provision for his natural children, under the name of nephews, out of the dignities and offices of the church. It is said, that one leading motive for his expelling the independent possessors of towns in the ecclesiastical state was, that he might have territories to form principalities for his nephew; and in pursuance of this plan, he sent Giulano de Rovere, afterwards Julius II., to take the city of Castello from Niccolo Vitelli. Niccolo, having obtained the assistance of the duke of Milan and the Florentines, made a vigorous resistance, but was at length obliged to capitulate. This produced an alarm in the neighbouring states, and occasioned a defensive league between the duke of Milan, the Venetians, and the Florentines. The latter people were under the influence of Lorenzo de Medici, whose political conduct could not but be highly displeasing to the pope; and he displayed his resentment by depriving Lorenzo of the office of treasurer of the holy see, which he had conferred upon him in the days of their friendship. This, however, was not sufficient, and he determined upon an attempt entirely to subvert the power of the Medici in Florence. In conjunction with his nephew, Girolamo Riario, he formed a most detestable conspiracy. By means of the powerful family of the Pazzi, rivals to the Medici in Florence, a revolution was to be effected in the government of that city, commencing with the assassination of Lorenzo and Giuliano

de Medici, when assisting at mass in one of the churches, and the elevation of the host was to be the signal. Fortunately their plans miscarried, but the pope thundered out an excommunication against Lorenzo and the magistrates of Florence, and laid the city and its territories under an interdict. Having in vain endeavoured by menace to induce the Florentines to deliver up Lorenzo, he formed a league with the king of Naples, whose troops, in conjunction with those of the church, invaded the territory of Florence, and spread devastation through it. They were, however, encountered by an opposite league, and the pope was at length, by the interposition of the king of France, and the alarm excited throughout Italy in consequence of the capture of Otranto by the Turks, obliged to consent to a peace. Italy did not long remain in peace. In 1482, Sixtus joined with the Venetians in an attempt to dispossess the duke of Ferrara of his territories, for which his motive was a hope of vesting the government of that city in one of his own family. The consequence was an invasion of the ecclesiastical state by the duke of Calabria, son of the king of Naples, which however terminated in the duke's total defeat. The success of the Venetians rendering them formidable to their neighbours, a league was formed against them, which the pope was persuaded to join, and he issued a solemn excommunication against his allies. The confederates, however, receiving proposals from the Venetians, concluded a peace without consulting Sixtus. This affected his holiness so much, that it occasioned a severe fit of the gout, which put an end to his life in 1484, just after he had completed his 70th year, and in the 13th of his pontificate. "Sixtus IV." says his biographer, "ranks among the most unprincipled of the Roman pontiffs with respect to political conduct, which seems to have been governed by no other motive than the passion for aggrandizing his family, and indulging a rapacious disposition. His concurrence in the detestable conspiracy of the Pazzi, and the eagerness with which he fermented the wars which disquieted Italy almost through the whole of his reign, shew him to have been steeled against all sentiments of public justice and humanity. He has been taxed with avarice, but the imputation has been refuted by recounting the splendid edifices, and the numerous charitable and useful establishments of which he was the founder. He was, in truth, liberal and magnificent in his expenditure; and having, like many other arbitrary princes of that character, exhausted his resources, he scrupled no means of replenishing them. In no pontificate were the offices and employments about the papal court more shamelessly set to sale, or the exactions in passing bulls and other official instruments from that court more scandalously augmented. The most favourable light in which he can be viewed, is as a munificent encourager of literature. He may almost be regarded as the founder of the Vatican library, for he not only enriched it with books, collected from various parts of the world, but caused them to be properly disposed for the convenience of the public, to which he opened the library, placed them under the care of men deeply learned in different languages, with competent salaries, and assigned funds for the purchase of new books. It is, on the other hand, to be mentioned, that he was the first who instituted inquisitors of the press, without whose licence no work was suffered to be printed." Sixtus was author of some theological pieces: several of his letters are extant, and he published some decrees, one of which had for its object to put an end to the disputes then subsisting relative to the conception of the Virgin Mary.

SIXTUS V., pope, was born in 1521, in the Marche of Ancona, at La Grotte, a village in the territory of Montalto.

talto. His father, whose name was Peretti, was a vine-dresser, who not being able to maintain his son, placed him, when he was only nine years old, in the service of a farmer, by whom he was, at first, chiefly employed in attending to his swine. While he was occupied in this low office, a Franciscan friar passing that way, took the lad for his guide on a journey to Ascoli. Pleas'd with the boy's vivacity, he caus'd him to accompany him to his convent, and introduced him to his father guardian, who admitted him into the convent in the quality of a lay brother. He soon manifested a great inclination for learning, and was taught the elements of the Latin language. He was soon admitted into the order, went through the usual courses of philosophy and theology, was ordained priest in 1545, and shortly afterwards, being made a doctor in theology, he was appointed to a professorship at Sienna, under the name of Montalto. He acquired a high reputation as a preacher in several Italian cities, and was in a very short time nominated commissary-general at Bologna, and inquisitor at Venice. In the exercise of the latter office he quarrell'd with the senate, always jealous of ecclesiastical authority, and thought proper to make his escape from Venice by night. Going to Rome, he became one of the council of the congregation, and afterwards procurator-general of his order. He accompanied cardinal Buoncompagno to Spain, in quality of theologian to the senate, and counsellor of the holy-office. Thus elevated, he suddenly changed his demeanour, which had been harsh and petulant, and put on an appearance of extraordinary gentleness and humility. Cardinal Alexandrini, formerly his pupil, being rais'd to the papal dignity by the name of Pius V., sent him the brief of general of his order, and soon after honoured him with the purple, when he took the name of cardinal Montalto. The successor of Pius was Gregory XIII., formerly cardinal Buoncompagno.

Montalto, without influence or connections to push him forward at the next vacancy, determin'd to appear entirely void of wishes and expectation of farther elevation, in order that he might not become an object of jealousy to any party. He accordingly withdrew from all public affairs, shut himself up like one entirely devoted to study and religious retirement, and ever complain'd of the infirmities of age hanging heavily upon him. Gregory died in 1585, and the cardinals split into factions. Montalto appear'd, but in the character of one bending under the weight of years, and as if ready to expire. In the course of the contests, which were long and severe, he was inform'd that the choice would probably fall on him; to which he replied by averring his own unfitness for the office; that his life would scarcely outlive the conclave; and that if he were elect'd, he should only be pope in name, while all the authorities must devolve upon others. This sort of argument, which he threw out as a bait to his ambitious brethren, was readily seized upon by them all, as well with the hope of a short pontificate, as with the expectation that they should all strengthen themselves against a new election. Montalto was chosen on the 24th of April, 1585. Scarcely, however, had the tiara been placed on his head, when he threw away his crutches, which had enabled him to assume his former character, walk'd perfectly erect, and chanted *Te Deum* with a voice so strong, that the roof of the chapel in which the ceremony was performed re-echo'd the sound. He also gave his benediction to the people with such an air of vigour, that they could scarcely believe him to be the decrepid cardinal Montalto. It was now that he assumed the name of Sixtus V., and he soon shew'd them that his mind

was as vigorous as his body. The territory of the church was at this time overrun with banditti, who plundered and even murdered the people with impunity; and in the metropolitan city itself, a relaxed police had encouraged all kinds of disorders. The first object of Sixtus was to exterminate these evils, and no sovereign ever employ'd the corrective powers with which he was invest'd with more vigour and effect. It had been usual, for the sake of acquiring popularity, on the election of a new pope, to set the imprison'd criminals at liberty; but the first act of Sixtus was to order four persons to be hang'd, on whom were found, a few days before, prohibited weapons. This system of rigour he pursu'd with the most inexorable severity, never, in a single instance, pardoning a criminal. There is no doubt that signal severity was necessary to stop the public disorders, and in that view of the subject, Sixtus was certainly a benefactor to the state; but unfortunately for his character as a just magistrate, in whom compassion should be found tempering the rigour of the law, instances are recorded on the page of history which go to prove that he took a real pleasure in acts of punishment, and that his soul was insensible to all the emotions of tenderness and pity; which, says a good writer and diligent observer of human nature, "is not an unusual effect of a monastic education."

A Spanish gentleman having been struck by a Swiss guard with his halberd in a church, retaliated by a blow which prov'd fatal to the soldier. Sixtus, having examin'd into the affair, gave an order to the governor of Rome to have the offender executed before he should sit down to table. The Spanish ambassador, with four cardinals, wait'd upon his holiness, not to plead for the criminal's life, but to entreat upon their knees, that, as he was a gentleman by birth, the punishment might be commuted to that of decapitation: this small favour he absolutely refus'd, and said in a tone of anger, bordering on frantic rage, "he shall be hang'd; but to alleviate the disgrace incurred by his family, I will do him the honour to assist at his execution." He accordingly order'd the gallows to be erect'd before his own house, and was witness to the deed of horror. When the sentence was executed, he turn'd with the utmost coolness to his domestics, and said, "Bring me my dinner; this act of justice has given me an additional appetite." He caus'd the heads of all those who had suffer'd the penalty of death for crimes committed against the state, to be plac'd on the city gates, and on each side of the bridge of St. Angelo, and sometimes went on purpose to view them; and a request being made by the conservators of the health of the city for their removal, when they, by their numbers and decay, became offensive, he replied, "You are too delicate; the heads of those that rob the public are still more offensive."

Another anecdote is told of him, to shew that he was not more rigorous to his own subjects, than strenuous in maintaining the rights and authority of the holy see, with respect to foreign powers. When the ambassador of the king of Spain present'd him with a beautiful genet and a purse of ducats, as a homage due for the kingdom of Naples, and complimented him in his master's name, Sixtus, in a tone of raillery, said, that the compliment was very fine, but that it would require a deal of eloquence to persuade him to take a horse in exchange for the revenues of a kingdom. At the time of his accession, France was in confusion on account of the machinations of the Catholic league to exclude from the crown Henry, king of Navarre, its presumptive heir. Though Sixtus did not approve the attempts of the Guises, at the head of the league, to ob-

tain a superiority over the king, Henry III.; yet he thought it became him, as head of the Catholic religion, to promote the exclusion of a Protestant heir, and he accordingly launched an excommunication against the king of Navarre, depriving him of the right of succession. That prince procured an appeal from this sentence to be fixed on the very gates of the Vatican, which act, Sixtus had the magnanimity to be pleased with, on account of the heroism which it displayed. When Henry III. had caused the duke of Guise to be assassinated, and the cardinal of Guise to be put to death, and the cardinal of Bourbon and the archbishop of Lyons to be imprisoned, the pope, highly incensed at the violation of the ecclesiastical immunities in the persons of the three last mentioned persons, issued a monitory, requiring the king to set at liberty the cardinal and archbishop within ten days, on pain of excommunication; and he afterwards approved, in an open manner, the assassination of Henry by the Dominican Clement. He refused, however, to renew the excommunication of Henry IV., saying, that he would pray for his conversion, and that no prince was more deserving a crown. He had also a high veneration for the character of queen Elizabeth of England, on account of the prudence and vigour of her government, though he was under the necessity of treating her as an enemy on account of her enmity to the Catholic religion. It is said, and the fact is surely quite in character, that he envied her the good fortune in having had the pleasure of taking off a crowned head, by the execution of Mary, queen of Scots. After the defeat of the Spanish armada, he entertained the design of wresting the kingdom of Naples from Philip, but was prevented by death from making the daring attempt.

It was the ruling passion of this pontiff, who, as we have seen, was only a peasant's son, to perpetuate his memory, by which he was led to many vain and ostentatious, and to some great and useful enterprises. He had already, while cardinal, engaged the celebrated architect Fontana, in erecting a splendid chapel in the church of St. Maria Maggiore, which he had been obliged to discontinue, from the withdrawing of his allowance by Gregory XIII.; and now having the means, as well as the good will, he employed the same artist in the arduous task of setting upright the fallen obelisk of Egyptian granite, which had once decorated the Circus of Nero. This was effected by great skill and labour, and the obelisk was dedicated by Sixtus to the Holy Cross. He afterwards caused three other obelisks to be dug out of the ruins among which they lay, and placed before different churches. If mere vanity and ostentation led him to erect useless buildings at his native place; it was universally allowed, that use and ornament were united in most of the works which he executed at Rome. For the supply of water to that metropolis, he directed the collection of a number of springs to one reservoir, at the distance of thirteen miles, whence it was conveyed by an aqueduct to the Quirinal mount. He undertook to rebuild the Vatican library upon an enlarged and more magnificent plan, by his favourite architect Fontana, and erected very near it a very fine printing-office, destined to give splendid as well as correct editions of the fathers, and other works relative to religion. There was not a part of Rome to which he had not given decorations, and perhaps no pope left so many monuments of grandeur after a long reign as Sixtus V., after occupying the papal see little more than five years. On these objects he must have expended immense sums, yet at his death he left five millions of crowns in the castle

of St. Angelo, with an injunction to his successor, that they should be expended only for the service of the church, against Turks and heretics, or to relieve the people in times of famine and pestilence. For the supply of the great expenditure of his reign, and the accumulation of the sums left behind him, he must have had recourse to a system of heavy taxation, although he managed his finances with great economy. He was not free from the papal vice of nepotism. Though never ashamed of the meanness of his origin, which could not be concealed, he was determined to leave his family great. He sent for a sister, the widow of a poor countryman, and instantly gave her the rank of a princess, with a suitable maintenance; and he raised one of her grandsons to the cardinalate, with a very large revenue. He was equally liberal to his other relations. He fixed the number of cardinals to seventy, a number which has been adhered to by his successors; and he decreed, that four at least of the number should be doctors of divinity, chosen from the religious orders. He is said to have been a decided enemy to the Jesuits, and was indignant that they should assume a name that implied, that their founder was the meek and benevolent Jesus; hence he proposed that they should change the name of their order to that of Ignatians. This celebrated pontiff died in August 1590, having reigned five years and four months. The news of his death was received with every demonstration of joy at Rome, where his government had been oppressive and tyrannical; but the vigour of his administration, and the mighty works which he effected, have thrown a splendour about his name, and gave him rank among the distinguished characters of the age. In the year 1590, a new Latin version of the Bible was made and printed by his order, of which a corrected edition was given in 1592, by Clement VIII.

SIZADA, in *Geography*, a town of Hindoostan, in Allahabad; 20 miles S.E. of Corah.

SIZANDRO, a river of Portugal, which runs into the Atlantic, N. lat. 39° 2'. W. long. 9° 19'.

SIZE, the name of an instrument used to find the big-ness of fine round pearls.

It consists of thin pieces, or leaves, about two inches long, and half an inch broad; fastened together at one end by a rivet. In each of these are several round holes drilled, of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains. Those of the second, for pearls from eight grains, or two carats, to five carats, &c.: and those of the third, for pearls from six and a half to eight and a half.

SIZE is also used for a kind of weak glue. (See GLUE.) The shreds and parings of leather, parchment, or vellum, by being boiled in water and strained, make size. Common size is made of leather boiled in water till it becomes of a viscid consistence. If it is wanted in painting for nicer purposes, it should be prepared by taking any quantity of the shreds or cuttings of glovers' leather, and putting to each pound a gallon of water; let these be boiled for six or eight hours, supplying water, so that it may not diminish to less than two quarts. Then strain the hot fluid through a flannel, and afterwards evaporate it till it is of the consistence of a jelly when cold. The size used in burnish gilding, and made of cuttings of parchment, is prepared much after the same manner. This substance is useful in many trades. Mr. Boyle mentions, among other uses, that fine red stands, and hanging-shelves, are coloured with ground vermilion tempered with size, and when dry, are laid over with common varnish.

SIZE, *Gold*. See GOLD-SIZE.

SIZE, *Inglass*. See *ICHTHYOCOLLA*.

SIZE, *Painting*. See *DISTEMPER*.

SIZE for *Silvering*. See *SILVERING*.

SIZE of *Cottage Grounds*, in *Agriculture*. See *COTTAGE*.

SIZE of *Farms*, the particular dimensions or extents of them. The advantages of the different sizes of farms, so far as they relate to the occupiers and the community at large, have not yet been by any means ascertained. See *FARM*.

SIZE of *Fields or Inclosures*. See *FENCE, FIELD, and INCLOSING of Land*.

SIZEBOLI, in *Geography*, a town of European Turkey, in Romania, on a point of land which projects into the Black sea, with a good road, in which men of war may moor. It is the see of a Greek archbishop; 14 miles E. of Burgos. N. lat. $42^{\circ} 30'$. E. long. $27^{\circ} 44'$.

SIZEL, in *Coining*, is used where pieces of money are cut out from flat bars of silver, after having been drawn through a mill into the respective sizes or dimensions of the money to be made; the residue is called fizele, and melted down again.

SIZING, in *Mineralogy*, a term used by the Cornish miners for a peculiar method of separating the purer from the impurer parts of an ore, by means of sieves. When the ore has been powdered, they put it into a wire-sieve with fine holes, and in this they sift it, till the fine part goes through: this is properly what is called sizing. They send the larger or coarser part to be powdered again, and putting the rest into a sieve with a close bottom, they let in a stream of water from the cock, and by means of continued shaking it about, they cause the lighter and fouler parts to be washed over the rims of the sieve, and the remaining powder is the black tin.

SIZRAN, in *Geography*, a town of Russia, in the government of Simbirsk, on the Volga; 27 miles S. of Simbirsk. N. lat. $53^{\circ} 10'$. E. long. $48^{\circ} 14'$.

SIZUN, a town of France, in the department of Finistère; 6 miles S.E. of Landerneau.

SIZZELA, a town of Istria; 9 miles S.S.W. of Cape d'Istria.

SIZZING, in *Rural Economy*, a term provincially applied to yeast or barm.

SKABOUGAN, in *Geography*, a river of America, which runs into lake Michigan, N. lat. $44^{\circ} 5'$. W. long. $86^{\circ} 46'$.

SKAGAFIORD, a bay on the N. coast of Iceland. N. lat. $65^{\circ} 50'$. E. long. $15^{\circ} 21'$. This Fiord receives the waters of two rivers, one of which is large, and is called Kolbeinsdalfaa. On the western side of the Skagafiord is situated a place of trade, called Hoffos, with a bad harbour, so that only one merchant has settled there. At the head of the Skagafiord, not far from Hoffos, is Hoolum, which, until the close of the last century, was the seat of one of the bishops of Iceland. A public school was also established there; but now (1810) the place consists only of a few cottages; and in its present state contains nothing particularly worthy of notice.

SKAGAFIORD *Syssel*, a district of Iceland, containing 412 farms, 492 families, and a population of 3141 persons.

SKAGASTRAND, a considerable place of trade on the northern coast of Iceland; situated on the western side of the large promontory which bounds the Skagafiord. The harbour is bad; and towards the end of September is particularly unsafe, on account of its being exposed to the north wind and floating ice. This place formerly furnished a cargo for one vessel every year; but since the commence-

ment of the war, the arrival even of one ship has not been regular.

SKAGEN, a promontory of Iceland, projecting from the N. coast, about 20 miles in length from N. to S. and from 5 to 15 in breadth; the N. point being in N. lat. 66° . E. long. $45^{\circ} 51'$.

SKAGEN. See *SCAGEN*.

SKAGER, a town of Sweden, in West Gothland; 85 miles E.N.E. of Uddevalla.—Also, a lake of Sweden, in Warmeland; 5 miles E. from the Wenner lake.

SKALDA and SKALDS. See *EDDA* and *SCALDS*.

SKALE, in *Geography*, a small island on the W. coast of Scotland, in Loch Fine. N. lat. $55^{\circ} 54'$. W. long. $5^{\circ} 23'$.

SKALEN, a town of Prussia, in the palatinate of Culm; 13 miles N. of Strasburg.

SKALEVAD, a town of Sweden, in the province of Angermanland; 50 miles N.N.E. of Hernofand.

SKALGRUND, a small island on the E. side of the gulf of Bothnia. N. lat. $55^{\circ} 54'$. W. long. $5^{\circ} 23'$.

SKALHOLT, a town of Iceland, the see of a bishop, suffragan of Drontheim. N. lat. 64° . W. long. 16° . The situation of Skalholt, about 24 miles from Thingvalla (which see), is beautiful. Towards the south there is a view of a noble river, formed by the junction of that discharged from Apa Vatn and the Huitea, bounded by a finely-shaped hill in the distance; another equally picturesque hill rising on the eastern bank of the latter, and facing Skalholt. Flat meadow land, gently swelling ground, and distant mountains towards the east, among which are Eyafialla Jokul, and Hekla, form altogether a magnificent amphitheatre, and compose a landscape which, even without wood, is highly gratifying to the eye. The first bishop of Skalholt was Isleif, who died in 1080; he was the earliest of the Icelandic historians, and a man of great general learning; but his works are now unfortunately lost. Paul, another bishop of Skalholt, as well as Sturleson, were distinguished by their attainments in mathematics and mechanical science. During a period of seven centuries, Iceland was divided into two bishoprics, that of Skalholt comprehending the southern, and that of Hoolum the northern districts of the island. The sees becoming vacant at the same time, they were united, in 1797, by the order of the Danish government; and the title of bishop of Iceland was conferred upon the learned and respectable Gein Vidalin, the present possessor of this dignity. The duties of his office are important and extensive. The place of his stated residence is Reikiavik. His revenue, since the union of the sees, is about 1800 dollars *per annum*, derived chiefly from the public treasury of the island. The appointment of the bishop is vested in the crown. The church of Skalholt is a neat small building of wood, erected on the site of the former one, which was taken down about the year 1804. The church, the bishop's house, and a few cottages, constitute the supposed capital of Iceland. The easiest route from the southern to the northern parts of Iceland is by the way of Skalholt. To Skagaltrand, the nearest road is by Thingvalla and Kalmanlunga, which last place is situated to the N.E. of Reikholt. See Mackenzie's Travels in Iceland in 1810. See *ICELAND*.

SKALL, a town of Bohemia, in the circle of Boleslaw; 4 miles N.N.W. of Turnau.

SKALLERUD, a town of Sweden, in the province of West Gothland; 50 miles N.N.E. of Uddevalla.

SKALOE, a small island of Denmark, near the N. coast of Laaland. N. lat. 55° . E. long. $11^{\circ} 23'$.

SKA-

SKANANDO CREEK, a small water of Oneida creek, which rises in Augusta, Oneida county, runs northerly through the said town and Vernon, and enters Oneida creek near the S.W. corner of Vernon. It furnishes good mill-seats in Augusta and Vernon. Its course is about four miles.

SKANDA, in *Hindoo Mythology*, is a name of Kartikya, commander of the celestial armies. He is a reputed son of Siva, and his history and exploits fill many volumes of Eastern poetry, translated into a variety of languages from the Sanscrit. He is also called Divimatri, having the same meaning in Sanscrit, as Dimeter or Bimeter among western mythologists. Shanmuka, or six-faced, Sestimatriya, meaning with six mothers, are others of his names; the origin of which will be found under those articles, and KARTIKYA. (See also SIVA.) Sir W. Jones informs us that the Persian poets, in borrowing their romantic histories from those of India, have ridiculously confounded the Skanda of the latter with Skander or Ilkander; their name of Alexander the Macedonian, as well as of a hero in their earlier romances.

SKANDERBORG, in *Geography*, a town of Denmark, in North Jutland, where the kings of Denmark have a royal palace: the chief trade of the inhabitants consists in the produce of the country, and agriculture; 10 miles S.S.W. of Aarhus. N. lat. $56^{\circ} 55'$. E. long. $9^{\circ} 54'$.

SKANEATETES, a lake of New York; 25 miles S.S.E. of lake Ontario.

SKANGERO, a small Grecian island below that of Pelagnisi, and near the isle of Dromi, in which are two rocks, called the "Brothers."

SKANKHEADHAW LAKE, a lake of North America. N. lat. $49^{\circ} 45'$. W. long. $90^{\circ} 45'$.

SKANO, a town of Sweden, in Schonen; 20 miles S.S.W. of Lund. N. lat. $55^{\circ} 24'$. E. long. $12^{\circ} 34'$.

SKANTZE, a town of Sweden, in Westmanland; 9 miles N. of Stroemsholm.

SKAPTAA-JOKUL, lofty mountains situated in the interior of Iceland, and known to the natives themselves only by the remote view of their summits, clad in perpetual snows. These were the scene of a most dreadful volcanic eruption in the year 1783. This is represented as the most tremendous, perhaps, in its nature and extent, by which Iceland, or any other part of the globe, has been afflicted. The sudden extinction of a submarine volcano near Cape Reikianes, which, during some months, had continued to burn with extreme violence, was succeeded by frequent and dreadful earthquakes, and by the bursting out of the volcanic fire, in a tract of country nearly 200 miles distant. From this desolate and unfrequented region vast torrents of lava issued forth, overwhelming all before them, and filling up the beds of great rivers in their progress towards the sea. For more than a year, a dense cloud of smoke and volcanic ashes covered the whole of Iceland, obscuring almost entirely the light of the sun, and extending its effects even to the northern parts of continental Europe: the cattle, sheep, and horses of the country were destroyed; a famine, with its attendant diseases, broke out among the inhabitants; and the small-pox invaded the island at the same time with its former virulence and fatal effects. From these combined causes, more than 11,000 people perished during the period of a few years; an extent of calamity which can only be understood, by considering that this number forms nearly a fourth part of the whole present population of the country. The destruction of the fishery upon the southern coasts of the island, by the volcanic eruptions just described, was another more permanent source of distress, which, even

at the present time (1810) is not entirely removed. Maekenzie's Travels in Iceland.

SKAPTAFELL, EAST, a district of Iceland, on the northern coast, containing 53 farms, 126 families, and a population of 911 persons.

SKAPTAFELL, West, a district of Iceland, on the same coast, containing 133 farms, 248 families, and 1539 inhabitants.

SKARA, a town of Sweden, in West Gothland, the most ancient town of the country, and formerly the capital of the kingdom of Gothland, and the residence of many of its kings. It had also several churches and convents, the ruins of which are still visible. The town was totally destroyed by fire in 1719; and the number of its inhabitants does not at present exceed 400. Its gymnasium or seminary was established in 1640, and its cathedral is one of the largest edifices of the kind in the whole kingdom. In 1611 the royal palace, built near the town in 1545, together with the whole town, was reduced to ashes by the Danes. At a distance from it stands Brunso, an episcopal see; 50 miles E. of Uddevalla. N. lat. $58^{\circ} 24'$. E. long. $13^{\circ} 30'$.

SKARDSA, BIORNO á, in *Biography*, a learned Icelander, was born at Ingelvelt in 1574. Having lost his father at eight years of age, he was placed by a relation under the care of Segurd Jonsen, who being well versed in the ancient history of the country, inspired Biorno with a strong taste for that kind of study. On the death of his master, in 1602, Biorno married, and having already been elected a magistrate, he applied himself with great diligence to history and jurisprudence. In old age he was borne down with heavy and very severe afflictions, became blind, and died a martyr to the stone in 1655. He collected a variety of documents and curious facts relating to the history of Iceland, and was, on account of his great knowledge in this department of learning, held in high estimation by his countrymen. His chief publication was "The Annals of Biörn à Skardsa, five Annales, &c. cum Interpretatione Latina, variantibus Lectionibus, Notis et Indice." He left behind him a great number of manuscripts, both juridical and historical, a catalogue of which may be seen in the Ecclesiastical History of Iceland by Johannæus; in Einarus' Literary History; and in the preface to the second volume of his Annals. Among his MSS. is one respecting Iceland, of which Torfæus made great use in his "Grönlandia Antiqua." Gen. Biog.

SKARDUPONEN, in *Geography*, a town of Prussian Lithuania; 1 mile N.W. of Stalluponen.

SKARO, a town of Norway; 32 miles N. of Stavanger.

SKARROE, a small island of Denmark, near the S. coast of Fyen; 6 miles S. of Svenborg. N. lat. $55^{\circ} 1'$. E. long. $10^{\circ} 29'$.

SKARSTÅ, a town of Sweden, in West Gothland; 40 miles E. of Uddevalla.

SKATE, in *Ichthyology*, the English name of a species of ray-fish, called by the generality of authors *raia undulata*, and *raia levis*, and by some *rubus*.

It is distinguished by Artedi by the name of the variegated ray-fish, with the middle of the back smooth, and with only one row of spines in the tail.

This species, which is the *RAIA Batis* of Linnæus, (see RAIA,) is the thinnest, in proportion to its bulk, of any of the genus, and also the largest, some weighing near two hundred pounds. The nose, though not long, is sharp-pointed; above the eyes is a set of short spines; the whole upper part of a pale-brown, and in some species streaked with

with black; the lower part white, marked with many small black spots; the jaws covered with small granulated but sharp-pointed teeth; the tail is of a moderate length; near the end are two fins; along the top of it is one row of spines, and on the edges are irregularly dispersed a few others. In the males of this species the fins are full of spines. Skates generate in March and April, at which time they swim near the surface of the water, several males pursuing one female. The females begin to cast their purses, as the fishermen call the bags in which the young are included, in May, and continue to do it till September. In October they are very poor and thin, but begin to improve in November, and grow gradually better till May, when they are in the highest perfection. The males go sooner out of season than the females. Pennant.

SKAW, in *Geography*. See SKAGEN.

SKAWIN, a town of Poland; 10 miles S. of Cracow.

SKEATTA, or PENNY, in the *History of Coinage*, one of the Heptarchic coins; the other being the *stycra*, which see. Dr. Combe, by causing two plates of the skeattas, or early pennies, to be engraved, brought them into notice. At first they had only rude figures of serpents, &c. but latterly they have legends. These skeattas were struck in Kent, and the other Heptarchic states, from the sixth to the eighth century, or from about the year 500 till 700. In 598 Kent was converted to Christianity, and was followed in half a century by the other kingdoms. Most of the skeattas, as appears from their symbols, were struck in the Pagan times. See *Modern MEDALS and COINS*.

SKEDE, in *Geography*, a town of Sweden, in Smaland; 42 miles S.E. of Jonkioping.

SKEEL, in *Agriculture*, provincially a large milking pail, having two handles, formed by two opposite staves, which rise above the rest. It also signifies a broad flat creaming or milk-dish, whether of lead or stone.

SKEEN, in *Geography*, a town of Norway, in the province of Christiania; 38 miles S.W. of Christiania.

SKEETS, in the *Sea Language*, narrow oblong ladles, or scoops, for wetting the sails, decks, or sides of a ship.

SKEG, in *Ship-Building*, the after-part of the keel, or that part whereon the stern-post is fixed.

SKEG-Shores, one or two pieces of four-inch plank, put up endways under the skeg of the ship, to steady the after-part a little, when in the act of launching. They are confined to the bottom of the slip by a hinge. The upper part is rounded, and they should be so carefully fixed as to fall readily when the ship starts. Skeg-shores are better avoided, as they have been the means of preventing ships from launching.

SKEGS, in *Agriculture*, a sort of oat, sometimes cultivated as a crop in Nottinghamshire: the *avena stipiformis* of Linnæus. It is paniced, the calyces two-flowered, awns twice as long as the seed, culm branchy, and stipeform. They are a crop mostly cultivated, according to the agricultural report of the above district, on the worst land, sometimes on a lea, sometimes after turnips, often taken as a last crop. On bad land they may produce about four quarters *per* acre, which are generally about two-thirds of the price of oats. But they answer to sow on good land, producing fourteen and fifteen quarters *per* acre. The kernel is reckoned remarkably sweet and good food for horses. They are sometimes threshed, sometimes cut and used in the straw. And they are chiefly grown about Carberton, and will grow where nothing else will. In regard to the quantity of seed *per* acre, eight strikes are said to be sown, and yield a crop double that of other oats, in quantity;

but not more than equal in weight. They will grow in the poorest land, and are reckoned very sweet food. They are seldom brought to market; but esteemed by farmers for their own use, and are often given in the straw by them.

It is stated by Mr. Neville in the same Report, in a letter to sir R. Sutton, that skegs are remarkably good for horses, in the straw, or threshed, and in the straw remarkably so for cows. Straw beats are also very fond of the straw. He can get taking up weak land from the sward, from four to six quarters an acre. On the same land he should not have been able to get, perhaps, above three sacks of black, red Friesland, or what is called short small, or any other kind of corn. If land is in the state in which all our bad land will be, more or less, after the seeds are quite run out, and as is frequently the case, when you cannot conveniently put it again into tillage so soon as you could wish, from either the too great quantity you may have to improve, or other circumstances; if in this state it were to be taken up with turnips, the most eligible way, it would be often impossible to provide manure *upon the farm* for any quantity of land sufficient for the purpose; which makes skegs a very desirable crop, and which, for that reason alone, he finds a great acquisition, and feels a pleasure in having been the first to introduce them into this country.

How far this crop may be capable of being grown in other districts as the food of live-stock, in the green state, must depend upon the trial.

SKEILAY ISLE, in *Geography*, a small island of the Hebrides, is situated near the western entrance of the firth of Harris. It is comprehended in the parish of Harris and shire of Inverness.

SKELBOO, a town of Norway, on the Glanmen; 12 miles N.E. of Frederickstadt.

SKELDNESS, a cape of Scotland, on the S.W. coast of the island of Shetland. N. lat. 60° 12'. W. long. 1° 48'.

SKELEFTEA, a town of Sweden, in West Bothnia, on a river of the same name; 40 miles S. of Pitea.

SKELEFTEA, a river of Swedish Lapland, which rises on the borders of Norway, and runs into the gulf of Bothnia, S.E. of Pitea.

SKELETON, in *Anatomy*, from *σκελετα*, *to dry*, is the assemblage and combination of all the bones in the body, excepting the os hyoides: it constitutes the basis or groundwork of the animal frame, being the point of support and union for all the other organs. Its component parts form a series of levers, of which the muscles are the moving powers: thus the skeleton comprehends one division of the moving organs. Its constituent pieces in some cases form cavities, as those of the head, chest, and pelvis, which contain the important internal organs, and protect them from external force.

The connections of the different pieces of the skeleton are called *joints*, and differ very considerably from each other; some of them admitting no motion, some an inconsiderable motion; and others allowing them to move freely, either in certain directions, or in every way. The word *skeleton*, denoting the bony fabric in its united state, of course includes the joints or media of union; and in this respect we distinguish two kinds of skeletons. A *natural* skeleton is that in which the bones are all joined by their natural connections; that is, the articular ends are covered by their cartilaginous strata, tied together by ligaments, and enveloped by synovial membranes: in this sense the skeleton includes, besides the bony system, the accessory structures of cartilage, ligament, and synovial membranes. When all

SKELETON.

the soft parts have been allowed to putrefy and rot, and the separated bones, after being cleaned and dried, have been joined again by wires, &c. so as to be reunited artificially in their former order, an *artificial* skeleton is formed. In the spine and the ribs, the places of the cartilages, which are lost in cleaning the bones, are supplied by portions of leather, cork, or other materials.

The latter, exhibiting merely the assemblage of the dried bones, is applicable to the study of osteology only in the mechanical points of figure, size, &c.; and although extremely useful to the anatomist and surgeon, by representing the parts in their natural connection and relations, is less convenient than the separate bones for the study of many points, particularly the articular ends of the bones.

For the formation of artificial skeletons, the bones are deprived of their soft parts, either by boiling, or by maceration in water. The boiling must be continued until the tendons, ligaments, periosteum, &c. are so loosened as to admit of being easily detached. The bony texture acquires in this method a dirty and greasy appearance, which cannot be entirely got rid of by any after-process. For the purpose of maceration, the bones, with the flesh, &c. roughly cut off, must be left in the same water for some months; the soft parts will then fall off, and leave the bones of a much better colour, and freer from grease than when they have been boiled. Exposure to the air, and frequently wetting them, will make them beautifully white after they have been well macerated. Their colour may be often much improved by exposure to chlorine (oxymuriatic gas). The bones which possess large medullary cavities should be bored at the articular ends, to get out the fatty substance.

Emaciated and particularly anasarctous subjects are the best for making skeletons; because there is no fat in the bones, and they consequently continue dry and clean, when they have been originally well prepared. Persons dying in good health, or from sudden attacks, have so much adipous matter in the interior of their bones, that they continue greasy, particularly at the articular ends, whatever pains may be taken to clean them.

In natural skeletons, the cartilages, ligaments, and synovial membranes being all left, the joints possess their natural mobility. But in order to keep them in this state, they must be preserved in spirits, or some other fluid capable of preventing the putrefaction of the soft parts. This is particularly necessary with the skeletons of young subjects, which are in great part cartilaginous. When a natural skeleton is dried, the soft parts shrink and are shrivelled up: the cartilages become contracted, and thus the natural figure is greatly impaired. The contraction of the cartilages diminishes the height by an inch or more.

So long as the bones are composed of separate pieces, and have more or less cartilage in their structure, the osseous system can only be studied in natural skeletons; but when the ossification is complete, artificial skeletons are preferable.

The bones, being the levers by which the motions of the body are performed, have the muscles or moving powers fixed to them. But as they are subservient, in the construction of our frame, to other purposes besides those of motion, there are some bones, though very few, to which no muscles are attached: such are the incus in the ear, the ethmoid and inferior turbinated bones, and some bones of the carpus.

Although the form of the bones is variously modified, according to the figure of the parts in which they are placed, or to their destinations, they may be classed under the three

divisions of broad or flat bones, cylindrical bones, and short bones. The broad bones represent flat shells, and consist of an inner stratum of reticular or spongy bony substance, which is covered on its surfaces with thicker or thinner plates of compact bony matter. The cylindrical, or long bones, form long shafts, expanded at their extremities into thicker heads, and containing a medullary cavity internally. The short bones are such as are nearly equal in their length, breadth, and thickness; variously shaped, according to their situations and offices; and consist of the loose spongy texture, covered by a thin rind of compact bone.

The long bones belong in general to the locomotive apparatus, where they form levers, moved by the muscles in various directions: they are all placed in the limbs, where they form a central column, moveable in various directions. They diminish in length, and increase in number, successively from above downwards; from the humerus and femur to the phalanges of the fingers and toes. Hence the upper part of the limbs is characterized by extent of motion, the lower by multiplicity and variety of movements.

The broad bones have not much to do with locomotion, except as they afford extensive surfaces for the attachment of muscles. They compose cavities, such as those of the cranium and pelvis, for which their form is well adapted. Several are united to form one cavity, and this circumstance adds to the solidity of the structure, as the effect of external force is lost in the joints. They are generally concave and convex on their two surfaces.

The short bones are found in parts which unite mobility and solidity, as the vertebral column, the carpus, and tarsus. They are always of inconsiderable size, and therefore are found in large number in the parts which they compose. These parts are strong, because external force is lost in the articulations: they are moveable, because the combinations of several small motions produce a considerable effect.

Of the first production of the bones, and their gradual development while the fœtus remains in utero, and of the nourishment and growth of bone in general, an account is given in the articles EMBRYO and BONE: in the latter of which, and in EXTREMITIES, there is a description of their external configurations, and of the disposition of the bony substance. The organization and properties of the system are considered under the article BONE. Under MEDULLARY *System* and CARTILAGE the accounts of these subjects will be found; and the periosteum is described under MEMBRANE.

The skeleton is divided into the head, trunk, and extremities or limbs. As almost all the bones are formed originally of more than one piece, which separate portions of osseous matter gradually come together, and are ultimately consolidated, the number of distinct pieces of bone belonging to the skeleton is different at different ages. The following is the number of bones, when the ossification is complete; that is, about the twentieth year.

I. In the HEAD, consisting of the *cranium*, and the FACE, the former is made up of

- 1 or 2 ossa frontis,
- 2 ossa parietalia,
- 1 os sphenobasilare, or spheno-occipitale,
- 2 ossa temporum,
- 2 mallei,
- 2 incudes,
- 2 stapedes,
- 1 os ethmoideum.

SKELETON.

The latter of

- 2 ossa maxillaria superiora,
- 2 ossa palatina,
- 2 ossa malarum, or zygomatica,
- 2 ossa nasi,
- 2 ossa lacrymalia,
- 2 ossa turbinata inferiora,
- 1 vomer,
- 1 maxilla inferior,
- 32 teeth.

The whole amount of bones of the head is 59 or 60. The five pieces of the os hyoides added to these, make 64 or 65.

II. The TRUNK, comprehending the spine, chest, and pelvis, consists of

- 7 cervical } vertebræ,
- 12 dorsal }
- 5 lumbar }
- 2 or 3 bones of the sternum,
- 24 ribs,
- 1 sacrum,
- 4 ossa coccygis,
- 2 ossa innominata.

—
57 or 58

III. The EXTREMITIES.

The upper contain

- In the shoulders, { 2 clavicles,
- { 2 scapulæ.
- In the arms, 2 humeri.
- In the fore-arms, { 2 radii,
- { 2 ulnæ.
- In the wrists, { 2 ossa navicularia or scaphoidea,
- { 2 ossa lunaria,
- { 2 ossa cuneiformia,
- { 2 ossa pisiformia, or orbicularia,
- { 2 ossa trapezia, or multangula majora,
- { 2 ossa trapezoidea, or multangula mi-
- nora,
- { 2 ossa capitata,
- { 2 ossa unciformia, or hamata.
- In the metacarpi, 10 ossa metacarpi.
- In the fingers, { 10 first or metacarpal phalanges,
- { 8 middle or second phalanges,
- { 10 third or ungual phalanges,
- { 8 sesamoid bones.
-
- 72

The lower extremities contain,

- In the thighs, 2 femora.
- In the legs, { 2 tibiæ,
- { 2 patellæ,
- { 2 fibulæ.
- In the tarfi, { 2 astragali,
- { 2 calcanei, or ossa calcis,
- { 2 ossa navicularia,
- { 2 ossa cuneiformia magna,
- { 2 ————— parva,
- { 2 ————— media,
- { 2 ossa cuboidea.

—
22

- Brought over 22
- In the metatarfi, 10 ossa metatarfi.
- In the toes, { 10 first or metatarsal phalanges,
- { 8 middle or second phalanges,
- { 10 third or ungual phalanges,
- { 6 sesamoid bones.
-
- 66
-

The whole number of bones will be 259 or 261. There is frequently a small bone of the sesamoid kind in the tendon of the external head of the gastrocnemius: and a roundish bit in the hyo-thyroid ligament. If both these should exist, we must add four to the preceding number.

A complete dry natural skeleton of a male subject of the middle size, weighs from 150 to 200 ounces; that of a female, from 100 to 160 ounces.

Of the bones just enumerated, the frontal, spheno-occipital, vomer, lower jaw, vertebræ, sacrum, coccyx, sternum, and os linguale medium, are single (imparia), and, being placed on the middle line of the body, symmetrical; all the others are double, or in pairs (paria); each pair being composed of a right and left corresponding bone. Hence the structure of the whole skeleton is symmetrical; that is, if we imagine a perpendicular line to be drawn through the whole body, from before backwards, it will divide the skeleton into two corresponding halves, a right and left; the single bones having their right and left sides exactly alike.

This observation, however, of the symmetry of the skeleton, is not to be understood rigorously; since the right and left of the double bones, or the right and left sides of the single ones, are not accurately alike. The right or left bone, or the right or left side of a bone, may be longer or shorter, broader or narrower, &c. &c. than the other. The vomer is generally bent to one side; the internal surface of the skull seldom symmetrical. The last rib is often an inch longer on one side than on the other. The sternum is seldom symmetrical; and the cartilages of the ribs are not fixed to it exactly opposite to each other. The articulations of the ribs with the spine often differ considerably on the two sides. But the symmetry of the external form is not disturbed by these differences. If the right side of a vertebra is more elevated than the left, the corresponding part of the neighbouring bone, or of the intervertebral cartilage, is accommodated to the deviation; so that the perpendicular line of the spinal column is not impaired, &c. &c.

The single bones may be regarded as the media of union of the two lateral halves, which constitute the skeleton: they join together these two halves into one solid whole. In this respect there is a marked difference between the bones and the other organic instruments of locomotion, the muscles. The diaphragm is the only muscle placed on the median line, and its structure is not symmetrical: it belongs in great measure to the internal or organic life, and corresponds, in its want of symmetry, to the arrangements of the internal organs. The skeleton, being the basis or point of support of the muscles, as well as of all the other organs, constitutes an entire and firm fabric; an attribute which it derives from the single bones, which may be regarded as the key-stones of the building. The muscles, not contributing to the solidity of the animal structure, are not united into such a single and firm assemblage.

The mode in which the different pieces of the skeleton are joined to each other, is considered under the article JOINT; to which, and to that of MEMBRANE, *Synovial*, we refer for the details regarding the anatomical structure of these connections.

SKELETON.

The osteology of the head, including the teeth, is considered under CRANIUM; that of the vertebral column under SPINE; of the chest under LUNG; of the pelvis under HEAD; and of the limbs under EXTREMITIES. The os hyoides, or linguale, is described in the article DEGLUTITION. The joints are considered together with the bones which they unite; except that the articulation of the lower jaw is described under DEGLUTITION; and those of the occiput, first and second vertebræ, under HEAD.

The observation, which we have made of the bones in general, that they influence and determine the form of the soft parts, holds good more particularly of the whole skeleton. Its form, in all men, and in all stages of their life, corresponds so entirely to the configuration of their body, that an experienced eye would easily determine, from a tolerably preserved skeleton, not only the age and sex, but the growth and most striking characters of bodily formation of the individual to whom it had belonged. Hence it is not enough for an artist to know the muscles: he must begin with studying the skeleton. However numerous the differences of individual configuration in the human race, still retaining its general character and resemblance, accurate examination will shew us not fewer diversities in the structure, form, size, greater or less elegance, and even greater or less fineness and firmness in the grain of the bone, in human skeletons, which still preserve the general character. Besides these endless individual traits, distinguishing each skeleton from others, we find very striking differences according to age and sex.

With respect to the former of these circumstances, skeletons have been divided into perfect and imperfect; the latter not very well chosen term being applied to fœtuses, children, and subjects in whom the epiphyses are not yet consolidated with the bodies of the bones, or converted into true apophyses; although, in relation to the rest of the structure, the bones are then as perfect as in the adult. The younger the subject, the more cartilage does the skeleton contain. Reckoning from the twentieth year backwards, the younger the subject the larger is the head, compared to the trunk and limbs; (the head is about one-half of the body, in the second month of utero-gestation; one-fourth in the ninth month; one-fifth at the age of three years; and one-eighth when the growth is complete;) the smaller are the bones of the face, and the larger the organ of hearing, in comparison to the cranium; the larger are the fontanelles; the flatter is the lower part of the face; the larger the chest in relation to the pelvis; the shorter the limbs; the larger the clavicles; the smoother and flatter the broad bones, and the rounder the cylindrical bones. See Albert Durer on the proportions of the body, particularly at the end of the first book; and Sue sur les Proportions du Squelette de l'Homme examiné depuis l'âge le plus tendre, jusqu'à celui de 25, 60 ans, &c. in les Mémoires présentés, &c. p. 572.

The male and female skeleton differ, not only in the whole combination, or the general impression, from a comparative survey, but also in the form and properties of the individual parts. These differences, however, are not clearly perceptible until some years have elapsed after birth. The plates of the female skeleton in Cheselden and Sue are not to be compared to the accurate delineations of the male skeleton by Albinus. Soemmering has, however, supplied the deficiency in his beautiful "Tabula sceleti femineæ junctæ descriptione," folio. He enumerates the following as the characters of the female. "The female skeleton is smaller and slenderer in all parts than the male. The ratio of the head, including the teeth, to the rest of the bony structure, is greater than in the male: the numbers are as 1 to 6 in

the former, 1 to 8 or 10 in the latter. The circumference of the female skull is larger on the first view, in skeletons of the same height. The skull is larger in proportion to the face: its foramina, the palatine arch, and the whole cavity of the mouth, are smaller. The whole thorax is shorter; larger above, as far as the fourth rib, narrower below; more moveable, less conical; more convex in front; more distant from the pelvis, the interval between the last rib and the os innominatum being greater; less prominent anteriorly, so that when the trunk is supine, the symphysis pubis is the highest point in the female, the thorax in the male subject. Generally, the cartilages of the true ribs are longer in proportion to the bone. The vertebral canal is more capacious, and the lateral openings for the nerves are also larger. The spinous processes are less prominent; the sternum is shorter, ending at the plane of the fourth rib, while it reaches to the plane of the fifth in the male.

"The loins are longer, and the angle between the last lumbar vertebra and the sacrum, constituting the promontory, is more acute.

"All the diameters of the pelvis are greater; the cruræ and tuberosities of the ossa innominata further apart; the space between the ossa pubis wider, and the ligaments of the symphysis consequently broader, although shorter.

"The sacrum is turned more backwards, so that its apex and the coccyx do not project so much into the pelvis. The acetabula are farther apart, and hence the unsteady gait of the sex: they are, however, nearer to the front of the pelvis, so that, when in the progress of pregnancy the centre of gravity is thrown more forwards, its equilibrium is better preserved.

"The lower limbs form a more acute angle with the pelvis; the feet are smaller.

"The shoulders are more slanting, and the articulations nearer together; the upper limbs are shorter, and the fingers more pointed.

"Female bones are distinguished from the male by having fewer asperities, smaller spines and protuberances, shallower impressions, smaller articulations, and being on the whole smoother and more finely turned. The shaft or body of a cylindrical bone is more slender, in comparison to the articular ends; and hence the fact which was specified above, of the greater weight of the head in proportion to the rest of the skeleton.

"The bones are not so hard in the female: they have, on the whole, a something peculiar, a feminine character, which is not easily described. Their extremities remain longer cartilaginous.

"The frontal sinuses are smaller; the interval between them, or the glabella, less elevated; and the superciliary arches less prominent. All the bones of the face are more slender. The figure of the alveolar circle is more elliptical in both jaws; in man more circular. The teeth are smaller. The os hyoides more slender.

"In the vertebræ, the bodies are longer, and more hollowed at the sides; the transverse processes are directed more backwards, so that the channels on each side of the spinous processes are deeper. The spinous processes are sharper pointed, shorter, and more slanting.

"The ribs are more slender, and flatter; their margins are consequently sharper.

"That the cartilages of the upper ribs are more frequently ossified; that those of the middle ribs are broader; and those of the lower longer, which has been asserted by some anatomists, does not seem clearly made out.

"The first bone of the sternum is longer in comparison to the second. The latter is more than double the length of

SKELETON.

the former in the male skeleton; but in the female it is often not so much as double. It is also thicker, in comparison with the second bone, in the female. These differences are observable in the embryo.

“The lumbar vertebræ are longer and more slender; the sacrum broader and more excavated.

“The ossa coccygis are smaller, more moveable, and directed more forwards. Some have observed, that five of these bones are met with more frequently in the female than in the male.

“The ossa innominata are broader, flatter, and more expanded horizontally. The angle formed between the descending ramus of the pubes and the symphysis is more open. The angle between the ossa pubis is acute in the male, but of 80° to 90° in the female, where it approaches much more to the figure of an arch.

“The ischiatic tuberosities are larger and smoother. The space between the tuberosity and the acetabulum is smaller; the ischiatic notch more considerable; the foramen ovale larger; the notch for the tendon of the obturator externus less considerable.

“The clavicles are less strongly curved, so that the scapulæ are thrown backwards; the male clavicles are more arched, and the shoulders therefore brought more forwards. In the male skeleton, the clavicles are inclined a little downwards, so as to form an obtuse angle with the sternum; while they form nearly a right angle in the female.

“The female scapulæ are smaller, slenderer, flatter, and have acuter angles.

“In the female, the thigh-bones are bent more forwards; the neck forms a greater angle with the body; the internal condyle is larger, more prominent, and longer, in comparison with the external.”

There are differences in some parts of the skeleton in the various races of mankind; that is, certain characters by which they can be distinguished from each other. The head is the part in which the strongest distinctive marks are observable. We have described these very fully, and entered at length into a consideration of the way in which they are produced, in the articles CRANIUM and MAN.

The national differences in stature, in the size, length, and proportion of the limbs, &c. must be accompanied with corresponding variations in the bony fabric. But there are no peculiarities of form in the individual bones, no varieties in the configuration of processes, or articular heads and cavities, nor in their mutual adaptation. On this subject also we refer to the article MAN.

The individual diversities of size and form must be attended with differences in the skeleton. The bones are sometimes longer, sometimes thicker. The head may be comparatively large or small; the shoulders broad or contracted; the thorax flat or prominent; the vertebral column more or less curved; the loins thick or slender; the thighs or legs, the fingers and toes, longer or shorter, &c.

Food seems to have no influence on the skeleton.

External causes have certainly, in some instances, influenced particular parts in individuals; as the application of artificial pressure to the head of the newly born. (See CRANIUM.) The effect of analogous pressure in contracting the feet of the Chinese women, producing anchylosis of the articulations, and thus rendering these instruments of locomotion nearly useless, is well known. Similar effects are produced daily on the feet, in compliance with the prevalent notions of beauty in Europe, under our own eyes.

But a more destructive process is that of the tight-laced stays of European females, who choose to fancy that beauty consists in having the chest large above and narrow below,

although nature has reversed these proportions. The ribs are contracted; the inferior aperture of the chest narrowed; the liver, stomach, and other abdominal viscera, subjected to a severe and most injurious pressure by this barbarous practice of civilized people. We have seen the figure of the thorax quite altered by this practice; the lower ribs being pushed in on the liver, and having left deep indentations in that organ. See Sömmerring's German treatise on this subject: “Von der Schädlichkeit der Schnurbrüsten.”

The effect of artificial causes in modifying the form, has, however, been much exaggerated: the round shape of the skull in the Turks being ascribed to their turbans, &c. A change is only to be effected by considerable and continued pressure on the bones in their growing state. These alterations are merely individual; they do not affect the race; as the offspring are born with the ordinary formation and characters of the species. See MAN.

Description of the Plates in which the Anatomy of the Skeleton is represented.

ANATOMY. *Osteology.* Plate XVIII.—Front view of the skeleton.

THE HEAD.

1. Os frontis.
2. Right os parietale or bregmatis.
3. Squamous portion of the right os temporis.
4. Mastoid process.
5. Meatus auditorius externus.
6. Condylod process of the inferior maxilla.
7. Coronoid process
8. Angle
9. Symphysis
10. Right superior maxilla.
11. Right os malæ or jugale.
12. Left ditto.

For the anatomy of the skeleton, see Cheselden's *Osteographia*, or the Anatomy of the Bones, fol.; *Traité d'Osteologie*, traduit de l'Anglois de Mr. Monro, &c. par Mr. Sue, 2 vols. fol.; C. J. Trew, *Tabulæ Osteologiæ*, 1767, fol.; Albinus de *Ossibus Corporis Humani*, 1726, 8vo.; Albinus *Tabulæ Sceleti & Musculorum*, 1747, fol.; Albinus *Tabulæ Ossium*, 1763, fol.; Albinus *Icones Ossium Fœtus*, 1737, 4to.; Albinus *Annotationes Academicæ*, 4to.; Soemmering *Tabula Sceleti Feminei, junctâ Descriptione*, fol.; Soemmering *de Corporis Fabrica*, t. i.; J. G. Walter von trocken *Knochen*, 1763, 8vo.; J. F. Blumenbach, *Gefichte und Beschreibung der Knochen*, 1786, 8vo.; Bertin *Osteologie*, 4 tom. 8vo.; Boehmer *Institutiones Osteologiæ*, 8vo.

We have, in the *Philosophical Transactions*, an account of a human skeleton, all the bones of which were so united, as to make but one articulation from the back to the os sacrum, and downwards a little way. On sawing some of them, where they were unnaturally joined, they were found not to cohere throughout their whole substance, but only about a sixth of an inch deep all round. The figure of the trunk was crooked, the spine making the convex, and the inside of the vertebræ the concave part of the segment.

The whole had been found in a charnel-house, and was of the size of a full-grown person.

SKELETON, Vegetable. The preparations of leaves, fruits, roots, &c. called vegetable skeletons, are made in this manner. Choose for this purpose the leaves of trees or plants, which are somewhat substantial and tough, and have woody fibres, such as the leaves of orange, jasmine, bay, laurel, cherry, apricot, peach, plum, apple, pear, poplar, oak, and the like; but avoid such leaves as have none of the woody fibres, which are to be separated and preserved by this method; such are the leaves of the vine, lime-tree, and the like. The leaves are to be gathered in the months of June or July, and such to be chosen as are found and untouched by caterpillars, or other insects. These are to be put into an earthen or glass vessel, and a large quantity of rain-water to be poured over them; and after this they are to be left to the open air, and to the heat of the sun, without covering the vessel. When the water evaporates, so as to leave the leaves dry, more must be added in its place: the leaves will by this means putrefy, but they require a different time for this; some will be finished in a month, and others will require two months or longer, according to the hardness of the parenchyma of them. When they have been in a state of putrefaction some time, the two membranes will begin to separate, and the green part of the leaf to become fluid: then the operation of clearing is to be performed. The leaf is then to be put upon a flat white earthen plate, and covered with clear water; and being gently squeezed with the finger, the membranes will begin to open, and the green substance will come out at the edges; the membranes must be carefully taken off with a finger, and great caution must be used in separating them near the middle rib. When once there is an opening towards this separation, the whole membrane always follows easily: when both membranes are taken off, the skeleton is finished, and it is to be washed clean with water, and then preserved between the leaves of a book.

The fruits are divested of their pulp, and made into skeletons in a different manner. Take, for instance, a fine large pear that is soft, and not strong; let it be nicely pared without squeezing it, and without hurting either the crown or the stalk; then put it into a pot of rain-water, cover it, set it over the fire, and let it boil gently till it is perfectly soft, then take it out, and lay it in a dish, filled with cold water; then hold it by the stalk with one hand, and with the other hand rub off as much of the pulp as you can with the finger and thumb, beginning at the stalk, and rubbing it regularly towards the crown. The fibres are most tender toward the extremities, and therefore to be treated with great care there. When the pulp is thus cleared pretty well off, the point of a fine penknife may be of use to pick away the pulp sticking to the core. In order to see how the operation advances, the foul water must be thrown away from time to time, and clean poured on in its place. When the pulp is in this manner perfectly separated, the clean skeleton is to be preserved in spirit of wine.

Skeletons of roots which have woody fibres, such as turnips, and the like, must be made by boiling the root, without peeling it, till it be soft, that the pulp may be squeezed away by the fingers in the same manner, in a dish of water. Many kinds of roots are thus made into elegant skeletons, and the same method succeeds with the barks of several kinds of trees; which, when thus treated, afford extremely elegant views of their constituent fibres. *Philos. Trans.* N^o 416.

SKELIGS, The Three, in *Geography*, islands in the Atlantic ocean, about 7 miles W. of Bolus Head, county of Kerry,

Kerry, Ireland, one only of which, the Great Skelig, is inhabitable. On this there was formerly an abbey; but it was removed to Ballinaskeligs, as a more convenient situation. See BALLINASKELIGS.

SKELL, a river of England, which runs into the Ure, near Rippon, in Yorkshire.

SKELLENBERG, a mountain of Bavaria, near Donauwert, where the French and Bavarians were defeated by the duke of Marlborough and prince Lewis of Baden.

SKELLFLETE, a river of England, which runs into the Humber, 12 miles W. of Hull.

SKELLINGE, a town of Sweden, in the province of Halland; 20 miles S.S.E. of Konfsback.

SKEMLIK. See KEMLIK.

SKENEATELES, a handsome post-village of America, in the state of New York, in Marcellus, Onondaga county, at the outset of the lake of the same name; 163 miles N. of W. from Albany. It has 60 houses, a handsome Presbyterian church, several mills, &c. on Skeneateles creek; and it has a brisk trade.

SKENEATELES Lake, a lake about fifteen miles long, and from half a mile to a mile and a half wide, principally in Onondaga county; six miles at its north end being in the township of Marcellus. Its trout and salmon trout are very large. The outlet is at the north end near the village of the same name, and the creek runs north, through Marcellus and Camillus, about ten miles to Seneca river, affording many fine seats for mills. Skeneateles, in the dialect of the Onondaga Indians, signifies long; and hence the name of the lake.

SKENECTADY. See SCHENECTADY.

SKENEK. See SCHENCK.

SKENESBOROUGH, a town of America, in Washington county, in the state of New York, situated on Wood creek, on the south side of lake George; burned by the Americans in 1777, with their baggage and military stores, when they were retreating before the British army under general Burgoyne. See WHITEHALL.

SKEOTISVAY ISLE, one of the Hebrides, in the parish of Harris, and shire of Inverness. It is about a mile long, and till of late years was uninhabited.

SKEP, in *Agriculture*, a coarse round farm basket. It is also provincially used to signify a bee-hive.

SKEPLE, or SKUTTLE, a sort of flat broad basket for winnowing corn.

SKER POINT, in *Geography*, a cape on the coast of South Wales, in the Brittol Channel. N. lat. $51^{\circ} 27'$. W. long. $3^{\circ} 42'$.

SKERAT, a rock in the Caledonian sea, near the west coast of Skye. N. lat. $57^{\circ} 24'$. W. long. $6^{\circ} 40'$.

SKERENIZ, a town of Bohemia, in the circle of Chrudim; 5 miles N. of Hohemaut.

SKERGULE, a rocky island near the south-west coast of Mull. N. lat. $56^{\circ} 18'$. W. long. $6^{\circ} 21'$.

SKERIVORE ISLES, a cluster of small islands, belonging to the Hebrides, Scotland; situated about 40 miles westward from the point of Mull.

SKERN, a river of England, in the county of Durham, which runs into the Tees.

SKERPING, a town of Sweden, in Upland; 38 miles N. of Upsal.

SKERRIES, a considerable fishing-town on the east coast of Ireland, in the county of Dublin, near which are several seats and villas. Opposite to it are some rocks, called Skerries, from which much kelp is procured. There are other islands of the same name off the coast of the county of Antrim, near Portrush.

SKERRIES, *The, or The Skerry Isles*, a cluster of small islands, situated to the eastward of the Mainland of the Shetland isles, to which they belong. The principal of them, and the only ones uninhabited, are Bruray, Grunay, and Houfay, which united contain about a hundred inhabitants, who are chiefly employed in fishing. These islands afford good anchorage for small vessels; but the want of a light-house renders the navigation in their vicinity very dangerous, and has been the occasion of many melancholy shipwrecks. Carlisle's Topographical Dictionary of Scotland, 4to. 1813. Sinclair's Statistical Account of Scotland, vol. vi. 8vo. 1794.

SKERRIES, *Isle of*, a small island, included in the parish of Llan Fair yn Ghorwy, cwmwd of Tâl-y-bolion, canttraef of Cemmaes, (now called the hundred of Tâl-y-bolion,) and county of Anglesea, North Wales, is situated at the distance of a mile and a half from the Mainland, and affords pasturage for a few sheep. The fossil stone called *asbestos*, is found here in great abundance; and at one extremity of the island is an excellent light-house, which is highly serviceable to vessels navigating between Ireland and the ports of Chester and Liverpool. The Welsh call this island Ynys y Mael Rhoniaid, *i. e.* the Isle of Seals. Carlisle's Topographical Dictionary of Wales, 4to. 1811.

SKERSTA, a town of Sweden, in Smaland; 10 miles N.N.E. of Jonkioping.

SKESMO, a town of Norway, in the province of Christiania; 14 miles E.N.E. of Christiania.

SKETHYE, a river of North Wales, in the county of Merioneth, which runs into the Irish sea, 3 miles N.N.W. of Barmouth.

SKEUDITZ. See SCHKEUDITZ.

SKEVERI, a town of Hindoostan, in Vissapour; 10 miles S.W. of Raibaug.

SKEW, or SKILE, *Facets*, among *Jewellers*. See FACETS.

SKEWRING CHBESE, in *Agriculture*, the practice of thrusting strong iron-wire skewers into cheeses, in order to draw off and discharge the whey from them. The skewers for this use are mostly about eighteen or twenty inches in length. See DAIRYING.

SKEYL, provincially to lean on one side, or throw up, as in unloading a cart.

SKEYL-Beast, in *Rural Economy*, provincially the partition of cattle-stalls.

SKEYLD, provincially parti-coloured, as geese, ducks, &c.; or shelled.

SKIALFAND'EFIORD, in *Geography*, a river of Iceland, which receives the waters of a large and rapid river called the Skialfandefiot, and also a river called Laxaa, which flows from the lake Myoatn. Husavik, a commercial station, lies on this river, N.E. of Eyafjord. Here is no good fishing; but many seals are caught during winter. Eider-ducks are very abundant on the coast.

SKIATIC STAY, in *Rigging*, a contrivance for hoisting and lowering burdens out of or in ships, which clinches or makes fast with two half-hitches, and the ends stopt, round the heads of the main and fore-masts, with a tackle depending from it over the hatchway.

SKIATO, in *Geography*, one of the Grecian islands, nearest to the coast of Greece, separated from the island of Scopoli only by a channel of about two leagues, and from the main land by one not much wider. Anchorages, rather numerous and safe, are to be found along the east coast, and between the small islets which are on the same side. To this circumstance the advantages of this little island are nearly reduced.

SKIBBEREEN,

SKIBBEREEN, a post-town of the county of Cork, Ireland, formerly called Stapletown. It is situated on the south side of the river Ilen, which flows into Baltimore harbour. This river is navigable nearly from Skibbereen for lighters; yet the trade is chiefly carried on by land-carriage, because the general prevalence of westerly winds renders the communication by sea always uncertain, and often tedious. Skibbereen, says Mr. Townsend, without patronage or encouragement, has, from the mere circumstance of its situation, become populous, thriving, and wealthy. At its markets and fairs, besides the other usual articles of merchandize, very large quantities of coarse linens and yarn are exposed to sale. The town is, notwithstanding, ill built, with a number of wretched cabins, and very dirty. It is 160 miles S.W. from Dublin, and 38 W. by S. from Cork. Townsend's Statistical Survey.

SKJCIE, a town of European Turkey, in Moldavia; 40 miles W. of Jally.

SKID, in *Rural Economy*, a term applied to the chain by which the wheel of a waggon is fastened, so as to prevent its turning round, upon descending a steep hill. See **DRAG**.

SKID-Beams, in *Ship-Building*, are the beams in the waist, which connect the fore-castle with the quarter-deck.

SKIDS, *Boat*, square pieces of timber bolted one on each side, and projecting over the stern, with sheaves in their outer ends to hoist the boat up. Boat-skids over the quarters are fixed at the heel, and suspended by a lift at the head; the latter of iron lately in the navy.

SKIDS, *Whale*, are long square pieces of timber, projecting from the sides of Greenland ships, for the convenience of hoisting and canting the whale out of the water.

SKIDDAW, in *Geography*, a mountain of Cumberland, England, is remarkable as being classed among the greatest eminences of the island. It is also distinguished for its romantic and grand scenery, as well as for the lakes in its different hollows, and near its base. Maurice, in his poem of "Netherby," thus characterises this august mountain:

"There, tow'ring Skiddaw, wrapt in awful shade,
Monarch of mountains, rears his mighty head;
Dark'ning with frowns fair Keswick's beauteous vale,
He views beneath the gathering tempests fail,
Secure, nor heeds the rolling thunder's rage,
Though Schruffel, trembling, marks the dire preface."

According to the trigonometrical survey, by colonel Mudge and his assistants, it is stated that the highest point of Skiddaw is 3022 feet above the level of the sea. Seafell, in the same county, is 3166 feet in height. Like the generality of mountains in this part of the kingdom, Skiddaw consists of numerous inequalities; deep hollows, and bold crags; irregular fissures, and gentle slopes. Its surface also presents a variety of substances, colours, and forms. In some places are vast masses of bare rock; in other parts, a soft short grass presents itself; and in others are heath, furze, and brambles. Wildness and grandeur are the general features. Mrs. Radcliffe gives a very interesting description of different parts of this mountain, in her "Journey through Holland," &c. 2 vols. 8vo. 1795. Other accounts are given in the following works: Hutchinson's *Excursion to the Lakes*, 8vo. 1776; *Well's Guide to the Lakes*, 8vo. 1802; Gilpin's *Observations and Remarks chiefly to picturesque Beauty on the Mountains and Lakes of Cumberland and Westmoreland*, 2 vols. 8vo. 1786.

SKIERENDAL, a town of Norway, in the province of Aggerhuus; 20 miles N.W. of Chriftiania.

SKIERN, a river of Denmark, which runs into the sea, 12 miles S. of Ringkiobing.

SKIFF, a boat much used in the river Thames. It differs from a wherry by being shorter and broader in proportion, and having a transom aft.

SKIFFI, in *Geography*, a small island in the Grecian Archipelago. N. lat. 38° 44'. E. long. 24° 13'.

SKILJI, a town of Asiatic Turkey, in Natolia; 48 miles E.N.E. of Constantinople.

SKILLING, in *Rural Economy*, a term signifying an ile, or bay of a barn; also a slight addition to a cot tage.

SKILLINGE, in *Geography*, a town of Sweden, in the province of Blekingen; 4 miles W. of Carlscrona.

SKILLINGS, a river of America, in the district of Maine, which runs into the sea, 4 miles W. of New Bristol.

SKILSKIOER, a sea-port of Denmark, in the island of Zealand, in a bay which communicates with the Great Belt; 48 miles S.W. of Copenhagen. N. lat. 55° 16'. E. long. 11° 27'.

SKILUGRUND, a small island on the east side of the gulf of Bothnia. N. lat. 63° 55'. E. long. 20° 50'.

SKIM-COULTER, in *Agriculture*, a sort of coulter invented by Mr. Duckett, for paring off the surface of coarse grass or other lands, and placing it in the bottom of the furrow, so as to be fully covered and secured. It has been used in different districts with the greatest advantage and success. It is stated in the Agricultural Report of Hertfordshire, that Mr. Biggs, near St. Albans, finds it of excellent effect in clover lays, and also wherever any rubbish is on the land that wants burying, as well as in breaking up old faintoin lays. And it may be beneficially employed on many other occasions.

SKIM-Coulter Plough, that sort of plough which has a skim-coulter of some kind or other attached to it. See **PLOUGH**.

SKIM-Milk, in *Rural Economy*, that sort of milk which is left, after the cream has been taken away or skimmed off from the surface of it. This process is mostly performed by means of a slight thin skimming-dish, after the milk has been set by for some time in shallow vessels, either in its natural state, or when having undergone, in some cases, the operation of scalding. Where the latter practice is followed, though it might at first be reasonably supposed that all the oily unctuous matter of the milk would be brought to the surface, yet it is found by experience that that is not the case; but that, on the contrary, the scalded skimmed-milk is much richer, and better even for the purpose of suckling calves, as well as capable of making far better cheese than the raw skimmed-milk. In Devonshire, the scalded skim or skimmed-milk is estimated at the value of a penny farthing the quart, either for the use of cheese-making, or that of feeding hogs.

The skim-milk in the county of Essex, as well as in many others, especially those more towards the north, is converted to the purpose of keeping and fattening porkers, and that of being disposed of, at the rate of about three-pence or four-pence the gallon, to the lower classes of the people; or that of taking in pigs to keep, at the price of about from three shillings and sixpence to four shillings and sixpence the week. A hog has been known to be fattened, in the above named district, in this way, to the weight of sixty-six stone, without the offal, at eight pounds to the stone, skim-milk only being given for the purpose.

In other districts, the farmers rear and bring up their calves, and keep their own hogs, on this sort of milk, as
well

well as prepare cheese from it, finding these the most profitable applications of it.

The result of a number of trials has shewn, that in forming skim-milk, about ten ounces of butter is taken from twelve pints of milk, under the scalding practice. See DAIRYING.

SKIM-Milk Cheese, that sort of cheese which is made from skim or skimmed-milk. It is mostly a poor inferior sort of cheese, though much of it is made in different districts of the kingdom. It is, however, frequently a practice to take away the cream from only a certain portion of the milk that is intended for cheese, as that of the night meal, &c. In Devonshire, when cheese is to be made, much care is taken that the milk be not heated so far as to produce bubbles under the cream, which is first to be taken off from it, or when it is to be used with it.

SKIMMER, in *Ornithology*. See RYNCHOPS.

SKIMMIA, in *Botany*, a name adopted by Kämpfer from its Japanese vernacular appellation, *Mijanea Skimmi*.—Kämpf. Amœn. fasc. 5. 779. Thunb. Nov. Gen. 57. Fl. Japon. 4. Schreb. 81. Willd. Sp. Pl. v. 1. 671. Mart. Mill. Dict. v. 4. Jusl. 425.—Class and order, *Tetrاندria Monogynia*. Nat. Ord. *Plantæ incertæ sedis*; Jusl.

Gen. Ch. Cal. Perianth inferior, of one leaf, very small, permanent, cloven nearly to the base into four, ovate, acute segments. Cor. Petals four, ovate, concave, minute. Stam. Filaments four, very short; anthers Pist. Germen superior, roundish; style solitary; stigma Peric. Berry ovate, umbilicated, slightly furrowed, smooth, full of mealy pulp, and splitting imperfectly into four parts. Seeds four, nearly triangular or convex externally, oblong, white.

Obf. The Perianth is occasionally cloven into five segments.

Eff. Ch. Petals four, concave. Calyx four-cleft. Berry with four seeds.

1. *S. japonica*. Japanese Skimmia. Thunb. Japon. 6a. Kämpf. Ic. Select. t. 5.—Native of Japan, near Nagasaki, ripening its fruit in December. Stem shrubby, erect, smooth. Branches alternate, nearly square. Leaves at the summits of the branches, alternate, stalked, numerous, oblong, undulated, entire, slightly notched towards the tip, erect, about a finger's length, with a reflexed margin; green and rugose above; pale and dotted beneath. Footstalks convex beneath, flat above, thickish, short. Flowers white, on round, thickened stalks, in terminal panicles.

The foliage is evergreen, and has an aromatic flavour.

SKIMMING-DISH, in *Rural Economy*, that sort of light thin-edged dish, which is employed in skimming the cream off the surface of milk, in the practice of the dairy. Dishes of this kind are made either of hard wood or tin, being formed in a nice, thin, light manner, with fine sharp edges. See DAIRYING.

SKIMMING-Spade, in *Agriculture*, that sort of sharp-mouthed spade which is employed in skimming or paring off the grassy surface, or sward of land, which is intended to be burnt. See PARING and BURNING.

SKIN, in *Anatomy*, a large thick membrane, spread over the whole body, serving as the external organ of feeling, and as a covering and ornament of the parts underneath. See INTEGUMENTS.

SKIN, Diseases of the. See CUTANEOUS Diseases; where an outline of the classification of these maladies, devised by the late ingenious Dr. Willan, by whom the pathology of these neglected and undistinguished disorders has been greatly elucidated, will be found. For more particular information, consult the articles LEPROSY, LICHEN, PSORIASIS, POR-

RIGO, HERPES, &c. and Dr. Bateman's Pract. Synopsis of Cutaneous Diseases, according to the arrangement of Dr. Willan.

SKIN, in *Rural Economy*, the hide of an animal. The refuse and waste of it which are caused by the different manufactures, and which arise in the various purposes to which it is applied, are capable of forming very useful manures, when they are in any suitable quantity; such as the chips of the shoemaker, the dressings and trimmings of the currier, the clippings of the farrier, and the waste offal matters of the tan-yard as well as the glue manufactory.

It has been suggested by the writer of the work on "Agricultural Chemistry," that the gelatine which is contained in every kind of skin is in a state fitted for its gradual solution or decomposition; and that when buried in the soil, it lasts or continues for a considerable time, and constantly yields a supply of nutritious matter to the plants, which are placed within the neighbouring range of its action. All waste matters of this nature should therefore be carefully preserved for the purpose of being applied as manures.

SKIN, in *Commerce*, is particularly used for this membrane stripped off the animal, to be prepared by the tanner, skinner, currier, parchment-maker, &c. and converted into leather, &c.

The use of skins is very ancient; the first garments in the world having been made of them. The Danes and other northern nations have a long time dressed themselves in skins. Moroccos are made of the skins of a kind of goats. (See MOROCCO.) Parchment is usually made of sheep-skins; sometimes of goat-skins. (See PARCHMENT.) Velum is a kind of parchment made of the skin of an abortive calf, or at least of a sucking calf. (See VELUM.) The true shammy is made of the skin of an animal of the same name; though frequently it is counterfeited with common goats' and sheep-skins. See SHAMMY.

The Indians in Carolina and Virginia dress buck and doe-skin in this manner: the felt being taken off, they strain them, with lines or otherwise, much like the clothiers' racks, in order only to dry them. When the hunting time is over, the women dress the skins, by putting them in a pond or hole of water, to soak them well; then with an old knife, fixed in a cleft stick, they force off the hair whilst they remain wet. This done, they put them into a kettle, or earthen-pot, and a proportion of deer's brains, dried and preserved for this purpose, is put along with them; this vessel is set on the fire till they are more than blood-warm, which will make them lather and scour clean; after this, with small flicks, they wrest and twist each skin, as long as they find any wet to drop from them, letting them remain so wrested for some hours, and then they untwist and stretch each of them in a sort of rack, so that every part is extended, and as the skin dries, they take a dull hatchet, or some such instrument, and rub them well over to force all the water and grease out of them, till they become perfectly dry, and then their work is done.

In this manner one woman (for the men never employ themselves in this work) will dress eight or ten skins in a day, that is, begin and finish them. Phil. Transf. No. 194. See BUFF.

For the manner of preparing shagreen, see SHAGREEN.

SKINS, lacquering and gilding. See LACQUER.

SKINK. See SCINCUS.

SKINKER, a cup-bearer, or butler. See ARCH Butler.

SKINNER, STEPHEN, in *Biography*, an antiquary, was born about the year 1622, in or near London. He received his academical education at Christ-church college, Oxford, in the year 1638, but the civil war caused him to leave the university

verfity without taking a degree. He thence travelled on the continent, and ftudied at various univerfities. On his return to his native country, he went to Oxford, and took his degree in arts, and then fettled as a phyfician at Lincoln, where he died in 1667. He was a man of very extenfive erudition, but is chiefly known by his works in etymology, which, after his death, came into the hands of Mr. Thomas Henshaw, who digefted, corrected, and enlarged them, and publifhed them in 1671, with the title of “*Etymologicon Linguae Anglicanae* ;” a work that has always been confidered as of high authority among the learned, and is ftill regarded as a moft ufeul book of reference.

SKINNERA, in *Botany*, Forft. Gen. t. 29, was fo named in honour of Mr. Skinner, an Oxford gentleman, whom Forfter terms “a moft acute and clear-fighted botanift,” but we have met with no record of him elfewhere ; and the genus thus denominated is in no refpect different from **FUCHSIA** ; fee that article. By the fpecific name, *excorticata*, the author feems to have had a punning allufion in his mind.

SKINNERS, *Company of*. See **COMPANY**.

SKINNING, in *Ship-Building*, a term often ufed for planking the bottom.

SKINOSA, in *Geography*, a defart ifland, or rather rock, in the Grecian Archipelago, about 12 miles in circumference ; 5 miles S. from the ifland of Naxia. N. lat. 36° 55'. E. long. 25° 32'.

SKINSKATTEBERG, a town of Sweden, in Weftmanland ; 25 miles N.N.W. of Stroemfholm.

SKINTEL, a town of European Turkey, in Moldavia ; 10 miles S. of Jaffi.

SKINUS, *σκινος*, a name given by the ancient naturalifts to the lentil-tree, and alfo to a peculiar fpecies of the fquill, or feilla, which was not naufeous and emetic as the common fquill, but efulent and pleafant to the tafte.

SKIOLDS, in *Geography*, a town of Norway, in the province of Bergen ; 32 miles N. of Stavanger.

SKION, a town of Sweden, in Medelpadia, near the coaft of the gulf of Bothnia. The church was formerly a cattle, and the fteeple is full of loop-holes for arms ; 30 miles S. of Hernofand.

SKIPNESS POINT, a cape of Scotland, on the E. coaft of Kintyre, with a village called Skipnefs ; 22 miles N. of Cambletown. N. lat. 55° 49'. W. long. 5° 24'.

SKIPPACH CREEK, a creek of America, in the Delaware, where general Washington was encamped before the battle of German Town, in the county of Montgomery.

SKIPPACK, a townfhip of Pennsylvania ; 20 miles N. of Philadelphia. Shippack and Perkiomen contain 902 inhabitants.

SKIPPER. See **SHIPPER**.

SKIPPER, an Englifh name for the common gar-fifh. See **ACUS**.

SKIPPON, in *Geography*, a river of England, in the county of Lancafter, which runs into the Wyre.

SKIPSILAR, a town of European Turkey, in Romania ; 72 miles E. of Emboli.

SKIPTON, or *Skipton in Craven*, a market-town in the eaft divifion of the wapentake of Staincliffe and Ewcrofs, Weft Riding of the county of York, England, is fituated at the diftance of 48 miles W. by S. from the city of York, and 216 miles N.N.W. from London. This town, which previoufly was a poor place, has, fince the inclofure of Knareborough foreft, become the chief mart for the diftrict of Craven. The market-day is Saturday, weekly ; when there is always a large fupply of different forts of grain, which is thence difperfed throughout Craven, and the ma-

nufacturing country in the north-eaft part of Lancafhire. Brown, in his Agricultural Survey of the Weft Riding of the County, affirms that upwards of two hundred carts regularly attend this market. The fairs here are numerous, *viz.* on the firft Saturday after old Twelfth-day, the 13th of March, the Saturday before Palm-Sunday, the Tuefday in Eafter-week, and every other Tuefday till Whitfuntide, chiefly for lean cattle ; Saturday before Whitfun-eve, and Saturday before Trinity Sunday, old St. James, old Martinmas, befides fortnight fairs every other Tuefday throughout the year for fat cattle, fheep, &c.

Skipton ftands clofe to the Leeds and Liverpool canal, a circumftance which greatly facilitates its trade. It confifts chiefly of one very wide and long ftreet, where the markets are held, with feveral ftaggling lanes on each fide of it. The church, which is fituated at one extremity of the main ftreet, is a fpacious ftructure, with a tower at the weft end, which appears, from an infcription thereon, to have been rebuilt, in 1655, by the celebrated Ann Clifford, countefs of Dorfet, Pembroke, and Montgomery. Here are infcriptions, on plain ftones, in memory of the three firft earls of Cumberland.

Skipton caftle ftands at a fhort diftance to the eaftward of the church, and on the left fide of the road leading to Knareborough. This ancient ftructure is faid to have been originally erected foon after the Conqueft by Robert de Romeli, then lord of the honour of Skipton, whofe daughter and heirs carried it by marriage to William Fitz-Duncan, earl of Murray. From his family it paffed in the fame manner to William le Gros, earl of Albemarle, and afterwards fucceffively to William de Mandeville, earl of Effex, to Baldwin de Betun, and to William de Fortibus. In the reign of Richard I. Avelin, daughter to the fecond William de Fortibus, a minor, fucceeded, and became ward to king Henry III., who, in 1269, gave her in marriage to his fon Edmund, earl of Lancafter. On the forfeiture of her fon, earl Thomas, for rebellion againft king Edward II. the caftle was granted, in 1309, to Robert de Clifford, a Herefordfhire baron, whofe defcendants, earls of Cumberland, continued to enjoy it till the early part of the feventeenth century, when it devolved to Richard Sacville, earl of Dorfet, by his marriage with Ann Clifford, the diftinguifhed lady above-mentioned. By her daughter and heirs, Margaret, it was conveyed to John Tufton, fecond earl of Thanet, in whofe family it yet remains.

Skipton caftle, though apparently little calculated for defence againft the engines of modern warfare, appears to have been of confiderable importance during the civil wars between king Charles and his parliament. It was firft garrifoned in the royal caufe, and is faid to have held the furrrounding country for fome time in great awe. At length, however, it was vigorously befieged by a detachment of the parliamentary army, to whom it furrendered upon honourable terms on the 20th of December, 1645. In the following year, its works and defences were deftroyed by order of parliament. Lady Clifford, after the death of her fecond husband, the earl of Pembroke, repaired this caftle, in which fhe was born, and made it occasionally the place of her refidence. Though not much elevated above the furrrounding country, it nevertheless commands a pleafing view over the town and vale of Skipton, which is one of the fineft and moft fertile in England, extending about twelve miles in length, and from one and a half to two miles in breadth. It contains little tillage, but difplays the moft luxuriant meadows and paitures that can any where be feen.

Skipton, according to the parliamentary returns for 1811, contains 609 houfes, and 2868 inhabitants. The parifh is

of great extent, and is partly comprehended in Claro water-pentake. Beauties of England and Wales, vol. xvi. by John Bigland, 1812. Pennant's Tour in Scotland, 4to. 1790. Whitaker's History, &c. of Craven, 4to. 1805.

SKIPTON, a town of America, in Maryland, on the Potomack; 11 miles S.E. of Fort Cumberland.

SKIRINGLASS, a small island near the W. coast of Scotland. N. lat. 58° 2'. W. long. 5° 10'.

SKIRINTARSAN, a small island near the E. coast of Skye. N. lat. 57° 19'. W. long. 5° 33'.

SKIRKY, a cluster of small islands in Kenmare river, on the S.E. coast of Kerry; 5 miles E. of Lamb's Head.

SKIRMISH, in *War*, a disorderly kind of combat, or encounter, in presence of two armies, between small parties, or persons, who advance from the body for that purpose, and introduce to a general, regular fight.

The word seems formed from the French, *escarmouche*, which signifies the fame, and which Nicod derives from the Greek *χαρμν*, which signifies, at the same time, both *light*, *combat*, and *joy*. Menage derives it from the German, *schirmen* or *shermen*, to fence or defend: Du Cange, from *scarramuccia*, a light engagement, of *scara* and *muccia*, a body of soldiers hid in ambush; in regard many skirmishes are performed by persons in ambushade.

SKIRMISH Bay, in *Geography*, a bay on the E. coast of Chatham island, so called from an unhappy dispute between captain Vancouver's crew and the natives. S. lat. 43° 49'. E. long. 183° 25'.

SKIRO. See SCIRO.

SKIRRET, in *Botany*. See SRUM.

SKIRRID VAWR, or *Great Skirrid*, in *Geography*, a mountain of Wales, in the county of Monmouth; 2 miles N. of Abergavenny.

SKIRRIES, a rock in the North sea, near the E. coast of Scotland; 2 miles S. of Peterhead.

SKIRTING, in *Agriculture*, a mode of performing the business of sod-burning. See *SOD-BURNING*.

SKIT, in *Geography*, a town of Walachia, on the Ribnik; 80 miles N. of Bucharest.

SKITTIKISS, a bay on the E. side of Washington's islands, near the W. coast of North America.

SKITTISH, in the *Manege*. A horse is said to be skittish, in French *écouteux*, or *retenu*, that leaps instead of going forward; that does not set out, or part from the hand freely, nor employ himself as he ought to do.

SKIVE, in *Geography*, a town of Denmark, in North Jutland; 15 miles N.W. of Viborg. N. lat. 56° 34'. E. long. 9° 1'.

SKLENO, or *Glass Huts*, a town of Hungary, celebrated for its warm baths; 5 miles N. of Cremnitz.

SKOBELEKA, a town of Russia, in the government of Irkutsk; 48 miles S.S.W. of Kirensk.

SKODNY, a town of Silesia, in the principality of Oppereln, in which is a royal foundery for the casting of bombs; 10 miles S. of Oppereln.

SKOFDE, a town of Sweden, in West Gothland; 62 miles E. of Uddevalla.

SKOG, a town of Sweden, in the province of Helsingland; 34 miles W.N.W. of Hudwickswall.—Also, a town of Sweden, in Angermanland, on a lake; 20 miles N. of Hernofand.

SKOKHAM, *Isle of*, a small island situated in St. George's Channel, at the distance of five miles from St. Anne's Head, in Pembrokeshire, South Wales. It contains 200 acres, 2 roads and 2 poles of ground, and is the property of John Lloyd of Mabus, esq. Its products are barley,

oats, rye-grass, and rabbits. Fenton's Tour in Pembrokeshire, 4to. 1810.

SKOKI, a town of the duchy of Warfaw; 18 miles N. of Pofen.

SKOLEN, or SCHOLEN, a town of Saxony, in Thuringia; 8 miles S. of Naumburg.

SKOLOMISI, a town of Poland; 25 miles N.E. of Cracow.

SKOLOSCHIA, a town of Russia, in the government of Irkutsk; 44 miles N.E. of Kirensk.

SKOMAR, *Isle of*, a small island situated on the south side of St. Bride's bay, off the coast of Pembrokeshire, North Wales. It is divided from the Mainland by a narrow strait, called Jack's Sound. This isle contains 700 acres of land, a large portion of which is under cultivation, and is most prolific in rabbits, 2000 couple being killed annually for sale. It is the property of Charles Phillips, esq. of St. Bride's Hill. Fenton's Tour in Pembrokeshire, 4to. 1810. Carlisle's Topographical Dictionary of Wales, 4to. 1811.

SKOMPE, a town of the duchy of Warfaw; 16 miles N.E. of Wladislaw.

SKON, a town of Sweden, in the province of Medelpadia; 3 miles N. of Hernofand.

SKONE. See SCHONEN.

SKONGEN, a town of Norway, on the coast of Drontheim bay; 26 miles N.N.E. of Drontheim.

SKOPIA, or USKUP, a town of European Turkey, in Macedonia, on the river Varda, the see of an archbishop; 54 miles N. of Akrida. N. lat. 42° 40'. E. long. 21° 2'.

SKOPIN, a town of Russia, in the government of Riazan; 44 miles S. of Riazan. N. lat. 54°. E. long. 39° 14'.

SKORBY, a town of Sweden, in Schonen; 22 miles S.E. of Lund.

SKOTGRUND, a small island on the east side of the gulf of Bothnia. N. lat. 62° 17'. E. long. 21° 3'.—Also, a small island on the west side of the gulf of Bothnia. N. lat. 60° 39'. E. long. 17° 28'.

SKOTSCHAU, SCHOLSCH, or SKOZOW, a town of Silesia, in the principality of Teschen; 7 miles E.N.E. of Teschen. N. lat. 49° 47'. E. long. 18° 45'.

SKOVES, in *Agriculture*, provincially reaps, shoves, grips, or bundles of unbound up grain; also unbound sheaves of corn.

SKOUT, in *Ornithology*. See LOMWIA.

SKRABBA, in *Ichthyology*, a name given by some to a fish, called by Jonston and Schoneveldt the *scorpius marinus*, but wholly different from the *scorpana* of other authors. See FATHER-LASHER.

SKREED, in *Agriculture*, provincially a border or narrow slip of land.

SKREEN. See SCREEN.

SKREY, in *Geography*, a town of Bohemia, in the circle of Rakonitz; 8 miles S. of Rakonitz.

SKRUBBAN, a small island on the W. side of the gulf of Bothnia. N. lat. 63° 8'. E. long. 18° 34'.

SKRYNE, a small town of the county of Meath, Ireland, which received its name from being supposed to contain the shrine (*scrinium*) of St. Columba. There were a castle and two abbeys here, of which some ruins remain. Skryne is 19½ miles N. by W. from Dublin.

SKRZIWANE, a town of Bohemia, in the circle of Rakonitz; 4 miles S. of Rakonitz.

SKUA, in *Ornithology*. See CATARACTA.

This bird inhabits Norway, the Feroe isles, Shetland, and the noted rock Foula, a little west of them. It is also a native of the South sea. It is the most formidable gull; its prey being not only fish, but the lesser sorts of water-fowl,

fowl, as teal, &c. and it is also said to prey on ducks, poultry, and even young lambs; it has all the fierceness of the eagle in defending its young; when the inhabitants of the Ferro islands visit the nest, it attacks them with great force, so that they hold a knife erect over their heads, on which the skua will transfix itself in its fall on the invaders. In Foula it is a privileged bird, because it defends the flocks from the eagle, which it beats and pierces with great fury; and the natives impose a fine on any person who destroys one of these birds. Pennant.

SKUFE, in *Agriculture*, provincially a precipice or declivity.

SKULA, in *Geography*, a mountain of Sweden, in Angermanland; 10 miles N. of Hernofand.

SKULL, in *Anatomy*. See CRANIUM.

SKULL, *Injuries of the, &c.* See INJURIES of the Head.

SKULL-Cap, in *Botany*. See SCUTELLARIA.

SKULL-Cap, *Blue*, in *Agriculture*, the common name of a weed which is often found troublesome on wet boggy grounds, or near the sides of ponds. It is perennial in its growth, and of course more difficult in its removal from land. There is also a lesser sort, which has the same nature and habits of growth. They should both be eradicated from out of the land as much as possible.

SKUNK, in *Zoology*. See AMERICAN POLE-Cat.

SKUOE, in *Geography*. See SCUOE.

SKUOPING, a lake of North Carolina. N. lat. $35^{\circ}45'$. W. long. $76^{\circ}42'$.

SKUPPERNONG, a river of North Carolina, which communicates by means of a canal with the lake in Dismal Swamp.

SKURUP, a town of Sweden, in Schonen; 16 miles S.E. of Lund.

SKUSCH, a town of Bohemia, in the circle of Chrudim; 8 miles S.E. of Chrudim.

SKUTERAD, a town of Norway, in Aggerhuus; 22 miles W. of Christiania.

SKUTTOCK HILLS, five eminences in Hancock county, on the coast of Maine, that serve as landmarks for sailing into Gouldsborough harbour.

SKWERNIOW, a town of Bohemia, in the circle of Kaurzim; 6 miles S. of Kaurzim.

SKWORETZ, a town of Bohemia, in the circle of Kaurzim; 12 miles W.N.W. of Kaurzim.

SKY, the blue expanse of air or atmosphere.

The azure colour of the sky fir Isaac Newton attributes to vapours beginning to condense therein, which have got consistence enough to reflect the most reflexible rays, *viz.* the violent ones; but not enough to reflect any of the less reflexible ones.

M. de la Hire attributes it to our viewing a black object, *viz.* the dark space beyond the regions of the atmosphere, through a white or lucid one, *viz.* the air illumined by the sun; a mixture of black and white always appearing blue. But this account is not originally his; it is as old as Leonardo da Vinci. See BLUENESS and COLOUR of the Clouds.

SKY-Colour. To give this colour to glass, set in the furnace a pot of pure metal of frit from rochetta, or barilla, but the rochetta frit does best; as soon as the metal is well purified, take for a pot of twenty pounds of metal six ounces of brass calcined by itself; put it by degrees, at two or three times, into the metal, stirring and mixing it well every time, and diligently scumming the metal with a ladle; at the end of two hours the whole will be well mixed, and a proof may be taken; if the colour be found right, let the whole stand twenty-four hours longer in the furnace, and it will then be fit

to work, and will prove of a most beautiful sky-colour. Neri's Art of Glass, p. 40.

SKY-Flower, in *Botany*. See CINERARIA.

SKY-Rocket. See ROCKET.

SKYE, in *Geography*, one of the Hebrides, or Western islands of Scotland, is situated off the coast of Inverness and Ross-shires, from which it is separated by the found of Skye, and a branch of the sea called Lochalsh, while the Minch channel divides it from Long island. From the Point of Sleat in the south-east, to the Aird of Trotternish in the north-west, it extends 45 miles in length, but its breadth varies from 10 to 24 miles. The whole contents, measured carefully from Arrowsmith's map, are stated in the General Report of Scotland to amount to 535 square miles, including 336,000 acres of land, and 10 square miles of fresh-water lakes. From the numerous indentations of the sea, no part of the land is farther distant from salt-water than four miles and a half.

The general aspect of this island is extremely mountainous, so much so indeed, that not above twelve parts in a hundred of it are susceptible of arable cultivation; and even these are disposed in small patches or strips by the margin of the different bays, except at its north-westerly extremity, where, for four miles, the land is flat, the soil fertile and well cultivated, and the farms inclosed and divided. But notwithstanding this great proportion of mountain, Skye is far from being sterile or barren. On the contrary, its hills, so widely extended, and towering so proudly to the skies, are in general of considerable value, from the excellent pasture with which they abound. This is particularly the case in the central and southerly districts, where the hills of Cullin, resting on a bed of limestone, produce very rich herbage, on which are fed a remnant of the ancient herds of deer, for which this island was formerly famed, and which continue still to roam at large on these verdant heights. Most of the hills, in remote times, were clothed with wood; but except on the south coast of Sleat, scarcely any forest-timber now remains in Skye. Here, however, are still some good flocks of natural wood, consisting of oak, ash, elm, and birch, besides alder and willow.

The crops cultivated in this island are beans, oats, potatoes, and some flax. Artificial grasses and turnips are little known; but they are partially introduced, and it seems probable will soon become more extensive, as they are so very essential to the welfare of cattle, which are the staple commodity of the island. In the gardens and "kail yards," most of the esculent vegetables cultivated on the Mainland are raised with great success, as are also the smaller fruits.

The live-stock of Skye is estimated at 4000 horses, of a small but hardy race; 18,000 head of cattle of an excellent breed, of which about 3800 are exported annually, forming the principal export of the island. The sheep are computed at about 40,000 in number; but this computation is confessed by the reporter to the Board of Agriculture to be little more than conjecture. They consist partly of the native yellow-faced kind, partly of Cheviots, and partly of the black-faced Lintons, which are the most esteemed. Several thousands of this useful animal are exported every year. Hogs, goats, and rabbits abound here, but they are all of them so wild, and so little under controul, as to afford no permanent source of revenue. Game of all kinds is abundant, but is thought to decline more and more, in proportion as the country is progressively cultivated. There are on the island two kinds of serpents or vipers, both of which are reckoned very venomous.

In the surrounding seas, which embrace 750 miles of coast,

there are myriads of fish, particularly herring, mackarel, turbot, skate, ling, cod; and shell-fish, such as oysters, lobsters, &c.; so that combining the situation with other facilities, the inhabitants of Skye have an opportunity of enriching themselves by the fisheries, beyond any other islanders in Scotland, and in fact they apply themselves to them with considerable industry, and frequently with great effect. Sometimes, however, they are miserably tantalized with a profusion of fish, when they cannot procure an ounce of salt to cure them, owing to the distance from the custom-house, and to the complicated salt-duty regulations, which shut them up completely from either bettering their own circumstances, or promoting the general prosperity of the nation by this otherwise abundant bounty of providence.

Kelp is made annually to the extent of 500 tons; and the manufacture of this article is capable of being greatly increased, to the no small emolument of the natives, as well as to the increase of proprietors' rents.

The want of good roads has hitherto greatly retarded the internal prosperity of Skye, from the difficulty of conveyance, and this disadvantage does not admit of being easily removed; not merely from the inequality of the surface, but from the circumstance of its being so much cut up by brooks and rivulets, which, on every shower, swell into torrents that would require a great number of bridges.

The number of inhabitants in Skye, which, notwithstanding continued emigration, is still increasing, was 17,775 in 1809, the time when the last census was made; being at the rate of 33 to the square mile, reckoning the whole island, or 275 to the same extent, limiting the estimate to the cultivated land only. It has been for many ages, and still is, the property of the great clans, Macdonald, Macleod, and, till of late, Mackinnon. From the first of these has lately sprung up the kindred clan of Macalister. The people, ingenious, shrewd, and active, are nearly all of the established church of Scotland. Among them reside a number of gentlemen, who have been in the army or navy, cadets of the chief families, whose manners have given a polish to those of the inhabitants at large, which is observable in the behaviour even of the lowest peasant. In fact, every man in Skye seems to be a gentleman; whilst the demeanour of the females exhibits an ease and an affability that no person could expect in a country so remote, and having so little communication with strangers. Mr. Macdonald, in his Survey, justly observes, that "it is in truth a singular island, well deserving the attention of the geologist and natural historian, and capable, by nature, of one day astonishing the patriot and political economist."

The General Report, &c. of Scotland, drawn up under the directions of sir John Sinclair, bart. 8vo. 1814. Husbandry of Scotland, by sir John Sinclair, 8vo. 1815. Johnson's Journey to the Western Islands of Scotland, 8vo. 1775. Martin's Description of the Western Islands, 8vo. 1716. Account of the present State of the Hebrides, by James Anderson, L.L.D. 8vo. 1787. Macdonald's Survey of the Hebrides, 8vo. 1807.

SKYRO. See SCIRO.

SKYTTE, JOHN, in *Biography*, was born at Nyköping in 1577. After being some time secretary in the Swedish chancery, he was chosen by the states to be preceptor to prince Gustavus Adolphus, and at the same time by king Charles to superintend the education of John, duke of Oltrogothia, who was five years older than Gustavus. It was, therefore, considered as a master-piece of policy in the king, that he placed the crown-prince and the pretender to the throne under the inspection of so faithful and trusty an instructor. In 1622 he was made chancellor of the academy

of Upsal, and in 1629 governor-general of Ingria, Livonia, and Carelia. He was held in high estimation by the learned of his time, and acquired great celebrity on account of his eloquence, and was employed either as envoy or ambassador to many foreign courts. Gustavus Adolphus entertained for him the highest respect, and in 1624 the rank of baron was conferred on him. He was a great patron of literature, and rendered essential service to the academy of Upsal, by founding a professorship for the cultivation of the Latin language, literary criticism, and the political sciences. As a politician, he was a determined enemy of the aristocracy, and laboured with great zeal to establish royal authority. He died in 1645. Among his works was one, of which the following was the title; "Brief Instructions in regard to the Virtues and Arts which a Prince, who wishes to rule happily over his Kingdom and States, ought to exercise and employ; addressed to that exalted Lord and Prince Gustavus Adolphus."

SKYTTE, BENEDICT, son of the preceding, was born in 1614, and studied at Upsal. In 1629 he accompanied the Swedish ambassador, general Spence, to England, where, on taking his leave, he was knighted by king Charles I. After this he continued his studies at Dorpat, and travelled for his improvement, during which queen Christiana gave him a place in her household. He bore the marshal's staff at the diet in 1648, was appointed chancellor of the academy of Dorpat, and the year after was sent to Denmark, to be queen Christiana's proxy at the baptism of the princess Sophia Amelia, daughter of Frederic III. He enjoyed for several years the favour of his sovereign, and in 1651, when the queen established the order of the Amaranth, he was nominated one of the knights. Afterwards he fell into disgrace, and was brought to trial, but he made such an able defence that he was acquitted, and all the proceedings against him were annulled. He was restored to his seat as senator, and in 1665 was appointed governor of Esthonia. He was employed on an important mission from king Charles Gustavus to the duke of Courland, and he managed the business so well, that he received the approbation and cordial thanks of his sovereign. In 1663 he was made supreme judge in Ingria, president of the tribunal of Wismar, and at the same time envoy in Germany. But his good fortune again deserted him, he was dismissed from his offices at the diet held in 1664, and declared incapable of ever being employed either at home or abroad. After this he retired to his estate, and spent his time in literary pursuits till his death, in 1683. He was a man of great learning, and made himself known by various works, among which were the following: "Dissertatiuncula de Argumento quod Fœminæ Officium Legati mandari possit," 4to. "Oratio qua probatur Utilitatem pro Justitia, in Administratione Rerum publicarum colendam." Gen. Biog.

SLAA, in *Geography*. See SALLEE.

SLAB, an outside fappy plank or board sawed off from the sides of a timber-tree: the word is also used for a flat piece of marble.

SLABS of Tin, the lesser masses which the workers at the tin-mines call the metal into: these are run into moulds made of itone.

SLAB-Line, in *Sea Language*, a small cord passing up behind a ship's main-sail or fore-sail, and being reeved through a block attached to the lower part of the yard, is then transmitted in two branches to the foot of the sail to which it is fastened.

It is used to truss up the sail as occasion requires, and more particularly for the convenience of the pilot or steersman,

man, that they may look forward beneath it as the ship advances. Falconer.

SLABBERING-BIT, in the *Manege*. See **MASTIGADOUR**.

SLABETZ, in *Geography*, a town of Bohemia, in the circle of Rakonitz; 7 miles S. of Rakonitz.

SLABODA, a town of Poland, in the palatinate of Braclaw; 40 miles N.W. of Braclaw.

SLAB-TOWN, a village of America, in Burlington county, New Jersey, about half-way between Burlington and Mount Holly, and about four or five miles from each.

SLACK, in *Agriculture*, provincially a valley or small shallow dale or dip.

SLACK a Leg, in the *Manege*, called in French *mollir la jambe*, is said of a horse when he trips or stumbles.

SLACK the Hand, is to slack the bridle, or give a horse head.

SLACK-CLOTH, in *Sail-Making*, a certain quantity of cloth allowed to be gradually gathered up, in fewing on the bolt-rope to the sail, more than the length of the bolt-rope; otherwise the rope, by stretching in the wearing, might occasion the sail to split.

SLACKEN, in *Metallurgy*, a term used by the miners to express a spongy and femivitrified substance, which they use to mix with the ores of metals, to prevent their fusion. It is the scoria, or scum, separated from the surface of the former fusions of metals. To this they frequently add a lime-stone, and sometimes a kind of coarse iron-ore, in the running of the poorer gold-ores.

SLACK-WATER, in *Sea Language*, denotes the interval between the flux and reflux of the tide, or between the last of the ebb and the first of the flood, during which the current is interrupted, and the water apparently remains in a state of rest.

SLADE, in *Agriculture*, a term provincially signifying a sledge. See **SLEDGE**.

SLADE Down, a provincial term signifying to draw back part of the mould into the interfurrow with the plough dragging or sliding upon its side.

SLADE Point, in *Geography*, a cape on the N.E. coast of New Hoiland; 15 miles S.E. of Cape Hillsborough.

SLAG, in *Metallurgy*, &c. denotes vitrified cinder. See **SMELTING**.

Slag is found an useful material in repairing the roads in many places.

SLAGE, **SLAGEN**, or *Schlagen*, in *Geography*. See **SCHLAWA**.

SLAGELSE, a town of Denmark, in the island of Zealand; 42 miles W.S.W. of Copenhagen. N. lat. 55° 26'. E. long. 11° 29'.

SLAIGHTWAITE, a township and chapelry in the parish of Huddersfield, in Aylrig wapentake, and West Riding of the county of York, England, is four miles from the town of Huddersfield, and 190 from London. According to the population reports of 1811, this township contained 425 houses and 2277 inhabitants, the greater part of whom are engaged in the manufacture of cotton goods, which is the staple trade of this district.

SLAKE, in *Agriculture*, a term signifying the saturating of quick-lime with moisture, as water, &c.

SLAKED LIME, such as is reduced into a powdery state by the action of water upon it, or the hydrate of lime. In this case, the lime is combined with about one-third of its weight of water, that is, about 55 parts of the former absorb or drink up about 17 parts of the latter. See **LIME**.

SLAM, the refuse of alum-works, which is used as a manure with sea-weed and lime, in Yorkshire.

SLAMMERSDORP, in *Geography*, a town of the duchy of Holstein; 7 miles N.E. of Segeborg.

SLANDER, in *Law*. See **SCANDALUM Magnatum**.

SLANE, in *Geography*, a post-town of the county of Meath, Ireland, situated on the river Boyne. In the time of Hugh de Lacy this was a town of some note, being one of the boroughs in his palatinate of Meath. Here were many religious buildings, one of which was sometimes used as the residence of a royal prince, and was rebuilt by the lord of Slane in 1512. In the present remains of lord Slane's building, there are, according to Mr. Archdale, several fragments of the ancient abbey, and many of the architraves were evidently cut out of the ornamental parts, particularly one with the appearance of a head crowned. The castle that belonged to the lords of Slane, and was forfeited by them in 1641, is now the property of the Conyngham family. It has been much beautified, and is an elegant residence. At New Grange, near Slane, is a most remarkable mount, barrow, or rath, with a curious chamber in the centre, constructed of rude stones, and accessible only by a long passage, low, and very narrow. Governor Pownall has given a minute description of this barrow in the *Archæologia*, &c. It is also described in the "Collectanea de Rebus Hibernicis." Slane is 24 miles N. by W. from Dublin.

SLANETZ, a river of Russia, which runs into the Tobol; 60 miles S. of Tobolsk.

SLANEY, a river of Ireland, rising in the Wicklow mountains, near the source of the Liffey, and flowing in a southern direction through the counties of Wicklow, Carlow, and Wexford, to the harbour of Wexford. The towns of Stratford on Slaney, Baltinglase, Rathvilly, Tullow, Newtown Barry, Enniscorthy, and Wexford, are situated on it, and it receives the waters of the Derry, Bann, Urrie, and several smaller streams. It is navigable for small sloops to Enniscorthy.

SLANGE, NICHOLAS, in *Biography*, a Dutch historian of considerable celebrity, was born at Slagelse in the year 1657, of which place his father was the minister, and he was afterwards bishop of Viborg. Nicholas travelled at an early period, and in 1679 he paid a visit to Oxford, and in the year following he went to Cambridge. On his return he became, in 1681, secretary to the Danish chancery, and after going through various gradations of rank and office, he was ennobled in the year 1731. He died in 1737. He wrote "A History of Chrillian IV." which was published at Copenhagen in 1749, in two volumes, folio. It was afterwards translated into the German language. Gen. Biog.

SLANGER, in *Geography*. See **TUMB**.

SLANGERUP, a town of Denmark, in Zealand; 16 miles N.W. of Copenhagen. N. lat. 45° 51'. E. long. 12° 10'.

SLANT, in *Commerce*, a copper coin of Sweden. Here are single and double slants, at 1 and 2 ore silver, or 3 and 6 ore kopper; and rundtycken, of 1 ore kopper; and also half rundtycken: 96 double slants, 192 single slants, or 576 rundtycken, are 10 pafs for 1 specie rikfdaler: and this, commonly called the Swedish dollar, is worth 4s. 7½d. sterling.

SLAPANITZ, in *Geography*, a town of Moravia, in the circle of Brunn; 5 miles E.S.E. of Brunn.

SLAPDASH, in *Rural Economy*, provincially rough cast, or the liquid external coating of buildings.

SLAPER'S

SLAPER'S BAY, in *Geography*, a bay on the W. coast of Africa; 10 miles E. of Cape Blanco.

SLARADIA, a town of Asiatic Turkey, in Natolia; 28 miles N.N.W. of Eskir-Shehr.

SLASHER, in *Rural Economy*, a term sometimes applied to a plaster of hedges.

SLATCH, at *Sea*. When a rope or cable hangs slack, the seamen call the middle part, which hangs down, *the slatch of the cable*, or rope: so also, after long foul weather, if there come a small interval of fair, they say, *this is a slatch of fair weather*. But the term is generally applied to the period of a transitory breeze of wind.

SLATE, *Argillaceous Schistus* and *Argillite* of Kirwan; *Clay-slate*, *Jamelon*; *Thonfschiefer*, Werner; *Schiste Argilleux*, Fr.; in *Mineralogy* and *Geology*, one of the great rock-formations composing the crust of the globe, of which roof-slate is a well-known variety. The slaty or schistose structure is common to numerous rocks, which differ from each other, both in their geological position and constituent parts; hence we have a great variety of slate-rocks, amongst rocks which have been denominated primary, transition, and secondary. (See ROCKS.) The term slate appears to have a more appropriate meaning, when restricted to those rocks which, in their composition and structure, are most nearly allied to roof-slate or the clay-slate of Werner.

The most common colours of slate are a yellowish-grey, a greenish-grey, or a dark-blue or purple-grey: some varieties incline to a red, and others to a black-grey. Slate of the most perfect kind has a glistening lustre. It passes by gradation into mica-slate in the rocks called primary; and in rocks considered as secondary, it passes into slate-clay or shale.

The structure of slate-rocks *en masse* is tabular, the small structure laminar, the cleavage of the laminæ being parallel with the tables; hence slate has been represented by some geologists as most distinctly stratified; and the slaty cleavage is said to be always parallel with the strata; but this we believe to be a mistake, arising from confounding the divisions or joints of the tabular masses with the inclination of the beds. In the slate-quarries of Westmoreland and Cumberland, we have invariably observed the tables or divisions of the slate rise at a more elevated angle than the bed of which they form a part; and they are sometimes perpendicular, when the true dip of the bed is not more than forty degrees.

The slaty structure of the stone is the result of a process analogous to crystallization, by which the slate is divided into rhomboidal blocks or tables: between the bottom of one block and the top of another, there is frequently a seam of clay, which forms, what the workmen call, the foot of the slate. The slate will divide to this seam in a direction nearly at right angles with it; and sometimes between the upper and the lower block, there will be a thin horizontal stratum of slate occupying the place of the clay. This proves that the slate is not formed by mechanical stratification, and that the elevation of the tabular masses is unconnected with the elevation of the rock itself.

Slate-rocks vary in hardness, but they yield to the knife. They consist of an intimate intermixture, in various proportions, of siliceous earth, alumine, and iron; and sometimes contain a portion of lime, magnesia, manganese, and bitumen. Slate forms entire mountains, and mountain chains, and sometimes distinct beds, alternating with other rocks. It most frequently rests upon granite, gneiss, or mica-slate.

Slate-rocks are frequently intersected by veins of quartz,

and by metallic veins of lead, cobalt, and silver: it also contains beds of copper pyrites, red copper-ore, copper-green, malachite, iron pyrites, magnetic pyrites, glance cobalt, grey cobalt-ore, arsenical pyrites, blende and galena. The tin-veins in Cornwall sometimes pass through the killas, which is a variety of slate-rock.

Various rocks frequently occur imbedded in slate, particularly whet-slate, or hone, chlorite-slate, talcous-slate, drawing-slate, and alum-slate. Beds of flinty slate occur in this rock, and alternate with as well as graduate into it. Flinty slate appears to be slate in which a large proportion of siliceous earth is combined, until it approaches nearly to the nature of chert or flint. Organic remains are occasionally found in slate, on which account it is not considered by many geologists as a primary rock, if indeed there be any to which that term is appropriate. The slate which contains organic remains has been called by the Germans *the newer clay-slate*, and *transition-slate*; but remains of vegetables have been discovered in the slate of the Higher Alps in the vicinity of Mont Blanc, which may be supposed to have a better claim to the rank of primary than any other slate-rocks in Europe.

In a very large proportion of slate-rocks, the basis of the slate is intermixed with particles or fragments of other rocks; and when these are sufficiently large to be discerned without a lens, this kind of rock has received from the Germans the name of *grauwacke slate*. It is generally incumbent on the rocks denominated primary, and is supposed to be of more recent origin than the finer slate; but late observations have shewn that *grauwacke* is sometimes covered with granite and mica-slate. The killas of Cornwall appears, in many situations, to approach the nature of mica-slate, having a shining lustre, and a light grey colour, as if composed of an intimate intermixture of clay-slate with mica-slate. In Cornwall and Devonshire it occupies, in general, the same relative position with granite, in which mica-slate frequently occurs in other districts resting immediately upon it. The metallic veins which intersect these rocks are principally filled with ores of tin and copper, imbedded in a matrix of quartz; but it is observed, that the contents of the vein frequently vary as it passes through different rocks: if it contain tin-ore in the granite, it will change to copper-ores in the killas; and if tin be most abundant in the killas, the vein will change its contents as it passes into the granite. Veins of granite are also observed to shoot up into the killas, which is a proof that this kind of slate-rock is at least as ancient as the granite. This fact has given rise to some controversy among geologists, the disciples of Werner contending that the granite in the slate or killas was not in veins, but formed ridges or inequalities rising above the surface, which had been inclosed by subsequent depositions of the slate. For this explanation there can be no better reason given than its convenience in suiting a particular hypothesis respecting the formation of these rocks. Among other facts, which might be cited to prove that the granite veins penetrate the slate, there is one described in the "Annals of Philosophy," May 1814, which appears decisive. It occurs in Tonschole, in Cornwall. "The slate or killas is of a greyish dark colour, rather hard, but breaks into large fragments in the direction of the strata. The granite is of a fine grain, and the felspar is of a light flesh-colour, and contains but a small portion of mica. At the junction, numerous veins of granite may be traced from the rock of granite into the slate. Some of these veins may be observed upwards of fifty yards, till they are lost in the sea; and in point of size, vary from a foot and a half to less than an inch.

It may deserve notice, that as the felspar is of a flesh-red colour, it is impossible for any observer to consider them as quartz veins. One of these large veins is dislocated, and heaved several yards by a cross course. Another of these veins of granite, after proceeding vertically some distance, suddenly forms an angle, and continues in a direction nearly horizontal for several feet, with schistus, or slate, both above and below it. This appearance most completely destroys one of the theories suggested for the explanation of similar veins at St. Michael's Mount; *viz.* that a ridge of projecting granite had been left, and slate deposited afterwards on its sides." It is, indeed, quite impossible to conceive that a narrow vein of granite should shoot up into empty space for a considerable distance, and then assume a zig-zag direction, unsupported by any solid substance on the sides. The slate-rock must have existed when the vein was formed, and from its resistance have given it the form above described. Slate is one of the most abundant rocks in alpine districts, though that variety which splits into thin durable laminæ, forming good roof-slate, is far from being so common. The localities of common slate are so numerous in mountainous districts, that it were useless to point them out. Roof-slate, the *schiste ardoise* of the French, is found on the western side of our island in the counties of Cornwall and Devon, in various parts of North Wales and Anglesea, on the north-west parts of Yorkshire, near Ingleton, and in Swaledale, also in the counties of Cumberland and Westmoreland. It occurs in a low range of mountains at Chamwood forest, in Leicestershire, near the centre of England. Several geologists have stated that slate is found in Derbyshire, which is a mistake, as no rock similar to clay-slate or roof-slate occurs in that county. The inhabitants of that part of England make use of a micaceous sand-stone for roofing, which they denominate slate. This stone is found in strata among the other strata accompanying coal. Of the quality of the different kinds of English roof-slate, we shall offer some observations at the conclusion of this article. Slate abounds in various parts of Scotland, and in the county of Wicklow, and other mountainous parts of Ireland. France possesses many valuable beds of roof-slate, near Laferriere in Normandy, and in the neighbourhood of Angers. The last is the most important, as furnishing slate of the most perfect quality, and its extent and prodigious thickness make it regarded as inexhaustible. It is further remarkable on account of the very singular and interesting organic remains that occur between some of the laminæ of slate. It is, perhaps, one of the most valuable repositories of slate at present known.

This bed extends for a space of two leagues, passing under the town of Angers, which is built, as well as covered, with the slate; those blocks being employed in masonry which are the least divisible. The quarries which are actually explored, are all in the same line from west to east, as well as the ancient pits, the bed of the best roof-slate rising to the surface in this direction. Immediately under the vegetable earth is found a brittle kind of slate, which, for four or five feet deep, splits into rhomboidal fragments.

A little lower is what is called the building-stone, which is a firm slate, but scarcely divisible. This is employed in the construction of houses, after it has been sufficiently hardened by exposure to the air. At fourteen or fifteen feet from the surface is found the good slate, which has been quarried to the perpendicular depth of about three hundred feet; the remaining thickness being unknown.

As to the interior structure of this great mass of slate, it is divided by many veins or seams of calcareous spar and

quartz, about two feet thick, by fifteen or sixteen in height; these veins are parallel, and proceed regularly from west to east, in a position rising seventy degrees to the south; they are intersected by other veins at intervals of a similar kind, but whose rise is seventy degrees north; so that when they meet the former, they either form rhombs, or half rhombs, which have been compared to the letter V, some being upright, and others reversed.

All the layers, or laminæ, of the slate, have a direction similar to those of the veins of quartz, which rise south seventy degrees; and when intersected by veins that have an opposite inclination, the direction of the slaty laminæ is not changed. The whole mass is thus divided into immense rhomboids, composed of plates all parallel among themselves, and with two of the faces of the rhomboid.

The slate of Angers is extracted in blocks of a fixed size, which are divided into leaves for roofing-slate. It is betwixt these leaves that there are frequently found vestiges of marine animals, and particularly pyritous impressions of *pous de mer* (the sea-louse, a small univalve shell), also of small cheviettes (shrimps or prawns), and a species of crab, of which the body is about a foot in breadth, and fourteen or fifteen inches in length, the tail having nine or ten rings. The shrimps are sometimes so numerous, that forty have been counted on a slate of a foot square.

None of the above animals resemble any known existing species. But the most remarkable circumstance in these impressions, particularly in the large crabs, is, that though there be no sign of the body having been crushed, yet it can scarcely be said to have any thickness whatever. They rather resemble engravings than figures in relief, the convexity of these crabs above a thin leaf of slate not rising more than the fourth, and sometimes not more than the tenth part of a line; nor is it perceivable that the body of these crabs penetrates into the leaves of slate. What adds to the surprise, is the nearly vertical position in which these impressions are found in the mine.

A series of these leaves of slate may be compared to a set of books placed upon shelves; and the impressions of crabs, and other marine animals, to engraved plates in the volumes: they do not, in fact, occupy more thickness. It is equally difficult to conceive how the bodies of these animals, though perfectly defined, could be reduced to a simple surface, without thickness. These slates also present beautiful dendritical pyrites, more than a foot in extent. The pyrites are sometimes in small grains, disseminated, like dust, upon the surface of the slates, where may also be observed many little stars of selenite.

When the blocks of slate have been drawn from the quarry, if they are left exposed to the sun, or the open air, for some days, they lose what is called the *quarry-water*, and then become hard and untractable, and can only be employed as building stone. Frost produces a singular effect on these blocks: while frozen they may be broken with more ease than before; but if thawed rather quickly, they are no longer divisible: yet this quality may be restored by exposing them once more to the frost; but if the operation be often repeated, it becomes impossible to reduce them to leaves.

Some smaller beds of slate are worked on the northern elevities of the Pyrenées; but we have no account of any slate-quarries on the southern side, or in any part of Spain: yet it can scarcely be doubted that this rock exists in some of the mountainous parts of that kingdom.

Only one quarry of slate is said to be opened in Italy; it is at Lavagna, in the state of Genoa, and furnishes slate of an excellent quality, and so impervious, that it serves

erves to line the cisterns in which olive oil is preserved. The canton of Glaris, in Switzerland, is the only one in which roof-slate is procured. Roof-slate occurs in Saxony, and in various mountainous districts in the north of Europe; it is found also on the continent of North America; and as it is only a modification of clay-slate, which is an abundant rock, it is probable that its localities are much more numerous than are at present known in alpine districts in every part of the globe.

As this substance forms the most light, elegant, and durable covering for houses, and is, of course, of considerable value; it is rather surprising that so much indifference prevails respecting the search for it, in those districts where common slate, or *clay-slate*, abounds. We believe all the roof-slate quarries at present worked are those which accident has discovered. This neglect is the more remarkable, when we consider the great expence frequently incurred in searching for coal, a substance of much less value in proportion to the weight.

All the best beds of roof-slate with which we are acquainted, improve as they sink deeper into the earth; and few, if any, are of a good quality near the surface, or are indeed suitable for the purpose of roofing. There cannot be a doubt that many beds of slate, which appear shattered and unfit for architectural use, would be found of a good quality a few yards under the surface; for the best slate, in many quarries, loses its property of splitting into thin laminae by exposure to the air. Notwithstanding the value of slate, few quarries are worked to a very great depth, or have subterranean galleries, like mines. The quarry or slate-mine at Rimeuse, four leagues to the west of Charleville, on the Meuse, in France, is an exception. The mouth of the mine is near the summit of a hill: the bed inclines forty degrees to the horizon: it is about sixty feet in thickness, but its extent and depth are unknown. It has been pursued, by a principal gallery, to the depth of 400 feet; and they have driven many lateral galleries, which extend about 200 feet on the side of the main gallery, where 26 ladders are placed in succession, for the passage of the workmen and the carriage of the slate. In this bed, which is 60 feet in thickness, there are only forty feet of good slate, the other being mixed with quartz. They cut the slate into blocks of about 200 lbs., which they call *saix*: every workman, in his turn, carries them on his back to the very mouth of the pit, mounting the 26 ladders, or a part of them, according to the depth of the bed where he is working. When brought to day, these blocks are first split into thick tables, which are called *repartons*. The workman holds the block between his legs, puts a chissel on the side, and divides it with a blow of a mallet. The *repartons* are divided in a similar manner into roof-slates. These operations must be performed soon after the blocks are drawn from the quarry; for if the stone has time to dry, it would no longer be possible to split it. Some of the slate-galleries pass under the river Meuse.

There are few places in Great Britain where slate is worked as a mine under ground; most of the quarries are open to the day; and the covering of other rocks, or of coarse slate, which requires removing, greatly increases the expence. There is one slate-quarry worked as a mine by penetrating the interior of the mountain at Place-Fell, on the head of the lake of Ullswater, in Cumberland. Slate is also worked under ground on the western side of Yorkshire, adjoining Westmoreland. In many other situations it is probable that slate might be worked to advantage, in subterranean galleries, similar to those described in the quarries at Charleville; for as this mineral is generally of a better

quality at a considerable depth, the expence of procuring it by mining would be much less than that of removing the load of upper rocks, and working it in open quarries, as at present; at least the most valuable slate might be pursued to a far greater depth than is practicable in the common method in open quarries.

Slate, to be of a good quality for roofing, should have the property of splitting into thin even laminae: it should resist the absorption of water; to prove which, it should be kept some time immersed in water, being weighed before and after the immersion, wiping the surface dry; it is obvious, that the slate which gains the least weight by this process is the least absorbent. It should resist the process of natural decomposition by air and moisture: this depends on its chemical composition and compactness, and is shewn by its resisting the process of vegetation. That slate which is the most liable to decay, will be the soonest covered with lichens and mosses. The slate from Chamwood forest, in Leicestershire, resembles, in colour and appearance, the Westmoreland slate, but it will not split so thin, nor would this be desirable, for the vegetation which takes place upon it requires the roofs to be frequently scraped; this carries away a portion of the surface: a second growth of mosses produces a further wearing of the slate: hence a slate of a certain thickness from this part of England is not so durable as that from North Wales, Cornwall, or Westmoreland. This decay is probably owing to the greater quantity of alumine in its composition; it does not contain pyrites, nor have any organic remains been discovered in it.

Few slate-rocks have been accurately analysed; a reddish-purple slate from North Wales contained, according to Kirwan, .38 silice, .26 alumine, .8 magnesia, .4 lime, and .14 parts iron; but as there is in this analysis a loss of 10 per cent., it cannot be considered as very accurate. As the hardness of slate arises principally from the silice it contains, which is of all the earths the least favourable to vegetation, those slates which are the hardest when first taken from the quarry, and which have the least specific gravity, are to be preferred; for the increase of weight in slates is owing to the presence of iron, either in pyrites, or a slate of oxyd. To the presence of iron, many kinds of stone and slate also owe their tendency to decomposition. The pyrites being decomposed by moisture, and the iron admitting a still higher degree of oxygenation, the surface of the stone swells and peels off, or falls into an ochrey powder.

According to Dr. Watson, (bishop of Landaff,) the specific gravity of the Westmoreland slate varies in different quarries, from 2797 to 2732 ounces the cubic foot. The effect of frost is very sensible on tiled houses, but is scarcely felt on slated houses; for good slate imbibes very little water. According to an experiment made by Dr. Watson on Westmoreland slate, compared with tile, in which two pieces of each, about 30 inches square, were immersed in water 10 minutes, and then taken out and weighed as soon as they ceased to drop; the tile had imbibed about $\frac{1}{4}$ th of its weight of water, and the slate had not absorbed the $\frac{1}{20}$ th part of its weight: indeed the wetting of the slate was merely superficial. When placed before the fire, in a quarter of an hour the slate was of the same weight as it had been before it was put into the water; but the tile had only lost about 12 grains of its moisture, which was as near as could be expected to the quantity which had been spread over its surface; for it was the amount gained by the slate, the surface of which was equal to that of the tile. The tile was left to dry six days, in a room heated to sixty degrees, but did not lose all the water it had imbibed till the end of that time.

The slate in Westmoreland is blasted from the quarry in large

large masses, and split with proper tools by the workmen. Though the specific gravity of Westmoreland slate from different quarries is nearly the same, yet all the sorts are not capable of being split into an equal degree of thinness. Here also the quality varies with the depth of the quarry, that being the best which is raised from the greatest depth.

The grey-blue slate from Donyball, in Cornwall, weighs only 2512 ounces to the cubic foot, which is considerably lighter than that of Westmoreland. This slate is generally preferred to any other for its lightness, and enduring the weather; but Dr. Watson is of opinion, that in durability it does not excel that of Westmoreland. The Donyball slate is split into laminæ about one-eighth of an inch thick when it is applied to the covering of a roof; it then weighs rather more than 26 ounces to the square foot. The pale blue slate from Ambleside, in Westmoreland, weighs about two ounces more in the square foot than the former. In many instances, we believe slate of a thinner kind is used in several modern buildings to save the expence of timber in the roof, where cheapness rather than durability is a principal object with the architect. According to an estimate of Dr. Watson, the relative weights of a covering of the following different materials, for forty-two square yards of roof, are as under:

	Cwt.
Copper - - -	4
Fine slate - - -	26
Lead - - -	27
Coarse slate - - -	36
Tile - - -	54

A ton of fine slate will cover a larger surface than a ton of lead; and where there is water-carriage, does not cost one-fourth of the price. Slate might, therefore, be used generally instead of lead, with great advantage. Watson's Chemical Essays, vol. iv.

The most extensive slate-quarries in Great Britain are the property of lord Penryn, near Bangor, in Caernarvonshire. There is a rail-road formed from the quarries to the sea for the conveyance of the slate, which is of an excellent quality, and is sent to various parts of the world. The most remarkable situation where slate is procured in Cumberland, or perhaps in Great Britain, is Hourlton cragg, a lofty mountain near the lake of Buttermere, about 2000 feet above the level of the lake, and nearly perpendicular. On account of the difficulty of access, the workmen take their provisions for the week, and sleep in temporary huts on the summit. During the winter months they are generally involved in clouds, and not unfrequently blocked up by the snow. The slate is conveyed down a zigzag path cut in the rock on sledges, one man attending to prevent the acceleration of the descent. When the slate is emptied at the bottom, the sledge is carried back on his shoulders to the summit.

There are considerable slate-quarries near Ulverstone, in Lancashire. A coarse slate is got near Ingleton, in Yorkshire, and also in the vicinity of Settle in that county. The Ingleton slate frequently contains cubical pyrites, and is sometimes covered with dendritical pyrites.

Alum-slate, *ampellite* of Haiiy, is sometimes imbedded in clay-slate, but more frequently in stratified secondary rocks, and is not essentially different from some of the coal-shales. (See ALUM.) The alum-slate, or alum-shale of Whitby, is of vast and unknown thickness, forming the base of the Cleveland Hills in the North Riding of Yorkshire, extending about thirty miles east and west from Robinhood's bay,

to Gainsborough, Stokesly, and Osnotherly. On the south side of the Cleveland Hills the alum-slate is principally covered by sand-stone and marl. On the north-east, the alum-rock extends along the coast, about thirty miles from Robinhood's bay to Huntcliff. The height of the alum-cliffs, which are perpendicular from the sea, varies from 100 to 140 yards. Whitby abbey stands near an awful precipice of alum-slate or rock, which is undermined by every returning tide. At low water the alum-rock may be seen extending far to the east, forming a flat pavement, on which the observer may walk secure, treading at almost every step on the organic remains of the inhabitants of a former world, which are abundantly disseminated through the whole mass beneath, and projecting from the sides of the black and frowning cliffs above. The alum-slate has been perforated near the sea to the depth of 130 yards, without discovering the subjacent rock, to which we may add the height of the cliffs above, which will make a total thickness exceeding 220 yards. The upper parts of the bed are found more productive of alum than the lower. From the quantity of pyrites contained in this rock, it sometimes takes fire spontaneously, when a heap of it which has fallen from the cliffs becomes moistened with sea-water.

The animal remains are scattered through every part of the rock. They consist principally of numerous ammonites, nautilites, belemnites, fossil vertebræ (supposed to belong to the shark), with bivalve shells, fossil wood, and jet. Mr. Bakewell considers the alum-shale or slate, and the strata which cover it, as a peculiar local formation subjacent to the roe-stone, but above the coal-formation of Yorkshire or Durham. The alum-slate is in fact a thin bed of indurated pyritous slate-clay, differing little, except in geological position and its organic remains, from some of the coal-shales.

The alum-slate of Whitby has a very dark grey colour, a slaty structure, and rather a silky lustre; it splits, by exposure to the atmosphere, into very thin laminæ; it varies in hardness, but is all softer than roof-slate. The particular advantage which the country near Whitby possesses for the manufacture of alum, is derived from the alum-slate rising in precipitous cliffs, which afford facilities for working and burning the stone. Though many of the coal-shales might yield an equal quantity of alum, the difficulty of raising them to the surface would in most situations be too great to repay the expence. The alum-slate is piled in vast heaps and set fire to; a slow combustion is continued for several months, by the inflammable matter combined with the stone. The saline contents are extracted by solution, a small quantity of potash is added, and the alum is crystallized by evaporation. (Bakewell's Introduction to Geology.) From the alum-rock of Yorkshire, nearly all the alum of commerce in England is produced.

According to the analysis of Klaproth, alum-slate contains

Sulphur - - -	0.28
Carbon - - -	1.96
Alumine - - -	1.60
Silex - - -	4.00
Black oxyd of iron - - -	64
Sulphate of iron, lime, and potash, each - - -	15
Water - - -	70

M. Klaproth remarks, that the sulphur in the alum-slate which he analysed was not united to the iron but to the carbon, in a manner at present unknown. In the alum-slate of Whitby, we believe the sulphur is combined both with the iron and carbon.

Drawing-slate frequently accompanies alum-slate; it is much softer than common slate, and contains, like alum-slate, a considerable portion of carbon: its colour is a greyish-black: it is known by the property which it possesses of leaving a dark line when rubbed on paper. It is soft, and sometimes rather unctuous: some varieties have a small degree of lustre. The fracture, in small fragments, is scarcely slaty, and sometimes approaches the conchoidal. Drawing-slate is easily cut with the knife. Under the blowpipe it turns white or yellow. It sometimes effloresces like alum-slate. According to Wiegleb, it contains

Silex	-	-	-	64
Alumine	-	-	-	21.25
Carbon	-	-	-	11
Oxyd of iron	-	-	-	2.75
Water	-	-	-	7.50

Drawing-slate is employed by masons, carpenters, &c. to mark with. When fine and pure, it is used by artists for designs. In France it is called *Pierre d'Italie*, in England, *French chalk*. It is found in France, near Séer, in the department of l'Orne, and in the environs of Cherbourg. It is found also in Spain and Italy.

Whet-slate, or hone, the *novaculite* of Kirwan, occurs imbedded in clay-slate: its most common colour is greenish-grey, inclining to yellow: it is much harder than common slate: its texture is fine-grained, nearly compact, and the fracture of the small pieces splintery or conchoidal, resembling flinty slate. Its specific gravity is about 2.72. Whet-slate is translucent on the edges; it does not effervesce with acids, and it melts into a brown enamel under the blowpipe. From its green colour, and rather greasy feel, it may be considered as intermediate between hard talcous-slate and clay-slate. Though it yields to the point of a knife, or even of a copper tool, it acts upon the flattened or round surfaces of metals, and is used for sharpening and polishing the finer kinds of cutlery. It is of considerable value on account of this property, and was first brought from the Levant. We have no whet-slate of a fine quality in England. An inferior kind is procured from Chamwood forest, in Leicestershire. It exists of a finer quality in the promontory of Howth, near Dublin. The common whet-slate of commerce is procured from Saxony.

SLATE-Spar, *Schiefer-spath*, Werner, occurs in lime-stone beds, in mountains called primitive. Its colour is milk-white, or greenish and reddish-white, its lustre shining and pearly. Slate-spar is translucent and soft, its structure coarsely lamellar, passing into slaty, and sometimes curved or undulating: it is infusible, and effervesces with violence in acids.

SLATE, in *Rural Economy*, a well-known, neat, convenient, and durable material, for the covering of the roofs of buildings. There are great varieties of this substance; and it likewise differs very greatly in its qualities and colours. In some places it is found in thick laminæ, or flakes; while in others it is thin and light. The colours are white, brown, and blue.

It is so durable, in some cases, as to have been known to continue found and good for centuries. However, unless it should be brought from a quarry of well reputed goodness, it is necessary to try its properties, which may be done by striking the slate sharply against a large stone, and if it produce a complete sound, it is a mark of goodness; but if in hewing it does not shatter before the edge of the *set*, or instrument commonly used for that purpose, the criterion is decisive. The goodness of slate may be farther estimated by its colour: the deep black-blue is apt to imbibe moisture,

but the lighter blue is always the least penetrable: the touch also may be in some degree a guide, for a good firm stone feels somewhat hard and rough, whereas an open slate feels very smooth, and as it were greasy. And another method of trying the goodness of slate, is to place the slate-stone lengthwise, and perpendicularly in a tub of water, about half a foot deep, care being taken that the upper or unimmerged part of the slate be not accidentally wetted by the hand, or otherwise; let it remain in this state twenty-four hours; if good and firm stone, it will not draw water more than half an inch above the surface of the water, and that perhaps at the edges only, those parts having been a little loosened in the hewing; but a spongy defective stone will draw water to the very top. There is still another mode, held to be infallible. First, weigh two or three of the most suspected slates, noting the weight; then immerge them in a vessel of water twelve hours; take them out, and wipe them as clean as possible with a linen cloth; and if they weigh more than at first, it denotes that quality of slate which imbibes water: a drachm is allowable in a dozen pounds, and no more.

It may be noticed, that in laying of this material, a bushel and a half of lime, and three bushels of fresh-water sand, will be sufficient for a square of work; but if it be pin plastered, it will take above as much more: but good slate, well laid and plastered to the pin, will lie an hundred years; and on good timber a much longer time. It has been common to lay the slates dry, or on moss only, but they are much better when laid with plaster. When they are to be plastered to the pin, then about the first quantity of lime and sand will be sufficient for the purpose, when well mixed and blended together, by properly working them.

Slates differ very much in thickness as well as colour, which suits them for different situations and purposes. A great deal of good slate of various kinds is raised in different parts of Wales, and much excellent blue and other coloured sorts is procured from the northern parts of Lancashire, and other neighbouring places, as well as from different other counties throughout the kingdom. In some parts the slate is distributed into three kinds, as the best, the middling, and the waste or common sort. See QUARRY.

SLATE-*Axe*, provincially a mattock with a short axe-end, used in slating, &c.

SLATE *Mount*, in *Geography*, a mountain of Virginia; 6 miles W. of Richmond. N. lat. 37° 35'. W. long. 72°.

SLATE *River*, a river of Virginia, which runs into James river, N. lat. 37° 40'. E. long. 78° 34'.

SLATEE, an African appellation of free black merchants, often traders in slaves.

SLATERS, in *Entomology*. See MILLEPEDES and ONISCUS.

SLATERS and *Tilers*, are those artificers who are employed in slating or tiling houses. In calculating and estimating the value of their work, they find the content of a roof by multiplying the length of the ridge by the girt over from eaves to eaves; making allowance in this girt for the double row of slates at the bottom, or for the quantity or space by which one row of slates or tiles is laid over another. In angles formed in a roof, running from the ridge to the eaves, when the angle bends inwards, it is called a valley; but when outwards, it is called a hip. And in tiling and slating, it is common to add the length of the valley or hip to the content in feet. Deductions are seldom made for chimney-shafts, or small window-holes. *E. gr.* Required the content of a slated roof, the length being 45 feet 9 inches, and whole girt 34 feet 3 inches.

E. gr. What is the amount of the tiling of a house, at 25s. 6d. per square; the length being 43 feet 10 inches, and the breadth on the flat 27 feet 5 inches, and the eaves also projecting 16 inches on each side. Ans. 24l. 9s. 5½d.

SLATINA, in *Geography*, a town of Bohemia, in the circle of Schlan; 6 miles E. of Schlan.—Also, a town of Wallachia, on the E. side of the river Alaut; 2 miles N.E. of Brancovani.—Also, a town of European Turkey, in Moldavia; 18 miles N.W. of Niemez.

SLATTBOG, a town of Sweden, in the province of Smaland; 15 miles N.W. of Wexio.

SLATY ROCK, or *Schistus*, in *Agriculture*, a substance of a mouldering, enriching nature, which is sometimes blended up with other matters as a compost for land. The sort of material of this kind which forms the under-soil in many parts of Cornwall, and some other districts, is of an argillaceous, unctuous, soapy quality; which in some cases is ploughed up with a strong plough; and after being well exposed to the summer sun and winter frost, is mixed with lime or sand; in which state it is said to become a very capital thickener and fertilizer of thin poor worn-out soils, and by which much improvement is afforded at little trouble or expence.

SLAVANESS, in *Geography*, a cape on the E. coast of the island of Shetland. N. lat. 60° 31'. W. long. 1° 13'.

SLAVE, a person in the absolute power of a master, with regard to his life, liberty, and fortune. See SERVANT.

Menage and Vossius derive the word from *Sclavus*, the name of a Scythian people, whom Charlemagne condemned to perpetual imprisonment. See SCLAVONIC.

The Romans called their slaves, *servi*, from *servare*, to keep, or *save*; as being such as were not killed, but saved to yield money, either by sale, or by their work. Though other authors are of opinion, that the Roman name *servi* might come from that of *serbi*; as that of slaves from *Sclavi*, a people.

The term for a slave born and bred in the family, was *verna*; equivalent to *scurra*, denoting the petulance and impudence of these slaves. They seem to have been entitled by custom to privileges and indulgences beyond others.

Among the Romans, when a slave was set at liberty, he changed his name into a surname; he took the nomen or pre-nomen of his master, to which he added the cognomen he had been called by when a slave. See NAME.

Among those who were denominated slaves in the more lax and general use of the term, we may reckon those who were distinguished among the Romans by the appellation of "mercenarii," so called from the circumstance of their hire. These were free-born citizens, mentioned in the law-books by the name of *liberi*, and thus contradistinguished from the *alieni*, or foreigners, who, from the various contingencies of fortune, were under a necessity of recurring for support to the service of the rich. To this class belonged those who, both among the Jews and Egyptians, are recorded in the sacred

writings. (Gen. ch. xvii. Levit. xxv. 39, 40.) The Grecian *Thetes* (*Θητες*, see Hom. Odyll. Δ. 642.) were also of this description. The situation of these persons resembled that of our servants; a contract subsisting between the parties, and most of the subordinate dependants having a right to demand and obtain their discharge if they were ill used by their masters.

Among the ancients there was another class of servants, which consisted wholly of those who had suffered the loss of liberty from their own imprudence. Such were the Grecian *prodigals*, who were detained in the service of their creditors, till the fruits of their labour were equivalent to their debts; the *delinquents*, who were sentenced to the oar; and the German *enthusiasts*, mentioned by Tacitus, who were fo addicted to gaming, that when they had parted with every thing, also itated their liberty and their persons. "The loser," says the historian, "goes into a voluntary servitude; and though younger and stronger than the person with whom he played, patiently suffers himself to be bound and sold. Their perseverance in so bad a custom is styled *honour*. The slaves thus obtained are immediately exchanged away in commerce, that the winner may get rid of the scandal of his victory." The two classes now enumerated comprehend those that may be called *voluntary slaves*, and they are distinguished from those denominated *involuntary slaves*; who are forced, without any previous condition or choice, into a situation, which, as it tended to degrade a part of the human species, and to class it with the brutal, must have been, of all situations to which a human being can be reduced, the most wretched and insupportable.

We find no mention of slaves before the Deluge, but immediately after, *viz.* in the curse of Canaan, Gen. ix. 25; whence it is easily inferred, that servitude commenced soon after that time; for in Abraham's days we find it generally established. Some will have it to have commenced under Nimrod, because it was he who first began to make war, and of consequence to make captives; and to bring such as he took, either in his battles or irruptions, into slavery.

"Proud Nimrod first the bloody chace began,
Almighty hunter, and his prey was man." Pope.

Hence probably arose the connection between victory and servitude, an idea of which has prevailed among the nations of antiquity, and which has uniformly existed, in one country or another, to the present day. Accordingly, the first class of *involuntary slaves*, included those who were "prisoners of war;" and these were more ancient than the *voluntary slaves*, who are first mentioned in the time of Pharaoh. The practice of reducing prisoners of war to the condition of slaves, subsisted both among the eastern nations and the people of the West; for as the Helots became the slaves of the Spartans, merely from the right of conquest, so prisoners of war were reduced to the same situation by the other inhabitants of Greece. The Romans, also, were actuated by the same principle; and all those nations which contributed to overturn the empire, adopted a similar custom; so that it was a general maxim in their polity, that those who fell under their power as prisoners of war, should immediately be reduced to the condition of slaves. See PRISONERS of War.

The slaves of the Greeks were generally, or very commonly, barbarians, and imported from foreign countries.

By the civil law, the power of making slaves is esteemed a right of nations, and follows, *jure gentium*, as a natural consequence of captivity in war. "Jure gentium servi nostri sunt, qui ab hostibus capiuntur." Justinian, l. i. 5. 5. 1.

This is the first origin of the right of slavery assigned by

Justinian, Inst. i. 3, 4. whence slaves are called *mancipia quasi manu capti*.

The conqueror, say the civilians, had a right to the life of his captive; and having spared that, has a right to deal with him as he pleases. But this position, taken generally, is denied by judge Blackstone; who observes, that a man has a right to kill his enemy only in cases of absolute necessity, for self-defence: and, it is plain, this absolute necessity did not subsist, since the victor did not kill him, but made him prisoner. Since, therefore, the right of making slaves by captivity depends on a supposed right of slaughter, that foundation failing, the consequence drawn from it must fail likewise. Farther, it is said that slavery may begin "jure civili," when one man sells himself to another: but this, when applied to strict slavery, in the sense of the laws of old Rome or modern Barbary, is also impossible. Every sale implies a price, a *quid pro quo*, an equivalent given to the seller in lieu of what he transfers to the buyer; but what equivalent can be given for life and liberty, both of which, in absolute slavery, are held to be at the master's disposal? His property, also, the very price he seems to receive, devolves *ipso facto* to his master the instant he becomes his slave: and besides, if it be not lawful for a man to kill himself, because he robs his country of his person, for the same reason he is not allowed to barter his freedom: the freedom of every citizen constitutes a part of the public liberty. In this case, therefore, the buyer gives nothing, and the seller receives nothing; of what validity then can a sale be, which destroys the very principles upon which all sales are founded? Lastly, we are told, that besides these two ways by which slaves "sunt," or are acquired, they may also be hereditary, "*servi nascuntur*;" the children of acquired slaves are, *jure natura*, by a negative kind of birth-right, slaves also; but this being founded on the two former rights, must fall together with them. If neither captivity, nor the sale of one's self, can, by the law of nature and reason, reduce the parent to slavery, much less can they reduce the offspring. Blackst. Comm. b. i. c. 14. Montesquieu's Spirit of Laws, b. 15. c. 2, &c.

The Lacedæmonians, say some, or, as others say, the Assyrians, first introduced the practice; which the Romans not only approved of, but they even invented new manners of making slaves; for instance, a man born free among them might sell his freedom, and become a slave. This voluntary slavery was first introduced by a decree of the senate, in the time of the emperor Claudius, and at length was abrogated by Leo.

The Romans had power of life and death over their slaves, which no other nations had; but this severity was afterwards moderated by the laws of the emperors; and by one of Adrian it was made capital to kill a slave without a cause.

The slaves were esteemed the proper goods of their masters, and all they got belonged to them: but if the master were too cruel in his domestic corrections, he was obliged to sell his slave at a moderate price.

The custom of exposing old, useless, or sick slaves in an island of the Tyber, there to starve, seems to have been pretty common in Rome; and whoever recovered, after having been so exposed, had his liberty given him, by an edict of the emperor Claudius, in which it was likewise forbidden to kill any slave merely for old age or sickness. (Suet. in Claud.) Nevertheless, it was the professed maxim of the elder Cato, to sell his superannuated slaves for any price, rather than maintain what he deemed an useless burden. (Plut. in Caton.) The ergastula, or dungeons, where slaves in chains were forced to work, were very com-

mon all over Italy. Columella (l. i. c. 6.) advises that they be always built under ground; and recommends it as the duty of a careful overseer, to call over every day the names of these slaves, in order to know when any of them had deserted. Sicily was full of ergastula, and was cultivated by labourers in chains. Eunus and Athenio excited the fervile war, by breaking up these monstrous prisons, and giving liberty to 60,000 slaves.

In the ancient and uncivilized ages of the world, "piracy" was regarded as an honourable practice; and this was supposed to give a right of making slaves. "The Grecians," says Thucydides (l. i.) "in their primitive state, as well as the contemporary barbarians, who inhabited the sea-coasts and islands, addicted themselves wholly to it: it was, in short, their only profession and support." The writings of Homer are sufficient to establish this account; as they shew that this was a common practice at so early a period as that of the Trojan war. The reputation which piracy seems to have acquired among the ancients, was owing to the skill, strength, agility, and valour, which were necessary for conducting it with success; and the erroneous notions that were thus entertained concerning it led to other consequences, immediately connected with the slavery of the human species. Avarice and ambition availed themselves of these mistaken notions; and people were robbed, stolen, and even murdered, under the pretended idea that these were reputable adventures. But in proportion as men's sentiments and manners became more refined, the practice of piracy lost its reputation, and began gradually to disappear. The practice, however, was found to be lucrative; and it was continued, with a view to the emolument attending it, long after it ceased to be thought honourable, and when it was sinking into disgrace. The profits arising from the sale of slaves presented a temptation which avarice and interest could not resist; many were stolen by their own countrymen, and sold for slaves; and merchants traded on the different coasts in order to facilitate the disposal of this article of commerce. The merchants of Thessaly, if we may credit Aristophanes, (Plut. Act ii. Sc. 5.) who never spared the vices of the times, were particularly infamous for this latter kind of depredation; the Athenians were notorious for the former; for they had practised these robberies to such an alarming degree of danger to individuals, that it was found necessary to enact a law, which punished kidnappers with death. From the above statement it appears, that among the ancients there were two classes of involuntary slaves; one consisting of those who were taken publicly in a state of war; and another composed of those who were privately stolen in a state of peace. To which might be added a third class, comprehending the children and descendants of the former.

The condition of slaves, and their personal treatment, were sufficiently humiliating and grievous; and may well excite our pity and abhorrence. They were beaten, starved, tortured, and murdered at discretion; they were dead in a civil sense; they had neither name nor tribe; they were incapable of judicial process; and they were, in short, without appeal. To this cruel treatment, however, there were some exceptions. The Egyptian slave, though perhaps a greater drudge than any other, yet if he had time to reach the temple of Hercules (Herodotus, l. ii. 143.), found a certain retreat from the persecution of his master; and he derived additional comfort from the reflection that his life could not be taken with impunity. But no place was so favourable to slaves as Athens. Here they were allowed a greater liberty of speech; they had their convivial meetings, their amours, their hours of relaxation, pleasantries, and mirth; they were treated in such a manner as to warrant

rant the observation of Demosthenes, in his second Philippic, "that the condition of a slave at Athens was preferable to that of a free citizen in many other countries." And here, if persecution exceeded the bounds of lenity, they had their temple, like the Egyptian, for refuge; where the legislature was so attentive, as to examine their complaints, and to order them, if they were founded in justice, to be sold to another master. Besides, they were allowed an opportunity of working for themselves; and if their diligence had procured them a sum equivalent to their ransom, they could immediately, on paying it down, demand their freedom for ever. To this privilege Plautus alludes, in his "Casina," where he introduces a slave, speaking in the following manner:

"Quid tu me vero libertate territas?
Quod si tu nolis, filiusque etiam tuus
Vobis *invitis*, atque amborum *ingratis*,
Una libella liber possum fieri."

Thus we find, to the eternal honour of Egypt and Athens, that they were the only places, if we except the cities of the Jews, where slaves were considered with any humanity at all. The inhabitants of all other parts of the world seemed to vie with each other in the debasement and oppression of these unfortunate people.

The writer, of whose valuable publication we are now availing ourselves, and to whom the cause of humanity is under inexpressible obligations, proceeds to inquire by what circumstances the barbarous and inhuman treatment of slaves was produced?

The first of these circumstances, which he mentions, was "commerce;" for if men could be considered as "possessions;" if, like "cattle," they might be *bought* and *sold*, it will be natural to suppose, that they would be regarded and treated in the same manner. This kind of commerce, which began in the primitive ages of the world, depressed the human species in the general estimation; and they were tamed, like brutes, by the stings of hunger and the lash, and their education was so conducted, as to render them commodious instruments of labour for their possessors. This degradation of course depressed their minds, restricted the expansion of their faculties, stifled almost every effort of genius, and exhibited them to the world, as beings endued with inferior capacities to the rest of mankind. But for this opinion there seems to have been no foundation in truth or justice. Equal to their fellow-men in natural talents, and alike capable of improvement, any apparent or even real difference between them and some others must have been owing to the mode of their education, to the rank they were doomed to occupy, and to the treatment they were appointed to endure.

This commerce of the human species, which produced so pernicious an effect on the nature and state of man, commenced at a very early period. The history of Joseph, recorded in the book of Genesis, leads us to a very remote era for the introduction of this nefarious traffic. In his time it seems to have been prevalent, and to have been carried on in a manner, that sufficiently indicated its having been long before established. Egypt seems to have been at this time the principal, as it was probably the first, market for the sale of the human species. It was, indeed, so famous, as to have been known, within a few centuries from the time of Pharaoh, both to the Grecian colonies in Asia, and the Grecian islands. Homer mentions Cyprus and Egypt as the common markets for slaves, about the time of the Trojan war. (*Odyl. l. xvii. 448. l. xxvi.*) Egypt is also represented, as we have already intimated, in the book

of Genesis, as a market for slaves, and in Exodus (ch. i.) as famous for the severity of its servitude. Homer also, in the place above cited, points out to us Egypt as a market for the human species, and by the epithet of "*bitter Egypt*," alludes in the strongest manner to that severity and rigour, of which the sacred historian transmitted to us the first account. The *Odyssey* of Homer shews farther, that this species of traffic was practised in many of the islands of the *Ægean* sea; and the *Iliad* informs us, that it had taken place among those Grecians on the continent of Europe, who had embarked from thence on the Trojan expedition. To this purpose, at the end of the seventh book, a fleet is described, as having just arrived from Lemnos, with a supply of wine for the Grecian camp. The merchants are described also, as immediately exposing it to sale, and as receiving in exchange, among other articles of barter, "a number of slaves." Tyre and Sidon, as we learn from the book of Joel, ch. iii. 3, 4, 6, were notorious for the prosecution of this trade. This custom appears also to have existed among other states; it travelled all over Asia; it spread through the Grecian and Roman world; it was in use among the barbarous nations, which overturned the Roman empire; and was therefore practised, at the same period, throughout the whole of Europe. However, as the northern nations were settled in their conquests, the slavery and commerce of the human species began to decline, and on their full establishment they were abolished. Some writers have ascribed their decline and abolition to the prevalence of the feudal system; whilst others, much more numerous, and with greater strength of argument, have maintained, that they were the natural effects of Christianity. The advocates of the former opinion allege, that "the multitude of little states, which sprung up from one great one at this era, occasioned infinite bickerings and matter for contention. There was not a state or seignory, which did not want all the hands they could muster, either to defend their own right, or to dispute that of their neighbours. Thus every man was taken into the service: whom they armed they must trust: and there could be no trust but in free men. Thus the barrier between the two natures was thrown down, and slavery was no more heard of in the west."

That this was not the necessary consequence of such a situation, is apparent. The political state of Greece, in its early history, was the same as that of Europe, when divided by the feudal system into an infinite number of small and independent kingdoms. There was the same matter, therefore, for contention, and the same call for all the hands that could be mustered: the Grecians, in short, in the heroic, were in the same situation, in these respects, as the feudal barons in the Gothic times.

It must be allowed, on the slightest consideration of the subject, that Christianity was admirably adapted to this purpose. It taught, "that all men were originally equal; that the Deity was no respecter of persons; and that, as all men were to give an account of their actions hereafter, it was necessary that they should be free." These doctrines could not fail of having their proper influence on those who first embraced Christianity, from a conviction of its truth; and on those of their descendants afterwards, who, by engaging in the crusades, and hazarding their lives and fortunes there, shewed at least an attachment to that religion. We find them accordingly actuated by these principles. We have a positive proof, that the feudal system had no share in the honour of suppressing slavery, but that Christianity was the only cause; for the greatest part of the charters, which were granted for the freedom of slaves

in those times (many of which are still extant), were granted "pro amore Dei, pro mercede animæ." They were founded, in short, on religious considerations, "that they might procure the favour of the Deity, which they conceived themselves to have forfeited, by the subjugation of those, whom they found to be the objects of the divine benevolence and attention equally with themselves."

These considerations, which had thus their first origin in Christianity, began to produce their effects, as the different nations were converted; and procured that general liberty at last, which, at the close of the twelfth century, was conspicuous in the west of Europe.

Within two centuries after the suppression of slavery in Europe, the Portuguese, in imitation of those piracies which existed in the uncivilized ages of the world, made their descents on Africa, and committing depredations on the coast, first carried the wretched inhabitants into slavery. This practice, thus inconsiderable at its commencement, became general; and our own ancestors, together with the Spaniards, French, and most of the maritime powers of Europe, soon followed the piratical example: and thus did the Europeans, to their eternal infamy, revive a custom, which their own ancestors had so lately exploded, from a consciousness of its impiety. The unfortunate Africans fled from the coast, and sought, in the interior part of the country, a retreat from the persecution of their invaders; but the Europeans still pursued them; they entered their rivers, sailed up into the heart of the country, surprised the Africans in their recesses, and carried them into slavery. The next step, which the Europeans found it necessary to take, was that of settling in the country; of securing themselves by fortified posts; of changing their system of force into that of pretended liberality; and of opening, by every species of bribery and corruption, a communication with the natives. Accordingly they erected their forts and factories; landed their merchandize; and endeavoured, by a peaceable deportment, by presents, and by every appearance of munificence, to allure the attachment and confidence of the Africans.

The Portuguese erected their first fort at D'Elmina, in the year 1481, about 40 years after Alonzo Gonzales had pointed out to his countrymen the southern Africans as articles of commerce.

The scheme succeeded: an intercourse took place between the Europeans and Africans, attended with a confidence highly favourable to the views of ambition and avarice. In order to render this intercourse permanent as well as lucrative, the Europeans having discovered the chiefs of the American tribes, paid their court to these; and at length a treaty of peace and commerce was concluded; in which it was agreed, that the kings, on their part, should, from this period, sentence *prisoners of war* and *convicts* to European servitude; and that the Europeans should supply them, in return, with the luxuries of the north. This agreement immediately took place, and laid the foundation of that commerce, of which the following articles contain a brief history.

Slavery is absolutely abolished in England and France as to personal servitude; our servants are not slaves, but only are subject to certain determinate services. It is said, that the moment a slave steps on English ground, he by law becomes free. See NEGRO.

When an attempt was made to introduce slavery within this nation, by stat. 1 Edw. VI. c. 3. which ordained, that all idle vagabonds should be made slaves, and fed upon bread, water or small drink, and refuse of meat; should wear a ring of iron round their necks, arms, or legs; and

should be compelled, by beating, chaining, or otherwise, to perform the work assigned them, were it ever so vile; the spirit of the nation could not brook this condition, even in the most abandoned rogues; and, therefore, this statute was repealed in two years afterwards. 3 & 4 Edw. VI. c. 16.

For the custom of marking or stigmatizing slaves, see STIGMATIZING.

SLAVE-TRADE. At the close of the preceding article we have stated the manner in which this species of commerce commenced; nor is it necessary to mention one ostensible reason that was alleged for introducing the Africans, in particular, as labourers into the newly discovered parts of the western world, and placing them under European masters, *viz. the duty of converting the heathen*; because this was but an idle pretence. It was soon found that a usage, different from that which Christianity would have dictated, was necessary, where people were transported, and made to labour against their will. A system, therefore, of severity sprung up, as it related to their treatment, which became by degrees still more cruel and degrading; so that when in after-times the situation of master and slave came to be viewed, as it existed in practice between the two, the masters seemed to have attained the rank of monarchs, and the slaves to have gone down to the condition of brutes. Hence, very early after the commencement of the slave-trade, the objects of it began to be considered as an inferior species, and even their very colour as a mark of it; and under this latter notion they continued to be transported for years and years, till different persons, taking an interest in their sufferings, produced such an union of public sentiment in their favour in England, that the parliament there were obliged, as it were, to consider their case, by hearing evidence upon it. It is from this evidence, as from the highest authority, which was heard in the years 1791 and 1792, that we shall chiefly give our account of the trade in question.

The treaty to which we have referred, stipulated to supply the Europeans with captives and convicts; but these were not sufficient for their demand, on the establishment of their western colonies. In order, therefore, to augment the number, not only those who were fairly convicted of offences were now sentenced to servitude, but even those who were suspected; and with regard to prisoners of war, they delivered into slavery not only those who were taken in a state of public enmity and injustice, but those also who, conscious of no injury whatever, were taken in the arbitrary skirmishes of the venal sovereigns of Africa. Wars were made, not as formerly, from motives of retaliation and defence, but for the sake of obtaining prisoners alone, and the advantages resulting from the sale of them. When an European ship came in sight, this was considered as a motive for war, and a signal for the commencement of hostilities. The despotic sovereigns of Africa, influenced by the venal motives of European traffic, first made war upon the neighbouring tribes, in the violation of every principle of justice; and if they did not thus succeed in their main object, they turned their arms against their own subjects. The first villages at which they arrived were immediately surrounded, and afterwards set on fire; and the wretched inhabitants seized, as they were escaping from the flames. These, consisting of whole families, fathers, brothers, husbands, wives, and children, were instantly driven in chains to the merchants, and consigned to slavery. Many other persons were kidnapped, in order to glut the avarice of their own countrymen, who lay in wait for them; and they were afterwards sold to the European merchants: while

SLAVE-TRADE.

while the seamen of the different ships, by every possible artifice, enticed others on board, and transported them to the regions of servitude.

The collectors of slaves were distributed into several classes. The first consisted of such black traders as preserved a regular chain of traffic, and a regular communication with each other, from the interior parts of the country to the sea-shore. Many of the slaves, thus driven down, are reported to have travelled at least 1200 miles from the place where they were first purchased. A pistol or a sword may have been the full value of one of these slaves, at the first cost; but his price advances, as he travels towards the sea-shore. The second class of slave-traders is composed of such as travel inland, but have no chain of commerce or communication with the shore. At a certain distance they strike off in a line parallel to the shore, and visiting the fairs and villages in their way, drop down occasionally to the coast, as they have procured slaves. The third class consists of such as travel by water up the great rivers, in their canoes, which are very long, well-armed, and carry from 50 to 70 hands. These often proceed to the distance of 1000 miles, and bring down from 60 to 120 slaves at a time. The fourth class includes those who, living near the banks of the rivers, or the sea-shore, scarcely travel at all, but coming by some means or other into the possession of slaves, either drive them, or send them immediately to the ships and factories. Most of the traders now described traffic on their own account; but there are some of the poorer sort, who travel for the ships. The different sorts of goods, with which the traders deal for slaves in the inland country, may be divided into three sorts, *viz.* East Indian, home-made or colonial, and Venetian. The first consists of cowries, or small shells, which pass for money on some parts of the coast; blue and white basks, romals, bandanoes, and other cloths and productions of the East. The second consists of bar-iron, muskets, powder, swords, pans, and other hardware; cottons, linen, spirits in great abundance, with other articles of less note. The third consists totally of beads. Almost every ship carries the three sorts of articles now stated, but more or less of one than of the other, according to the place of her destination; every different part of the coast requiring a different assortment, and the Africans, like the Europeans, repeatedly changing their taste. This is particularly the case with respect to beads. The same kind of beads, which finds a market one year in one part of the coast, will probably not be saleable there the next. At one time the green are preferred to the yellow, at another the opaque to the transparent, and at another the oval to the round.

The slave-trade, at the time of its subsistence, may be said to have begun at the great river Senegal, and to extend to the farther limits of Angola, a distance of many thousand miles. On the rivers Senegal and Gambia, the Europeans proceed in their ships till they come to a proper station, and then send out their boats armed to different villages; and on their approach to them, fire a musket, or beat a drum, to apprise the inhabitants that they are in want of slaves. The country people supply them in part, and they also procure them from the large canoes above-mentioned.

The Moors, who inhabit the left bank of the river Senegal, are notorious for depredations of this sort. They cross the river without any previous provocation, and make war upon those on the other side of it, and bring them in as prisoners, and sell them at Fort St. Louis for slaves. Mr. Kiernan has seen the remains of villages, which they had broken up in such expeditions.

Captains Hills and Wilson, and Mr. Wadstrom, and lieu-

tenant Dalrymple, inform us, that the kings in this part of the country do not hesitate to make war upon their own subjects, when in want of money. They send out their soldiers in the night, who lying before, or attacking or burning a village, seize such as come out of it, and return with them as slaves.

On the river Sierra Leona there are several private factories, belonging to the merchants of Europe, in which their agents, being white people, resided. These agents kept a number of boats, which were sent up the river for slaves; and thus they procured for the factories a regular supply.

On the Windward Coast, which reaches from Cape Mount to Cape Palmas, the natives, when they have any slaves to sell, generally signify it by fires. Practices similar to those already recited prevail from the river Gambia to the end of the Windward Coast. Lieutenant Storey says, that public robbery is here called war. Mr. Bowman, another evidence, says, that when parties of robbers were setting fire to villages, war was said to be carrying on. This account is confirmed by Mr. Town and Sir George Young, and all of them concur in stating, that these parties go out at night, break up villages, and carry off the inhabitants as slaves. Messrs. Town, Bowman, and Storey, have seen them set out upon such expeditions; and the latter, to satisfy himself, accompanied them on one occasion. These came to a town in the dead of the night, set fire to it, and took away many of the inhabitants. The above practice is so common, that both up the river Scaffus, Sierra Leona, and Junk, and at Cape Mount and Bassau, the remains of burnt and deserted villages are to be seen, on which such attacks have been made, and that the natives are found to be constantly armed. In one of the towns, two or three houses only are described to have been left standing, and two plantations of rice, which were ready for cutting down, but which the inhabitants, by being carried off, had been deprived of enjoying. Lieutenant Simpson, of the royal marines, another evidence, understood that the villages on the Windward Coast were always at war; and the reason given was, that the kings were in want of slaves. Mr. Morley, another evidence, speaks in the same language. Slaves, he says, are generally made by robbers going from village to village in the night.

The Gold Coast, which is next to the Windward Coast, presents us with the same melancholy scene. The Rev. Mr. Quakoo, who had resided as chaplain to one of the factories there for many years, informed lieutenant Simpson that wars were often made for the sole purpose of making slaves. Dr. Trotter says, by prisoners of war, the traders mean such as are carried off by robbers, who ravage the country for that purpose; the Bush-men making war to make trade, being a common way of speaking among them; and in a large cargo of slaves, he could only recollect three who had not been so obtained. Surgeon Falconbridge defines the term war, when used by the slave-dealers on this part of the coast, to mean a piratical expedition for making slaves. Mr. Morley says, what they call war, is putting the villages in confusion, and catching the inhabitants, whom they carry down to the coast and sell, where, it is well known, no questions are asked how they had been obtained. Indeed a slave-captain, when examined by the house of commons, acknowledged, that he believed a captain would be reckoned a fool by any trading man, to whom he should put such a question. And Mr. Marsh, the resident at Cape Coast castle, told Mr. How, that he did not care how the slaves he purchased had been obtained; and showed him instruments which were put into the slaves' mouths, to prevent

vent their crying out for assistance, while the robbers were conveying them through the country.

From the end of the Gold Coast to the extremity of Angola, which is the boundary of the slave-trade, and which vast districts comprehends many navigable rivers, we are shocked by the repetition of the same atrocious practices. Here, as before, going to towns in the night, setting them on fire, and seizing the people, or putting the villages in confusion, and catching the inhabitants, are called *war*. These piratical expeditions are frequently made by water in these parts. Mr. Douglass says, when a slave-ship arrives, the king sends his war-canoes up the river, where they surprise and seize all they can. Surgeon Falconbridge, Mr. Morley, and Mr. Isaac Parker, confirm the account. Up the great rivers Bonny and Calabar the king sends fleets of canoes, with armed men, which return with slaves. Mr. I. Parker was twice up the river Calabar in one of these fleets, and perhaps the only white person who was ever permitted to go with them. In the day-time, he says, when they approached a village, they lay under the bushes; but at night flew up to it, and seized every one they could catch. In this way they proceeded up the river, till they had gotten forty-five persons, which they brought back to New Town, and sold to the European ships. About a fortnight afterwards, he was allowed to accompany them on another expedition. Here, he says, they plundered other villages higher up the river than before, taking men, women, and children, as they could catch them in their huts. They seized on much the same number, and brought them to New Town, as before.

On the Gold Coast, a vessel seeking slaves, generally anchors at Annamaboe. A certain quantity of gold must be included in the articles designed for purchasing slaves, or else none can be obtained. At Whidah, Bonny, Calabar, Benin, and Angola, gold is not demanded in exchange; and boats are unnecessary, except for reaching the shore, wooding and watering, and services of a similar kind. This is particularly the case at Calabar and Bonny, which have been the greatest markets for slaves. The traders of the first class, after an absence of about nine days, have returned frequently with 1500 or 2000 slaves at a time.

The number of slaves that have been annually transported from the African coast has fluctuated according to circumstances. In the year 1768, 104,000 natives of Africa were taken from their own continent; and it continued much the same for the next five years. During the American war it was diminished. In the year 1786 the numbers may be stated at 100,000, and the ships that conveyed them to the colonies at 350. The trade, before the abolition, was confined to the English, Dutch, Danes, Portuguese, and French. England, in 1786, employed 130 ships, and carried off about 42,000 slaves. These were fitted out from the ports of London, Bristol, and Liverpool; the latter of which alone sent out 90 vessels.

The unhappy slaves are divided by Mr. Clarkson into seven classes. The most considerable, and that which contains at least half of the whole number transported, consists of kidnapped people. This mode of procuring them includes every species of treachery. Mr. Wadstrom tells us, that at Dakard lived one Ganna, who was a notorious man-stealer, and employed as such by the merchants there. He saw a boy and a woman there in confinement, both of whom had been stolen. The boy had been privately taken from his parents, in the interior part above Cape Rouge; and the woman from her husband and children at Rufisque. He saw afterwards many of the natives, who had been thus taken, brought to Goree. At Sallum the king sent for

a poor woman, under pretence of buying her millet, and then seized and sold her. General Rooke, who was governor of Goree, detected three young persons who had been stolen and brought there; and at their request, he sent them back to their friends. The same governor was applied to by three slave-captains, to kidnap one hundred and fifty men, women, and children, the king of Cayor's subjects, who had come to Goree in consequence of the friendly intercourse which had subsisted between him and that king. He refused, and was much shocked by the proposition; but the captains said, such things had been done by a former governor of the place. Captain Wilson says, that in his time, when he commanded the *Racehorse* ship of war, such private robberies were frequent on the continent, opposite to Goree. His predecessor, captain Lacy, had sent one of the natives into the country with dispatches on his Britannic majesty's account; but the poor man was soon way-laid, seized, and sold. Captain Wilson rescued him afterwards from the hold of a slave-vessel, where his life had been endangered by the inhumanity of the French captain. So generally prevalent were these robberies, that they were acknowledged by all. It was the first principle of the natives, never to go out unarmed while a slave-vessel was upon the coast, for fear of being stolen. When he has met them armed, and enquired the reason, they have pointed to a ship of this description then lying at Portudal, and said, their fears arose from that quarter. Captain Hills, when he commanded the *Zephyr* sloop of war on the same part of the coast, came to the knowledge of facts similar to those related. He tells us, he knew the same Ganna mentioned by Mr. Wadstrom, and that this very Ganna offered him a young man for sale, whom he had kidnapped; and that all the natives went armed, for fear of being so taken. Captain Hills, while lying in the river Gambia, expressed a wish, in the hearing of the black pilot, to obtain a few black volunteers for his ship. Upon this the black pilot called to two boys, who were on the shore carrying baskets of shallots, and asked captain Hills if he thought the boys would suit him; in which case, he would take them off, and bring them on board. The captain declined taking them. The black pilot appeared much mortified, and said that the merchantmen would not have refused such an offer. On the Windward Coast, robbery of this kind was so notorious, that, according to sir George Young and captain Thompson, it went by a distinct name. It was there called *panyaring*. Many are the instances testified in the evidence of this kind of depredation, and this all over the coast. Let the following suffice. At Sierra Leona a beautiful boy is stolen. Off Galenas a trader, returning home with goods, is seized by the way, and sold. Lower down a young man is surprised on the beach, and disposed of in the same manner. Off Piccanini Sestus not only a young girl is kidnapped, but her kidnapper is seized in turn, and sold to the same vessel. To the right of Piccanini Sestus a young man is invited to a feast, and then betrayed and enslaved. A little farther on, a countryman, having occasion to go to a black trader's house, the trader asks him if he had seen a ship: the other replying, no; he then engages to shew him one. Taking him on board a vessel, he receives the money for him, and leaves him there. A young woman comes out of the woods at Bonny Point to bathe: robbers watch her, and then seize her, and sell her. Three persons, crossing the river Benin, are overtaken by a black trader and his people in one of their large canoes, and carried to a ship, and sold. On the other side of the river Benin, a woman is kidnapped, as she is returning from a visit; and a father and his son, as they are planting yams for food; and all of them

them passed down to the shore, and disposed of in the same manner.

The second order of slaves, and that not inconsiderable, consists of those whose villages have been depopulated for obtaining them. The third class consists of such as have been said to be convicted of crimes. Captain Wilson says, that such as are sold on this account are sold for the benefit of their kings or judges. On asking king Dame's officer, who had brought down a culprit for sale, whether the man was guilty of the crime imputed to him, he was answered by the officer, that this was of no consequence. Mr. Town says, it is not uncommon to impute crimes falsely, or to bring on palavers, that is, accusations or trials, in order to make slaves. Mr. Morley remembers a woman sold on pretence of adultery at Old Calabar; and in the river Ambris, says Mr. Falconbridge, a king's officer wanting brandy and other goods, but having no slave with which to purchase them, accuses a man of extortion in the sale of his fish, and after a summary trial on the spot, procures him to be condemned and sold.

The fourth class includes prisoners of war; being either such as are the produce of wars that have originated in common causes; or such as have been supplied by wars made solely for the purpose of obtaining them. The fifth class comprehends those who are slaves by birth. Some traders on the coast, it is said, who have slaves in their possession, make a practice of breeding from those, for the purpose of selling to others. After having been brought up to a certain age, they are reckoned saleable. The sixth class is composed of those, who have sacrificed their liberty to gaming. The seventh and last class consists of those, who having run into debt, are seized according to the laws of the country, and sold to their creditors. The two last classes are very inconsiderable, and scarcely deserve mention.

Having lost their liberty in one or other of the ways now described, they are conveyed to the banks of the rivers, or to the sea-coast. Some are found to have belonged to the neighbourhood; others to have lived farther up the country; and others in very distant parts. It has been calculated, that some of the latter have been brought 1000 miles from their homes. Of those who come from a distance, many have travelled by water, many have been made to walk also over land. These march in droves, or cauffles, as they are called. They are secured from rising or running away, by pieces of wood, which attach the necks of two and two together; or by other pieces, which are fastened by staples to their arms. They are made to carry their own water and provisions, and some of them elephants' teeth, and other commodities, which their masters may have picked up on their route. They are watched and followed by drivers, who make the weak keep up with the strong. As they pass through different places, others, who have been reduced to slavery in a similar manner, are purchased, and added to the cauffle. Many in these cauffles speak different languages, and cannot at all understand one another.

When they reach the banks of the rivers on the coast, they are offered for sale: some to land factories, or depots kept for that purpose by the Europeans; others, where the rivers are small and shallow, to ships' boats and tenders, which are constantly plying about to purchase them; and others immediately to the ships themselves. In the rivers Senegal and Gambia, from ten to forty are brought down at a time; in the rivers Bonny and Calabar, from a thousand to fifteen hundred; and on the Windward Coast, perhaps a solitary individual, or only two or three at a time; so that slaving, as it is called, is very tedious in that quarter. All those, who are thus offered for sale, undergo previous

examination by a surgeon; and none are taken but such as are free from disorder, and in the prime of life. Indeed 25 years of age is the standard, beyond which the purchasers do not like to take them. In making their bargains, the goods as well as the slaves are valued by a medium, which is known to the parties concerned. From Senegal to the end of the Windward Coast, this medium is called a bar both by African and European brokers; on the Gold Coast and at Whidah, an ounce; at Calabar, a copper; at Benin, a pawn; and at Angola, a piece. Thus every slave is valued at so many bars, ounces, &c. Every piece of goods, every barrel of powder, every knife and cutlafs, is valued in like manner. One article is marked half a bar or ounce; another a whole bar or ounce; another five, ten, twenty, and so on. By means of this arrangement, the bill is easily made out on both sides. The Europeans reckon the amount by pen and ink; the Africans by small stones or beads. Some of the latter, however, reckon entirely by their heads, and are found to be correct.

When the slaves are conveyed to the shore, they are carried in boats to the different ships whose captains have purchased them. The men are immediately confined two and two together, either by the neck, leg, or arm, with fetters of solid iron. They are then put into their apartments; the men occupying the fore-part, the women the after-part, and the boys the middle of the vessel. The tops of these apartments are grated for the admission of light and air, and they are stowed like any other lumber, occupying such quantity of room as has been allotted to them. Many of them, whilst the ships are waiting for their full lading, and whilst they are near their native shore, from which they are to be separated for ever, have manifested great appearance of oppression and distress; and in some cases have recurred, for apprehended relief, to suicide; others have been affected with delirium and madness; others, again, have been actuated by a spirit of revenge, and have resolved on punishing their oppressors at the hazard of their own lives. In the day-time, if the weather be fine, they are brought upon deck for air. They are placed in a long row of two and two together, on each side of the ship: a long chain is then made to pass through the shackles of each pair, by which means each row is at once secured to the deck. In this state they take their meals, which consist chiefly of horse-beans, rice, and yams, with a little palm-oil and pepper. Captain Hall informs us, that they are made, after meals, to jump as high as their fetters will let them, on beating a drum. If they refuse, they are whipped till they comply. This the slave-merchants call dancing. Surgeon Falconbridge explains to us the reason of this custom, by stating that the slaves are compelled to jump for exercise; and surgeon Claxton says, that the parts on which the shackles are fastened, are often excoriated by the violent exercise they are forced to take: and of this they made many grievous complaints to him. In the same manner the song is said to be promoted among them; whereas all their songs, says surgeon Falconbridge, Mr. Morley, surgeon Claxton, Mr. Ellison, and others, are of a melancholy nature, consisting of lamentations for the loss of their country and of their friends.

When the number of slaves is completed, the ships weigh anchor, and begin what is termed the *Middle* passage, to carry them to their respective colonies. The vessels in which they are transported are of different dimensions, from 11 to 800 tons, and they carry from 30 to 1500 slaves at a time. The height of the apartments is different, according to the size of the vessel, but may be stated to be from six feet to less than three; so that it is impossible to stand erect in most

of the vessels that transport them, and in some scarcely to sit down in the same posture.

When the vessel is full, their situation is truly pitiable. A grown-up person is allowed, in the best regulated ships, but sixteen English inches each in width, two (English) feet eight inches in height, and five feet eleven inches in length; or, as surgeon Falconbridge expresses himself, not so much room as a man has in his coffin. Surgeon Wilson describes the slaves as much crowded below. He generally took off his shoes before he went down among them, and was obliged to be very cautious how he walked, lest he should tread upon them. Captain Knox admits, that they had not room to lie on their backs. It also appears, that if they are the least dilatory or reluctant in packing themselves, they are quickened by the application of the whip. Dr. Trotter says, they are so crowded below, that it is impossible to walk through them without treading on them; and also, that it is the first mate's duty to see them stowed or packed together. Those who do not get quickly into their places, are compelled by a cat-o'-nine-tails. But now their situation becomes too wretched to be described. No language has words to explain it properly. Captain Hall has often heard them cry out from below for want of air. The space between decks was so hot, that often, after he has been there but a few minutes among them, he found his shirt so wetted by perspiration, that he could have wrung it. Mr. Ellison says, that the steam from their confined bodies below comes up through the gratings like a furnace. Surgeon Wilson has often heard them complain of heat. The bad effects, which resulted from this and their confinement, were weakness and fainting. He has seen some die a few minutes after being brought up, which proceeded from corrupted air and heat jointly. He has seen others go down apparently well at night, and found them dead in the morning. He had an hospital on board, but the sick slaves were obliged to lie on the bare boards, so that the motion of the vessel often occasioned excoriations from the prominent parts of their bodies. Surgeon Falconbridge declares, that he has known slaves go down apparently in health, and brought up dead in the morning. He once opened one of them surgically, to discover with certainty what was the cause of his death; and found, from the appearance of the thorax and abdomen, that it was from suffocation. He says, that once on going below, he found that twenty of the slaves had fainted. He got them instantly hauled up on deck; but notwithstanding the quickness of his movements on this occasion, two or three of them died. And once, though he was only fifteen minutes in their room below, he became so ill himself, that he could not get up again to the deck without help; and he never was below many minutes together, but his shirt was as wet as if it had been dipt in water. He says also, that as the slaves, whether well or ill, always lie on the bare planks, the motion of the ship rubs the flesh from the prominent parts of their body, and leaves the bones almost bare. And when the slaves have the flux, which is frequently the case, the whole place becomes covered with blood and mucus, like a slaughter-house; and as they are fettered and wedged close together, the utmost disorder arises from endeavours to get to three or four tubs, which are placed among them for necessary purposes: and this disorder is still further increased, by the healthy being not infrequently chained to the diseased, the dying, and the dead. Dr. Trotter, speaking on the same subject, gives us an equal melancholy account. When the scuttles, says he, in the ship's sides, are obliged to be shut in bad weather, the gratings are not sufficient for airing the rooms. He never himself could breathe freely below, unless im-

mediately under the hatchway. He has seen the slaves drawing their breath with all that laborious and anxious effort for life, which are observed in expiring animals, subjected by experiment to foul air, or in the exhausted receiver of an air-pump. He has also seen them, when the tarpaulings have been thrown over the gratings, attempting to heave them up, crying out, in their own language, *Kickeraboo, kickeraboo*, that is, "We are dying." Most of them have been recovered, by being brought upon deck; but some have perished, and this entirely by suffocation, as they had no previous signs of indisposition.

The slaves, after having been stowed, soon begin to experience the effects that might be naturally expected from their situation. The pestilential breath of many in so confined a state renders them sickly, and the vicissitude of heat and cold generates a flux. Several die, and others are induced to destroy themselves, or to revenge themselves on their oppressors. The ships, having completed the middle passage, anchor in their destined ports; and the unhappy Africans on board are prepared for sale. Some are consigned to brokers, who sell them for the ships. With this view they are examined by labourers, who want them for their farms; and in the selection of them, friends and relations are parted without any consideration; and when they part with mutual embraces, they are severed by a lash. Another mode of sale is by vendue; in which case, they are carried to a tavern, or other public place, where, being put up to sale, they become the property of the highest bidder. These are usually such as are in a sick and emaciated state, and are generally sold for a few dollars. The third mode of selling them is by the "scramble." In this case, the main and quarter-decks of the ship are darkened by sails, which are hung over them at a convenient height. The slaves are then brought out of the hold, and are made to stand in the darkened area. The purchasers, who are furnished with long ropes, rush, as soon as the signal is given, within the awning, and endeavour to encircle as many of them as they can.

These scrambles, however, are by no means confined to the ships. They are made frequently on the shore. When the latter happens to be the case, the unhappy objects of them are shut up in an apartment, or court-yard, the doors of which being thrown open, the purchasers rush in, with their ropes in their hands, as before described.

Nothing can exceed the terror which the wretched Africans exhibit on these occasions. An universal shriek is immediately heard. All is consternation and dismay. The men tremble. The women cling together in each other's arms. Some of them faint away, and others have been known to expire. If any thing can exceed the horror of such a scene, it must be the iniquity of valuing a part of the rational creation in so debased a light, and of scrambling for human flesh and blood.

During the time that elapses from the slaves being put on board, on the African coast, to the time when the receivers leave the colonies, after having disposed of their cargoes, about 25,000 lives are destroyed, *i. e.* one-fifth, or nearer one-fourth of the number put on board. About 20,000 of those who are annually imported die during the "seasoning;" which seasoning is said to expire, when the first two years of servitude are completed. This is the time which an African must take to be so accustomed to the colony, as to be able to endure the common labour of a plantation, and to be put into the *gang*. From the period when their seasoning terminates, their situation is as follows. They are summoned at five in the morning to begin their work. This work may be divided into two kinds, the culture of

the fields, and the collection of grafs for cattle. The laft is the moft laborious and intolerable employment; as the grafs can only be collected blade by blade, and is to be fetched frequently twice a day at a confiderable diftance from the plantation. In thefe two occupations they are jointly taken up, with no other intermiffion than that of taking their fubfiftence twice, till nine at night. They then feparate for their refpective huts, when they gather flicks, prepare their fupper, and attend their families. This employs them till midnight, when they go to reft. Such is their daily way of life for rather more than half the year. They are fixteen hours, including two intervals at meals, in the fervice of their matters: they are employed three afterwards in their own neceffary concerns; five only remain for fleep, and their day is finifhed.

During the remaining portion of the year, or the time of crop, the nature, as well as the time, of their employment is confiderably changed. The whole gang is generally divided into two or three bodies. One of thefe, befides the ordinary labour of the day, is kept in turn at the mills, that are constantly going, during the whole of the night. This is a dreadful encroachment upon their time of reft, which was before too fhort to permit them perfectly to refresh their wearied limbs, and actually reduces their fleep, as long as this feafon lafts, to about three hours and an half a night, upon a moderate computation. Thofe who can keep their eyes open during their nightly labour, and are willing to refift the drowfinefs that is continually coming upon them, are prefently worn out; while fome of thofe, who are overcome, and who feed the mill between fleeping and being awake, fuffer, for thus obeying the calls of nature, by the lofs of a limb; a hand or arm being frequently ground off. In this manner they go on, with little or no refpite from their work, till the crop feafon is over, when the year (from the time of our firft description) is completed. They are badly clothed, and very feantly fed; and on fome plantations treated with great feverity.

The condition and treatment of the Africans are juftified by the affertion, that they are an inferior link of the chain of nature, and made for favery. Accordingly the inferiority of their capacities has been urged, and alfo their inability for any mental exertions and attainments. But inftances of genius and of improvement, and of skill in the mechanical arts, have been adduced, both among the ancients and moderns, fufficient to refute this objection. Some have inferred their inferiority in the fcale of nature, from their colour. We refer thofe, who wifh to fee this argument difcuffed, to Mr. Hume's Effays, Eff. xxi. p. 222, note M; Dr. Beattie's Effay on Truth; and Clarkfon's Effay, &c.

Sir George Young and captain Thompfon, both of the royal navy, and the reverend Mr. Newton, and furgeons Falconbridge and Wilfon, who were feverally called upon for their public testimony on this fubject, all declare, that the capacities of the Africans are good; and that they would be equal, under equal advantages, to thofe of the Europeans.

Mr. Wadftrom, another of thofe examined, who travelled on difcovery in Africa, by order of the king of Sweden, afferts the fame thing; for he fays, they are as capable of improvement as the whites. He found among them perfons who could manufacture gold and iron. Others made cloth and leather with neatnefs, dyeing the former, and tanning the latter. Others made indigo, falt, foap, and earthenware, with confiderable skill. He offered to produce different fpecimens of their work.

This account of their capacity and manufacture is corroborated by captain Wilfon of the royal navy, lieutenant

Dalrymple of the army, and Mr. Kiernan, three other witnesses, all of whom vifited the fame part of the coaft.

Of their fenfibility, feveral inftances occur in the evidence. Mr. Wadftrom is convinced that they furpafs in affection fuch of the Europeans as he has known, and that they are honeft and hofpitable. He has been among them without fear, though alone, and was always treated by them with civility and kindnefs. Captain Wilfon fays, that they are grateful and affectionate; that when he was many miles up their country, alone and unprotected, they treated him moft kindly, vying with each other in entertaining him, and shedding tears at his departure. Captain Thomfon, before mentioned, lieutenant Storey of the royal navy, lieutenant Dalrymple, Mr. How, the botanift, Mr. Towne, and captain Hall of the merchants' fervice, concur in defcribing them as harmlefs, friendly, hofpitable, juft and punctual in their dealings, and as capable of virtuous actions as the reft of mankind. Mr. Bowman, who refided among them as a trader, found them good and honeft, friendly and hofpitable, induftrious, difpofed to trade, raifing rice for fale. They faid, they fhould like to trade with good white men, and would foon raife more plantations of rice. Captain Hills of the royal navy has feen them raifing provifions, and drefling their corn. They appeared to him to poffefs great fenfibility. Several of them fpoke good French and Englifh.

This is the character given of them by the witnesses now mentioned. It is melancholy, however, to obferve, that as they become acquainted with the European fave-traders, their difpofition feems to be changed; and that they are belt, where they have the leaft intercourfe with the latter. Lieutenant Storey tells us, they are more honeft inland than upon the coaft. Mr. Towne, who was three or four hundred miles up the country, fays, the natives are hofpitable, kind, and ready at learning languages; that in the inland country they are innocent, but, on the coaft, their intercourfe with Europeans has made them adepts in roguery, and taught them to plunder, and pick up one another to fell. Dr. Trotter, phyfician, fays, that they are fufceptible of all the focial virtues. He has known inftances of feeling equal to thofe of any civilized people whatever, and has feen no bad habits but among thofe engaged in trade with white men. Captain Hall found cultivation in the higheft ftate at Fernandipo, where they had no trade in faves. Mr. How, the botanift, had been upon almoft every Britifh fettlement, and always found the culture in a higher degree, where there was but a little of the fave-trade; and juft the reverse, where it prevailed. The reverend Mr. Newton fays, the belt people were thofe who had the leaft intercourfe with the Europeans; and they were worfe, in proportion to their acquaintance with us; and when charged with a crime, would fay, "Do you think I am a white man?" He lived alone among the Sherbro people in fafety, who were friendly and civilized. Lieutenant Dalrymple fates, that in natural capacity the Africans equal any people whatever. They are humane, hofpitable, and well difpofed. He apprehends, that if they had a proper market for their produce, they would be as induftrious as any Europeans; for where there was no fave-trade, they were very induftrious, manufacturing cotton-cloth, working in gold, fiver, and iron, and alfo in wood and leather, making faddles, bow-cases, fceabbards, and other articles.

It appears from the above account, that the Africans are perfons of the like feelings as ourfelves; that they have the fame intellectual powers, and the fame capability of improvement; the fame focial difpofitions, and the fame moral qualifications; but that they are more or lefs in-

nocent, as they have more or less connection with the Europeans.

To one argument that has been alleged in favour of slavery, we wish to direct the attention of our readers, before we close this article. It has been said, that slavery was not formally abolished by the gospel, and that it therefore continued for a long time after the introduction of Christianity. It has been said, that St. Paul, having converted Onesimus to the Christian faith, who was a fugitive slave of Philemon, sent him back to his master. This circumstance has furnished the receivers with a plea, that Christianity encourages slavery. But they have not only strained the passages which they produce in support of their assertions, but are ignorant of historical facts. The benevolent apostle, in the letter which he wrote to Philemon, the master of Onesimus, addresses him to the following effect: "I send him back to you, but not in his former capacity, not now as a servant, but above a servant, a brother beloved. In this manner I beseech you to receive him, for though I could enjoin you to do it, yet I had rather it should be a matter of your own will, than of necessity."

It appears that the same Onesimus, when he was sent back, was no longer a slave, that he was a minister of the gospel, that he was joined with Tychicus in an ecclesiastical commission to the church of the Colossians, and was afterwards bishop of Ephesus. If language, therefore, has any meaning, and if history has recorded a fact which may be believed, there is no case more opposite to the doctrine of the receivers, than this which they produce in its support.

It is said again, that Christianity, among the many important precepts which it contains, does not furnish us with one for the abolition of slavery. But the reason is obvious. Slavery, at the time of the introduction of the gospel, was universally prevalent, and if Christianity had abruptly declared, that the millions of slaves should have been made free, who were then in the world, it would have been universally rejected, as containing doctrines that were dangerous, if not destructive, to society. In order, therefore, that it might be universally received, it never meddled, by any positive precept, with the civil institutions of the times: but though it does not expressly say, that "you shall neither buy, nor sell, nor possess a slave," it is evident that, in its general tenor, it sufficiently militates against the custom.

The first doctrine which it inculcates is that of brotherly love. It commands good will towards men. It enjoins us to love our neighbour as ourselves, and to do unto all men, as we would that they should do unto us. And how can any man fulfil this scheme of universal benevolence, who reduces an unfortunate person, against his will, to the most insupportable of all human conditions; who considers him as his private property; and treats him, not as a brother, nor as one of the same parentage with himself, but an animal of the brute creation?

But the most important doctrine is that, by which we are assured that mankind are to exist in a future state, and to give an account of those actions which they have severally done in the flesh. This strikes at the very root of slavery. For how can any man be justly called to an account for his actions, whose actions are not at his own disposal? This is the case with the *proper* slave. His liberty is absolutely bought and appropriated; and if the purchase is just and equitable, he is under the necessity of perpetrating any crime, which the purchaser may order him to commit; or, in other words, of ceasing to be accountable for his actions.

These doctrines, therefore, are sufficient to shew, that slavery is incompatible with the Christian system. The

Europeans considered them as such, when, at the close of the twelfth century, they resisted their hereditary prejudices, and occasioned its abolition. Hence one, among many other proofs, that Christianity was the production of infinite wisdom; that though it did not take such express cognizance of the wicked national institutions of the times, as should hinder its reception, it should yet contain such doctrines, as, when it should be fully established, would be sufficient for the abolition of them all. See Clarkson's Essay on the Slavery and Commerce of the human Species, passim.

SLAVE-TRADE, *Abolition of the.* It is a circumstance favourable to the historian, that this great work was never regularly attempted till our own times; because the facts relating to it being fresh in every one's memory, an opportunity has been afforded him of examining them, and of estimating their truth: hence posterity will have the advantage of having more than usually accurate statements on the subject. Mr. Thomas Clarkson, a gentleman now living, who was among the warmest patrons of this sacred cause, has published an account of the different measures pursued to promote it. These were registered at the time, either by himself, or the estimable committee which acted in concert with him. His history, in two volumes octavo, has been now more than six years before the public, and not the shadow of a doubt has been expressed as to the authenticity of any thing asserted therein; we cannot, therefore, we conceive, hand down information on this great subject in a more satisfactory manner, than by giving to the reader a concise abridgment of the work itself.

The great work of the abolition, according to Mr. Clarkson, was not the entire produce of his own day. It was too mighty to have been accomplished, either by a few individuals, or in a short period of time: it was necessary that men's minds should have been previously instructed and prepared: hence, from the very beginning of the infamous traffic, to the time when he became a public actor in the scene of its suppression, which was in the year 1787, there had not been wanting good men to lift up their voices against it: and as the sentiments of these, who were most of them authors, had been given to the public in their respective works, either in poetry or prose, for a long succession of years, hundreds of persons had been then taught in England to condemn it. These, that is, the good men just alluded to, Mr. Clarkson considers as so many necessary forerunners (indeed he gives them that title); and considers them also, though most of them lived before his own time, as so many coadjutors in the work. The first mentioned are cardinal Ximenes, the emperor Charles V., pope Leo X., queen Elizabeth of England, and Louis XIII. of France; concerning all of whom he gives anecdotes in support of the title thus given them.

Having spoken first of the men in power, Mr. Clarkson divides the forerunners who walked in humbler life into four classes. The first consists principally of persons in England, of various religious descriptions, who bore their testimony against the trade in their successive writings up to the year 1787. Among the poets were Pope, Thomson, Shenstone, and Cowper; among the divines, bishop Warburton, Rd. Baxter, Beattie, Wesley, Whitfield, Wakefield, and Paley; among the others, were Montesquieu, Hutcheson, Wallis, Burke, Pottlethwaite, Day, Hartley, Millar, and Granville Sharp. The latter, however, is to be particularly distinguished from the rest, and also to be borne in mind; for whereas the others had only handed down the traffic in question as infamous, by the mention made of it in their respective works, this good man spent whole years in bringing
the

the cruelty and wickedness of it into public notice. He tried, at his own expence, the famous case of *Somerfet*, and several others, in our courts of law. He was, in fact, the first labourer in the cause. He began to be the public advocate of the oppressed Africans in 1765, and was waiting for opportunities for farther exertion in 1787, the particular epoch before-mentioned.

The second class consists of the Quakers in England. This estimable society passed a public censure upon the traffic at their yearly meeting in London, in 1727. Thus they followed up, by other resolutions as a body, in 1758, 1761, 1763, and 1772, when they had become principalled against it as against a crime of the deepest dye. In 1783 they petitioned parliament against its continuance. In this year certain members of the society thought it their duty to make their fellow countrymen at large acquainted with the horrible nature of it: these were, Thomas Knowles, George Harrison, Samuel Hoare, John Lloyd, Joseph Woods, and William Dillwyn. They formed themselves into a committee in London for this purpose; they wrote and circulated books; they conveyed also information on the subject through the London and country newspapers. It was not known, however, from whom the information came, as their names were concealed from the public. In this manner they continued to work their way from 1783 to 1787.

The third class consists of the Quakers and others in North America. The Quakers there entertained the same opinion as their brethren in England on this subject. In 1696 and in 1711, they condemned, as a religious body, this cruel traffic; and in 1754, 1755, 1774, 1776, and 1778, they not only passed resolutions against it, as far as their own members were concerned, but also against slavery itself. In process of time, however, individuals rose up out of this benevolent body, and became public labourers in the cause of the unhappy Africans. The two principal of these were John Woolman and Anthony Benezet. The former travelled many hundred miles on foot, to converse with planters, and others, on the iniquity of holding their fellow creatures in bondage; and the latter laboured for years in collecting information concerning Africa and the slave-trade, and in handing it to the world. At this time other people, of other religious denominations, came forward in North America, and contributed to increase the odium which the Quakers had been the first to excite there against the traffic; when, in 1774, James Pemberton, a pious Quaker in Pennsylvania, and Dr. Rush, an eminent physician, and a man of weight among the Presbyterians in the same province, formed a committee, in which persons of different religious sects joined for the purpose of abolishing both the slave-trade and slavery on their own continent. This committee was obliged to suspend its operations during the war with Great Britain, but afterwards resumed its functions. In 1787 it added considerably to its numbers, and took in, among others, the celebrated Dr. Franklin, who was its first president in its renovated state.

It will be proper to stop here, and to interrupt the thread of the history for a moment. It has appeared, from what has been said above, first, that Mr. Granville Sharp, the most conspicuous member of the first of the classes now mentioned, was alive in 1787, and then waiting for an opportunity of exerting himself farther in behalf of the injured Africans; secondly, that of the second class, William Dillwyn was one of a committee for the same object in the same year; and, thirdly, that James Pemberton was also alive in the very same year, and a very conspicuous member of the third. Now it happened that William Dillwyn, who had been born and long resident in America, had been in ha-

bits of intimate friendship with James Pemberton; and that in consequence of his acquaintance also with the venerable Anthony Benezet, he had been introduced, by means of a letter from him, upon coming to England, to Mr. Granville Sharp. Here then we find that a member of the second class was accidentally known to a member of the first, and also to a member of the third: thus we see how easily William Dillwyn might be made the medium through whom the members of all the classes might be easily united, if a fit occasion should offer.

To return, we come now to the fourth class of forerunners. The first in this class was Dr. Peckard, master of Magdalen college, in the university of Cambridge. This gentleman had not only censured the slave-trade in the severest manner, in a sermon preached before the university itself; but when he became vice-chancellor of it, in 1785, he gave out the following subject for one of the bachelors' prizes, "Anne liceat invito in servitute dare?" or, "Is it right to make slaves of others against their will?" At this time Mr. Thomas Clarkson, before-mentioned, who had obtained the bachelor's prize of the former year, determined to become a candidate for that of the present. He took prodigious pains to make himself master of the subject, as far as the time would allow, both by procuring proper books, and by seeing as many persons as he could of those who had been in Africa, and who had become in any degree acquainted with the nature of the slave-trade. Having thus gained a considerable stock of necessary information, he wrote his Latin essay, and having sent it in to the vice-chancellor, he soon found himself honoured with the first prize. After this, being then in London, he went down to Cambridge at the time of the commencement, in order to read it publicly, as is usual, in the senate-house. The next day he returned towards London; he was then on horseback; but while upon the road the subject of the essay entirely engrossed his thoughts; he became at times seriously affected as he travelled on. He once stopped his horse, and dismounted and sat down on a bank by the roadside. Here he tried to persuade himself, that the contents of the essay which he had read in the senate-house the day before, were not true. The more, however, he reflected upon the authorities on which he knew them to be founded, the more he gave them credit; and the more he gave them credit, the more he was convinced that it was an imperious duty in some one to endeavour to see the sufferings of the unhappy Africans to an end. Agitated in this manner, he reached London. This was in the summer of 1785. In the autumn of the same year, he found himself often similarly exercised; till at length he began to have serious thoughts of devoting his life to the cause of injured Africa. Being then but twenty-four years of age, he considered his youth and his want of knowledge of the world as a great obstacle. Many other circumstances occurred to discourage him. He thought, however, that there was one way, in which he might begin to be useful to the cause; namely, by translating his Latin essay, and publishing it in English. Accordingly he began the work, and having finished it, he was looking out for a publisher, when he accidentally met an old friend of his family, who belonged to the religious society of the Quakers. This gentleman, of his own accord, asked him why he had not published his prize essay in English. Many of his brethren (the Quakers), he said, were anxiously expecting it. Upon farther conversation, this gentleman introduced Mr. Clarkson to Mr. Phillips, a bookseller in George-yard, Lombard-street, and who was also of the religious society before-mentioned; at which interview it was agreed that the latter should immediately

mediately publish the work. In a short time after this, Mr. Phillips introduced Mr. Clarkson to Mr. Dillwyn of Walthamstow, one of the second class of coadjutors before-mentioned, with whom he spent the day. Here it was that he heard for the first time of the labours of Mr. Granville Sharp. But how surprised was he to learn that Mr. Dillwyn had two years before associated himself with five others (as has been already mentioned), for the purpose of enlightening the public mind in England on this great subject. How astonished was he to find that a society had been formed in North America for the same purpose, with some of the principal of which Mr. Dillwyn was himself acquainted. He was almost overwhelmed with the thoughts, which darted upon him on this occasion. He could not but consider that he had been providentially led to Mr. Dillwyn's house; that the day-star of African liberty was rising; and that probably he himself might be now permitted to have the honour of becoming a humble instrument in promoting it. Soon after this he was introduced to the venerable Mr. Sharp, the last and most eminent of the second class of coadjutors, and soon after this his work came out under the title of "An Essay on the Slavery and Commerce of the human Species, particularly the African, which was honoured with the first Prize in the University of Cambridge, for the Year 1785." The work having been now ushered into the world, (this was in June 1786,) Mr. Clarkson resolved upon the distribution of it in the most select manner he could, in order that the case of the unhappy Africans might be known by those who had in some degree the power of relieving them. Accordingly, at his request, Dr. Baker, a most exemplary clergyman in London, lord and lady Scarfdale, sir Charles and lady Middleton, and Mr. Bennet Langton, the intimate friend of Dr. Johnson, of Jonas Hanway, of sir Joshua Reynolds, of Edmund Burke, and of other celebrated persons, undertook to distribute copies of it personally among their own friends, in the higher ranks of life, and to use their interest in procuring a perusal of them. Under their auspices the book was first introduced into the polite world. The mind, however, of the author became daily more and more agitated on the subject of it. He was not satisfied that what he was then doing was all that was necessary to be done; or that it was all that was required of him. To make the case of the unhappy Africans known, was desirable as a first step; but would this of itself put a stop to the horrors of the trade? He believed not: he believed there would be no hope of success, unless some one would resolve to make it the business of his life. The question then was, was he himself called upon to do it? His own peace of mind required that he should give a final answer to this question. To do this he retired frequently into solitude. The result was, after the most mature deliberation, and the most painful struggle, that he determined to devote his whole life, should it be necessary, to the cause. This determination was made about the latter end of December, 1786; in the beginning of 1787 the distribution of the essay went on, but by additional hands. Mr. Sheldon, sir Herbert Mackworth, lord Balgonie (now lord Leven), each took a part on the occasion. The Quakers joined in the distribution also, among whom, Mr. Richard Phillips (now living) is to be particularly noticed. This arrangement having been made, Mr. Clarkson was now able to devote all his time to qualify himself for the arduous situation to which he had devoted himself. He gained introductions to persons who had been in Africa and the West Indies, and obtained still farther information on the subject in its different branches. He visited slave-ships lying in the Thames, either as they came in or sailed out of port, that

he might know their construction and other particulars. He went frequently to the custom-house in London, where he learnt the nature of the articles which constituted the traffic, the loss of seamen employed in it, and other matters which he found it essential to know. He kept up a correspondence with persons in Liverpool for the same purpose. He visited also members of parliament, and this almost daily, to interest them in his cause; to give them information; to answer questions; and to explain doubts, if they had any, on any part of the subject. Among those who appeared most affected by his visits, and most anxious to co-operate with him, was Mr. Wilberforce, the member for the county of York. This gentleman not only read the evidence which Mr. Clarkson sent him on the subject, as he collected it fresh from day to day, but actually sent for, and took the pains to examine, at his own house, those persons who had given it, that he might judge for himself, from their own mouths, of the truth or falsehood of the enormities which had been charged upon the slave-trade. The same gentleman appointed also a meeting once a week, at his own house, of a few select friends, to deliberate on the propriety, and, if this were resolved upon, on the proper method of taking up the cause. These meetings continued for some time, when at length, at a dinner at the house of Mr. Bennet Langton, who has been before-mentioned, where several persons of consequence were invited for the purpose of talking over the matter, and of coming to a final determination upon it, Mr. Wilberforce pledged himself to bring forward the great question of the abolition of the slave-trade in parliament, as soon as ever he should feel himself prepared for so tremendous a task. Here then the matter began to assume a shape. A parliamentary leader had been secured, and one whose virtuous life corresponded with the sacredness of the cause which he was to advocate. Mr. Clarkson, who was present at this dinner, carried directly the news of what had taken place to several of his friends, but particularly to Mr. Granville Sharp, Mr. Dillwyn, and three or four others of the religious society of the Quakers, all of whom he had previously taught to expect such a result. The consequence was, that the following persons met the next day, and without loss of time formed themselves into a committee, "for procuring such information and evidence, and publishing the same, as may tend to the abolition of the slave-trade, and for directing the application of such monies as may be collected for the above purpose," *viz.* Granville Sharp, Samuel Hoare, George Harrison, John Lloyd, Joseph Woods, William Dillwyn, Thomas Clarkson, Richard Phillips, James Phillips, Philip Sansom, John Barton, and Joseph Hooper. Mr. Granville Sharp, the first mentioned, may be considered, from what has been before said, as representing the first of the classes which have been described. The four next were the real representatives of the second. The third class, or that of the Quakers in America, may be considered as represented in the person of William Dillwyn, by whom, indeed, it was afterwards united to the committee now formed; and Mr. Clarkson and Mr. R. Phillips as representing the fourth, most of the members of which they had been the means of raising. "Thus," says the historian, "on the 22d of May, 1787, the representatives of all the four classes, of which I have been giving a history from the year 1716, met together, and were united in that committee, to which I have been all along directing the attention of the reader; a committee, which, labouring afterwards with Mr. Wilberforce as a parliamentary head, did, under Providence, in the space of twenty years, contribute to put an end to a trade, which, measuring its magnitude by its crimes and sufferings, was the greatest practical evil that ever afflicted the

SLAVE-TRADE.

the human race. After the formation of the committee, notice was sent to Mr. Wilberforce of the event; and a friendship began, which has continued uninterruptedly between them from that to the present day." In the following month, that is, in June 1787, the committee simplified its former title, and was ushered into the world. It professed to have nothing to do with the emancipation of slaves already in bondage. Its only object was the abolition of the African slave-trade. From this period we shall give a history of its proceedings, year by year.

The committee was no sooner formed, than Mr. Clarkson drew up "A Summary View of the Slave-Trade, and of the probable Consequences of its Abolition." It consisted only of about a dozen pages. It detailed the different methods of making slaves in Africa, their treatment, sufferings, and mortality in the passage; and also the treatment of the survivors in the colonies to which they were carried; and it promised the publication of an Essay on the Impolicy of the Slave-trade. This summary the committee determined to print, and to circulate all over the kingdom. In the mean time Mr. Clarkson was to take a journey to the different slave-ports, to increase his own knowledge of the subject. Such knowledge was absolutely necessary in case parliament should call for evidence: and if there was any one time more fit than another for procuring such evidence, it was the present; for men's minds had not then been heated by talking upon the subject, nor had interest hitherto felt itself biased to conceal the truth; but as soon as ever it should get abroad that parliament was to look into the subject, all avenues to farther information would be shut against him. The first place he visited was Bristol, where he resided for some weeks. Here he obtained a knowledge of several articles of African produce, such as rice, indigo, cotton, spices, and woods, and collected specimens of them. He obtained specimens also of the different manufactures of the natives of Africa, both in wood, cotton, leather, iron, and gold. He examined the construction of slave-ships, and took the dimensions of several. He obtained histories of their former voyages. He collected chains, handcuffs, thumb-screws, and other horrid instruments used in this execrable traffic. He discovered the scandalous modes of procuring and paying those seamen who were employed in it, the sad ratio of their mortality on the voyage, and the prodigious difference between the mortality of these and of those employed in other trades, of which he was enabled to take a comprehensive view, from procuring the muster-rolls of almost every ship belonging to the port. But that which hurt his feelings the most, and which kept him indeed in a state of constant misery while in Bristol, was the barbarous usage, and this almost without an exception, of the seamen employed in this traffic. He took many out of the slave-vessels there. He took up the cause of some of these, and obtained damages for them in the courts of law. He sent a chief mate to prison for the murder of one of the crew acting under him. While at Bristol, he formed a committee to act in union with that of London, and obtained promises of petitions to parliament against the continuance of the inhuman traffic from that city, and from Bath, Monmouth, and Bridgewater. On his journey from Bristol to Liverpool, he procured the promise of similar petitions from Gloucester, Worcester, and Cheller, and secured the provincial newspapers as he travelled on in behalf of his cause. On his arrival at Liverpool, he followed the same line of enquiry as at Bristol, for six weeks, after which period (so incensed were merchants, captains of ships, and others connected with the trade, against him) it would have

been dangerous to stay. From thence he visited Lancaster, the last of the slave-ports, and at length returned to London, after an absence of five months, in the December of 1787. The committee, in the mean while, that is, during his absence, had been equally well employed, and had been equally indefatigable. The first thing they did was to make known, by public advertisement, their existence as a committee, and the great object they had in view. They ordered a seal to be engraved for their correspondence. The device upon it was a negro in chains, kneeling, and in a supplicating manner lifting up his hands to heaven. The motto round the device consisted of these words, "Am I not a man and a brother?" They then added to their committee, to increase their labourers; and having done so, they directly opened a correspondence throughout England, Wales, and Scotland, which they extended afterwards to America. This gave them an opportunity of making their cause known in the most extensive manner. Accordingly, when things had been thus prepared, they circulated many thousands of the summary views before-mentioned, and, at the same time, addressed by letter all the corporate bodies in the kingdom. These efforts soon convinced them, that there were thousands of kindred souls in their own country, who felt with them on the great subject of their institution. The Quakers were the first, as a body, to acknowledge and approve it; the general Baptists the next: then followed letters of approbation, and promises of support from people of all religious denominations. Among these were, the famous Dr. Price and John Wesley; Mr. Roscoe, the historian and poet; Dr. Porteus, bishop of Chester; Dr. Woodward, bishop of Cloyne; Dr. Hinchliffe, bishop of Peterborough; Dr. Horne, afterwards bishop of Norwich; Dr. Bathurst, now bishop of the same; archdeacons Paley and Plymley (now Corbett); the celebrated marquis de la Fayette, now alive, who was soon afterwards conspicuous in the French revolution; and Brissot and Claviere, afterwards two distinguished members of the national convention in France, and who suffered under the tyranny of Robespierre. This good feeling continued to spread, when, in the month of February, 1788, there appeared to be among the people of England a general feeling in behalf of the injured Africans. By this time thirty-five petitions had been presented to parliament from different places, praying for the abolition of the slave-trade, and several others had been resolved upon. These proceedings produced such an effect upon the government, that the king was advised to order a committee of privy-council to inquire into the nature of the slave-trade. This order was dated February 11. An inquiry was of course immediately set on foot. The first witnesses examined, were persons sent expressly as delegates from Liverpool, who had not only been themselves in the trade, but who were then interested in its continuance. These endeavoured to shew, that none of the enormities with which it had been charged belonged to it; and that it was even attended with circumstances favourable to the unhappy victims of it. A great prejudice therefore was excited, in the very beginning of the inquiry, in the minds of some of the privy-council against the abolitionists; whom they considered as misinforming the public mind with respect to a traffic, which appeared to be so vitally connected with the manufacturing and commercial interests of the country, that it would be almost national ruin to abolish it. Happy was it for the cause, at this moment, that Mr. Clarkson had taken his journey to Bristol and other places, as before-mentioned; for he had become acquainted, in the course of it, with persons who had witnessed the horrors of the trade; but who, having then quitted it, had no
interest

interest in concealing the truth. These, though few, were highly respectable; and their evidence, when called before the council, contributed to counteract that of the Liverpool delegates, and others, and to turn the tide, which had run so strong against the abolitionists, in their favour. The inquiry which had been thus set on foot, continued through February, March, April, and a part of May. During this time the petitions from the people to parliament had increased to one hundred and three. The committee also had circulated many new books throughout the kingdom, written by eye-witnesses of the several facts they contained, and all contributing to give new information, and to add new horror to the trade. Mr. Wilberforce also had been preparing to introduce the subject into parliament; but at the time when his motion was expected, he was too ill to make it. Indeed, his life was despaired of. Under these circumstances, his friend, Mr. Pitt, then chancellor of the exchequer and prime minister, undertook to supply his place. On the 9th of May he opened the business in the house of commons, and concluded by a motion, "that this house will, early in the next session of parliament, proceed to take into consideration the circumstances of the slave-trade complained of in the petitions, and what may be fit to be done thereupon." A discussion took place in consequence, during which there was an apparent enthusiasm in the house in behalf of the injured Africans. The members for Liverpool, however, denied the existence of any of the cruelties complained of; but they did not oppose the motion, and therefore it was unanimously agreed to. This pledge having been given by parliament, the public seemed satisfied with it, and of course nothing more was expected in that session; when, on the 21st of May, sir William Dolben suddenly rose up in the house of commons, and moved for leave to bring in a bill on the subject of the slave-trade. As the trade, he said, was evidently allowed to go on till the next session, he thought it was the duty of the house to take care that it should be carried on with as much humanity as possible in the interim. His great object, therefore, was to alleviate the sufferings of the poor Africans in their transportation, by allowing them more room, which might be done by regulating the number to be carried by the tonnage of the vessel. Leave was accordingly given; but the merchants of Liverpool determined to oppose the bill in every stage. They dispatched immediately to London those very persons to be examined before the house, whom they had before sent for examination to the privy-council. When counsel had closed their case, a debate ensued, in which the statements of these witnesses were exposed, greatly to their mortification, and the bill passed by a majority of fifty-five to five. It was then carried to the lords. Here a still more determined opposition was begun, and carried on in such a manner, and with so much apparent success (the house being very thin at that season), as to alarm the abolitionists, not only for the fate of the bill itself, but for that of their great question the ensuing year. At length it passed the upper house, as through an ordeal of fire, and received the king's assent, on July 11. During all this time, the privy-council continued their examinations. Mr. Clarkson underwent an examination among others. It was at this time that he brought out his powerful essay on the impolicy of the slave-trade. This was circulated in great numbers by the committee, upon whom too much praise cannot be bestowed for their labours. From July 1787 to July 1788, the time we are now come to, they had held fifty-one long committees: they had held as many more sub-committees: they had distributed (besides 26,526 reports, debates in parliament, and other

matters) 51,432 pamphlets or books. They had roused the feelings of the whole English nation, and had attracted the notice of some of the most distinguished persons in France and Germany.

The session of 1788 was no sooner over, than Mr. Clarkson undertook a journey to all the sea-ports of the kingdom lying between Kent and Cornwall. His object was to find out, if possible, new witnesses to strengthen the good cause. He met with considerable success in his journey, and he formed committees, auxiliary to that of London, as he went along. On his return to London he was again examined by the privy-council, to whom he shewed, by way of evidence, his collection of African curiosities, consisting of produce and manufactures, which he had now completed. He introduced also to their lordships, for examination, all the new witnesses he had discovered, and whose testimony was of the highest value. The committee, in the mean time, had been indefatigable. They had directed their correspondence to new parts of the kingdom, as well as of North America. They had addressed the rulers of Spain, Portugal, and Sweden, in behalf of their institution, and had opened a communication with Germany on the same subject. They had printed and circulated no less than five new works to promote their cause, and, besides, that famous engraving of the section of the slave-ship (where the bodies of the negroes were seen packed in the different parts of it), which afterwards excited such universal sympathy in the country, and which caused such an universal abhorrence of the trade. About this time, that is, on the 19th of March, 1789, Mr. Wilberforce, who was then but just recovered from his long and severe illness, moved in the commons, that the house should on Thursday, the 29th of April, take into consideration its own resolution of the last session. This motion was agreed to, but it became immediately the signal to all those who supposed themselves interested in the continuance of the trade, such as planters, mortgagees, merchants, manufacturers, and others, to begin a tremendous opposition. Meetings were called, and frightful resolutions entered into. The public papers were filled with them. Here, as well as in pamphlets, the most bitter invectives were poured forth against the abolitionists. Emancipation was industriously confounded with abolition. Compensation was demanded to a most monstrous degree. The cry, indeed, was such, that many began to be staggered about the propriety of the total abolition of the trade. At this time Mr. Pitt, his majesty's chancellor of the exchequer, laid the privy-council report, consisting of the examinations before-mentioned, which came out in the shape of a large folio volume in print, upon the table of the house of commons, and moved, in order that members might have time to become acquainted with the evidence it contained, that the consideration of the slave-trade, which stood, by Mr. Wilberforce's motion, for the 29th of April, should be postponed to the 12th of May. This was agreed to. On the day appointed, Mr. Wilberforce rose, and in a speech of three hours and a half, introduced the great question into parliament. He reasoned entirely from the evidence contained in the report just mentioned, and deduced from it twelve grand propositions, which he read, and then laid them upon the table. These propositions contained the whole question. He wished them to be argued at a future day. Upon this, great opposition was manifested by the members for Liverpool and others, and a warm debate took place, when it was agreed that they should be taken into consideration on the 21st of May. When the day arrived, several petitions were presented to the house,

by persons interested in the traffic, against its abolition. Mr. Wilberforce rose up and addressed the house. After this, an altercation took place rather than a debate, in which much heat and animosity were manifested. Those members who espoused the cause of the interested persons, seeing that it would be overthrown, if they judged of the merits of it by the privy-council report, would not now abide by the latter; but rejected it as an imperfect sort of evidence, and demanded that witnesses should be heard at the bar of the house of commons in explanation of many of the mis-statements which that book contained. By these means they endeavoured to get rid of the propositions altogether. Their demand, however, after a good deal of contention, was complied with, and on the 26th of May counsel were heard, and one witness, a slave-captain, was examined. Their object now was to interpose every legal species of delay, and in this they succeeded so well, that from the 26th of May to the 9th of June, only two of their witnesses had been examined. In this slow way they went on till the 23d of the same month, when it was seen that it would be utterly impossible to bring the question to a final decision in that session, for they declared that they had many evidences yet to produce, and that they must and would be heard. Accordingly they moved, and Mr. Wilberforce agreed, that the farther consideration of the subject should be postponed to the next sessions.

As those who were interested in the continuance of the trade had now got rid of the privy-council report, and had introduced new evidences to the commons in behalf of their case, it became the committee to collect as respectable a body of witnesses as possible on their own side of the question. Mr. Clarkson had undertaken to traverse the kingdom again for this purpose, and had set out, when, hearing that the French revolution had broken out, and that a committee for the abolition of the slave-trade had been formed in Paris, he returned, and immediately hastened to the latter city, where he arrived at the latter end of July. He soon became acquainted with the marquis de la Fayette, monsieur Necker, the duke de la Rochefoucauld, the marquis de Condorcet, and Messrs. Mirabeau, Petion, Brissot, Claviere, and other distinguished persons. He spent his time, while in Paris, in attending the committee there, in visiting members of the National Assembly, and in the personal distribution of books among them, but particularly his "Essay on the Impolicy of the Slave-Trade," which he had caused to be translated into French for that purpose. Returning to London in January 1790, he found that Mr. Wilberforce had carried a motion in the commons, that witnesses should not be examined in future at the bar of that house, but in a committee-room, which should be open to all members. This was necessary for the sake of dispatch, as the examinations otherwise might have taken up ten years. Mr. Clarkson now resumed the journey which he had begun in the preceding summer, in search of new and respectable witnesses. He made a tour of 1200 miles in three weeks, during which he found out sixteen persons capable of giving good testimony on the subject, but could only prevail upon three to be examined. On his return to London, he found that the examinations of witnesses in behalf of those interested were going on in the committee of the house of commons, and with so much rapidity, that it was expected their case would be soon closed. This alarmed him exceedingly; for out of seventeen persons who stood upon his list as having promised to give their testimony in behalf of the abolition, one had lately died, and no less than eight, being seafaring persons, were then out of the kingdom. He determined, therefore, upon another journey; and on

turning the subject over in his mind, he thought he should obtain the greatest number of disinterested witnesses in the shortest possible time, if he could go on board all the ships of war lying in ordinary at the king's ports in different parts of the kingdom. Impressed with this idea, he went to Deptford, and first boarded all the men of war that were lying there. He then proceeded to Woolwich, and afterwards to Chatham, Sheerness, Portsmouth, and Plymouth, where he boarded others in like manner, to the number altogether of four hundred, in which he picked up several very excellent and important witnesses. On the 20th of April, the persons interested had just closed their case. Accordingly Mr. Wilberforce moved, on the 23d of the same month, in the house of commons, that witnesses should be heard in behalf of the abolition. Upon this much clamour ensued. The members, who acted in union with the persons interested in the continuance of the slave-trade, wished to have the case directly argued, that is, upon their own evidence, and without hearing any on the other side, and resisted accordingly. Their opposition, however, proved ineffectual against the eloquence of Mr. Wilberforce, supported powerfully as he was by that of Mr. Pitt and Mr. Fox. At length, the witnesses in behalf of the abolition took possession of the ground which the others had left, and no less than twenty-four, some of whom had been found out since the last tour, were examined before the close of the session. At this time it is very curious to remark, that the feelings of parliament, and those of the people, were very different on this great question. The tide certainly ran against the abolitionists in the house of commons. The old hue and cry had been revived of intended emancipation under the pretence of abolition; of monstrous indemnification to the planters; and of the certain massacre of the whites by the negroes, if the trade were to be abolished, but in more furious language, and to a greater extent than before. The feeling, on the other hand, in the country, was warmly on the side of the abolition. It had been kept up and increased by various circumstances. The committee had been daily employed in answering, through the medium of the public papers, every objection which had been started as hostile to their cause. They had also by this time distributed all over England, Scotland, and Wales, the horrible and affecting engraving of the section of the slave-ship before-mentioned. Individuals, too, had kept alive the popular feeling in various ways. Wedgwood, the celebrated manufacturer, had taken the committee's seal, as before explained, for a model, and had struck off and distributed many thousand small cameos in plaster. The ground of each of these cameos was white, but the negroe, who was seen imploring compassion on his knees in the middle of it, was of his own native colour. Cowper also, and other poets, had written beautiful and affecting songs on the subject. These were circulated very copiously through the kingdom, and some of them were sung in the very streets.

Not more than half the evidence, which was deemed necessary, having been heard on the side of the abolition in the session just passed, it became an imperious duty in the committee to use every possible exertion to complete it, and this in the best possible manner, before the next. Such exertion was absolutely essential to victory. Mr. Clarkson was, therefore, again solicited to traverse the kingdom for this purpose. This journey being of the utmost importance, Mr. Wilberforce prepared an ingenious list of questions to assist him in his examinations and inquiries. With this he departed, and travelled from August 1790, to February 1791, during which time he went over the greatest part of the

the island, and had the good fortune to add a considerable number of new and important witnesses to his list. At length the examinations were resumed in the committee of the house of commons, and they were closed finally on the 4th of April. No less than sixty-nine persons had given their testimony in this and the preceding session in behalf of the abolition of the slave-trade. The evidence having been printed on both sides for the use of the members, as the basis upon which to argue the case, the 18th of April was fixed upon as the day for deciding it. By this time every effort had been made by the persons interested to render the question unpopular in the commons. Emancipation, indemnification, massacre, ruin, had been vociferated over and over again in the ears of the members there. At this time, unhappily the most sanguinary scenes were taking place in St. Domingo, in consequence of the revolution which had been effected there, and an insurrection had broken out in the British island of Dominica. All these had been industriously detailed in print, but with great exaggeration, and added to the cries just mentioned. This union of reports and cries had produced such a terrific effect upon many members, that they considered the abolitionists, by persevering in their question, as ferocious monsters; and in this unfavourable frame of mind they went into the house on the day fixed for the discussion, to discharge their duty with respect to this great question. On this day, namely, the 18th of April, 1791, Mr. Wilberforce made a most luminous and affecting speech, in which he took a most masterly view of the whole question in all its different departments, as it related both to Africa and the West Indies. He argued the inhumanity of the traffic; he argued its impolicy; he appealed to feeling; he appealed to reason; he tried to disarm his opponents by candour; he exhorted them to attend to their own interest; and concluded by moving for leave to bring in a bill to prevent the farther importation of slaves into the British colonies in the West Indies. After this, a most serious discussion ensued, which lasted till three in the morning, when several members, being yet desirous of speaking, the business was adjourned to the next day. It was then argued again till half past three in the morning, when the house divided on the original motion. There were for it but 88 votes, and against it 163; so that this great cause of humanity, justice, and religion, which had cost so many years of labour, was lost by a majority of 75 votes. Upon the news of this signal defeat, the committee for the abolition of the slave-trade held a meeting, which was conducted with the most solemn dignity. They voted thanks to the illustrious minority which had lately stood forth the assertors of British justice and humanity, and the enemies of a traffic in the blood of man; and entered into several resolutions, the substance of one of which was, that they considered the late decision of the house rather as a delay than a defeat; that they did not despair of final success; and that they would never desist from appealing to their countrymen, till the commercial intercourse with Africa should cease to be polluted with the blood of its inhabitants. These resolutions were followed up by a suitable report, and sent to all the country committees throughout the kingdom. At length the session ended, and a cruel one it had proved to those who had interested themselves in the abolition of this cruel traffic. The defeat, however, which they had experienced, had been rendered more tolerable, because, in consequence of the unjust clamours by which the minds of many members of parliament had been affected, it had been expected. It had been rendered more tolerable again, by knowing that several of the most distinguished characters in the kingdom,

and all of splendid talents in the house of commons, such as Pitt, Fox, Burke, Grey, Sheridan, Wyndham, Whitbread, Courtnay, Francis, Rider, W. Smith, and H. Thornton, had supported the sacred cause; and because a bill had been carried through both houses of parliament in this very session for the establishment of the Sierra Leona company, the object of which was to form a settlement on the coast of Africa, which should be made a medium for civilizing that continent through two channels, viz. by the introduction of a new species of commerce there, and of cultivation also in its neighbourhood, on the principle of free labour.

The people of England, soon after the news of the defeat just spoken of had been communicated to them, began to be sensibly affected, and many, in order to wash their hands of the blood of Africa, left off the use of fugar. Mr. Clarkson, after a consultation with Mr. Wilberforce and the committee, undertook to abridge the evidence which had been offered to the house of commons on the side of the abolition, with a view of circulating its horrible contents through the kingdom, and of thus making the public impression still deeper. This abridgment was begun in June 1791, and was written, printed, and in the hands of all the committee's correspondents in England, Wales, and Scotland, by the latter end of September. Mr. Clarkson now undertook to follow the book, and to see, if possible, that it was actually read. Accordingly he left London in the beginning of November. It was his intention to wait personally upon every person in every county in the kingdom, to whom the book had been sent, to get others of the town or neighbourhood to meet him there, to converse with them on the subject, to treat their individual perusal of the abridgment, and their united efforts in lending it out judiciously, and in seeing that it was read. This he attempted to realize, but the process was very tedious. He had travelled 6000 miles in the execution of his plan, when he found that he had yet 4000 to go. To perform this was impossible, so as to answer the purpose. He therefore made his situation known to the committee. The consequence was, that Dr. Dickson, a gentleman who had greatly assisted the cause by his writings, set off from London, and took the whole of Scotland off his hands. The result of the two journeys was soon visible. The people could not bear the facts which the abridgment had disclosed to them. Great numbers left off immediately the use both of fugar and rum. The great bulk of the nation, however, vented their feelings in public meetings to address the legislature on the subject, and this they did with so much earnestness and activity, that by the latter end of the month of March, 1792, no less than 517 petitions, including several from whole counties, were laid on the table of the house of commons, praying for the total abolition of the slave-trade. Emboldened and supported in this manner by the voice of the people, Mr. Wilberforce introduced the question again into the commons. This was on the 2d of April. After a speech of four hours, during which he added a profusion of new light to the subject, and during which he endeavoured, in the most mild and persuasive manner, to do away objections and prejudices, he moved, "that it is the opinion of this house that the African slave-trade ought to be abolished." This led to a very long and uncommonly interesting debate. Never, certainly, in the house of commons, and never probably in any other place, was so much splendid oratory displayed, as on that night, on the side of the abolition of the slave-trade. It appeared, in the course of the debate, to be the sense of the house, that some sort of abolition should take place. Two divisions took place. In

the first, there were 193 votes for gradual abolition, and 125 for immediate; and in the second, there were 230 for gradual, and 85 for no abolition at all. In this state the question was left till the 23d of April, when Mr. Dundas (afterwards lord Melville) came forward and proposed a plan conformable with the resolutions of the house just mentioned. The outlines of it, however, were opposed by Messrs. Pitt, Fox, and Wilberforce, not only as being very defective, but as built upon false data. The business was accordingly adjourned to the 25th. On that day, Mr. Dundas brought forward the subject again. He considered that eight years ought to be allowed the planters to stock themselves with negroes, and therefore moved that the year 1800 should be the epoch, after which no more slaves should be imported from Africa in British vessels to the West Indies. Lord Mornington (now marquis Wellesley), in a most brilliant speech, moved an amendment, which was, that the year 1793 should be substituted for that of 1800. There appeared, on a division, to be 158 for Mr. Dundas's motion, and 109 for the amendment. On the 27th of April the subject was resumed in the house. Mr. Dundas proposed the year 1800, as before, and lord Mornington the year 1795. His lordship's motion was again lost, but by a less majority than on the former occasion, *viz.* by 161 to 121, when sir Edward Knatchbull struck out a middle line, by proposing the year 1796, which motion was carried by a majority of 151 to 132. The gradual abolition having been thus agreed upon for 1796, a committee of the commons carried the resolution to the lords. On the 8th of May the lords met to consider it, when, cruel to relate, a motion was made by lord Stormont, on the part of the planters, merchants, and other interested persons, to hear new evidence. This, after some little opposition, was acceded to. On the 15th of May, the first witness on this side of the question was introduced; and on the 5th of June, when only seven witnesses had been examined on the same side, all further examination was postponed to the next session.

Nothing could be more distressing to the abolitionists than the determination of the lords now mentioned; first, because there was no saying how many, even years, the hearing of evidence there might take; and secondly, because they (the abolitionists) had the laborious work to do over again, of finding out and keeping up a respectable body of witnesses on their own side of the question. This latter work was essentially necessary; for it was impossible to allow the persons interested to throw in a weight of testimony for the furtherance of their own cause, and not to take means to counteract it. Mr. Clarkson, therefore, set out again in the month of July, on his old errand. Dr. Dickson, the gentleman before-mentioned, left London about the same time, in order to assist him. He was to take a different route, which had been before settled. They were very successful in their respective journeys, and both returned in the month of February, 1793. The house of commons was then sitting. The only step to be taken there (but this was essentially necessary), was to bring before it, in some part or other of the session, its own vote of the former year, by which the slave-trade was to be abolished in 1796, in order that this vote might be reconsidered and renewed. Accordingly Mr. Wilberforce moved the house upon the subject. It is only necessary to state, that his motion was most furiously opposed, and actually lost by a majority of 61 to 53. By this determination the commons actually refused to sanction their own vote. In this distressing situation, Mr. Wilberforce scarcely knew what to do. He was not, however, to be dismayed by one un-

expected defeat. He resolved, therefore, that he would not allow the session to pass without trying the question in some other shape. Accordingly, in the month of May, he moved for leave to bring in a bill to abolish that part of the trade by which the British merchants supplied foreigners with slaves. His motion was carried, but only by a majority of 7; and, alas! on the third reading, it was lost by a majority of 31 to 29! During all this time the examination of witnesses had been going on in the house of lords. Only seven witnesses, however, had been heard there in the course of the whole session.

After this most cruel session, the abolitionists were at a loss how to act for the advantage of their cause. One measure, however, was obviously necessary, *viz.* to endeavour to keep up a respectable body of evidence to oppose that which should be heard against the abolition in the lords. For this purpose, Mr. Clarkson, at the request of the committee, once more traversed the kingdom. He began his journey in September, and returned in February, 1794. Mr. Wilberforce, in the interim, moved in the commons for leave to renew his former bill for the abolition of the foreign slave-trade, as carried on by British subjects. He carried it, though with great difficulty, in all its stages, through the house of commons; but it was almost directly lost in the house of lords. In this latter house only two evidences had been examined in the course of the session. At this time Mr. Clarkson was in such a wretched state of health, as to be unable to lend any farther assistance to the committee. The incessant labour of body and mind for so many years, aggravated by anxiety and disappointments, had made a very serious inroad upon his constitution. His nervous system had been literally shattered to pieces; his hearing, memory, and voice, were nearly gone. He was, in short, utterly incapable of any farther exertion; and he was therefore obliged, though very reluctantly, to be borne out of the field, where he had placed the great honour and glory of his life. The question was now in a very desperate state, for if the house of commons would not renew its own resolution, and if the lords would not abolish even the foreign part of the slave-trade, what hope was there of success? But neither, however, were Mr. Wilberforce nor the committee to be deterred by the prospect. They determined never to abandon the cause. Accordingly Mr. Wilberforce moved in the commons, in the session of 1795, for leave to bring in a bill for the abolition of the slave-trade. This motion was now necessary, and justifiable on that account, if the trade, according to a former resolution of that house, was to cease in 1796; but it was lost by a small majority.

In the session of 1796, Mr. Wilberforce resolved upon trying the question again, but in an entire new form. He moved that the slave-trade be abolished in a limited time, but without assigning to its duration any specific date. He wished the house to agree to this as a general principle. After much opposition the principle was acknowledged; but when, in consequence of this acknowledgment of it, he brought in a bill, and attempted to introduce into one of the clauses the year 1797, as the period when the trade should cease, he lost it by a majority of 74 to 70.

He judged it prudent, after mature consideration, to let the session of 1797 pass without any parliamentary notice of the subject, but in that of 1798 he renewed his motion for abolition in a limited time. This, however, met with the same fate as the former.

In 1799, undismayed by former defeats, he tried the same motion again, when there appeared for it 74, and against it 82 votes. He determined, however, that the remainder of the session should not pass without an effort to obtain some-

thing, if it were only a small part, of what belonged to the cause. Accordingly his estimable friend, Mr. Henry Thornton, lately deceased, brought in a bill, at his request, to abolish a very small part of the slave-trade. It may be remembered, that a colony had been established at Sierra Leona, to promote agriculture and a new species of commerce in its neighbourhood. Now, while the slave-trade was carried on all around it, it was found that these objects could be but little advanced. The bill, therefore, of Mr. Thornton, went only so far as to say that the slave-trade should not be carried on within a certain distance of that colony. This bill was carried through the commons, but though it only asked that an infant establishment, founded on the principles of liberty, and this by parliamentary sanction, should be protected from the ravages of the slave-trade, it was lost in the house of lords. This latter circumstance was indeed truly disheartening; yet amidst the clouds which darkened the horizon, one gleam of hope appeared; for the question had been so argued, so sifted, and put into such various lights, that it began now to be understood. The consequence was, that conviction flashed upon many, among whom were three planters, Mr. Ellis, Mr. Barham, and Mr. Vaughan. These gentlemen had the candour to rise up in the house of commons, and express themselves in favour of the abolition, in one of the last debates.

The question had been now tried and lost in almost every possible shape; Mr. Wilberforce and the committee seemed to have but two alternatives of choice left them, either to persevere against all hope, or to hold themselves in readiness to seize the first favourable opportunity which should present itself for furthering the cause. It was determined to adopt the latter, and by no means to let the question degenerate into a mere annual motion of form. It was thought proper also, as several members of the house of commons were changing their opinions on the subject, to give others time to digest the powerful eloquence which had been expended upon it. Mr. Wilberforce, therefore, suffered the years 1800, 1801, 1802, and 1803, to pass over without noticing it. In 1804, however, he resolved to renew his exertions. The committee resolved to second them, and immediately increased its number, that it might act with extraordinary vigour. The circumstance, which marked this year in particular as favourable for another trial, was the union with Ireland, in consequence of which a great number of Irish members, generous, and open-hearted, and in general friends to the poor Negroes, were added to the British parliament. Mr. Wilberforce, therefore, under these circumstances, asked leave to renew his bill for the abolition of the slave-trade within a limited time. This motion was as violently opposed as any of the former, but was carried at length in a very handsome manner: no less than 124 divided in favour of it, and but 49 against it. The bill was opposed in its second reading, for which however there were 100, and against it but 42. When a motion was made for going into a committee it was opposed, but carried by 79 to 20. The bill also was opposed in its last stage, but carried by a majority of 69 to 36. It was taken up to the lords, but on a motion by lord Hawkebury (now lord Liverpool) the discussion there was put off till the next session.

In the session of 1805, Mr. Wilberforce renewed his former motion. Leave was at length given him to bring in the bill, but not till after a most furious opposition. On the second reading of it the opposition increased, and an amendment was proposed, *viz.* to put it off to that day six months. This amendment was actually carried by a majority of 77 to 70. This defeat occasioned the abolitionists the severest disappointment. The committee instantly met, when

forrow was seen in the countenances of all present. Their first object was to endeavour to develop the causes of the miscarriage now mentioned. It appeared clearly, after the most minute examination, that these were accidental. The committee, therefore, resolved upon renewing the contest with redoubled vigour the ensuing year. Just at this moment, who should join them but Mr. Clarkson! Eight years' retirement had nearly restored him, and the first moment he found himself able to embark again in the cause, he returned to his post. As it then seemed probable that the question would be carried the next year through the commons, and, if so, that it would go to the lords, and that the lords would probably require farther evidence, it was judged proper that evidence should be prepared. But, alas! the noble band of witnesses which had been last collected, had been broken by death and dispersion, and a new one was to be formed. Herculean task! tremendous, however, as it was, Mr. Clarkson undertook it. He left London in two or three days afterward, and returned in January 1806, after having travelled in pursuit of his object above 5000 miles. In this month died Mr. Pitt, who was then prime minister, and who had been one of the great supporters of the cause.

On the 31st of March, 1806, this great question was ushered again into parliament, but under new auspices, namely, under the administration of lord Grenville and Mr. Fox. It was thought proper that Mr. Wilberforce should be as it were in the back-ground on this occasion, and that the attorney-general, as a conspicuous officer of the government, should introduce it. The latter accordingly brought in a bill, one of the objects of which was to prohibit British merchants and British capital from being employed in the foreign slave-trade. This bill passed both houses of parliament, and was therefore the first that dismembered this cruel traffic. In the debate which ensued upon it, it was declared in substance, both by lord Grenville and Mr. Fox, in their respective houses, that they would do every thing to effect the abolition, and should they succeed in such a noble work, they would regard their success as entailing more true glory on their administration, and more honour and advantage on the country, than any other measure in which they could be engaged. Conformably with this sentiment, Mr. Fox himself, on the 10th of June, in a speech most luminous and pathetic, followed up the victory which had been just gained, by moving a resolution, "that this house, considering the African slave-trade to be contrary to the principles of humanity, justice, and policy, will, with all practical expedition, take effectual measures for the abolition of it, in such manner and at such a period as may be deemed most adviseable." This motion produced an opposition as before, and an interesting debate. It was supported by sir Ralph Milbank, Mr. Francis, sir Samuel Romilly, Mr. Wilberforce, lord Henry Petty (now marquis of Lansdown), sir John Newport, Mr. Canning, and Mr. William Smith. It was carried by a majority of 114 to 15. Mr. Wilberforce directly moved an address to his majesty, "praying him to direct a negotiation to be entered into, by which foreign powers should be invited to co-operate with his majesty, in measures to be adopted for the abolition of the African slave-trade." This was also carried, but without a division. On the 24th of June, the lords met to consider both the resolution and address. A proposition was directly made in that house (in order to create delay), that counsel and evidence should be heard. This, however, was happily overruled. Lord Grenville then rose up and introduced the subject. His speech was among the master-pieces of eloquence. He was supported in the debate, which followed by the

lord chancellor (Erskine), the bishop of London (Dr. Porteus), the bishop of St. Asaph (Dr. Horsley), earl Grosvenor, earl Stanhope, earl Spencer, earl of Suffolk, and the lords Holland and Ellenborough. The resolution and address were at length both carried, by a majority of 41 to 20. After this a belief was generally prevalent, that the slave-trade would fall in the next session. This occasioned a fear in the abolitionists, lest it should be carried on in the interim, being as it were the last harvest of the merchants, to a tenfold extent, and therefore with tenfold murder and desolation to Africa. It was therefore thought necessary, as the session was about to close, to introduce another bill into parliament, and this as quickly as possible, that no new vessel should be permitted to go to the coast of Africa for slaves. Accordingly a bill to that effect was prepared, and it passed both houses. In the month of October following, after these great and decisive victories, died the right honourable Charles James Fox, one of the noblest champions of this noble cause. He had lived just to put it into a train for final triumph. This triumph, however, he enjoyed in anticipation. The prospect of it soothed his pains, and cheered his spirit in the hours of his sickness. At this melancholy season it became with him a frequent topic of conversation, and the hope of it was perceived to quiver on his lips, in one of the last moments of his life.

The session of 1807 had not long commenced, when the contest was renewed. Lord Grenville judged it expedient, at this particular crisis, to reverse what had been hitherto the order of proceeding, that is, to agitate the question first in the house of lords. On the 2d of January he presented a bill there, which he called an act for the abolition of the African slave-trade. It was very short; he proposed that it should be printed, and that it should then lie on the table for a while, that it might be maturely considered before it was discussed. On the 4th, no less than four counsels were heard against it. On the 5th the debate commenced. Lord Grenville took a brilliant part in it. He was supported by his highness the duke of Gloucester, the bishop of Durham (Dr. Barrington), the earls Moira, Selkirk, and Rosslyn, and the lords Holland, King, and Hood. The bill was at length carried, at four in the morning, by a majority of 100 to 36. On the 10th of February it went to the commons. On the 20th counsel were heard against it there. On the 23d a debate ensued upon it, on the motion of lord viscount Howick (formerly Mr. Grey, and now lord Grey), who urged the commons to confirm it. The other speakers in favour of it were Mr. Roscoe, Mr. Fawkes, Mr. Lushington, the lords Mahon and Milton, sir Samuel Romilly, sir John Doyle, Mr. Wilberforce, and earl Percy; and it was carried by the vast majority of 283 to 16. On the 6th of March the blanks were filled up. It was proposed, first, that no vessel should clear out for slaves from any port within the British dominions, after the 1st of May following, that is, 1807, and that no slave should be landed in the British colonies after the 1st of March 1808. This and almost every other proposition were opposed, but happily without effect. Suffice it to say, that on the 18th the bill, with the blanks filled up, was carried back to the lords; that in consequence of various amendments, it passed and repassed from one house to the other, but always with opposition; that on the 24th it passed both houses; and that on the 25th, at half past eleven in the morning, it received the royal assent. Thus passed, after a twenty years' hard struggle, during which the field had been disputed inch by inch, and won at last by the arms of reason, this magna charta for Africa in Britain, under the administration of lord Grenville and Mr. Fox, an administration which, on account of its noble exertions in behalf of the oppressed

African race, will pass to posterity, living through successive generations, in the love and gratitude of all the most virtuous of mankind. The news of this great event gave uncommon joy throughout the kingdom, and this joy was farther heightened by authentic news just then received from North America, that the government there had passed a similar bill, which was to be observed as a law through the United States.

In France, on the re-establishment of the Bourbon dynasty, it was proposed to abolish the slave-trade at a distant period. Upon the return of Bonaparte from Elba, an order was issued for its immediate abolition; and a decree to the same purpose has been passed since the expulsion of Napoleon, and the restoration of the present reigning monarch.

SLAVE-COAST, in *Geography*, a tract of country in Africa, bordering on the Atlantic, situated between the Gold Coast and Benin, and comprehending the kingdoms of Ardra, Koto, Popo, and Whidah. See each respectively, and also **SLAVE-TRADE**.

The inhabitants resemble those of the Gold Coast in their politics, religion, and manners.

SLAVE-FALLS, a cataract of North America, in Winnipeg river, 100 yards wide and 20 feet in height. N. lat. 50° 6'. W. long. 95° 20'.

SLAVE-INDIANS, Indians of North America, who were driven from their original country by their enemies the Knisteneaux, along the borders of the Unjigah or Peace river, where it assumes from them the name of the Slave river; though the term by no means involves the idea of servitude, but was given to those fugitives as a term of reproach, that denoted more than common savageness.

SLAVE-LAKE, *Great*, a large lake of North America, so called by the Knisteneaux, which derived its name from that of its original inhabitants, who were called slaves. This lake is well known to the Knisteneaux, who are among the inhabitants of the plains on the banks of the Saskatchewan river; for formerly, when they used to make war in this country, they came in their canoes to that lake, and left them there; from whence there is a beaten path all the way to the Forks, or E. branch of this river, which was their war-road. This lake is said to be more than 200 miles in length, and about 12 in breadth. It is supposed to be the same with Hearne's *Athapuscoru*, which see. Bitumen is found on the coast of this lake, in N. lat. 60°, near its discharge by Mackenzie's river, which, flowing from Slave-lake, discharges itself into the North sea, on the banks of which are coal and bitumen, as far north as latitude 66°. N. lat. 61° 20'. W. long. 115°.

SLAVE-LAKE, *Lesser*, a lake of North America, in N. lat. 55° 30'. W. long. 115°, which discharges itself into the Elk river.

SLAVENSK, a town of Russia, in the government of Ekaterinoflav, on the Dnieper; 48 miles S. of Ekaterinoflav. N. lat. 47° 24'. E. long. 34° 44'.

SLAVE-RIVER, a river of North America, being a continuation of Unjigah or Peace river, which discharges itself into the greater Slave-lake. Near that part of the Slave-river, where it first loses the name of Peace river, and along the extreme edge of the adjoining plains, are very strong salt springs, which in the summer concrete and crystallize in great quantities.

SLAUGHTER. See **MANSLAUGHTER**, **HOMICIDE**, **MURDER**, **BUTCHER**, &c.

SLAUGHTER-HOUSE, in *Rural Practice*, the place where neat cattle and other animals are killed for the butcher. In common houses for this purpose, the blood, filth, and other nastiness are left to remain upon the floors; but in those of the improved kind, the floors are laid in such a manner as to have a proper full degree of fall or declination towards the middle

middle parts, where there is a drain made for taking away all such offensive matters, and keeping the houses quite clean and sweet, merely by pumping or throwing water upon the floors of them.

Houses of this sort have usually the dimensions of about twenty-two feet in length by sixteen in width; but they may be constructed in this way to any suitable extent that may be necessary. The drains of slaughter-houses are often connected with pits or reservoirs, by which means large quantities of excellent manure are accumulated.

These houses, likewise, sometimes form parts in the arrangement of farm buildings in large farm-yards.

SLAUGHTER-Skins, a term used by our curriers and leather-dressers for the skins of oxen, or other beasts, when fresh, and covered with the hair: such as they receive them from the slaughter-houses where the butchers slay the carcass.

SLAUGHTER Creek, in *Geography*, a bay of America, on the coast of Maryland, in the Chesapeake.

SLAUGHTERING of Animals, the custom of killing them for the purpose of food. This operation, for the sake of humanity, should constantly be performed in the most sudden and ready manner possible, and not in the lingering, brutal, protracted way which is usually practised by the generality of butchers in this country. See **STRIKING or Pitting Animals**.

SLAVI, SLAVONIA, and SLAVONIANS. See **SCLAVI, SCLAVONIA, and SCLAVONIANS**.

SLAWATICZE, in *Geography*, a town of Lithuania, in the palatinate of Brzesc, near the Bug; 16 miles S. of Brzesc.

SLAWENTITZ, a town of Silesia, in the principality of Oppeln; 24 miles S.E. of Oppeln.

SLAWIETIN, a town of Bohemia, in the circle of Schlan; 12 miles N.W. of Schlan.

SLAWKOW, a town of Austrian Poland, in the palatinate of Cracow; 25 miles N.W. of Cracow.

SLAWKOW. See **AUSTERLITZ and SCHLAKENWALD**.

SLAWONICA. See **ZLABINGS**.

SLEAFORD, or **NEW SLEAFORD**, a market-town in the wapentake of Flaxwell, parts of Kesteven, and county of Lincoln, England, is situated 16 miles S. of Lincoln and 116 N. of London, on a small rivulet called the Sleaf, which rises in the vicinity, and runs to Chapel Hill, where it joins the river Witham. Many Roman coins of the Constantine family have been found here, from which, and other circumstances, Dr. Stukeley conjectures, that this was a Roman town. "We find the distance," he observes, "between Caistor and Lincoln about forty miles, has two towns upon it at proper intervals for lodging: these are Sleaford and Stanfield. The original names of them are irrecoverable silence, but the eternity of the Romans is inherent. It is probable that Alexander, bishop of Lincoln, built his work upon the site of a Roman citadel. Beside, at Sleaford comes in the other Roman road from the fen country by Brig End Caufy, and at the intersection of these two roads the old town stood." The work here alluded to was the castle, which, in Leland's time, was standing, and is thus described by him. "Withoute the towne of Sleaford standith, west-fourth-west, the propre castell of Sleaford, very well mantayned; and it is compassed with a renning streame, cumming by a cut oute of a little feene, lying almoste flatte weste against it. In the gateway be two portcullises, a high towre in the middle of the castelle, but not set upon a hill of raised earth: the vaults of the castle by the ground be fair. The house, or manor place, lately almost new, buildid of stone and timbre, standith southward without the town. The town nor market is of

no price: the ornaments of it is the bishop of Lincoln's castle, and the late lord Husley's house." Since Leland's time, however, Sleaford has become a different place, and is still improving both as to buildings and population. In the return to parliament in the year 1811, the houses are stated to be 385, the inhabitants 1781. The castle has been wholly levelled with the ground, and lord Husley's mansion, at Old Sleaford, is now a farm-house. A weekly market is held on Mondays, and four fairs are held annually.

The church is a handsome, spacious structure, and, from a manuscript found in the parish chest, appears to have been built in the year 1271, by Roger Blunt and Roger Brickham, of Sleaford, merchants. It consists of a chancel, nave, transept, and two aisles; with a tower crowned by a spire, which rises to the height of 144 feet. In the chancel are several monuments to the family of Carr, by one of which a free-school was erected and liberally endowed in the year 1603; and also an hospital for twelve poor men. The manor and estates were conveyed by marriage, with an heiress of the Carr family, to the late earl of Bristol.

At Kyme, about three miles from Sleaford, Leland says, there was in his time "a goodly house and park." Philip de Kyme, in the reign of Henry II., built here a priory for black canons of the order of St. Augustine, to the honour of the Blessed Virgin. Its surrender by a prior and nine canons to Henry VIII. is noticed by Willis.

About seven miles east of Sleaford, is Haverholme priory, the seat of sir Jenison William Gordon, bart. The house and grounds occupy an area of about 300 acres, which constitute an island, formed by two branches of a river. It was given by bishop Alexander, in 1139, to the nuns and canons of the order of St. Gilbert of Sempringham; and at the dissolution was granted to Edward, lord Clinton. The present possessor of Haverholme made numerous additions to the old remains in 1788, and has formed a mansion in a style corresponding with the importance of the place. Beauties of England and Wales, vol. ix. by J. Britton, F.S.A.

SLEAMORE POINT, the southern extremity of the island of Inisherkan, opposite to Baltimore, in the county of Cork, Ireland. N. lat. 51° 24'. W. long. 9° 19'.

SLEASY HOLLAND, a kind of holland thus called, because made in Silesia in Germany; and which, from its lightness, occasions all thin, slight, ill-wrought hollands, to be called *slasy*.

SLEBÉZE, or **SLYBZE**, in *Geography*, a small island in the straits of Sunda. S. lat. 5° 54'. E. long. 105° 24'.

SLECK, in *Rural Economy*, a provincial term applied to the small of pit-coal; also to the black matter of smutty grain.

SLED, in *Agriculture*, provincially a sledge.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, bells, &c. The sledge for carrying criminals, condemned for high treason, to execution, is called *burdle*.

The Dutch have a kind of sledge, on which they can carry a vessel of any burden by land. It consists of a plank of the length of the keel of a moderate ship, raised a little behind, and hollow in the middle; so that the sides go a little aslope, and are furnished with holes to receive pins, &c. The rest is quite even.

SLEDGE, in *Agriculture*, an implement employed for conveying various articles upon. It is made of two strong pieces of wood framed together.

It is a very useful sort of contrivance for different kinds of work and purposes in farming in different situations of land, but especially those that are rather of a hilly nature; such as the conveying away various sorts of heavy materials,

as those of stones and earthy matters, and in some instances the produce of the land. Sledges also serve the purpose of transporting ploughs and other heavy tools of agriculture to the different fields and other places where they are to be used or employed, being contrived expressly for such uses and intentions. They are a kind of tool, which are made much use of in many of the northern districts of the kingdom, as well as in some of the southern ones.

In the county of Cornwall they employ a sort of sledge or dray, on most farms, for the carriage of their hay, corn, faggot-wood, and many other matters. Their sledges mostly consist of two strong side-pieces of wood, somewhat in the form of a common boat, only more sharply turned upwards at the ends, which have five, six, and sometimes seven cross-bars mortised into each, being shod below with thick rough portions of strong timber, on which the whole slides upon the surface of the ground.

In some cases two, small, low wheels are attached, on which the machine moves. These sledges are drawn either by horses or oxen in the above district, and are found to be handy and convenient in various ways.

SLEDGE is a large smith's hammer, to be used with both hands: of this there are two sorts, the *up-hand sledge*, which is used by under workmen, when the work is not of the largest sort; it is used with both the hands before, and they seldom raise it higher than their head. But the other, which is called the *about-sledge*, and which is used for battering or drawing out the largest work, is held by the handle with both hands, and swung round over their heads, at their arms end, to strike as hard a blow as they can.

SLEDGE, among *Miners*. See DIGGING.

SLEDGES, in *Rope-making*, are frames of oak mortised together, and clamped with iron in different parts. They are from three feet wide, and eight or twelve feet long, to five feet wide and fifteen feet long. The two sides are the length of the sledge, five by seven inches thick, and tied in by oak bars at each end: near the front are two uprights five feet high, mortised into the sides, and supported by two slanting pieces from the upper end. A breast-board nine inches wide, and from three to five inches thick, is fastened with iron pins to the uprights, and contains holes for the hooks to go through, on which the yarn is hung, which being turned by men, is twisted into strands, and then closed and finished into rope. These sledges are loaded to any degree the rope in making may require.

SLEDGE *Island*, in *Geography*, an island in the North Pacific ocean, near the west coast of North America; about 12 miles in circuit. This island is composed of large loose stones, covered with moss and other vegetables, of which there are twenty or thirty different species, mostly in flower. Captain Cook saw neither shrub nor tree, either upon the island or continent. He observed one fox, a few plover, and other small birds, and also some decayed huts constructed partly below the ground. A beaten path was seen from one end of the island to the other, and these circumstances indicated its having been lately visited by some people. A sledge also was found, which gave name to the island: this was such as the Russians in Kamtschatka used to convey goods from one place to another, over the ice or snow. It was 10 feet long, 20 inches broad; it had a kind of rail-work on each side, and was shod with bone. Its construction was admirable, its parts being neatly put together, partly with wooden pins, but principally with tongues or lashings of whale-bone. N. lat. 64° 50'. W. long. 166° 3'.

SLEDINGEN, a town of France, in the department of the Scheld; 5 miles N. of Ghent.

SLEEAN, in *Rural Economy*, provincially the smut in corn.

SLEEP, in *Physiology*, the more or less complete suspension of the functions of sensation and volition, that is, of the action of the five senses, of the brain, of the voluntary muscles, and the voice, or the organs which connect us with the external world, to which animals, at least those of the classes mammalia and birds, are subject at certain more or less regular intervals, for the purpose of renewing the power of action exhausted by exercise.

In the article LIFE we have stated, that the internal functions, which make up the *organic* life, differ remarkably from the external, which compose the *animal* life, in the duration of their action; that while the former go on incessantly, the latter are subject to intermissions or periods of complete repose, each particular organ experiencing, from its activity, an exhaustion of power, a fatigue, which renders rest absolutely necessary before it can be again exerted; which exhaustion or fatigue is unknown in the organic life. This law, of the intermission of action, has been very satisfactorily applied by Bichat to the theory of sleep. "General sleep," says he, "is the assemblage of particular sleeps. It is derived from that law of the animal life, which causes in its functions a constant succession of periods of activity, and times of intermission;—a law, which pointedly distinguishes it from the organic life. Hence sleep influences the latter only in an indirect way, while it exerts its full operation on the former.

"Numerous varieties may be remarked in this periodic state, to which all animals are exposed. The most complete sleep is that, in which the whole external life, that is, the senses, perception, imagination, memory, judgment, locomotion, and the voice, are suspended; the least perfect affects only a single organ. We see numerous gradations between these two extremes; sometimes the senses, perception, locomotion, and the voice, are suspended; imagination, memory, and judgment remaining active; sometimes locomotion and the voice are added to the latter. Such is the sleep which is agitated by dreams. A portion of the animal life still continues active, having escaped the torpidity in which the rest is plunged. Three or four senses only may have passed into the state of repose, and ceased to be influenced by external objects; then that kind of somnambulism occurs, in which, to the action of the brain, the muscles, and the larynx, are added those of hearing and touch, often in a very distinct form.

"Let us then no longer regard sleep as a constant state, invariable in its phenomena. Scarcely do we sleep twice together in the same way; a multitude of causes modifies this condition of our being, by applying to a greater or smaller portion of the animal life the general law of intermittent action. The various modifications must be characterized by the functions, which are affected in different instances. The principle is the same throughout, from the simple relaxation, which follows the contraction of a voluntary muscle, to the entire suspension of the animal life. Sleep is in all cases a consequence of that general law of intermission, which exclusively characterises this life, but the application of which to the various external functions varies infinitely.

"This explanation of sleep is undoubtedly very different from those narrow systems, which place its cause in the brain, the heart, the large vessels, the stomach, &c. and thus present an insulated phenomenon, often illusory, as the basis of one of the great modifications of life.

"Why do light and darkness, in the natural order of things, correspond respectively to the activity and repose of the

the external functions? Because, during the day, the animal is surrounded with a multitude of exciting causes; a thousand things exhaust the powers of the sentient and locomotive organs, fatigue them, and thus prepare a relaxation, which is favoured at night by the absence of all stimuli. Thus, in the modern way of life, in which this order is partly inverted, we assemble round us, during the night, various stimuli, which prolong the state of watchfulness, and make the intermission of the animal life coincide with the first hours of the dawn, favouring it by removing all circumstances that might produce sensations.

“By multiplying around them causes of excitation, we can, for a certain time, prevent the organs of the animal life from obeying the law of intermission; but they yield at last, and nothing, after a certain time, can suspend its influence. Exhausted by continued exertion, the soldier sleeps at the side of the cannon, and the criminal even amid the tortures of the question.

“Let us, however, distinguish natural sleep, the consequence of fatigue of the organs, from that which is caused by affections of the brain, as apoplexy, or concussion. In the latter case the senses are awake, they receive impressions, and are affected by them as usual; but these impressions cannot be perceived by the disordered brain, and we consequently are not conscious of them. In sleep, on the contrary, the intermission of action affects the senses as much, and even more than the brain.” *Recherches Physiol. sur la Vie et la Mort*, p. 34—37.

Although the remarks of Bichat in the preceding quotation, respecting the sleep of the particular senses, may be regarded rather as illustrations, than as proofs that the state of fatigue from exertion of any particular organ is exactly the same as its condition in sleep, we consider the general view of the subject as perfectly correct. In the most complete sleep, our relations to external objects are entirely suspended, and consciousness undergoes an equally complete interruption. The appropriate stimuli, presented to the external senses, excite no sensations; the operations of the mind do not go on; hence there is nothing to excite volition, and the voluntary powers are consequently quiescent. The portion of existence passed in such sleep is a perfect blank. We have examples of it in the most tranquil and healthy states of the body and mind, and after considerable fatigue, or in the recovery from severe and painful disease.

But this sound sleep is much less common, than that which is more or less interrupted by dreams, in which a series of sensations, perceptions, and reflections, passes through the mind, as in the waking state. We are conscious of the same kind of transactions as occupy our waking hours; we see, hear, walk, talk, and perform all the customary offices of life. The mind reasons, judges, performs volition, and experiences the various affections, as love, hatred, indignation, anxiety, fear, joy, even in a much more lively degree, than when they are excited by their real causes. In dreaming, as in the soundest sleep, the action of the external senses is suspended; but the internal faculties are active in greater or less number. Volition takes place, but the muscles do not obey the will. That dreaming is a less sound species of sleep, appears from the familiar fact, which has probably been observed by every individual; *viz.* that the first sleep is much freer from it than the second. We retire to rest, fatigued by the exertions of the day, and sleep soundly for five or six hours: we wake, and then fall asleep again towards the morning, and dream the whole time of this second sleep.

Haller, who mentions that he had attended much to his

dreams, observes, that in perfect health he remembered only the sensation of flying through the air, conceiving himself suspended above the earth and carried to a distance.

The order of the images and reflections, which pass through our minds in sleep, and the laws of their succession and connections, are the same as when we are awake. We must observe, however, that these internal processes now go on by themselves, and are not corrected by that reference to external objects, and that exercise of the external senses, which takes place in the waking state. Thus we see a friend long dead, without being aware that he is not alive; and gross inconsistencies and absurdities take place without being remarked.

The great activity of the imagination and judgment in the act of dreaming, is evident from the nature of many dreams. “Often,” says Haller, “in my dreams, I seem to read books, printed poems, histories of travels, &c.; and I even see the plants of distant regions, suited to their climates.” Others solve problems, write, make verses, &c. The reasonings which are carried on in sleep, the speeches which are made, &c. are often more quickly and easily performed than when we are awake.

The causes of dreams are very obscure; we cannot determine how the intellectual powers are called into exercise, nor what stimuli should be applied for that purpose. It is known, however, that various bodily derangements have an important influence. The state of the stomach, which so often acts on the brain, will frequently disturb our rest; if a person, unaccustomed to such indulgence, eat a hearty supper, he will experience nightmare, that is, a sense of pressure about the chest, and of some most dreadful impending danger, without the possibility of escaping it. When the painful sensation is arrived at its height, we awake, and can immediately move. Or the same cause, instead of producing nightmare, may distress us with terrific dreams, in which dangers assail us in every shape: we fancy that we cannot escape from the intricate passages and rooms of a house; that we shall fall from a precipice, or into a river. In these instances, too, some very strong impression generally rouses us in a state of great alarm. Instances are not wanting of persons who have determined to remember that the dangers presented to the mind in dreaming are fallacious, and have recollected this at the time, so as to be protected from the alarm, which would otherwise have been caused. Professor Stewart mentions that Dr. Reid freed himself in this way from the distress of frightful dreams, which had annoyed him for some time. The writer of this article has experienced the same circumstance, and Haller mentions a similar fact: “*Ita ille, quem diximus, ad vitandas pollutiones voluntatem firmam attulisse, expurgiscebatur ad sensum lubricæ imaginis.*”

In many bodily disorders, broken sleep, and alarming dreams, which make the patient start and awake, are common symptoms; such is the case in hydrothorax, and diseases of the heart. The delirium of fever is an unnatural activity of the internal faculties, the senses being more or less quiescent, produced by the excitation of the brain, and not differing in its essential nature from dreams.

Immediate impressions sometimes influence us during sleep; children will evacuate their urine on a chamber-pot being put in their hands; and the same effect is said to have been produced by putting the hand of a sleeping child in cold water. The cause acts more powerfully than it would in the waking state; and the same remark holds good with respect to the excretion of the seminal secretion in sleep. “*Somnum,*” says Haller, “*quam sensatio fortius est, et vehementius animam percellit. Id tribuas solitudini, quieti, adtentioni ad unicum objectum. Certe vix unquam sanus homo ex quacunque*

cunque libidine semen profuderit. In fomiis id fit, certa quidem ætate, neque fere in senis, perfacile in pueris. Sed neque fenatio, quæ fomni causa est, aut sola aut pura menti representatur. Ex lege associationis idearum ad simplicem stimulum nascitur idea femine pulchræ, amatæ, quam ambias, quæ cedat facilis: accedit lectulus, et omne satellitium arcani amoris. Et magis et magis post primos sermones adpropinquat comicus sperata voluptas, ut vicissim perinde anxietatis hieroglyphæ continuo graviora menti incumbunt.”

The dreams which occur almost nightly in most individuals, shew the activity of the internal mental operations during sleep: voluntary motions are less commonly performed. Some horses sleep standing; and the lower jaw is maintained elevated in us during sleep. The hand is often raised when any stimulus is applied to the body, although it may not be strong enough to interrupt sleep. The fact of children expelling their urine, when the pot is brought to them, has been already noticed. Many persons laugh, weep, sigh, and talk in their sleep: the words are indeed generally indistinctly pronounced, and the sentences incomplete.

The sleep-walkers differ from these only in degree. They execute the voluntary motions, which arise out of the mental processes carried on in sleep. It would be endless to recount the particular cases belonging to this subject. It is sufficient to mention that individuals rise from bed asleep, and with their eyes closed, and not only walk about the room or house, going up or down stairs, finding their way readily, and avoiding obstacles, but pass safely through very dangerous places, as windows, or on the roofs of houses. They execute, too, still more difficult feats. They dress themselves, go out of doors, light a fire, undress and bathe, saddle and bridle a horse, ride, write, make verses, and execute all the actions of life correctly, and even sometimes acutely. During this time they are asleep; the eyes are shut, or do not see if open; the iris is not irritable. When awakened, which is sometimes not easily effected, they do not remember what they have done.

The proportion of time passed in sleep differs in different individuals, and at different ages. From six to nine hours may be reckoned about the average proportion. Men of active minds, whose attention is engaged in a series of interesting employments, sleep much less than the listless and indolent; and the same individual will spend fewer hours in this way, when strongly interested in any pursuits, than when the stream of life is gentle and undisturbed. The great Frederic of Prussia, and John Hunter, who devoted every moment of their time to the most active employments of body and mind, generally took only four or five hours sleep. A rich and lazy citizen, whose life is merely a chronicle of breakfasts, dinners, suppers, and sleep, will slumber away ten or twelve hours daily. When any subject strongly occupies us, it keeps us awake in spite of ourselves. These phenomena are consistent with what we have already said; the animal organs, when the period of their intermission and repose has arrived, are kept in activity by new and unusual causes of excitation, and thus the ordinary period of sleep may be passed over, and its ordinary quantity much diminished. When a person, who has thus been kept long awake by the occupation of his mind with important and urgent subjects, at last falls asleep, the slightest irritation calls up in the fancy all the trains of thought which have just occupied us, and sets at work again all the internal machinery which has hardly yet become quiet; the sleep, under such circumstances, is imperfect, and much disturbed by dreaming.

The newly-born child sleeps most of its time; it seems to

wake merely for the purpose of feeding. Some have called fatal existence a perpetual sleep; but the animal organs, never having been yet exercised, can hardly be said to be in a state of repose. See EMBRYO.

For the first two or three years, children sleep more than once in the twenty-four hours. Again; very old persons sleep much of their time: in the natural progress towards death, the animal faculties are first extinguished; accordingly, when they begin to decline in decrepid old age, the periods of their intermission are longer. The celebrated De Moivre, when eighty-three years old, was awake only four hours out of the twenty-four (Hist. de l'Acad. des Sc. for 1754); and Thomas Parr at last slept the greatest part of his time. Animals which do not prey by night, seem to pass as much time asleep as awake; that is, they sleep during the dark, and are awake so long as the sun is above the horizon.

The state of torpidity in which many animals pass the winter months, cannot properly be called sleep; it is not a repose of the animal organs, consequent on the fatigue produced by their exercise; but is a peculiar condition of the whole frame, affecting the internal as well as the external organs, and caused directly by the action of cold.

The exhaustion of the powers of the animal organs by exercise being the determining cause of sleep, it comes on after the close of our daily occupations, when darkness necessarily causes an intermission of labour and a general quiet, which are favourable to repose. The number of hours devoted to active occupation, and the time at which disposition to sleep is felt, are influenced considerably by habit: after considerable and unusual exertion, sleepiness will be felt in the day-time.

The period of sleep may be protracted, by unusual excitation, much beyond the ordinary period; but the effect is lost after a certain time, and sleep comes on under circumstances, which appear at first most unfavourable to it. An eye-witness reported that some boys, completely exhausted by exertion, fell asleep amid all the tumult of the battle of the Nile; and other instances are known of soldiers sleeping amid discharges of artillery, and all the tumult of war. Couriers are known to sleep on horseback, and coachmen on their coaches. A gentleman who saw the fact, reported to the writer of this article, that many soldiers in the retreat of sir John Moore, fell asleep on the march, and continued walking on. Even stripes and tortures cannot keep off sleep beyond a certain time; but it then indicates the greatest exhaustion, and consequently affords an unfavourable prognosis. Noises at first prevent us from sleeping, but their influence soon ceases, and persons rest soundly in the most noisy situations. The proprietor of some vast iron-works, who slept close to them, through the incessant din of hammers, forges, and blast-furnaces, would awake if there was any interruption during the night. And a miller, being very ill and unable to sleep, when his mill was stopped on this account, rested well and recovered quickly when the mill was set a going again.

Great hunger prevents sleep; and cold affecting a part of the body has the same effect. These causes operated on the unfortunate woman who lived thirty-four days in a small room overwhelmed by snow, and with the slightest sustenance: they hardly slept the whole time. (Somis Ragionamento sopra un fatto avvenuto in Bergemolletto, &c. p. 74.) Indigestion, and various bodily affections, produce sleeplessness. We have already noticed, that all mental occupations attended with intense thought, and great interest, prevent sleep; and any great affections of the mind have the same effect.

It will easily be understood that circumstances opposite to those just enumerated are favourable to sleep. Bodily exercise with tranquillity of mind, and absence of all excitation, are the most important of these. A full repast is often followed by sleep, even in animals, as dogs. The distention of the stomach excites the circulation, and thus brings on a condition of the brain favourable to sleep. Various vegetable substances taken into the stomach act on the brain in the same way. Intense cold, affecting the whole body, exhausts the animal powers and brings on sleep, which is speedily fatal. See COLD.

Sleepiness, when it occurs naturally, after our daily occupations, is marked, first, by a sense of muscular fatigue, particularly in the long muscles: it may be experienced in various parts, according as they have been more exercised. We begin to gape; the intellectual functions languish; curiosity is blunted; attention becomes painful; and a great desire of repose is felt over the whole body. The impressions on the external senses are indistinct; we cannot read well, nor does the memory act with its usual force or order: an uneasy sensation is perceived in the eye; the upper eye-lid falls in spite of every effort to keep it elevated. Now the muscles of the whole body are more or less relaxed: hence the head inclines forwards, and the whole body would come to the ground if the person were standing. The sense of hearing seems to be suspended last; we hear and understand the conversation of those near us, when the eyes no longer act. Now the succession of our mental operations becomes quite involuntary; and a kind of delirium takes place, in which the trains of thought preserved in the memory succeed according to their natural associations and connections. These operations are then suspended, and sleep is complete.

Respecting the state of the body in sleep we have very little to add to our general account already given. In complete sleep the body is perfectly motionless; the senses are not affected by their respective external objects, unless the impressions should be strong enough to arouse us. Hunger and thirst are not felt; nor are we conscious of the necessity of emptying the bladder or bowels, until the distention is sufficient to waken us. The functions of the organic life go on uninterruptedly; digestion, chylification, and the conversion into feces, absorption, circulation, respiration, nutrition, secretion, are all continued. There may be some slight modifications, but they are unimportant.

After the sleep has lasted long enough to restore the animal powers, we awake, without any change or occurrence which can be shewn to affect particularly the brain or other parts, of which the action was suspended by sleep. We open our eyes, and often rub them. We move the limbs and stretch them; and in a few seconds we have the full use of our senses, intellectual faculties, voice and voluntary muscles, and they recover their powers of action completely.

There are rare examples of individuals, who have gone on sleeping for days, weeks, and months; but these histories are not accompanied with such particulars as would enable us to judge of the cause for such a deviation from the ordinary course of nature.

SLEEP, *Somnus*, in *Mythology*, the son of Erebus and of Night, according to Homer and Hesiod, and the brother of *Mors* or *Death*.

Virgil (*Æn.* vi. v. 278.) assigns to this deity an abode with death, in the subterraneous or invisible world.

Statius and Ovid place the chief residence, or great palace of *Somnus* on our earth, in the country of the *Cimmerians*; no country agreeing better with sleep than that which is

overspread with eternal darkness. *Theb.* x. v. 84 to 117. *Met.* xi. v. 592 to 645.

Dreams were the children of sleep; Ovid names three of them, *viz.* *Morpheus*, *Phobetor*, and *Phantasia*.

This deity is most commonly represented by the artists as a soft youth, stretched at his ease on a couch, resting his head on a lion's skin, and sometimes on a lion; with one arm either a little over or under his head, and the other dropping negligently by the side of the couch, and either holding poppies, or a horn with the juice of poppies in it. He is often winged, and much resembles a little Cupid, from whom he is distinguished by the lizard (an animal supposed to sleep half the year) placed at his feet. There is scarcely any one of the deities that is more fully and particularly described by the poets than this deity of sleep. *Spence's Polymetis*, p. 263, &c.

SLEEP of *Plants*, *Somnus Plantarum*, in *Vegetable Physiology*, is a term used by Linnæus, to express a peculiar state in the constitution of many plants during the night, evinced by a change of position, generally a drooping, or a folding together, of their leaves or leaflets. Such a change, being occasioned by the withdrawing of the stimulus of light, is probably a state of rest to their vital functions, and therefore the above term is not so hyperbolic as at first appears. Linnæus has given a curious treatise on this subject, in the *Amenitates Academice*, v. 4. 333. The phenomenon itself had been noticed long before, by Acofta and Prosper Alpinus, in the Tamarind-tree; and the latter points out several parallel instances in other leguminous plants with pinnated leaves, natives of Egypt. It is indeed most remarkable in such plants. Herbs with ternate leaves, as the Trefoil and *Oxalis*, sleep with their leaflets folded together in an erect posture; and Pliny has observed that the former of these assumes that position at the approach of storms. Cloudy weather, no doubt, produces this effect, in proportion as the plant is in vigour, and the stimulus of preceding sunshine has been strong. Not that a cessation or diminution of heat appears to cause the change alluded to; for Linnæus has well remarked, from observing stove-plants, that such is not the case. It is the withdrawing of a considerable portion of light. The more young and tender the plant, the more sensibly is it affected by this cause.

Linnæus has, in the above-mentioned treatise, elaborately described the various positions which the leaves of different plants assume in their sleep. In general, it may be remarked that they cover, or fold together, the upper surfaces of their leaves, exposing the under, which latter is almost uniformly impatient of light. This is so much the case, that we cannot but suspect the effect of the returning light upon the backs of such leaves, may be the immediate cause of their withdrawing from it, and thus the upper surface becomes necessarily presented to its rays.

A similar effect of light is seen in many flowers, particularly of the compound tribe. But the expansion of these is regulated by other and more abstruse laws, which often limit their changes to certain hours of the day, partly, though not absolutely, independently of light. Many of the *Campion* tribe, especially, unroll their delicate petals in an evening only, in a precise and determinate manner, not to be attributed either to the presence or the absence of light. So the moving-plant, *Hedysarum gyrans*, performs its curious gyrations with apparently perfect indifference as to the degree of light to which it is exposed, provided the surrounding atmosphere be warm and still. The closing or drooping of flowers, moreover, when it depends only on the diminution of light, generally answers an evident secondary purpose, in sheltering the organs of impregnation from the injurious

SLEEP.

injurious effects of rain, or nocturnal dews. But such is seldom the case with leaves, except incidentally, as in *Lotus ornithopodioides*, which plant first led Linnæus to attend particularly to the subject before us.

SLEEP of the Soul, in Theology, denotes that insensible, unconscious, and inactive state, into which some have supposed that mankind are removed at death, and in which they remain till the period of the general resurrection and last judgment. The term sleep has been used by way of contradistinction to that which has been commonly called the intermediate or separate state. Of the advocates of this opinion, some have allowed the essential distinction between body and spirit, and the natural immortality of the human soul; so that, being a substance and not a mode, it will go on to exist, till by some positive act of the Creator it is annihilated. They cannot admit the supposition, that the whole man becomes extinct at death, or that death destroys or annihilates the thinking substance; because, they say, the resurrection on this hypothesis, will not be a resurrection, but a creation of a new set of beings: if death annihilates us in this sense, there can be no future state; because, a being who has lost his existence cannot be recovered. Accordingly, they maintain, that what happens to the soul at death can be no more than a suspension of the exercise of its faculties, or an incapacitation, from which it will, by the power of Christ, be delivered at the resurrection: and they allege, that there is an infinite difference between the annihilation of the soul at death, and its incapacitation; because, one who believes the former, could not possibly entertain the hope of a future state; but one who believes the latter, might reasonably entertain such a hope. Death, they say, is a distress in which our species has been involved by extraordinary causes, and from which we have obtained the hope of being saved by the most extraordinary means, viz. by the interposition of Jesus Christ, who, taking upon him our nature, and humbling himself to death, has acquired the power of destroying death, and is on this account styled the Saviour of the world. However, most of those who deny the notion of an intermediate state of conscious perception between death and the general resurrection, reject the supposition of two distinct natures in man, and consider that principle, which is called the *soul*, not as a spiritual substance, but as a quality, or property, either superadded to matter by the creator of our frame, or resulting from the organization of the human body, and particularly of the brain. See SOUL.

Accordingly, they allege, that when the organized system, to which the power of thinking, &c. is annexed, on which it depends, and from the organization of which, as some maintain, it necessarily results, is dissolved by death; all the percipient and thinking powers of man, all his capacities of action, and of suffering, or of enjoyment, must be extinguished, and cease of course. And if the property of thinking necessarily attends the property of life, as some apprehend, nothing can be requisite to the restoration of all the powers of the man, but the restoration of the body (no particle of which can be lost) to a state of life. Whatever is decomposed, it is said, may certainly be recomposed by the same Almighty power that first composed it, with whatever change in its constitution, advantageous or disadvantageous, he shall think proper; and then the powers of thinking, and whatever depended upon them, will return of course, and the man will be, in the most proper sense, the same being that he was before. Those who hold this opinion maintain, that, according to the scriptures, life and immortality were brought to light by the gospel of Christ, in a sense exclusive of all other teachers,

and all other revelations, at least from the birth of Moses downwards; exclusive, likewise, of all information from the light of nature, or the result of philosophical disquisition on the substance or qualities of the human soul. They hold, moreover, that the sentence pronounced upon our first parents, imported a total deprivation of life, without any reserve, or saving to the life of the soul; and consequently, that eternal life, or a restoration and redemption from the consequences of this sentence, was effected for, revealed, consigned, and insured to man, in and through Christ, and will be accomplished in no other way than that spoken of by Christ and his apostles, who, they say, have left no room to conclude, that there is a separate or intermediate life for the soul, when disunited from the body.

The learned Dr. Law, bishop of Carlisle, having, with a particular view to the controversy concerning the intermediate state, enumerated the several passages both in the Old and New Testament, in which the words, that are translated soul or spirit in our version, occur, maintains, that none of them ever stand for a purely immaterial principle in man, or a substance wholly separable from, and independent of, the body; and after examining the account which the scriptures give of that state to which death reduces us, he observes, that it is represented by sleep, by a negation of all life, thought, or action; by rest, resting-place, or home, silence, oblivion, darkness, destruction, or corruption. He adds, that the scripture, in speaking of the connection between our present and future being, doth not take into account our intermediate state in death; no more than we, in describing the course of any man's actions, take in the time he sleeps: and that, therefore, the scriptures, in order to be consistent with themselves, must affirm an immediate connection between death and judgment. As for those texts that are usually alleged on the other side of the question, which he has cited and endeavoured to accommodate to his own opinion, he thinks that they are quite foreign to the point, or purely figurative, or capable of a clear and easy solution on the principle which he adopts, viz. that the times of our death and resurrection are coincident; and that they cannot be fairly opposed to the constant, obvious tenor of the sacred writings. With respect to philosophical arguments, deduced from our notions of matter, and urged against the possibility of life, thought, and agency, being so connected with some portions of it as to constitute a compound being or person, he imagines that they are merely grounded on our ignorance, and that they will equally prove against known fact and observation, in the production of various animals, as against the union of two such heterogeneous principles as those of the soul and body are supposed to be. With respect to the consequences of either opinion, he says, that on the one side, there is nothing more than a temporary cessation of thought, which can hurt nobody, except the self-interested papist, or the self-sufficient deist; but on the other side, there is a manifest derogation from, if not a total subversion of, that positive covenant, which professes to entitle us to everlasting life. He adds, that all proper and consistent notions of death, resurrection, and a future judgment, are confounded, and in fine, all the great sanctions of the gospel rendered unintelligible or useless.

The doctrine of the New Testament, says another writer against a separate state, is that man shall become immortal, by the way of a resurrection of the dead, a restoration of the whole man to life; and the New Testament is so far from acknowledging any intermediate consciousness in man, between death and the resurrection, that it always speaks of that interval as a sleep, which implies a suspension of

the thinking faculty, a rest from those labours, which require thought, memory, consciousness, &c. during which those faculties are useless.

Besides, the scriptural system of immortality supposes, that man had forfeited his original title to immortality, and would never have received it, but for the interposition of a Redeemer. The consequence of this doctrine is, that between the time of the forfeiture and the actual appearance of the Redeemer, the dead could have life in no sense at all; and that neither before nor after the appearance of the Redeemer, dead men were, or would be restored to life, otherwise than in the way revealed by him, namely, a resurrection of the dead.

On the other hand, the advocates of a separate state insist, that the soul, being an active, simple, un compounded, immaterial substance, is immortal in its own nature, and capable of an active and conscious existence, in a state of disunion and separation from the body; that this natural capacity of the soul was not impaired, or at all affected by any thing that happened upon the transgression of our first parents; that the death, to which they were condemned, was only the death of the body: hence they infer, that there is, and would have been, a future immortal state of being beyond the present life, and (the moral attributes of God presupposed) a just retribution therein, independent of the doctrine of a resurrection of the dead; and that in the interval between death and the general resurrection, there is an intermediate state, in which the departed souls of good men are supposed to have an imperfect reward, and the souls of the wicked an imperfect punishment; but that every one, at the period of the reunion of the soul and body, and of final judgment, will receive a full and complete recompense for the deeds done in the body.

In proof of this opinion, they allege a variety of passages both from the Old and New Testament, the principal of which we shall here enumerate; several of which they think cannot be consistently explained on the other hypothesis. Gen. ii. 7. xv. 15. xxxvii. 35. Exod. iii. 6. 1 Sam. xxviii. 11—19. 1 Kings, xvii. 21, 22. Ps. xxxi. 5. Eccles. iii. 21. xii. 7. Matt. x. 28. xvii. 3. Luke, xvi. 19. xx. 38. xxiii. 43. xxiv. 39. Acts, i. 25. vii. 59. 2 Cor. v. 8. xii. 2. Phil. i. 21—24. 1 Pet. iii. 19. iv. 6. Heb. xi. 40. xii. 23. Rev. vi. 9, 10. xiv. 13.

To these authorities of scripture, they add the testimony of the fathers of the church, who lived in or near the time of the apostles, who are said to be unanimous in this opinion, and persuaded that the soul of every man upon the dissolution of the body died not, but had a proper place to go to, and that accordingly this doctrine is to be found in the most ancient Christian liturgies.

Great stress has been laid, in this controversy, on the meaning of the term death, as it occurs in scripture, and particularly in the sentence denounced against the first parent of the human race. (See DEATH, in *Theology*.) The bishop of Carlisle observes, that the word *death*, in its original and obvious sense, implies a cessation of all natural life, or a real dissolution and destruction of the whole man. But Mr. Farmer, a well-known and excellent writer, in the introduction to his learned work of the "General Prevalence of the Worship of Human Spirits, &c." 1783, has taken some pains to ascertain the meaning of the word *death*, in the threatening denounced against Adam. To this purpose, he says, that if human spirits were worshipped in the age of Moses, particularly in Egypt and Phœnicia, the word death could not at that time, and in those countries, denote more than the destruction of bodily life; for, if this term had farther included in it the insensibility or

extinction of the soul, the dead would not have been honoured as gods. And if Moses had used it in this extensive sense, he would have been misunderstood by the Egyptians, who asserted the immortality of the soul, and by the Hebrews, who dwelt among them, and had adopted their system of religion.

This learned writer, in confirmation of this interpretation of death, observes, that although one great design of Moses, in giving an account of the introduction of death into the world, was to guard against the worship of departed spirits, and though nothing could have answered this design more effectually than representing the soul of Adam as a mere quality, or as the result of the peculiar structure and organization of his body, yet, so far is he from supposing this to be the case, that according to him, after the body of the first man was perfectly organized by the immediate hand of the Almighty, he did not become a living soul or person, till God breathed into his nostrils the breath of life; a principle distinct from the dust out of which his body was formed, and, therefore, capable of subsisting in a state of separation from it. Nor does Moses use the same language in relating the formation of any other living creatures; which proves that the principle of life in man is of a superior kind to that in brutes.

Besides, the ancient patriarchs did not believe that the soul of man perished with his body. Agreeably to the most ancient opinion concerning departed spirits, the sacred writers supposed the souls of the dead to exist in *sheol*, or *hades*, a place invisible to human sight, and that, in the distribution of them, regard was had to the former relation in which they stood to one another. Moreover, Moses himself believed the separate subsistence of the soul, and has even given it a divine sanction. Gen. xv. 15.

Nor do any of the sacred writers ever describe death in terms different from those used by persons, who certainly acknowledged the continuance of the soul after it.

Sleep, by which it is described, is not a state of non-existence, but of rest; and it is well known, that this soft image of death was commonly used to express the thing itself, by those who asserted the existence of souls in *hades*. Silence, oblivion, darkness, and corruption, by which the state of the dead is described, refer only to the body, or to the supposed state of the soul, while it was in *sheol*, and are not peculiar to the sacred writers, but were common in all countries, where both the popular belief, and the established worship, were inconsistent with the notion of the soul's perishing with the body.

And many of the terms, by which death was described in all countries, clearly imply, and are built upon, a belief of the distinction between soul and body, and of their being separated at death.

According to the Greeks, to die was to depart, to go away; and the writers of the New Testament describe death by a departure, (Luke, ix. 31.) that is, of the soul from the body to another state. To all which it may be added, that the Jews, from the time of their return from Babylon, asserted the separate existence of the soul after death; as appears from their imitation of the heathen idolatry, from their evocation of the dead, and from the early references in scripture to the receptacle of departed souls, and many other proofs. This was the opinion, not only of a few eminent individuals, such as Philo, but of the learned sects, the Essenes and Pharisees, and of the whole body of the people, almost without exception, in the time of our Saviour. To this principle the Pharisees, whose doctrine formed the popular creed, added another, *viz.* the resurrection of the dead. The Sadducees believed the extinc-

tion of the soul at death, but did not admit the resurrection; the Pharisees, on the other hand, admitted the latter and denied the former. By the term reviviscence, or return to life, by which the resurrection is described, the Jews could not mean creating anew the soul, that had been destroyed, because, if it were possible, they did not allow that the former soul perished at death. Nor did they believe, that man had no soul; and, therefore, that his resurrection consisted in the re-organization of his former body, or in furnishing him with a new body, organized as that was; because this is a flat contradiction to their belief of the distinction between soul and body, and the separate existence of the former. What then did they, or could they mean by the resurrection to life, but the restoration of that kind of life which they had lost, by the reunion of their souls to a human body, either the same which they had before, or one in effect the same? In virtue of this reunion, the *dead* man became a *living* man, the same as he was before he died, with the same consciousness and recollection, the principle of consciousness having never perished. And if, in or near the time of Christ, the terms resurrection, reviviscence, or living again, as used both by Jews and Gentiles, denoted the reunion of a soul to a human body, the same terms, when adopted by Christ and his apostles, must have the same meaning; and every one would understand them in their common and ordinary signification. Consequently, if life, as expressing the resurrection, signifies the soul's return to a human body, death, its opposite, denotes its separation; both terms imply the continuance of the soul after death: a principle, says Mr. Farmer, held in the most ancient times, by Heathens and Jews, by patriarchs and prophets, and by the people, particularly in the times of Moses and the Messiah, and which gives great probability to the doctrine of a resurrection.

The advocates of the sleep of the soul, on the other hand, earnestly contend, that it was the opinion of the apostles and early Christians, that, whatever be the nature of the soul, its percipient and thinking powers cease at death; and that they had no hope of the restoration of those powers, but in the general resurrection of the dead.

Dr. Campbell, in his "Preliminary Dissertations," (Part ii.) has introduced some remarks, that deserve attention, on the controversy concerning an intermediate state between death and the resurrection. He observes, *first*, that the arguments, on which the deniers of that state chiefly build, arise, in his opinion, from a misapprehension of the import of some scriptural expressions. *Καθευδων, κοιμων, to sleep*, are often applied to the *dead*; but this application is no more than a metaphorical euphemism, derived from the resemblance which a dead body bears to the body of a person asleep. Traces of this idiom may be found in all languages, whatever be the popular belief about the state of the dead. They often occur in the Old Testament; yet it has been shewn, that the common doctrine of the Orientals favoured the separate existence of the souls of the deceased. But if it did not, and if, as some suppose, the ancient Jews were, on all articles relating to another life, no better than Sadducees, this shews the more strongly, that such metaphors, so frequent in their writings, could be derived solely from bodily likeness, and having no reference to a resurrection, could be employed solely for the sake of avoiding a disagreeable or ominous word. It is acknowledged, at the same time, that Christians have been the more ready to adopt such expressions, as their doctrine of the resurrection of the body, presented to their minds an additional analogy between the bodies of the deceased and the bodies of those asleep, that of being one day awakened.

But our author fees no reason to imagine that, in this use, they carried their thoughts further than to the corporeal and visible resemblance now mentioned. Another mistake about the import of scriptural terms, is in the sense which has been given to the word *ανασηαις*. They confine it, by a use derived merely from modern European tongues, to that renovation which we call the reunion of the soul and the body, and which is to take place at the last day. But this is not always the sense of the term in the New Testament.

Dr. Campbell remarks, *secondly*, that many expressions of scripture, in the natural and obvious sense, imply that an intermediate and separate state of the soul is actually to succeed death. Such are the words of our Lord to the penitent thief upon the cross (Luke, xxiii. 43.); Stephen's dying petition (Acts, vii. 59.); the comparisons which the apostle Paul makes in different places (2 Cor. v. 6, &c. Philip. i. 21.) between the enjoyment which true Christians can obtain by their continuance in this world, and that on which they enter at their departure out of it, and several other passages. Let the words referred to be read by any judicious person, either in the original, or in the common translation, which is sufficiently exact for this purpose, and let him, setting aside all theory or system, say candidly, whether they would not be understood, by the gross of mankind, as presupposing that the soul may and will exist separately from the body, and be susceptible of happiness or misery in that state. If any thing could add to the native evidence of the expressions, it would be the unnatural meaning that is put upon them, in order to disguise that evidence. The apostle Paul, they are sensible, speaks of the saints as admitted to enjoyment in the presence of God, immediately after death. Nevertheless, in order to palliate the direct contradiction this bears to their doctrine, that the vital principle, which is all they mean by the soul, remains extinguished between death and the resurrection, they remind us of the difference between absolute or real, and relative or apparent, time. They admit that, if the apostle be understood as speaking of real time, what is said flatly contradicts their system: but they say, his words must be interpreted as spoken only of apparent time. He talks indeed of entering on a state of enjoyment, immediately after death, though there may be many thousands of years between the one and the other: for he means only, that when that state shall commence, however distant in reality the time may be, the person entering on it will not be sensible of that distance, and consequently there will be to him an apparent coincidence with the moment of his death. But, says Campbell, does the apostle any where give a hint that this is his meaning? or, is it what any man would naturally discover from his words? Did the sacred penman, then, as our author proceeds, mean to put a cheat upon the world, and, by the help of an equivocal expression, to flatter men with the hope of entering, the instant they expire, on a state of felicity; when, in fact, they knew that it would be many ages before it would take place? But, were the hypothesis about the extinction of the mind between death and the resurrection well founded, the apparent coincidence they speak of is not so clear as they seem to think it.

Our author remarks, *thirdly*, that even the various equivocation, (or, perhaps, more properly, mental reservation,) that has been devised for them, will not, in every case, save the credit of apostolical veracity. The words of Paul to the Corinthians are, "Knowing, that whilst we are at home in the body, we are absent from the Lord." Again: "We are willing rather to be absent from the body, and present

present with the Lord." Could such expressions have been used by him, if he had held it impossible to be with the Lord, or indeed any where, without the body; and that, whatever the change was which was made by death, he could not be in the presence of the Lord, till he returned to the body? Absence from the body, and presence with the Lord, were never, therefore, more unfortunately combined, than in this illustration. Things are combined here as coincident, which, in the hypothesis of those gentlemen, are incompatible. If recourse be had to the original, the expressions in Greek are, if possible, still stronger. They are, *οι ενδημιοντες εν τω σωματι*, those who dwell in the body, who are *εκδημιοντες απο τη Κυριας*, at a distance from the Lord; as, on the contrary, they are *οι εκδημιοντες εκ τη σωματος*, those who have travelled out of the body, who are *οι ενδημιοντες προς τον Κυριον*, those who reside, or are present with the Lord. In the passage to the Philippians also, the commencement of his presence with the Lord is represented as coincident, not with his return to the body, but with his leaving it, with the dissolution, not with the restoration, of the union. We may here subjoin an inquiry, how the apostle could be in a *strait betwixt two* (Philip. i. 23.), that of *living in the flesh*, and *being with Christ*, which he pronounces to be *far better*, if the exercise of his powers of service and capacity of enjoyment ceased at death. A mind like his could not hesitate between living in the flesh, and thus serving the Christian cause, and sinking at death into a state of total inaction, and of thus continuing for a long but indefinite period.

The fourth remark made by Dr. Campbell on this subject is, that from the turn of the New Testament, the sacred writers appear to proceed on the supposition, that the soul and the body are naturally distinct and separable, and that the soul is susceptible of pain or pleasure in a state of separation. It were endless to enumerate all the places which evince this. The story of the rich man and Lazarus (Luke, xvi. 22, 23.); the last words of our Lord upon the cross (Luke, xxiii. 46.), and of Stephen when dying; Paul's doubts, whether he was in the body or out of the body, when he was translated to the third heaven and paradise (2 Cor. xii. 2, 3, 4.); our Lord's words to Thomas, to satisfy him that he was not a spirit (Luke, xxiv. 39.); and the express mention of the denial of spirits, as one of the errors of the Sadducees (Acts, xxiii. 8.): these are irrefragable evidences of the general opinion on this subject, both of Jews and Christians. By *spirit*, it is observed, as distinguished from *angel*, is evidently meant the departed spirit of a human being; for that man is here, before his natural death, possessed of a vital and intelligent principle, which is commonly called his soul or spirit, it was never pretended that they denied. It has been said, that this manner of expressing themselves has been adopted by the apostles and evangelists, merely in conformity to vulgar notions. To me, says Dr. Campbell, it appears a conformity, which (if the sacred writers entertained the sentiments of our antagonists in this article) is hardly reconcileable to the known simplicity and integrity of their character.

Before the council of Florence, held in 1439, under pope Eugenius IV., the ancient doctrine, both of the Greek and Latin churches, is said to have been, that the souls of the saints were in *abditis receptaculis*, or in *exterioribus atriis*, where they expected the resurrection of their bodies, and the glorification of their souls; and though the fathers believed all of them to be happy, yet they did not think they would enjoy the beatific vision before the resurrection. But in this council it was decreed, that the souls of those, who, after baptism, have incurred no stain of sin, and also those souls, which having contracted the stain of sin, whether in

their bodies or divested of their bodies, have been purged by the sacrifice of the mass, prayer, and alms, are received into heaven immediately, &c.

In the Lateran council, held under Leo X., in 1513, it was decreed, that the soul is not only truly, and of itself, and essentially the form of the human body, as is expressed in the canon of pope Clement V., published in the general council of Vienne, but likewise immortal, and according to the number of bodies into which it is infused, is singularly multipliable, multiplied, and to be multiplied.

However, Peter Pomponatius, a philosopher of Mantua, published a book in 1516, on the immortality of the soul, in which, after stating the moral arguments against the mortality of the soul, and endeavouring to shew that they are weak and inconclusive, infers upon the whole, that the immortality of the soul, being a problematical question, we can have no assurance of it but from revelation; and that they who would build immortality upon any other foundation, only verify the character given to certain self-sufficient reasoners by the apostle, *viz.* professing themselves wise, they became fools.

In 1520, Luther, in the defence of his propositions, which had been condemned by a bull of Leo X., ranks the natural immortality of the soul among the monstrous opinions of Popery; and he afterwards made use of the doctrine of the sleep of the soul as a confutation of purgatory and saint-worship, and he is said to have continued in that belief to the last moment of his life.

William Tyndall also, the famous translator of the bible into English, in defending Luther's doctrine against sir Thomas More's objections, considers the sleep of the soul as the doctrine of the Protestants in his time, and founded on the scriptures: though, in consequence of the opposition given to this doctrine by Calvin, in his *Psychopannychia*, published in 1534, and the turn hereby given to the sentiments of the Reformed in general, he seems to have recanted his opinion. Calvin, however, seems to have been embarrassed with the souls of the wicked, and says, he would only be responsible for the faithful.

The first express condemnation of the doctrine of the sleep of the soul, in a Protestant confession, occurs in the fortieth of king Edward's Articles, composed in 1552.

After the long prevalence of the doctrine of the intermediate state, that of the sleep of the soul has of late years been revived, and, as one of its zealous advocates affirms, gains ground, not so much from considerations of philosophy, as from a close attention to the sense of the scriptures.

We shall close this article with observing, that a singular hypothesis was advanced a few years ago by Dr. Caleb Fleming, and of late vindicated by an anonymous writer; and this is, that the resurrection takes place immediately after death. On this subject, see Law's Appendix and Postscript to his Considerations on the Theory of Religion, &c. 1774. Historical View of the Controversy concerning an intermediate State, &c. 1772. Priestley's Disquisitions on Matter and Spirit, 1777. Correspondence between Dr. Price and Dr. Priestley, 1778; and the publications of Steffe, Warburton, Goddard, Coward, Peckard, Jortin, &c. on both sides of the question, cited by the author of the Historical View, &c. Fleming's Search after Souls.

SLEEPERS, in *Natural History*, a name given to some animals which sleep all the winter: such as bears, marmots, dormice, bats, hedge-hogs, &c. These do not feed in winter, have no sensible evacuations, breathe little, or not at all, and most of the viscera cease from their functions. Some of these creatures seem to be dead, and others to re-

turn to a state like unto that of the fœtus before birth. In this condition they continue, till by length of time maturating the process, or by new heat, the fluids are attenuated, the solids stimulated, and the functions begin where they left off. See Dr. Stevenfon in *Med. Ed. Edinb.* vol. v. art. 177. See *MIGRATION*.

SLEEPER, in *Building*, a name used for the oblique rafter, that lies in a gutter.

SLEEPERS, in the *Glass Trade*, are the large iron bars crossing the smaller ones, and hindering the passage of the coals, but leaving room for the ashes.

SLEEPERS, in the *Military Art*. See *PLATFORM*.

SLEEPERS, in *Ship-Building*, pieces of long compass-timber, fayed and bolted diagonally upon the transoms and timbers adjoining withinside, to strengthen the buttock of the ship. There are from two to three pairs.

SLEEPY CREEK, in *Geography*, a river of America, in North Carolina, which runs into the Atlantic, N. lat. 34° 43'. W. long. 76° 44'.

SLEETS, in *Gunnery*, are the parts of a mortar, passing from the chamber to the trunnions, for strengthening that part.

SLEEVE, *HIPPOCRATES'S*. See *HIPPOCRATES*.

SLEIDAN, *JOHN*, in *Biography*, a celebrated historian, was born in 1506 at Sleidan, a small town at Cologne. His origin, it has been inferred, was obscure, because he took no other name than that of the town in which he was born. He received the early part of his education in his native country, and then went to Paris, whence he removed to Orleans, in order that he might study the law as a profession. On his return to Paris, he was recommended by his countryman and school-fellow, J. Sturmius, to cardinal archbishop du Bellay, who obtained for him a pension, and initiated him into the routine of public business. In 1542 he was obliged, owing to his attachment to the reformed religion, to retire to Strasburg. He was at first a follower of Zuingle, but he afterwards joined the Lutherans, and became a considerable writer in their defence. He was also entrusted with employments of considerable importance to the welfare of the party which he had joined. In 1545 he was deputed to the king of England; and in 1551 he was one of the Protestant envoys to the council of Trent, which, however, was soon dissolved by the troops of Maurice, elector of Saxony. The death of his wife, which happened in 1555, threw him into a deep melancholy, which had the calamitous effect of obliterating his memory to such a degree, that he did not know even his own children. He died at Strasburg, in the following year. He is chiefly known as an author by a work, entitled "De Statu Religionis et Reipublicæ Carolo Quinto Cæsare, Commentaria, Lib. XXV." which was first published in 1555. It comprehends the history of his own times, from 1517 to the year of its publication, and has always been in great credit among the Protestants; though it has been charged with partiality by Catholic writers, and by the adherents of the emperor Charles. "Much of it," says his biographer, "is extracted from public records, and from the archives of the city of Strasburg, with which he was furnished by his friend J. Sturmius." De Thou speaks of it as a work drawn up "exacta fide et diligentia," and he praises very highly the writer's learning and talents for business. This work has been translated into several modern languages: the French version was made by Le Courayer. Another celebrated work of Sleidan's is a compendium of ancient history, entitled "De quatuor Summis Imperiis, Lib. tres," which has gone through a great number of editions. He published likewise a Latin translation of the History of

Philip de Comines, and an abridgment of that of Froissart, besides versions of other works on general history and politics.

SLEKTENES, in *Geography*, a small island in the North sea, near the coast of Lapland. N. lat. 70° 25'.

SLEMISH, or *SLENISH*, a mountain of the county of Antrim, Ireland, near the centre, and forming a very conspicuous object from most parts of the county. Dr. Richardfon calls it a round *hummock*, formed by an accumulation of rectilinear basaltic strata of steady parallelism. The height, as measured by the barometer, is 1398 feet. See *HUMMOCK*.

SLESWICK, *Duchy of*, sometimes called South Jutland, (see *DENMARK* and *JUTLAND*,) a province of Denmark, bounded on the north by Jutland, on the east by the Baltic, on the south by the duchy of Holstein, and on the west by the North sea; about 72 miles in length, and from 30 to 56 in breadth, without including several islands on the coast. The country is well supplied with corn, cattle, and fish; it has no mountains, and but few eminences that deserve the name of hills. The soil is, in general, well cultivated, and agriculture is much encouraged by the crown. Sleswick has from time immemorial been united to Denmark, but has sometimes been given to a brother of the reigning king, as a fief; but this grant has produced considerable disputes, more especially in the last century, when the duke in possession attempted to become an independent prince. In 1720 it was recovered to the crown. The administration is vested in a governor, chancellor, vice-chancellor, and counsellors: the governor resides at Gottorp. The inhabitants are a mixture of Danes, Saxons, Frisicians, and Hollanders, who respectively speak their own languages. The prevalent religion is Lutheran. This duchy contains several towns, and 1500 villages.

SLESWICK, the capital of the above duchy, situated on the river or gulf of Sley; formerly called "Hetheby," from queen Hetha, who was the founder. After having undergone a variety of vicissitudes, it is now no longer a port, the Sley being choked up with sand. It is an irregular town of great length, and contains about 5630 inhabitants. The houses are constructed with brick, and in neatness and manner of building resemble those of Holland; the inhabitants are also the Dutch, and many of them speak their tongue, though the usual languages are the German and the Danish. Close to Sleswick is the old palace of Gottorp, which is a large brick edifice, surrounded with a rampart and moat. It was formerly the ducal residence, and more lately inhabited by the stadtholder or governor, prince Charles of Hesse Cassel, who married Louisa, princess of Denmark. From this castle the ducal line, formed by Adolphus, son of Frederic I. king of Denmark, was denominated Holstein-Gottorp, which still subsists in the person of the great duke of Russia; 60 miles N. of Hamburg. N. lat. 54° 33'. E. long. 9° 34'.

SLETDALER, or *Basse Rixdollar*, in *Commerce*, a money of account in Denmark, reckoned at 4 marks, or 64 skillings Danish.

SLICES, in *Ship-Building*, tapering pieces of plank, used to drive between the timbers before planking, as now practised in the navy, for setting up a ship on her ways for launching, &c.

SLICH, in *Metallurgy*, the ore of any metal, particularly of gold, when it has been pounded, and prepared for farther working.

The manner of preparing the slich at Cremnitz, in Hungary, is this: they lay a foundation of wood three yards deep, upon this they place the ore, and over this there are four-

four-and-twenty beams, armed at their bottoms with iron; these, by a continual motion, beat and grind the ore, till they reduce it to powder: during all this operation, the ore is covered with water. There are four wheels used to move these beams, each wheel moving six; and the water, as it runs off, carrying some of the metalline particles with it, is received into several basons, one placed behind another; and finally, after having passed through them all, and deposited some sediment in each, it is let off into a very large pit, of almost half an acre of ground; in this it is suffered to stand so long, as to deposit all its sediment, of whatever kind, and after this it is let out. This work is carried on day and night, and the ore taken away, and replaced by more, as often as occasion requires. That ore which lies next the beams, where it was pounded, is always the cleanest or richest.

When the slich is washed as much as they can, a hundred weight of it usually contains about an ounce, or perhaps but half an ounce of metal; which is not all gold, for there is always a mixture of gold and silver, but the gold is in the largest quantity, and usually is two-thirds of the mixture: they then put the slich into a furnace with some lime-stone, and slaken, or the scoria of former meltings, and run them together. The first melting produces a substance, called *leeb*; this leeb they burn with charcoal, to make it lighter, to open its body, and render it porous, after which it is called *ross*; to this rost they add sand in such quantity as they find necessary, and then melt it over again.

They have at Cremnitz many other ways of reducing gold out of its ore, but particularly one, in which they employ no lead during the whole operation; whereas, in general, lead is always necessary, after the before-mentioned processes. See GOLD.

SLICKENBORCH, in *Geography*, a town of Holland, in the state of Friesland, on the river Linde, at its union with the Kuynder; 28 miles S. of Lewarden.

SLICKENBURG, a small island near the N.W. coast of Borneo. N. lat. $3^{\circ} 59'$. E. long. $112^{\circ} 31'$.

SLIDE-Butt, in *Agriculture*, a sort of sledge contrived in the form of a strong, oblong box, and slid underneath with strong, rough, thick pieces of timber. It is capable of holding about three or four common wheel-barrows full of earth or compost. In Cornwall and other hilly districts, it is found useful and convenient for drawing out dung and other dressings to small distances from the large heaps deposited in the fields or other places. They are used with one or two oxen or horses for the most part. They have sometimes also low wheels, when they are denominated gurry butts in the above county.

SLIDE-Rails, or *Guard-Rails*, in the construction of *Canals*, are long pieces of timber fixed to piles or plugs in the face of the walls of locks, bridges, tunnels, &c. generally a little above the surface of the water, to prevent boats from striking and injuring the walls.

SLIDING, in *Mechanics*, *Superincessus radens*, is, when the same point of a body, moving along a surface, describes a line on that surface.

Such is the motion of a parallelepiped, protruding along a plane.

SLIDING-Rule, a mathematical instrument, serving to work questions in gauging, measuring, &c. without the use of compasses; merely by the sliding of the parts of the instrument one by another, the lines and divisions of which give the answer, by inspection.

This instrument is variously contrived, and applied by various authors, particularly Everard, Coggeshall, Gunter,

Hunt, and Partridge; but the most usual and useful ones are those of Everard and Coggeshall; the description and uses of which are as follow.

SLIDING-Rule, *Everard's*, is principally used in gauging; being ordinarily made of box, a foot long, an inch broad, and $\frac{1}{16}$ ths of an inch thick. It consists of three parts: a rule, on each side of which, *ab* and *cd* (*Plate VII. Surveying, fig. 4.*) is a groove, and two small scales, or sliding-pieces, *m, n*, slide in the grooves. When both these pieces are drawn out to their full extent, the instrument is three feet long.

On the first broad face of the instrument, *ab*, are four lines of numbers; for the properties, &c. of which, see GUNTER'S *Line*. The first, marked A, consisting of two radiuses numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, 1; and then 2, 3, 4, 5, &c. to 10. On this line are four brass centre-pins, two in each radius; one in each of which is marked MB, to signify that the number it is set against, 2150.42, is the number of cubic inches in a malt-bushel; the other two are marked with A, to signify that the numbers they are set against, *viz.* 282, are the cubic inches in an ale-gallon. The second and third lines of numbers are on the sliding-pieces, and are exactly the same with the first. They are distinguished by the letter B. Close to the figure 7, in the first radius, is a dot, marked Si, set exactly over .707, denoting .707 to be the side of a square inscribed in a circle, whose diameter is unity. Close to 9 is another dot, marked Se, set over .886, which is the side of a square equal to the area of a circle, whose diameter is unity. Another dot, near W, is set over 231, the number of cubic inches in a wine-gallon; and another, near C, is set over 3.14, the circumference of a circle, whose diameter is unity. The fourth line of numbers, marked MD, to signify *malt depth*, is a broken line of two radiuses, numbered 2, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1, 9, 8, 7, &c. the number 1 being set directly against MB on the first radius.

On the second broad face, marked *cd*, are 1. A line of numbers of one radius, numbered 1, 2, 3, &c. to 10, noted by the letter D. On this are four centre-pins; the first, marked WG, is the gauge-point for a wine-gallon, *i. e.* the diameter of a cylinder, whose height is an inch, and content 231 cubic inches, or a wine-gallon, which is 17.15 inches: the second centre-pin, AG, stands at the gauge-point for an ale-gallon, which is 18.95 inches. The third, MS, stands at 46.3, the side of a square, whose content is equal to the inches in a solid bushel. The fourth, MR, is the gauge-point for a malt-bushel, which is 52.32 inches. 2. Two lines of numbers on the sliding-piece, which are exactly the same as those on the sliding-piece on the other side, called C. Close to the division 8 is a dot, marked e, which is set to .795, the area of a circle, whose circumference is unity; and another, marked d, stands at .785, the area of a circle, whose diameter is unity. 3. Two lines of segments, each numbered 1, 2, 3, to 100; the first, for finding the ullage of a cask, taken as the middle frustum of a spheroid, lying with its axis parallel to the horizon; and the other for finding the ullage of a cask standing.

Again, on one of the narrow sides, noted e, are 1. A line of inches, numbered 1, 2, 3, &c. to 12, each subdivided into ten equal parts. 2. A line, by which, with that of inches, we find a mean diameter for a cask, in the figure of the middle frustum of a spheroid: it is numbered 1, 2, 3, &c. to 7, and marked *spheroid*. 3. A line for finding the mean diameter of a cask, in the figure of the middle frustum of a parabolic spindle, which gaugers call the *secondary variety of casks*; it is numbered 1, 2, 3, &c. and noted *second variety*. 4. A line, by which we find the mean

SLIDING-RULE.

mean diameter of a cask of the third variety, *i. e.* of a cask in the figure of two parabolic conoids, abutting on a common base; it is numbered 1, 2, 3, &c. and noted *third variety*.

On the other narrow face, marked *f*, are, 1. A foot divided into 100 equal parts, marked F M. 2. A line of inches, like that before-mentioned, noted I M. 3. A line for finding the mean diameter of a fourth variety of casks, which is the middle frustum of two cones, abutting on a common base. It is numbered 1, 2, 3, &c. and noted F C, signifying frustum of a cone.

On the back side of the two sliding-pieces is a line of inches, from 13 to 36, when the two pieces are put endwise; and against that, the correspondent gallons, or hundred parts, that any small tub, or the like open vessel (from 13 to 36 inches diameter), will contain at one inch deep.

Mr. Overley, and other writers on this subject, have suggested some improvements in the construction of this instrument. See Overley's Young Gauger's Instructor, p. 108.

SLIDING-Rule, Use of Everard's.—1. To multiply one number by another. Suppose 4 required to be multiplied by 6: set 1 on the line of numbers B, to 4 on the line A; then, against 6 upon B is 24, the product sought upon A. Again, to multiply 26 by 68, set 1 on B to 26 on A; then, against 68 on B is 1768 on A, the product sought.

2. To divide one number by another. Suppose 24 to be divided by 4: set 4 on B to 1 on A; then against 24 on B is 6 on A, which is the quotient. Again, to divide 952 by 14; set 14 on A to 1 on B, and against 952 on A, you have, on B, 68, which is the quotient.

3. To work the rule of three. If 8 gives 20, what will 22 give? Set 8 on B to 20 on A, then against 22 on B stands 55 on A, the number sought.

4. To find a mean proportional between two numbers, suppose between 50 and 72: set 50 on C to 72 on D; then against 72 on C you have 60 on D, which is the mean required.

5. To extract the square root of a number. Apply the lines C and D to one another, so that 10 at the end of D be even with 10 at the end of C; then are these two lines a table, shewing the square root of any number less than 1000000 by inspection: for against any number on C, the number answering to it on D is the square root of it.

Note, if the given number consists of 1, 3, 5, or 7 places of integers, seek it on the first radius, on the line C, and against it is the root required at D.

6. Either the diameter or circumference of a circle, being given, to find the other. Set 1 on the line A against 3.141 (to which is written C) on the line B; and against any diameter on the line A, you have the circumference on B, and contrariwise: thus, the diameter being 20 inches, the circumference will be 62.831 inches; and the circumference being 94.247, the diameter will be 30.

7. The diameter of a circle given, to find the area in inches, or in ale or wine-gallons. Suppose the diameter 20 inches, what is the area? Set 1 upon D, to .785 (noted *d*) on C; then against 20 on D is 314.159, the area required. Now, to find that circle's area in ale-gallons, set 18.95 (marked A G) upon D, to 1 on C; then against the diameter 20 upon D, is the number of ale-gallons on C, *viz.* 1.11. The same may serve for wine-gallons, regard being only had to the proper gauge-point.

8. The two diameters of an ellipsis being given, to find the area in ale-gallons. Suppose the transverse diameter 72 inches, and the conjugate 50: set 359.05, the square of the gauge-point, on B, to one of the diameters (suppose 50)

on A; then against the other diameter 72 on B, you will have the area on A, *viz.* 10.02 gallons, the content of this ellipsis at one inch deep. The like may be done for wine-gallons, if, instead of 359.05, you use 249.11, the square of the gauge-point for wine-gallons.

9. To find the area of a triangular surface in ale-gallons. Suppose the base of the triangle 260 inches, and the perpendicular let fall from the opposite angle 110 inches: set 282 (marked A) upon B, to 130, half the base, on A; then against 110 on B is 50.7 gallons on A.

10. To find the content of an oblong in ale-gallons. Suppose one side 130 inches, and the other 180: set 282 on B, to 180 on A; then against 130 upon B is 82.97 ale-gallons, the area required.

11. To find the content of a regular polygon in ale-gallons, one of the sides being given. Find the length of the perpendicular let fall from the centre to one of the sides: this, multiplied by half the sum of the sides, gives the area. For an instance; suppose a pentagon, whose side is 1 inch, here the perpendicular will be found .837, by saying, as the sine of half the angle at the centre, which, in this polygon, is 36°, is to half the given side .5, so is the sine of the complement of 36°, *viz.* 54°, to the perpendicular aforesaid. Whence the area of a pentagon, whose side is unity, will be found 1.72 inches, which, divided by 282, gives .0061, the ale-gallons in that polygon.

12. To find the content of a cylinder in ale-gallons. Suppose the diameter of the base of the cylinder 120 inches, the perpendicular height 36 inches: set therefore the gauge-point (A G) to the height 36 on C; then against 120, the diameter on D, is found 1443.6, the content in ale-gallons.

13. The bung and head-diameters of any cask, together with its length, being given; to find its content in ale or wine-gallons. 1. Suppose the length of a cask taken (as the middle frustum of a spheroid, which is the first case or variety) be 40 inches, its head-diameter 24 inches, and bung-diameter 32 inches: subtract the head-diameter from that of the bung, the difference is 8. Look, then, for 8 inches on the line of inches, on the first narrow face of the rule; and against it, on the line *spheroid*, stands 5.6 inches, which, added to the head-diameter 24, gives 29.6 inches for that cask's mean diameter: set, therefore the gauge-point for ale (marked A G) on D, to 40 on C; and against 29.6 on D, is 97.45, the content of the cask in ale-gallons. If the gauge-point for wine (marked W G) be used instead of that for ale, you will have the vessel's content in wine-gallons.

2. If a cask, of the same dimensions as the former, be taken (as the middle frustum of a parabolic spindle, which is the *second variety*), see what inches, and parts, on the line marked *second variety*, stand against the difference of the bung and head-diameters, which, in this example, is 8; and you will find 5.1 inches, which, added to 24, the head-diameter, makes 29.1 inches, the mean diameter of the cask: set, therefore, the rule, as before, and against 29.1 inches, you will have 94.12 ale-gallons for the content of the cask.

3. If the cask taken be the middle frustum of two parabolic conoids, which is the third variety; against 8 inches, the difference of the head and bung-diameters, on the line of inches, you will find 4.57 inches on the line called *third variety*; this, added as before to 24, gives 28.57 for the cask's mean diameter; proceeding, as before, you will find the content 90.8 gallons.

4. If the cask taken be the frustums of two cones, which is the *fourth variety*, against 8 inches on the line of inches,

you will find on the line marked F C, 4.1 inches to be added to 24 inches: the rest, carried on as before, gives the content of the cask 87.93 ale-gallons.

14. A cask partly empty, lying with its axis parallel to the horizon; to find the quantity of liquor in it. Find its whole content as above, which suppose 97.455 gallons; and suppose the inches left dry, 8, and the bung-diameter 32: then, as the bung-diameter on C is to 100 on the line of segments L, so are the dry inches on C to a fourth number on the line of segments: and as 100 upon B is to the cask's whole content on A, so is that fourth number to the liquor wanting to fill up the cask, which, subtracted from the whole content of the cask, gives the liquor remaining therein; *e. gr.* set 32, the bung-diameter on C, to 100 on the segment-line L; then against 8, the dry inches on C, stands 17.6 on the segment-line: set, therefore, 100 on B to the cask's whole content on A; and against 17.6 on B, you have 16.5 gallons on A: subtracting, therefore, the said gallons from 97.45, the vessel's whole content, the liquor in the cask will be 80.95 gallons.

15. A cask standing upright, or with its axis perpendicular to the horizon, to find the liquor therein. Suppose the length of the cask 40 inches, and 10 of them dry; set 40 inches on the line C, to 100 on the segment-line S; and against 10, the dry inches on the line C, stands 24.2 on S, the segment-line. Set then 100 on B to 97.455, the cask's whole content on A; and against 24.2 on B, you will have 23.5 gallons, which is what is wanting to fill up the cask: this, therefore, subtracted from the whole content 97.455, gives 73.955 gallons, for the quantity of liquor remaining in the cask.

16. To find the content of any right-angled parallelepiped (*e. gr.* a cistern, uting-fat, or the like) in malt bushels. Suppose the length of the base 80 inches, the breadth 50, and depth 9 inches; set the breadth 50 on B, to the depth 9 on C; then against the length 80 on A, stand 16.8 bushels on B, the number required.

SLIDING-Rule, *Coggeshall's*, is principally used in measuring of the superficies and solidity of timber, &c.

It consists of two rulers, each a foot long, which are framed or put together various ways; sometimes they are made to slide by one another, like glaziers' rules: sometimes a groove is made in the side of a common two-foot joint-rule, and a thin sliding-piece put in, and *Coggeshall's* lines added on that side: but the most usual and commodious way is, to have one of the rulers slide in a groove made along the middle of the other, as it is represented in *Plate VII. Surveying, fig. 5.*

On the sliding side of the rule are four lines of numbers, three of which are double, that is, are lines to two radiuses, and one, a single broken line of numbers: the three first, marked A, B, C, are figured 1, 2, 3, &c. to 9; then 1, 2, 3, &c. to 10. Their construction, use, &c. are the same as those on Everard's sliding rule. The single line, called the *girt-line*, and noted D, whose radius is equal to the two radiuses of any of the other lines, is broken, for the easier measuring of timber, and figured 4, 5, 6, 7, 8, 9, 10, 20, 30, &c. from 4 to 5. It is divided into 10 parts, and each tenth subdivided into two, and so on from 5 to 10, &c.

On the backside of the rule are, 1. A line of inch-measure, from 1 to 12; each inch being divided and subdivided.

2. A line of foot-measure; consisting of one foot, divided into 100 equal parts, and figured 10, 20, 30, &c. The backside of the sliding-piece is divided into inches,

halves, &c. and figured from 12 to 24; so that when slid out, there may be a measure of two feet.

SLIDING-Rule, in measuring plain superficies, use of *Coggeshall's*. 1. To measure a square. Suppose, *e. gr.* the sides be each five feet: set 1 on the line B, to 5 on the line A; then against 5 on the line B is 25 feet, the content of the square on the line A.

2. To measure a long square. Suppose the longest side 18 feet, and the shortest 10: set 1 on the line B, to 10 on the line A: then against 18 feet on the line B is 180 feet, the content on the line A.

3. To measure a rhombus. Suppose the side 12 feet, and the length of a perpendicular let fall from one of the obtuse angles to the opposite side, 9 feet: set 1 on the line B, to 12, the length of the side, on the line A; then against 9, the length of the perpendicular on the line B, is 108 feet, the content.

4. To measure a triangle. Suppose the base 7 feet, and the length of the perpendicular let fall from the opposite angle to the base 4 feet: set 1 on the line B, to 7 on the line A: then against half the perpendicular, which is 2 on the line B, is 14 on the line A, for the content of the triangle.

5. To find the content of a circle, its diameter being given. Suppose the diameter 3.5 feet: set 11 on the girt-line D, to 95 on the line C; then against 3.5 feet on D, is 9.6 on C, which is the content of the circle in feet.

6. To find the content of an oval or ellipsis. Suppose the longest diameter 9 feet, and the shortest 4. Find a mean proportional between the two, by setting the greater 9 on the girt-line, to 9 on the line C; then, against the less number 4, on the line C, is 6, the mean proportional sought. This done, find the content of a circle, whose diameter is 6 feet; this, when found by the last article, will be equal to the content of the ellipsis sought.

SLIDING-Rule, in measuring timber, use of *Coggeshall's*.

1. To measure timber the usual way. Take the length in feet, half feet, and, if required, quarters; then measure half-way back again; there girt the tree with a small cord or line; double this line twice, very evenly; and measure this fourth part of the girt or perimeter, in inches, halves, and quarters. The dimensions thus taken, the timber is to be measured as if square, and the fourth of the girt taken for the side of the square, thus; set 12 on the girt-line D, to the length in feet on the line C; then against the side of the square, on the girt-line D, taken in inches, you have, on the line C, the content of the tree in feet.

For an instance: suppose the girt of a tree, in the middle, be 60 inches, and the length 30 feet, to find the content: set 12 on the girt-line D, to 30 feet on the line C; then against 15, one-fourth of 60, on the girt-line D, is 46.8 feet, the content on the line C. If the length should be 9 inches, and the quarter of the girt 35 inches, here, as the length is less than a foot, measure it on the line of foot-measure, and see what decimal part of a foot it makes, which you will find .75: set 12, therefore, on the girt-line, to 75 on the first radius of the line C, and against 35 on the girt-line is 6.4 feet on C, for the content.

2. To measure round timber the true way. The former method, though that generally in use, is not quite just. To measure timber accurately, instead of the point 12 on the girt-line, use another, *viz.* 10.635; at which there should be placed a centre-pin. This 10.635 is the side of a square equal to a circle, whose diameter is 12 inches. For an instance: suppose the length 15 feet, and $\frac{1}{4}$ th of the girt 42 inches: set the point 10.635 to 15, the length; then

SLIDING-RULE.

then against 42 on the girt-line is 233 feet for the content sought; whereas, by the common way, there arise only 184 feet. In effect, the common measure is only to the true measure, as 11 to 14. See **TIMBER**.

3. To measure a cube. Suppose the sides to be 6 feet each: set 12 on the girt-line D, to 6 on C; then against 72 inches (the inches in 6 feet) on the girt-line are 216 feet on C, which give the content required.

4. To measure unequally squared timber; that is, where the breadth and depth are not equal. Measure the length of the piece, and the breadth and depth (at the end) in inches; then find a mean proportional between the breadth and depth of the piece. This mean proportional is the side of a square equal to the end of the piece: which found, the piece may be measured as square timber.

For an instance: let the length of the piece of timber be 13 feet, the breadth 23 inches, and the depth 13 inches: set 23 on the girt-line D, to 23 on C; then against 13 on C is 17.35 on the girt-line D for the mean proportional. Again, setting 12 on the girt-line D to 13 feet, the length on the line C, against 17.35, on the girt-line is 27 feet, the content.

5. To measure taper timber. The length being measured in feet, note one-third of it; which is found thus: set 3 on the line A, to the length on the line B; then against 1 on A is the third part on B: then if the solid be round, measure the diameter at each end in inches, and subtract the less diameter from the greater; add half the difference to the less diameter; the sum is the diameter in the middle of the piece. Then set 13.54 on the girt-line D to the length on the line C, and against the diameter in the middle, on the girt-line, is a fourth number on the line C. Again, set 13.54 on the girt-line to the third part of the length on the line C; then against half the difference on the girt-line, is another fourth number on the line C: these two fourth numbers, added together, give the content. For an instance: let the length be 27 feet (one-third of which is 9), the greater diameter 22 inches, and the less 18; the sum of the two will be 40, their difference 4, and half the difference 2, which, added to the less diameter, gives 20 inches for the diameter in the middle of the piece. Now, set 13.54 on the girt-line, to 27 on the line C, and against 20 on D is 58.9 feet. Again, set 13.54 on the girt-line to 9 on the line C; and against 2 on the girt-line (represented by 20) is .196 parts; therefore, by adding 58.9 feet to .196 feet, the sum is 59.096 feet, the content.

If the timber be square, and has the same dimensions; that is, the length 27 feet, the side of the greater end 22 inches, and that of the lesser 18 inches; to find the content: set 12 on the girt-line to 27, the length on the line C; and against 20 inches, the side of the mean square on the girt-line, is 75.4 feet. Again, set 12 on the girt-line to 9 feet, one-third of the length, on the line C; and against 2 inches, half the difference of the sides of the squares of the ends on the girt-line, is .25 parts of a foot: both together make 75.65 feet, the content of the solid.

The girt or circumference of a tree, or round piece of timber, given; to find the side of the square within, or the number of inches of a side when the round timber is squared. Set 10 on A to 9 on B; then against the girt on A are the inches for the side of the square on the line B. See **DENDROMETER**.

Dr. ROGET has lately communicated to the Royal Society the "Description of a new Instrument for performing the Involution and Evolution of Numbers," by which he has very

much improved the construction, and extended the application of the "sliding-rule."

In his ingenious paper on this subject, he has stated and elucidated the general principles on which instruments of this kind are constructed, and the ordinary purposes to which they are applicable. It is well known, that the Gunter's line and common sliding-rule are derived from the properties of logarithms, and that their primary use consists in facilitating the *multiplication* and *division* of numbers. (See **GUNTER'S Line** and **GUNTER'S Scale**.) Our author's instrument is founded on a particular mode of employing logarithms, and is designed for immediate application to the *involution* and *evolution* of numbers. The common sliding-rule, it is obvious, serves for comparing the intervals between the numbers on Gunter's scale; and for this purpose it consists of a scale, called the slider, exactly of the same length with the former, and bearing the same divisions, which, by being moveable along the side of the other, allows of the application of any part of the one to any part of the other. If the two scales originally coincide, and the sliding scale is the undermost, then, by advancing the slider through any given distance, each of its divisions will be brought under those of the fixed scale, which before were respectively situated farther forwards by an interval equal to that given distance. Every number in the upper scale will therefore have to the number standing under it on the slider the same constant ratio; a ratio indicated by the number under which the unity, or commencement of the scale of the slider has been placed. The former numbers will therefore be the multiples of the latter by this constant number. Thus, by adjusting the slider so that its unity shall stand under any given multiplier or divisor, the upper line will exhibit the series of the products of all the subjacent numbers by the given multiplier; and conversely, the slider will exhibit the series of the quotients resulting from the division of the numbers immediately above them by the given divisor. In order to facilitate the general use of the sliding-rule, Dr. ROGET has pointed out the following proposition, as leading directly to the solution of every case to which the instrument can be applied. "In every position of the slider, all the fractions formed by taking the numbers on the upper line as numerators, and those immediately under them as denominators, are equal. Thus, every corresponding numerator and denominator, having to each other the same ratio, may be considered as two terms of a proportion. Any two of these equivalent fractions will therefore furnish the four terms of a proportion; of which any unknown term may be supplied when the others are given, by moving the slider till the numbers composing the terms of the given fraction are brought to coincide on the two lines. The required term will then be found occupying its proper place opposite to the other given term. Thus, from the proportion $A : B :: C : D$, we may derive

$$\frac{A}{B} = \frac{C}{D}; \text{ and adjusting the slider so that } B \text{ shall stand under}$$

A , D will be found under C , when C is given; or C will be found over D , when D is given. A similar process would have furnished A or B , when one of them, together with C and D , were given. Since the products of each numerator by the denominator of the other fraction are equal (that is, $AD = BC$); when one of the terms is unity, the question becomes one of simple multiplication or division. The product of A and B , which we may call P , will be found as before, by placing the slider so as to express the frac-

$$\text{tions } \frac{A}{1} = \frac{P}{B}. \text{ The quotient of } A \text{ divided by } B, \text{ which}$$

SLIDING-RULE.

we may call Q , will in like manner be found by forming the fractions $\frac{A}{B} = \frac{Q}{1}$; that is, in the former case, the product P will stand over B , when the 1 on the slider is brought under A ; and in the latter case, the quotient Q will stand over the 1 of the slider when B is brought under A ."

The sliding-rule has been variously modified, so as to serve for the calculation of exchanges, the measurement of plane and solid bodies, and the computations of trigonometry; and lately by Dr. Wollaston, in his synoptic scale of chemical equivalents; but notwithstanding these modifications, its use is necessarily limited to operations that are performed by the simple addition or subtraction of logarithms, and to the corresponding arithmetical operations above mentioned. It is not directly adapted to perform the involution or evolution of numbers, to which the multiplication and division of logarithms correspond. (See LOGARITHM.) Nevertheless, questions that involve geometrical progressions, or exponential quantities, and the computation of the terms of a series in obtaining approximate solutions, not infrequently occur. The common sliding-rule affords no direct method of determining even the simple power or root of any given number; but when the exponent of the required power or root is not an integral, but a fractional number, it is still more inadequate to the solution of the question. Indeed, the squares and square roots are often pointed out on the common rules by means of a supplementary line graduated so that each of its divisions is double in length to those of the other two lines. A line of cubes, or cube-roots, or of any other given power, might, in like manner, be subjoined. But the uses of such additional lines are restricted to cases where a particular power is concerned; but they afford no assistance in the case of any other power or root, which is not immediately related to the power.

Dr. Roget adopts a new mode of graduation, exhibiting on simple inspection all the powers and roots of any given number to any given exponent, with the same facility, and in the same way, that products, quotients, and proportionals are exhibited by the common sliding-rule. Accordingly it is a measure of powers, just as the scale of Gunter is a measure of ratios. The principle of its construction will be best illustrated by an example. If it were required to raise the number 2.123 to the fifth power; with the use of logarithms we should multiply the log. of 2.123 (or 0.32695) by 5 ; the product (1.63475) would be found by the tables to correspond to 43.127 , the fifth power of 2.123 . If the exponent, instead of being a whole number 5 , were fractional, as 4.3719 , the operation may be abridged by the aid of logarithms: thus, add the log. of 0.32695 or 9.5144813 , to that of 4.3719 or 0.6406702 , and the sum, or 0.1551525 , is a logarithm answering to the number 1.4294 , the product required, *viz.* 26.878 , or $\overline{2.123}^{4.3719}$.

In this example, the first of the numbers added together is the logometric logarithm (that is, the logarithm of the logarithm) of the given root; the second is the simple logarithm of the exponent, and the sum of these is the logometric logarithm of the power. If a table were constructed having three sets of columns, the first containing the natural series of numbers, the second their corresponding logarithms, and the third the logarithms of those logarithms, we should be able to raise any given number to any given power, by the simple addition of the numbers in the second and third columns; as common multiplications are performed by the addition of common logarithms. Hence it

is evident, that a line might be graduated so that its divisions should correspond to the numbers in the third column, or represent the logometric logarithms of the numbers marked upon them; and if this line were applied so as to slide against another line logometrically divided, we might be able by it to perform the operation that has been described; and we should thus have, by inspection, the powers corresponding to any given root and exponent.

The instrument proposed would therefore, in its simplest form, consist of two graduated scales applied to each other.

In *Plate VII. Surveying, fig. 6.* a portion of these scales is represented. The lower rule AA , called the slider, is the common Gunter's double line of numbers, or a line logometrically divided; the divisions of the first half being from 1 to 10 , and repeated on the second half in the same order. The upper, or fixed rule BB , is so graduated, that each of its other divisions is set against its respective logarithm on the slider; and, consequently, all the numbers on the slider will be situated immediately under those numbers in the upper rule, of which they are the logarithms. Thus, 2 on the rule will be over 0.30103 of the slider; 3 over 0.47712 ; 2 on the slider will stand under 100 on the rule; 3 under 1000 , and so on.

As the series of ordinary logarithms express the exponents of 10 , of which the corresponding numbers are so many successive powers, in this position of the instrument it is evident, that the upper line will exhibit the series of the powers of 10 , corresponding to all the exponents marked on the slider. *E. gr.* The $2d$ power of 10 is 100 ; the $3d$, 1000 , &c.; the $0.5th$ (or the square root) is 3.163 ; the $0.25th$ (or $4th$ root) is 1.778 ; the $0.2th$ (or the $5th$ root) is 1.585 , &c.

In every other position of the slider, the upper rule will exhibit, in like manner, the series of powers of that number, under which the unit of the slider has been placed, while the opposite numbers on the slider are the exponents of those powers. Thus, if (*Plate VII. fig. 7.*) the unit of the slider be placed under the division 3 of the upper rule (at R), the square of 3 , or 9 , will be found over the 2 of the slider; its cube, 27 , over the 3 ; its $4th$ power, 81 , over the 4 , &c. Hence, in order to find a given power of any number, the unit of the slider must be set underneath that number in the upper rule; and the number sought will then be found above that number in the slider, which expresses the magnitude of the required power. The use of the instrument will be obvious in performing the contrary operation of finding the roots. In this case the root might be considered as a fractional power; but as this would require a reduction into decimals, the easiest mode will be to place the number expressing the degree of the required root under the given number, and the root itself will then be found over the unit, or beginning of the scale, in the slider. For fractional powers, the denominator of the exponent must be placed under the root, and its numerator will then point out the power. By the same mode we may discover the exponent of any given power to any given root; since, whatever be the root over the unit of the slider, the whole series of the powers of that root, with their corresponding exponents, are rendered apparent. This circumstance may be considered as an additional recommendation to the employment of this instrument; for it affords to those less versed in the contemplation of numerical relations, an ocular illustration of the theory of involution. It presents, at one view, the whole series of powers arising from the successive multiplication of all possible numbers, whether entire or fractional; and exhibits this series in its whole continuity, when the exponents are fractional, and even incommensurate

with

SLIDING-RULE.

with the root itself. The production of the upper line in one direction, conveys a more accurate notion of the progressive and rapid increase of those powers, than can be acquired by mere abstract reflection; and its continuation on the other side shews the slow approximation to unity which takes place in the successive extractions of higher and higher roots. Among the variety of forms of construction of which instruments that operate on the principle now explained are capable, Dr. Roget conceives the following to be, upon the whole, the most convenient for practical purposes. Its representation, on a reduced scale, appears in *Plate VII. fig. 8.* With a view of preserving a sufficient extent of scale, the line of roots and powers is divided into two parts; one being placed above and the other below, and between them a slider with a double scale of exponents. The slider of the common sliding-rule is graduated in a way that is exceedingly well suited to this purpose, having divisions on each edge, and carrying two sets of numbers from 1 to 10. Adapting a blank ruler to one of these sliders, which must be fixed in a proper position, Dr. Roget marks off, on the upper line, the series of numbers against their respective logarithms on the sliders; placing 10 over the middle unit of the slider, 100 over the 2, 1000 over the 3, and so on, proceeding towards the right, from 10 to 1000000000, the 10th power of 10; an extent which is more than sufficient for all useful purposes. The space to the left is also graduated on the same principle, from 10 to 1.259, which is the 10th root of 10, or $10^{0.1}$. The upper portion of the rule being thus filled, Dr. R. places the continuation of the same line on the lower portion, beginning on the right hand, and proceeding in a descending series of fractional powers of 10, corresponding with the exponents on the intermediate slider, which, when applied to this portion, are to be taken as only $\frac{1}{10}$ th of their value when applied to the upper portion. While 1.259 therefore is marked on the right, $1.0233 (= 10^{0.01})$ will occupy the middle, and $1.002305 (= 10^{0.001})$ the left end of the lower line. The graduation, it is plain, might be thus continued indefinitely in both directions. But for all practical purposes, the limits thus obtained will be found amply sufficient. In proportion as numbers in a descending series approach very near to unity, their logarithms bear more and more exactly a constant ratio to the excess of those numbers above unity, viz. the ratio expressed by the modulus of the system, or 1 to .4342944819. As we descend in the scale, therefore, the decimal part of the exponents becoming smaller and smaller, the corresponding logarithms will approximate so nearly to the multiple of that decimal part by this modulus, that no sensible error will result from assuming them to be the same. Thus the log. of 1.05 is .021189; that of 1.005 is .0021661; and that of 1.0005 is .00021709, which differs from the product of the modulus by .0005 (or .00021715) by a quantity affecting only the 4th significant figure. The roots 1.0005, 1.00005, 1.000005, &c. may, therefore, without sensible error, be considered as coinciding with the division 217 on the slider. Hence, the divisions to the left of the lower portion of the rule may be taken as sufficiently accurate representations of the divisions which would occur in the succeeding portions of the line, if it were prolonged indefinitely in that direction.

This instrument may, from the principle of its construction, be applied to the solution of various problems in which geometrical progressions are concerned. *E. g.* As the successive amounts of a sum placed at compound interest compose a geometrical progression, all questions of compound interest are resolvable by this instrument. The rate of in-

terest, or the *per centage per annum*, being added to 1, gives the amount of 1*l.* at the end of one year. Thus, at 5 *per cent.* the amount is 1.05, at 3 *per cent.* 1.03, &c. In either case this number is to be regarded as the first term, or root of the series. Setting the unit of the slider against this number on the rule, we shall find the amount of 1*l.* at the end of $5\frac{1}{2}$ years opposite to the number 5.5 on the slider, and the same of any other interval of time. If it be required to ascertain in what time a sum placed at compound interest at 3 *per cent.* will be doubled; placing the unit over 1.03, the number 2 on the rule will indicate 23.45 on the slider, as the number of years required for doubling the sum at that rate of compound interest. The interpolation of a given number of mean proportionals between two given numbers, is sometimes required for the solution of a problem; and it is easily effected by the rule above described. Thus, in dividing the musical octave into 12 equal semitones, the following series of numbers must be calculated, viz. $2^{\frac{1}{12}}$, $2^{\frac{2}{12}}$, $2^{\frac{3}{12}}$, $2^{\frac{4}{12}}$, $2^{\frac{5}{12}}$, $2^{\frac{6}{12}}$, $2^{\frac{7}{12}}$, $2^{\frac{8}{12}}$, $2^{\frac{9}{12}}$, $2^{\frac{10}{12}}$, $2^{\frac{11}{12}}$: this may readily be done in one position of the slider; for when the 12 marked on it is placed under 2 on the rule, the 1 of the slider will point to $1.0595 = 2^{\frac{1}{12}}$, the 2 of the slider will indicate $1.1225 = 2^{\frac{2}{12}}$, the 3, $1.1892 = 2^{\frac{3}{12}}$, &c.

A variety of questions relating to the general theory of logarithms may be illustrated by this instrument. The assumption of the number 10, as the basis of our system of logarithms, is arbitrary, and chosen merely for greater convenience in computation. The hyperbolic system, whose basis is the number 2.302585093, &c. has its peculiar advantages, especially in the higher branches of analysis. The instrument may be made to exhibit at one view the series of any particular system of logarithms, that is, of a system with any given basis, or any given modulus, by merely setting the unity of the slider against the given basis on the rule, or the given modulus on the slider against the number 2.7182818, &c. on the rule. The divisions on the slider will then denote the logarithms of the numbers opposed to them on the rule.

Let it be required to determine the particular system of logarithms, in which the modulus shall be equal to the basis. Take out the slider, and introduce it in an inverted position, so that the numbers on it shall increase from right to left; and place the numbers .4343, &c. (the modulus of the common system) under 10 (its corresponding basis) on the rule, as represented in *Plate VII. fig. 9.* We shall find that, in this position, all the other numbers on the slider will be the moduli corresponding to the respective bases of each different system on the rule. Thus, the 1 on the slider, or the modulus of the hyperbolic system, is opposite to 2.718, the basis of that system. On the other hand, the division 2 on the rule is opposite to 1.4427, which is the modulus of the system having for its basis the number 2. Carrying the eye still more to the left, and observing the point where similar divisions appear, both on the rule and the slider, we shall find it to be at the number 1.76315, which therefore expresses the modulus and the basis in that particular system in which they are both equal. The reason of the above process will readily appear, when it is considered, that the modulus of every system is the reciprocal of the hyperbolic logarithm of its basis.

This inverted condition of the slider will also afford an easy method of solving exponential equations, for which there exists no direct analytical method. *E. g.* Let the root of the equation $x^x = 100$ be required. Set the unit of the inverted slider under 100 on the rule, and observe, as before, the point where similar divisions coincide: this will be at

3.6, which is a near approximation to the required root; and accordingly, $3.6^{100} = 100$.

Our author's instrument admits of being applied in various forms to the several purposes above recited, as well as to others which he has enumerated: but the following deserves particular mention, on account of the peculiarities that attend them. If to the upper scale, which we may suppose to be fixed, and to be graduated logometrically, constituting the line of exponents, a slider be adjusted, graduated on both edges, according to the logometric logarithms; and the line below, which, like the upper one, is supposed to be fixed, be graduated in the same manner as the slider, the instrument will possess the following property. When the division 10 on the slider is set against any particular number, or exponent, in the upper line, all the numbers on the lower line will be the powers, to the same degree, of the numbers opposite to them on the slider; the degree of the power being marked by the exponent on the upper line, which is above the 10 on the slider. The lower line will, therefore, exhibit the whole series of similar powers belonging to all possible roots; and conversely, the slider will exhibit all the roots of the same dimensions, with regard to all possible numbers. Thus, if the 10 on the slider be under 3 in the line of exponents, it will itself be above 1000 (which is its cube) in the lower line; all the other numbers in that line will be the cubes of their opposites on the slider; and, conversely, the former will every where be the cube-roots of the latter. This will sufficiently appear, when it is recollected that the addition or subtraction of logometric logarithms, answers to the multiplication or division of simple logarithms, and therefore to the involution and evolution of numbers. The rule in this form of it, therefore, bears a closer analogy to the common sliding-rule; since in every position it exhibits the series of similar powers and roots, exactly in the same way as the latter exhibits the series of similar products and quotients.

Dr. Roget has also contrived to give another form to the instrument, by throwing the whole scale, like Gunter's line, into a circular form: and of this form he has given a drawing. The circle on the outside being logometrically divided from 1 to 10 round the circumference, will constitute the line of exponents. The line of powers, being disposed in a spiral, will occupy the interior space, which may be made to revolve within the former, and should be provided with one or more threads, extending from the centre to the circumference, and serving as radii to mark the position of all the parts of the spiral line with regard to the divisions of the outer circle. One of these threads may be fixed at the unit or beginning of the scale, and will serve to mark the position for the root of any required power. The spiral itself must be graduated exactly as the upper line in the first described rule; that is, the situation of the division 10 must be first determined upon, and then brought under the unit in the circle of exponents; that is, under the fixed thread. Every other division must then be marked with reference to the place of its logarithm on the circle, or must be made to occupy the same angular distance from the thread. This graduation will be most conveniently made by means of the moveable leg of a sector revolving on the centre of the circle. The comparison of the divisions of the spiral with those of the circle may be made, either with this moveable sector, or with the threads already mentioned. The numbers on the spiral will increase as they recede from the centre, and each turn will carry on the powers to an exponent ten times higher than the preceding; and the converse will ob-

tain with regard to the descending portion. Thus, immediately in a line with the 10, on the superior branch of the spiral, is found the number 1000000000, or 10^{10} ; below it, on the inferior branches, we find successively $1.258926 = 10^{0.1}$, $1.023293 = 10^{0.01}$, $1.00230524 = 10^{0.001}$, $1.000230285 = 10^{0.0001}$, $1.0000230261 = 10^{0.00001}$, &c. of which the decimal figures approach nearer and nearer to 2.302585093, &c. the reciprocal of the modulus of the logarithmic system. Our ingenious author has further shewn how to exhibit in one view the whole series of roots, powers, and exponents, in all their possible relations, by a suitable disposition of lines. For further particulars we refer to the Phil. Trans. for 1815, part 1. p. 9, &c. For an account of Mr. W. Nicholson's improvements of the Gunter's scale, &c. see the Phil. Trans. for 1787, vol. lxxvii. part 2. See GUNTER'S *Line and Scale*.

SLIDING-Keels, in *Ship-Building*, an invention of the ingenious captain Schank, of the royal navy, to prevent vessels from driving to leeward. They were composed of plank of various widths, erected vertically by a winch, so as to slide up and down in a trunk, and through the keel. Many vessels were built with no less than three of these keels; but it has not seemed to have answered.

SLIDING-Planks, are the flat forms upon which the bilge-ways slide in launching the ship.

SLIDING-GUNTER-SAIL, in *Sail-Making*, a triangular sail, used in boats, bent at its foremoist leech to loops or grommets that slide on the lower mast: the peak or head is attached to a small top-mast, that slides up in the direction of the lower mast, through two hoops fixed at its head, about three feet asunder. When the top-mast is lowered, the sail furls up close to the lower mast.

SLIEBH, or **SLIABH**, the Irish name for a range of mountains, or a single one, covered with heath. O'Brien says it signifies heath-land, whether mountain or plain. It is prefixed to the names of many Irish hills.

SLIEBH-AN-ERIN, in *Geography*, a range of mountains in the county of Leitrim, Ireland, extending in a N.E. direction from Lough Allen.

SLIEBH-EN-EWR, called also *Dartry* mountains, a cluster of hills, covering almost the whole of the northern barony of the county of Leitrim, Ireland. Of these and the preceding it is observed by Dr. Beaufort, that they are far from unprofitable; for producing abundance of coarse grafs, they annually pour forth immense droves of young cattle.

SLIEVE-BAUGHT MOUNTAINS, a chain of mountains on the confines of the counties of Monaghan and Tyrone, and extending into both. They form an uninterrupted ridge of high land, the highest part of which is called Cairn-more. They have, in general, neither a fruitful soil, nor any natural beauties to recommend them, being an uninteresting waste, and almost always wet and moory. There are parts, however, which have beds of the richest limestone, and abundance of marble, particularly on the eastern side of Cairn-more. This mountain is famous for its millstone quarry; those most valued consist of a red and very hard grit or sand-stone, the grain of which is close: there is also a soft whitish sand-stone, more easily procured, but which soon wastes away. Potters' clay found in the neighbourhood is carried to the pottery at Dundalk. Stat. Ac. of Monaghan.

SLIEBH-BAUGHTA MOUNTAINS, an extensive range of rather low hills, which cover the southern part of the

the county of Galway, and the adjoining part of Clare, in Ireland.

SLIEBH-BLOOM, or **SLIE-BLOOM**, a mountain in Ireland, or rather a chain of mountains, of considerable extent, dividing the King's and Queen's counties, and extending into the county of Tipperary. It is about 25 miles in length, and, in some parts, 10 miles broad, at the base. It is very unequal in height. Some few ridges are of considerable altitude, especially those which divide Eli O Carrol from Offory. One of these is called *Ard-Erin*, i. e. the highest part of Ireland. This, however, is very doubtful, as it is probable that no accurate comparison on the subject has been ever made. Slie-bloom affords, in general, good pasturage, and in some parts, like many other Irish mountains, is green to the summit; but in other parts it is rocky, wild, and inaccessible, inasmuch that wolves are said to have found harbour in its caverns later than in any other part of the kingdom, even within the last century.

Some of the declivities of this mountain yield good corn, and are highly improved by plantations, and gentlemen's seats which command very extensive and picturesque views. It is remarkable for the number of fine rivers that spring from it. Three of these form an interesting subject to poets as well as geographers. "Near Offory," says Camden, "are those huge copling mountains named *Sliew-blamy*, which Giraldus calls *Bladinx Montes*, of a vast height, out of the bowels whereof spring three rivers, the Suire, the Nore, and the Barrow. These descend in three several channels, but join in one before they fall into the sea, which made the ancients call them the Three Sisters."

It may be observed, that the moderns likewise call them sisters, although Spenser represents them as brothers, the sons of the giant Blœmius and the nymph Rheufa, born in the mountain Sliew-bloome; and the poet thus describes their courses and final confluence.

"These three fair sons, which being thenceforth powr'd,
In three great rivers ran, and many countreis scowr'd.
The first, the gentle Shure, that, making way
By sweet Clonmel, adorns rich Waterford;
The next, the stubborn Newre, whose waters gray,
By faire Kilkenny and Rossepoite board;
The third, the goodly Barrow, which doth hoord
Great heaps of salmon in his deepe bosome:
All which, long hundred, doe at last accord
To ione in one ere to the sea they come;
So, flowing all from one, all one at last become."

Fairie Queen, book iv. canto xi.

For a more particular account of the three sisters of Slie-bloom, see **BARROW**, **NORE**, and **SUIRE**; and for a description of the foil, quarries, &c. of this mountain, see **KING'S** and **QUEEN'S Counties**.

SLIEBH-BONN MOUNTAINS, a range of mountains in the county of Roscommon, Ireland, extending nearly parallel to the Shannon, at a few miles distance, from Rusky-bridge to Lanefborough.

SLIEBH-BUY MOUNTAINS, a mountainous tract in the county of Wexford, Ireland, near the borders of Wicklow.

SLIEBH-CROOB MOUNTAINS, in the county of Down, Ireland, north of the Mourne mountains, and lying between Ballynahinch and Cattlewellan.

SLIEBH-DHAM, a mountainous range in the western part of the county of Sligo, Ireland, being part of the ridge to which Arrowsmith has given the name of *Knock-na-rec*.

SLIEBH-DONARD, one of the Mourne mountains,

in the county of Down, Ireland, said to be the highest of them, and to be 2800 feet in height. See **MOURNE**.

SLIEBH-GALLAN, a cluster of hills in the south of the county of Londonderry, Ireland; about 1250 feet above the level of the sea.

SLIEBH-GULLIEN, in the south-east of the county of Armagh, Ireland, which is thought to be nearly as high as Sliebh-Donard; and which, like it, consists of granite. It has a cairn on the summit.

SLIEBH-LEAGUE MOUNTAINS, a cluster which occupies the peninsula west of Killybegs, in the county of Donegal, Ireland; called by Arrowsmith *Slieve-long*.

SLIEBH-LOGHER MOUNTAINS, in the county of Kerry, Ireland, on the borders of the county of Cork. Spenser has represented this range as the source of the river Allow:

"Strong Allo tumbling from Sliebh-Logher steep:"

but in this he departs from geographical accuracy, as the Allow takes its rise in the Limerick mountains, and the Blackwater passes under Sliebh-Logher, from which it receives a large supply of water. See **BLACKWATER**.

SLIEBH-MISH, a range of hills south of Tralee, in the county of Kerry, Ireland.

SLIEBH-MORE, a mountain in Achil island, county of Mayo, Ireland.

SLIEBH-NA-COILTRA MOUNTAINS, a range in the county of Wexford, Ireland, south of the town of New Ross.

SLIEBH-NA-MAN, a high mountain of the county of Tipperary, Ireland, not far from the Nine-mile house, on the road from Clonmel to Kilkenny.

SLIEBH-NA-MUCK, a range of hills N. of the Galtees, in the county of Tipperary, Ireland, extending east and west, and lying southward of the town of Tipperary.

SLIEBH-RUSSEL, a mountain of the county of Cavan, Ireland, near Swanlinbar.

SLIEBH-SNAGHT, a mountain of the county of Donegal, Ireland, in the peninsula of Inishowen.

SLIGO, a county of Ireland, in the province of Connaught, bounded on the E. by the county of Leitrim, on the S. by Roscommon, on the S.W. and W. by Mayo, and on the N. by the bay of Donegal. Its greatest length, from Bunduff in the N. to the Curlew mountains in the S. is 31 Irish (39½ English) miles, and the greatest breadth 29 Irish (37 English) miles. It contains 247,150 acres, or 386 square miles, Irish measure, equal to 397,060 acres, or 620 square miles, English. The number of houses was 11,509, supposed to contain 60,000 inhabitants; but the documents on which this is stated were very imperfect, and the increase must have been inconsiderable. There are 39 parishes, of which 16 only had churches when Dr. Beaufort published his valuable work; they lie in the bishoprics of Elphin, Achonry, Killalla, and Ardagh. This county and the town of Sligo are represented in parliament by three members.

Sligo contains very good land, intermixed with large tracts of coarse and unprofitable ground. In the northern district, lying between the county of Leitrim and the sea, are the mountains of Benbulbin and Samore. A chain of rough hills extends from Lough Gilly to the bounds of Roscommon and Leitrim. The barony of Tyreragh, though level along the coast, is intersected by large bogs; and the southern part of it is bounded by the Ox mountain, Sliebh-Dham, and a great range of desolate hills, that extend across the middle of the country; whilst the Curlews

and other mountains cover much of the southern part of it. Among these hills there are many large lakes, and abundance of rivers. The Moy, which rises in the mountain of Knock-na-ree, flows first to the southward, and after a winding course, takes a northerly direction to the bay of Killalla. It receives in its course the superfluous waters of Lough Conn, and forms, for some miles, the western boundary of the county. Lough Arrow is about eight miles long, full of islands, and of a very irregular form: a river of the same name proceeds from it, and running northward to Ballyfadere, rushes at once into the sea in a stupendous cataract. Lough Garra, on the borders of Roscommon, in the most southern part of the county, communicates with Lough Key by the river Boyle, which joins the Shannon. Lough Gilly exhibits that variety of charming prospects which bold hills, wooded lawns, and large islands clothed with verdure, and crowned with trees, united with a great extent of water, cannot fail to produce. Upon the river by which the waters of this lake are discharged into the bay of Sligo, called by Arrowsmith the Garwoag, stands the town of Sligo, the only town of note in the county. There are, however, ports at Ballyfadere and Esky-bridge, at the mouths of the rivers Arrow and Esky. Hazlewood, the seat of Owen Wynne, esq. is distinguished for its beauty as well as for agricultural improvement, which has been carried here probably to a greater extent than at any other place in Ireland. The linen manufacture has made great progress in different parts of the county, especially in the vicinity of Ballymote, where it was established by the late Hon. Tho. Fitzmaurice.

SLIGO, a post-town of Ireland, chief town of the county of the same name, and a sea-port, situated at the mouth of the river which flows from Lough Gilly to the bay of Sligo. Vessels of 200 tons can come up to the quays, and the trade of Sligo has been increasing for many years. When Dr. Beaufort published, its population was estimated at upwards of 8000, the number of houses being 916. The county assizes are held here, and it sends a member to the imperial parliament. The magistrates are a provost and town-clerk. A castle was built here in 1245, and soon after a monastery, of which Mr. Archdall has said, "that the few ruins which remain evince its former splendour. Three sides of the cloister may still be seen, covered with an arched roof: the arches and pillars are of extraordinary workmanship, and a few of the pillars are ornamented with sculpture. The great east window is beautiful, and the high altar, adorned with reliefs, in the Gothic style. The nave is spacious, with a passage round it in the nature of a gallery, supported by stone pillars. This great and curious monument of antiquity seems to have fallen a prey to the devouring teeth of time, rather than to the hands of man, though Cromwell is said to have injured it." Sligo is 105 miles N.W. from Dublin.

SLIME, in *Agriculture*, a material left by the tides and other waters in different places, which is an useful manure. See OOZE.

SLINCK, or SLINGHE, in *Geography*, a river of Holland, which joins the Berchel, near Borckeloe, in the county of Zutphen.

SLINE-HEAD. See SLYME-HEAD.

SLING, FUNDA, a string instrument, serving for the casting of stones, &c. with the greater violence.

Pliny, l. lxvi. c. 5. attributes the invention of the sling to the Phœnicians; but Vegetius ascribes it to the inhabitants of the Balearic islands, now called Majorca and Minorca, who were famous in antiquity for the dexterous management of them. Florus and Strabo say, those people bore three

kinds of slings, some longer, others shorter, which they used according as their enemies were nearer or more remote. Diodorus Siculus adds, that the first served them for a head-band, the second for a girdle, and that the third they constantly carried with them in their hand.

In fight they threw large stones with such violence, that they seemed to be projected from some machine, inasmuch that no armour could resist their stroke. In besieging a town, they wounded and drove the garrison from the walls, throwing with such exactness, that they seldom missed their mark: this dexterity they acquired by constant exercise, being trained to it from their infancy, the mothers placing their daily food on the top of a pole, and giving them no more than they beat down with stones from their slings. This art is still, in some measure, preserved by the Minorquin shepherds. The invention of the sling has been erroneously ascribed by some writers to the inhabitants of these islands. Froissart (vol. i. c. 85.) gives an instance in which slings were employed for the English by the people of Brittany in a battle fought in that province during the reign of Philip de Valois, between the troops of Walter de Mauni, an English knight, and Louis d'Elpaigne, who commanded 6000 men in behalf of Charles de Blois, then competitor with the earl of Montfort for the duchy of Brittany. According to the same author, they were also used in naval combats. Slings were used in 1572, at the siege of Sancerre, by the Huguenots, in order to save their powder. D'Aubigné, who records this fact, says that they were hence called Sancerre harquebusses. Slings were constructed for throwing not only stones, but leaden bullets, and clay-balls, baked or hardened in the sun. They were made of different materials, chiefly flax, hair, or leather, woven into bands, or cut into thongs, broadest in the centre, for the reception of the stone or ball, and tapering off gradually towards both ends: with one of these slings, a good slinger would, it is said, throw a stone 600 yards. An ancient Icelandic treatise, entitled "Speculum Regale," supposed to have been written about the 12th century, mentions slings fixed to a staff.

SLING, in *Surgery*, a well-known bandage for the arm and hand.

SLINGS, in *Rigging*, short ropes used to hang the yards to the masts, &c. See SLINGING.

SLINGELANDT, PETER VAN, in *Biography*, was born at Leyden in 1640. He was a laborious disciple of Gerard Douw, and wrought in the highly finished style of that master; and is as neat in his execution. His pictures, however, do not possess the relish found in those of Gerard, either in composition or colour; and they are tasteless in design. He is said to have been most patiently persevering and industrious, employing months and years upon one performance; and never being satisfied till he found every individual part imitated, however trivial, of any object which he had chosen to represent. His works are often passed off for those of his master, and of Mieris; and it sometimes demands a considerable portion of connoisseurship to discover the imposition. He died in 1691.

SLINGER'S BAY, in *Geography*, a bay of the East Indian ocean, on the N. coast of New Ireland. S. lat. 3°. E. long. 151°.—Also, an inlet of the Pacific ocean, between the islands of Ramos and St. Juan.

SLINGING is used variously at sea; but chiefly for the hoisting up of casks, or other heavy things, with slings, *i. e.* contrivances of ropes spliced into themselves at either end, with one eye big enough to receive the cask, or any thing to be sling.

There are other slings which are made longer, and with a small eye at each end; one of which is put over the breech

breech of a piece of ordnance, and the other eye comes over the end of an iron crow, which is put into the mouth of the piece, to weigh and hoist the gun as they please.

There are also slings for the yards; which is done by binding them fast to the cross-tree aloft, and to the head of the mast, with a strong rope or chain, that if the tie should happen to break, or to be shot to pieces in fight, the yard, nevertheless, may not fall upon the hatches.

SLINGING a Man overboard, in order to stop a leak in a ship, is done thus: the man is trusted up about the middle in a piece of canvas, and a rope to keep him from sinking, with his arms at liberty, a mallet in one hand, and a plug, wrapped in oakum and well tarred in a tarpawling-clout, in the other, which he is to beat with all dispatch into the hole or leak.

SLIP, among *Ship-Builders*, denotes a place lying with a gradual descent on the banks of a river, convenient for *ship-building*; which see.

SLIPS, masses of earth which are apt to slip out of the banks of canals, reservoirs, &c.

SLIPS, in *Gardening*, such portions of plants as are slipped off from the stems or branches for the purpose of being planted out as sets. A great number of plants, both of the woody and herbaceous kinds, is propagated by slips, which is effected in the woody kinds by slipping off small young shoots from the sides of the branches, &c. with the thumb and finger, instead of cutting them off with a knife; but there is no material difference, in the success or future growth, between slips and cuttings, only the former in small young shoots is more proper to be slipped off by the hand, which, in numerous small shrubby plants, will grow; but it is more commonly practised in the lower ligneous plants, such as sage, winter-savory, hyssop, thyme, southern-wood, rosemary, rue, lavender, and others of slow shrubby growths. The best season of the year for effecting the work, is generally the spring and beginning of summer, though many sorts will grow if planted at almost any time, from the spring to the latter end of the summer, as shewn in speaking of their culture.

And in performing the work of slipping in these sorts, the young shoots of but one year's growth, and in many sorts the shoots of the year, should be chosen as growing the most readily, even when to plant the same summer they are produced, especially the hard-wooded kinds: but in the more soft-wooded plants, the slips of one year's growth will also often readily grow; being careful always to choose the moderately-growing side-shoots situated on the outward part of the plants, from three to six or eight inches long, slipping them off close to the branches, and clearing off the lower leaves; then planting them in a shady border, if in summer, and watered, or so as they can be occasionally shaded in hot sunny weather, especially small slips, inserting the whole two parts of three into the ground, giving occasional water in dry warm weather, till properly rooted; and then towards autumn, or in the spring following, transplanting them where they are to remain.

But in planting slips of the shoots of tender shrubby exotics of the greenhouse and stove, many sorts require the aid of a hot-bed or bark-bed, to promote their emitting roots more effectually, as shewn in their respective culture; but some others of the shrubby kinds, such as geraniums, will root freely in the natural earth in summer; and many of the herbaceous tribe, producing bottom-rooted offsets for slips, as aloe, &c. also readily grow, either with or without a hot-bed; but where there is the convenience of hot-beds in which to plunge the pots of slips of tender plants, it runs them off more expeditiously; and most hot-

house plants in particular require that assistance. But many shrubby plants, growing into large bunches from the root of the small under-shrubby kinds, as thyme, savory, hyssop, sage, &c. as well as those of larger growth, as roses, spiræas, raspberries, and numerous other sorts, may be slipped quite to the bottom into separate plants, each furnished with roots, and planted either in nursery-rows, or at once where they are to remain.

And as to the slipping of herbaceous plants, various sorts multiply by the roots, &c. into large bunches, which may be slipped into many separate plants, by slipping off the increased suckers or offsets of the root, and in some sorts by the offsets from the sides of the head of the plants, and in a few sorts by slips of their bottom shoots, as well as of the stalks and branches in plants of bushy growth; but the greater part by slipping the roots, as in many of the bulbous-rooted tribe, and numerous fibrous-rooted kinds of plants. The slipping of the bulbous plants is performed in summer when their leaves decay, the roots being then taken up, slipping off all the small offsets from the main bulb, which are generally soon planted again in nursery-beds for a year or two. See *BULBOUS Roots*.

In the fibrous-rooted sorts, the slipping should generally be performed in the spring or early part of autumn, which may be effected either by slipping the outside offsets with roots, as the plants stand in the ground; or more effectually, by taking the whole bunch of plants up, and slipping them into several separate parts, each slip being furnished also with roots, planting them, if small, in nursery-rows for a year, to gain strength; or such as are strong may be planted at once where they are to remain. See the culture of the different sorts under their respective heads.

SLIPPER. See *PLINTH*.

SLIPPER, a kind of iron sledge, or lock, for the use of a tram-waggon.

SLIPPER Island, in *Geography*, a small island in the East Indian sea. N. lat. 14° 8'. E. long. 93° 30'.

SLIPPER, Lady's, in *Botany*. See *CYPRIPEDIUM*.

SLIPPERY ROCK, in *Geography*, a township of America, in the state of Pennsylvania, and county of Mercer, containing 789 inhabitants.—Also, a township of Pennsylvania, in Butler county, containing 658 inhabitants.

SLIPPING, among *Gardeners*, the tearing off a sprig from a branch, or a branch from an arm of a tree. These sorts of slips take root more readily than cuttings. See *SLIPS*.

SLIPPING, in *Rural Economy*, a term used among animals to denote abortion in them. Thus, mares are said to slip their colts, ewes their lambs, and cows their calves. And it has been suggested, that cows in calf, by smelling to any flesh, particularly in a putrescent state, are affected by such a nausea as to stimulate the womb to action, and to eject the fetus: this is well known in the north of Scotland, where it is particularly guarded against. It is observed by Mr. Ross, in the 25th volume of the "Annals of Agriculture," that through the inattention of a game-keeper, there was always horse-flesh lying about his yards, and he had many cows which slipped calves. It is supposed, in the "Essex Agricultural Report," that bleeding, when one-third or half gone, is a preventative. When it happens, the abortion should be immediately buried, and the cow kept as widely apart as possible from the herd, and not receive the bull that goes with them. It is considered as certainly infectious.

And in *Suffex* it has been supposed by some that the slipping of lambs has been caused by too free a use of rape, as one large sheep-farmer, some years since, lost eighty or

ninety in this way; which was supposed to arise from feeding the ewes upon it about the end of the year, though it had been made use of before without any bad effect of this kind. The ewes in this instance had been hard kept. The same circumstance has also taken place among the flocks of other sheep-farmers. The same sort of crop has, however, been fed on the other side of the hedge at the same time with the same sort of stock without any inconvenience of this nature occurring. It is, therefore, most probably to be ascribed to some other unperceived cause. Ewes are, however, certainly, from some cause or other, very subject to slip their lambs, and of course require much care and attention in this respect. They should constantly be kept in a state of quiet, and free from all sort of disturbance for some time after the ram has been put to them.

SLIRE, in *Geography*, a town of Norway, in the province of Aggerhuus; 68 miles N.N.W. of Christiania.

SLIT, in *Agriculture*, a crack or cleft in the breasts of fat cattle, &c.

SLIT-Grafting. See ENGRAFTING.

SLIT-Planting, among planters, a mode of planting trees in small openings without the whole of the ground being dug out, a small slit or opening only being made for each tree. See PLANTING.

SLITTE, in *Geography*, a river of Scotland, which runs into the Tiviot, near Hawick, in Roxburghshire.

SLOANE, Sir HANS, in *Biography*, immortalized as the principal founder of the British Museum, was born at Killaleagh, in the county of Down, Ireland, April 16, 1660. His family is said to have been of Scottish extraction; but whatever their situation in life might be, they were desirous to acquire more honour from him, than he derived from them; though, by the education which he received, his circumstances appear to have been far from indigent. He is said to have been attached, from his youth, to the study of nature, and this led him perhaps to that of medicine, as a profession. A spitting of blood confined him at home for three years, and it was not till his 19th year that he was able to enter on a regular course of medical education at London. To this he devoted the four succeeding seasons, during which he was introduced to the acquaintance, and even the friendship, of Boyle and Ray; great names, whose continued favour affords sufficient testimony of the successful application of the young student, to the two sciences in which they respectively took the lead. Sloane proceeded to Paris, in company with Mr. Tancred Robinson; see ROBINSONIA. There he attended the lectures of Tournefort and Du Verney; and he is reported to have taken his medical degrees at Montpellier. This he could hardly have done as a Protestant, and therefore we presume another report to be more correct, of his having graduated at Orange, where possibly there might, at that time, be a sort of Protestant university. Returning to London late in 1684, Dr. Sloane became a favourite and inmate of the great Sydenham, who seems to have intended taking him by the hand as a physician. He was soon chosen a fellow of the Royal Society, and in April 1687, entered into the College of Physicians. These early advancements afford, as Dr. Pulteney remarks, the strongest presumptions in favour of his knowledge and abilities. Yet he relinquished his domestic prospects, to gratify his ardour for natural knowledge.

A desire of investigating the natural history of the West Indies, the appetite for which, among the learned of Europe, had rather been whetted than satisfied by slight and superficial information, induced Dr. Sloane to embark for Jamaica, in September 1687, as physician to the duke of Albemarle,

just then appointed governor of that island. But the death of this nobleman, on the 19th of December, soon after their arrival, putting an end to the office of his physician, the stay of the latter in the new world, which he had been so eager to visit, became abridged by his circumstances, and necessary prospects in life. He snatched fifteen months from these calls, and devoted that period, with all possible ardour, to the accomplishment of the real object of his voyage. The West Indies had hitherto been visited by Englishmen, for none but the most sordid purposes, and the passions, tastes, and characters of the settlers have generally been formed and moulded by the malignant influence of their domestic system, their luxurious habits, and the natural effects of the climate. Sloane passed through this triple ordeal untouched; for he was armed by a love of nature, a thirst for knowledge, and sufficient scientific acquirements to be sensible of the value of what he possessed, and of what lay within his reach. He made ample collections of natural history, bringing home from Jamaica, Barbadoes, Nevis, and St. Kitt's, about 800 species of dried plants, enriched with a most abundant store of information respecting their qualities and uses. He arrived in London, May 29, 1689, where he directly resumed his medical occupations, with which he happily and successfully associated his literary pursuits. A fine person, and agreeable manners, doubtless contributed more to his success as a London physician, than the skill of Hippocrates would have done by its own intrinsic worth. The interest of Dr. Sloane seems to have lain much in the city. In 1694 he became physician to Christ's hospital, and the next year he married Elizabeth, daughter of alderman Langley, who lived with him near thirty years, dying in 1724. She bore him a son and daughter, who died young; besides two daughters, who carried rich inheritances into the families of Stanley and Cadogan, and who both survived their father.—In 1693 Dr. Sloane was elected secretary to the Royal Society, which office he held for nineteen years, to the great honour and benefit of that body as well as himself, for he immediately revived the publication of its Philosophical Transactions, which had for six years been neglected. He was no less attentive to his medical duties in the College, for he projected and established a dispensary for the poor, steering skilfully through all the difficulties which usually attend any scheme for public benefit, where bodies of men are concerned. The opposition he encountered gave rise to Dr. Garth's celebrated and beautiful poem of the "Dispensary," by which alone the memory of these contests, and of most of the parties engaged, is now preserved. But it is not so with Sloane. Unfading wreaths, though not of poetic laurel, adorn his bust, and his favourite science consecrates his name in one of the most stately West Indian plants. See SLOANEA.

In 1696, the subject of our memoir published his Latin Catalogue of the Plants of Jamaica, a closely printed octavo of 232 pages. He follows Ray's system of arrangement, and is content with referring his species, as well as he could, like that great writer himself in his catalogues of British plants, to some popularly received genus; in which habit and general resemblance, rather than the structure of the fructification, are his guides. In scientific generic discrimination indeed, Sloane must yield the palm to Plumier and many others. His incompetence in this point, rendered him unfit to estimate the talents of Linnæus; when the latter visited him in 1736, and remarked to Haller, that no botanist in England, except Dillenius, understood, or cared about, generic characters. But Sloane is nevertheless entitled to rank high as a literary botanist from his uncommon attention

attention to synonyms, by which the little volume in question is rendered almost a complete *Pinax* of the plants it contains, and the history of the several species is preserved, as much as possible, from confusion. That such a work should be free from errors, is impossible, but it evinces the learning and diligence of its author. This catalogue was not followed up, till the year 1707, by the publication of the first volume of the great work, to which it was a kind of *Prodronus*, and which is entitled "A Voyage to the Islands Madera, Barbados, Nieves, St. Christopher's and Jamaica, with the Natural History of the Herbs and Trees, four-footed Beasts, Fishes, Birds, Insects, Reptiles, &c. of the last of those islands." To this volume is prefixed an introduction, of 154 pages, containing an account of the history and climate of Jamaica, the manners, domestic economy, food, trade, &c. of the inhabitants, and particularly an ample detail of their diseases. The whole is full of curious and instructive matter. The body of this volume, comprising 264 pages, 47 of which are devoted to a journal of the author's voyage, consists of descriptions of plants, with every thing that could be got together, relative to their history or qualities. The whole is illustrated by 256 plates, chiefly of plants, each plate often being occupied by several species. These were taken from the dried specimens, still extant in the author's herbarium; and are therefore very imperfect as to botanical details, though characteristic in their general appearance. It is scarcely necessary to remark that certain coloured copies which exist, are mere impositions upon the purchaser. It is more important to observe, that the genera or affinities of the plants are sometimes widely erroneous, in consequence of the work having been composed from a rather superficial inspection of dry specimens. Thus *Cardamomum minus*, *pseudo-asphodeli foliis*; *Cat.* 61; page 166. t. 103. f. 3, of the present work, is actually an *Orchidea*, of the genus *Neottia*; whilst *Orchis elatior latifolia*, *asphodeli radice*, *spicâ strigosa*; *Cat.* 119; p. 250. t. 147. f. 2, is, according to the herbarium, an *Alpinia*. The figure however represents an *Orchidea*.

The statistical part of this book is valuable, but there are some remarks relative to the management of slaves, which we cannot pass over, especially as the question of the slave-trade still calls for all the vigilance of the Christian moralist and politician, to defeat the machinations of its advocates, and secret promoters. The following, amongst others, are Sloane's words. "The punishments for crimes of slaves, are usually for rebellions burning them, by nailing them down on the ground with crooked sticks on every limb, and then applying the fire by degrees from the feet and hands, burning them gradually up to the head, whereby their pains are extravagant. For crimes of a lesser nature, gelding, or chopping off half of the foot with an axe. These punishments are suffered by them with great constancy." The author proceeds as coolly to describe "usual" whipping and other punishments, and concludes thus. "After they are whip'd till they are raw, some put on their skins pepper and salt, to make them smart; at other times their masters will drop melted wax on their skins, and use several very exquisite torments. These punishments are sometimes merited by the blacks, who are a very perverse generation of people; and though they appear harsh, yet are scarce equal to some of their crimes, and inferior to what punishments other European nations inflict on their slaves in the East Indies, as may be seen by Moquet, and other travellers." The author, in palliating these enormities, worthy of Spanish inquisitors, and perhaps originally derived from some such hellish source, does not inform us whether our Christian Protestant ministers preached against them; but we learn

from other documents that they durst not. We know also that the parent state, ecclesiastical as well as civil, for ages looked on, without interfering; and even at this moment, all the strenuous exertions of the virtuous few, supported by the awakened zeal of most Christian divines, of every persuasion, are scarcely able to succeed in demolishing the root of the evil. Regulations have indeed been made to guard against some of the above enormities, and the African slave-trade has been abolished by law. But let Britons never forget that such things have existed, and guard, with all their power and vigilance, against a possibility of their return. The coolness or partiality of Sloane, only proves the callous state of the public mind respecting this question, upon which he tried to make himself as easy as he could. He was, on the whole, a man of good feelings, charitable to the poor, alive to their interests wherever they came in his way, and friendly to all improvements in his profession; such as inoculation for the small-pox, and the use of the Peruvian bark; both which were combated in his day, even more absurdly, and no less dishonestly, than vaccination is at present.

The second volume of Sloane's Jamaica did not appear till the year 1725. By some accident, this is much the most common of the two, and frequently sells for a trifle, while both together fetch about twelve guineas. Of this second volume, 187 pages are devoted to the vegetable, and 148 to the animal, kingdom. There is besides a copious index of 102 pages. About 80 of the plates relate to plants, and 42 to animals. A short account is given of the author's return to England, with the dowager duchess of Albemarle; and numerous corrections, or additions, to the first volume are subjoined. The author frequently refutes his antagonist Plukenet in a decisive style, but with less acrimony than the latter has usually betrayed. It would be tedious and unprofitable to follow them through all the mazes of their criticism, but as far as we have incidentally done this, Plukenet is generally most exact. (See PLUKENET.) We must not omit to notice, that Sloane liberally allowed Ray to make use of his Jamaica manuscripts, in the third volume of the *Historia Plantarum*, where the original generic distributions of the author, if they merit that appellation, are followed. Though Sloane tells us, in the preface to his first volume, that some of the plants, with his observations upon them, had received the approbation of his illustrious friend; it does not any where appear that questions of botanical arrangement, or technical discrimination, had been particularly discussed between them. We must not therefore lay any defects of this kind to the charge of Ray, to whom the scientific botany of the West Indies was nearly an unexplored field, of which Sloane furnished him by no means with sufficient materials for the cultivation; the latter having examined nothing very deeply in this respect, and his dried specimens being mollly insufficient for the purpose.

The collections of natural history, made by Sloane in his voyage, seem to have laid the foundation of that museum, which became gradually so famous. A brother collector and friend, Mr. Courten, in 1702, left his own acquisitions to augment it, on condition of the payment of certain debts and legacies, to an amount much below the value of what was thus bequeathed. How soon curiosities of art were included in Dr. Sloane's museum, or whether such made a part of Mr. Courten's, we know not; but the whole collection was now very considerable, and continued increasing during the long life of its owner, who, the year before he died, reckoned up the articles of natural history, exclusive of 200 volumes of dried plants, as amounting to more than

30,600. His taste or collecting was followed by many persons, nor should his humble imitator, Mr. Salter of Chelsea, the founder of the well-known Don Saltero's coffee-house, be altogether despised. Who can answer for the taste or curiosity that may have been awakened by this humble popular museum, or the pursuits and discoveries to which it may have led? The writer of this is not ashamed to acknowledge his own obligations to it at a very early period. The discoveries of Sloane in the West Indies were moreover useful, in exciting collectors of living plants to enrich their gardens from that novel and fertile source, by which all the hot-houses in Europe profited. Hence the French were led to send out PLUMIER, see that article; and though at war with England in the year 1708, that nation was generous enough to admit the subject of our memoir, with the permission of queen Anne, as one of the eight foreign members of the *Academie des Sciences*. His honours and appointments at home were rapidly increasing. He was consulted by the royal family, and created a baronet by king George I. This rank, it is said, had never before been conferred on a physician; though such an application of it has since been frequent; as being easier to the giver, and more advantageous to the receiver, than more solid, but less brilliant, rewards for court service. Sir Hans became physician-general to the army, and in 1719 was elected president of the College of Physicians, which station he held for sixteen years; but all his other honours fade before that of the presidency of the Royal Society, conferred upon him, on the death of sir Isaac Newton, in 1727. He resigned the latter, at the age of fourscore, in 1740, when he retired to the manor-house of Chelsea, which manor he had purchased about the year 1720. Here he received the visits of his scientific and other friends, patronized the ingenious, and assuaged the distressed. The worthy George Edwards records, in his *Essays on Natural History*, that he seldom missed drinking coffee with "the good sir Hans Sloane" on a Saturday, during his retirement of about fourteen years at Chelsea. "He was so infirm as to be wholly confined to his house, except sometimes, though rarely, taking a little air, in his garden, in a wheeled chair." Edwards unexpectedly found him in the agonies of death, on the 10th of January, 1753, N.S. at four in the afternoon. He expired at four the next morning, in the 92d year of his age, and was buried, along with his lady, in a vault, at the south-east corner of Chelsea church-yard, where a handsome, and very conspicuous, monument to his memory still exists. His epitaph relates that he died "without the least pain of body, and with a conscious serenity of mind." Edwards says, "I continued with him later than any one of his relations, but was obliged to retire, his last agonies being beyond what I could bear; though under his pain and weakness of body, he seemed to retain a great firmness of mind, and resignation to the will of God." These accounts may not be totally irreconcilable. The convulsions of death are "agonies" probably in appearance more than reality; and it is consolatory to see a well-directed mind, even in ordinary cases, generally superior to them, in a remarkable manner. Sloane was, in every respect, prepared to meet them.

The person of sir Hans Sloane was tall and handsome; his manners easy, polite and cheerful. He delighted in exhibiting and explaining to strangers, and especially foreigners, whatever he possessed, and is said to have kept an open table once a-week, for his friends, particularly such as belonged to the Royal Society. That his reception of the great Linnæus was not peculiarly flattering, has often been mentioned with regret; nor can we account for it otherwise, than by recollecting that he was not sufficiently

gifted with the talismanic power of genius, by which kindred minds discover each other, through every disguise of rank, or external appearance. But the principal obstacle to the free intercourse of these distinguished men arose, perhaps, from the want of a common language. Linnæus could speak nothing but Latin, and that with the foreign accent. He was moreover, at this time, full of those novel ideas of botanical philosophy, by which he subsequently gave laws to the learned world. Boerhaave, who recommended him with enthusiasm to Sloane, could appreciate these; but to the latter, as at first sight to Dillenius, they promised nothing but confusion and inconvenience; and though the Oxford professor soon looked further into their merits; the opulent patron and collector, who had risen to eminence by his own means, felt no inclination to go to school to a poor Swedish student, hardly superior in his eyes to a working gardener. Few men can be serviceable in many different ways. The merits of sir Hans Sloane were transcendent in his own line. He neglected no means, that appeared to him eligible, for promoting literature or science. On purchasing his great estate at Chelsea, he presented the Apothecaries' company with the fee simple of the garden which they had already made there, on a condition, equally beneficial to their fame and to science, that it should for ever continue a *botanic garden*. "He was governor," says Dr. Pulteney, "of almost every hospital in London; and to each, after having given an hundred pounds in his life-time, he left a more considerable legacy at his death. He was ever a benefactor to the poor, who felt the consequences of his death severely. He was zealous in promoting the establishment of the colony of Georgia, in 1732; and formed, himself, the plan for bringing up the children in the Foundling Hospital, in 1739."

Nor was the pen of this active philosopher idle, amid his other occupations. To particularize even the titles of his papers, printed by the Royal Society, amounting to 35, would lead us too far. However curious and useful the contents of most of the rest may be, the last in the list, on Inoculation, vol. 49. 516, is pre-eminently important, as recording the introduction of that practice into England, and displaying the candour, as well as good sense, of the writer, in every thing relative to the subject.

It remains for us only to mention the establishment of the British Museum, for which the nation is entirely obliged to sir Hans Sloane. He bequeathed it to the public, on condition of a payment, to his heirs, of 20,000 pounds; a sum said barely to equal the intrinsic value of the precious metals and gems, of the medals and mineral specimens. Besides the abundance of natural and artificial curiosities, his library, amounting to 50,000 volumes, of books and manuscripts, was included in the bequest. In collecting these books, he is reported to have sent his duplicates, either to the College of Physicians, or the Bodleian library. Parliament having accepted the legacy of Sloane, augmented it with the library of sir Robert Cotton, and the valuable manuscripts of the lord treasurer HARLEY; see that article. The whole, with various additions, has been deposited in the vast and massy palace of Montagu House, where it is now, in the most easy manner, and free of expence, accessible to the public. Two of the founder's descendants are always hereditary trustees of these treasures, associated by the original act of parliament, or by particular election, with a limited number of the most eminent men in the kingdom. For the present state of this noble repository, and its more particular history, see MUSEUM, *Britisb*. Sloane's Works. Pulteney's Sketches of Botany. Aikin's Gen. Biog. S.

SLOANEA, in *Botany*, so named by Plumier, in honour of his celebrated predecessor in the botanical investigation of the West Indies, Sir HANS SLOANE. (See that article.)—Linn. Gen. 265. Schreb. 353. Willd. Sp. Pl. v. 2. 1155. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 296. Swartz Obf. 212. Juss. 291. Lamarck Illustr. t. 469. (Sloana; Plum. Gen. 48. t. 15.)—Class and order, *Polyandria Monogynia*. Nat. Ord. *Amentaceae*? Linn. *Tiliaceae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five, or more, acute, rather unequal, segments. *Cor.* none. *Stam.* Filaments very numerous, above 100, short, inserted into the downy, fleshy receptacle; anthers oblong, of two cells, attached lengthwise to the filaments. *Pist.* Germen superior, roundish, angular; style simple, awl-shaped, longer than the stamens; stigma nearly simple. *Peric.* Capsule large, roundish, prickly, of from three to six valves, and as many cells, bursting at the top, the partitions from the middle of each valve. *Seeds* two or three in each cell, oblong, obtuse, involved in a pulpy tunic.

Ess. Ch. Corolla none. Calyx of one leaf, inferior, in five or more segments. Anthers attached longitudinally to the filaments. Capsule prickly, of from three to six valves, and as many cells. Seeds two, with a pulpy tunic.

Obf. Linnæus seems to have been led by the very erroneous opinion of Miller, (who referred this genus to *Castanea* or *Fagus*;) to consider it as probably of his amentaceous order. Jussieu has far more correctly ranged it with his own genuine *Tiliaceae*, near *Sparrmannia*. Three species are now known; five South American, or West Indian, trees, of which Linnæus was acquainted with the first only. His *S. emarginata*, Sp. Pl. 731, taken up from Catesby's work, without the inspection of any specimen, is, as Willdenow remarks, no other than *Achras Sapota*. Concerning the rest, great confusion, originating with Aublet, is perpetuated by no less authority than that of Swartz, followed by Willdenow and Aiton. Jussieu also errs in supposing the Linnaean *Sloanea* to be *Aubletia*, or *Apiciba*. Such may indeed be the plant of the *Hortus Cliffortianus*, but that of *Sp. Pl.* is certainly Plumier's. We shall attempt a corrected view of the species and their synonyms, from authentic specimens.

1. *S. dentata*. Chestnut-leaved Sloanea. Linn. Sp. Pl. 730. Ait. n. 1. (S. Massoni; Swartz Ind. Occ. 938. Willd. n. 2. Sloana amplis caltanæ foliis, fructu echinato; Plum. Ic. 240. t. 244. f. 1.)—Leaves toothed; heart-shaped at the base. Stipulas linear, serrated. Calyx deeply divided.—Native of South America and the West Indies. Our specimens were gathered by Masson in the island of St. Kitt's. Miller is said to have cultivated this plant in the stove at Chelsea, but it has not been known to blossom in Europe. In its native country this is a lofty tree, with round leafy branches, finely downy when young. Leaves alternate, stalked, a foot or more in length, and half as broad, smooth, with one rib and many strong transverse veins, rather coriaceous; more or less heart-shaped at the base; the margin distantly and rather slightly toothed. Footstalks downy, two or three inches long. Stipulas near an inch in length, narrow, deeply toothed, almost pinnatifid, situated in pairs at the base of each footstalk. Clusters axillary, towards the ends of the branches, compound, many-flowered, drooping, not half so long as the leaves. Flowers green, about three-quarters of an inch wide, conspicuous for their numerous tufted stamens. Anthers, as well as germen, hairy. Capsule woody, above an inch in diameter, clothed with very long, rigid bristles, spreading in all directions.

2. *S. grandiflora*. Large-flowered Sloanea. (*S. dentata*; Swartz Obf. 213. Willd. n. 1, excluding the synonyms, except the following. *S. Plumierii*; Aubl. Guian. v. 1. 536.)—Leaves toothed; tapering at the base. Stipulas triangular-heart-shaped, serrated. Calyx with shallow segments.—Gathered in the forests of Guiana by Aublet, whose specimen is before us. He found it bearing flowers and fruit in November. The trunk is forty or fifty feet high, and two in diameter. Leaves pointed at each end. Stipulas very broad at the base, and more slightly serrated or toothed. Flowers almost twice as large as those of the preceding; the calyx remarkably and essentially different, having a broad, hemispherical, cup-like base, and very wide shallow segments in the border; whereas the *dentata* has a calyx divided nearly to the base, into lanceolate, or somewhat ovate, taper-pointed lobes. Capsule of from three to five cells. Seeds one, two, or three in each cell, enclosed in a red succulent tunic. The specific character and description given by professor Swartz, cannot be mistaken; but it is remarkable that he should not have detected Aublet's misapplication of Plumier's synonym. This error is indeed the more pardonable in Aublet, as he was acquainted with but one of these two species, and took it, of course, for what Plumier had figured.

3. *S. Aubletii*. Small-flowered Sloanea. Swartz Ind. Occ. 940. (*S. sinemariensis*; Aubl. Guian. v. 1. 534. t. 212. Willd. n. 3.)—Leaves roundish, abrupt, entire. Calyx in five deep ovate segments.—Gathered by Aublet in the forests of Guiana about the river Sinemari, 30 leagues above its mouth, bearing flowers and fruit in November. Swartz says it was found by Masson in St. Kitt's. The trunk is described as forty or fifty feet high, with a reddish, cracked, and wrinkled bark. Branches slender, finely downy when young. Leaves in Aublet's specimen near a foot long, on stalks about one-third that length, coriaceous, smooth, strongly veined. He describes the stipulas as being long, broad, and pointed. These we have not seen, any more than the flowers, which grow in short, simple, axillary clusters, and are much smaller than either of the preceding. The style in Aublet's plate, as well as his own French description, is represented divided into four or five deep slender segments. The capsule is oblong, an inch in length, with four or five cells and as many angles, clothed with long, slender, ascending filaments or bristles. We should gladly have given the name of *parviflora* to this species, but we have taken the least exceptionable of those that already exist. The *Galibis* call this tree *Oulouqua-Palou*, but nothing is recorded of their applying it to any use.

SLOATH, or **SLOTH**, in *Zoology*, the name of an animal remarkable for its slow motion. Of this animal there are two species. See **BRADYPUS**.

The *three-toed* sloth has a blunt black nose, a little lengthened; very small external ears; small, black, and heavy eyes, with a dusky line from the corner of each; the colour of the face and throat a dirty white; hair on the limbs and body long, and very uneven, of a cinereous brown colour, with a black line along the middle of the back; each side, about the shoulders, is dashed with rust colour; the rest of the back and limbs spotted irregularly with black; the tail short; legs thick, long, and awkwardly placed; the face naked; and three very long claws on each foot. Pennant.

This creature, which grows to the bulk of a middle-sized fox, is so very tedious in all its motions, that it will be three or four days in climbing up, and coming down a tree, and does not go the length of fifty paces upon even ground in a day. It never kills till compelled by hunger: its food is fruit, or the leaves of trees. Its motion is attended with a

very moving and plaintive cry, so that beasts of prey avoid it with horror.

The sound of its voice seems only to express the word *hau*, for which reason the Brazilians call him by that name; but he usually repeats the sound about six times together, descending, as if one should sing *la, fol, fa, mi, re, ut*.

Its look is so piteous as to move compassion, and accompanied with tears. Whatever he takes hold of, he does it so strongly, or rather so stiffly, that he will sometimes sleep securely while he hangs at it.

Clusius, Marcgrave, Piso, and others, have given descriptions of this animal, but they none of them mention the length of his fore-feet; which, according to the animal preserved in the Museum of the Royal Society of London, is double that of the hinder pair.

From the shag of his body, the shape of his legs, and his having little or no tail, as also from the slowness of his gait, and his climbing up trees as little bears use to do, he seems to come near the bear-kind, from which he differs chiefly in having but three claws upon a foot.

This creature breeds principally in Florida and Brasil. Grew's Mus. p. 11.

The *two-toed* sloth has a round head; short projecting nose; ears like the human; two long strong claws on the fore-feet, and three on the hinder; long and rough hair on the body, in some parts curled and woolly; in some, of a pale red above, and cinereous below; in others, of a yellowish-white below, cinereous-brown above; it has no tail. This animal inhabits South America, and the island of Ceylon. Pennant.

SLOATS of a Cart, the under pieces which keep the bottom of the cart together.

SLOB-FURROWING, in *Agriculture*, a particular method of ploughing land.

SLOBNA, in *Geography*, a town of the duchy of Warsaw; 25 miles S. of Kalish.

SLOBNICK, a town of the duchy of Warsaw; 24 miles N.N.W. of Posen.

SLOBODSKAIA, a fortress of Russia, in the government of Ekaterinoflav; 64 miles N.E. of Ekaterinoflav.

SLOBODSKOI, a town of Russia, in the government of Viatka; 20 miles N.N.E. of Viatka. N. lat. 58° 40'. E. long. 50° 44'.

SLOD'TZ, RENÈ MICHAEL, in *Biography*, surnamed Michael Angelo, a sculptor, was born at Paris in 1705. He studied under his father, who was a native of Antwerp, after which he went to Rome, and upon his return was admitted a member of the Academy of Paris, where he died in 1764. One of his most considerable works is the monument of Languet, in the church of St. Sulpice.

SLOE, *Prunus Sylvestris*, the English name for the wild plum. See PRUNUS.

The juice expressed from the fruit of the sloe-bush while unripe, inspissated by a gentle heat to dryness, is called German acacia. It differs from the Egyptian molt remarkably in this property, that it gives out its astringency in good measure to rectified spirit as well as to water, whereas that of the other is not at all dissoluble in spirit.

A conserve of this fruit has been prepared in the shops, by mixing the pulp, pressed out through a sieve after the sloes have been steeped in water over the fire, till they are sufficiently soft without bursting, with thrice its weight of double refined sugar.

In some places, the unripe sloes are dried in an oven, and then fermented with wines or malt liquors, for a restraining diet drink in alvine and uterine laxities. The bark, both of the branches and roots, is said to be successfully given in

intermitting fevers, and it has been recommended by some as equal to the Peruvian bark. It is apparently a strong styptic. The watery infusion of the flowers, sweetened with sugar, or made into a syrup, is said to be a very useful purgative for children. Lewis's Mat. Med.

SLOE-Worm, in *Natural History*, the name of an insect found on the leaves of the sloe, or black-thorn, and sometimes on those of the garden plum.

This, and a like worm, found on the leaves of the oak, both remarkable for the hairs which cover them, each of which is forked, or divided into two at the ends, are usually esteemed caterpillars, but they are in reality animals of a very different class: the caterpillar has, at the utmost, but sixteen legs; these have twenty-two, and have all the other characters of that class of insects called by the French naturalists *fausses chenilles*, or bastard caterpillars.

All the animals of that class are very remarkable for the different figure they make after the last change of their skins; but this is in none seen so obviously, as in these two species: that of the oak is of a greenish colour, and its hairs, which are so stiff that they almost deserve the name of spines, are black; that of the sloe is of a greyish hue, and its spines longer, and of a deep brown: every one of these is, towards the extremity, divided into two, in the manner of the tines of a fork. These give the animal a very remarkable figure, and are cast off with the several skins, while the new skins have others in their place; but in the last change, before that into the nymph state, the change made in the creature is such, that it could never be suspected to be the same animal by any one, who was not an eye-witness of the change.

The creature in this, throwing off its skin, becomes perfectly smooth, and of a dirty yellowish colour, with not the slightest variegation on it, nor the least appearance even of the remains of the spines. In this state it remains till it goes into the nymph state; and from that, after about sixteen days, it comes out in the shape of a four-winged fly. The whole process of the change is the same, in the two species of the oak and the sloe; but the flies they produce are very different. Reaumur's Hist. Inf. vol. ix. p. 119. See PRUNUS, in *Gardening*.

SLOKUM'S ISLAND, in *Geography*, a small island in Barnstable bay, near the coast of Massachusetts.

SLOMIGRODEK, a town of Austrian Poland, in Galicia; 20 miles W. of Lemberg.

SLONEK, a town of the duchy of Warsaw, on the Vistula; 15 miles N.W. of Ploczk.

SLONIM, a town of Lithuania, in the palatinate of Novogrodek; 32 miles S.S.W. of Novogrodek.

SLONITZ, a town of Bohemia, in the circle of Schlan; 4 miles S. of Seblan.

SLOOP, in *Sea-Language*, a small vessel furnished with one mast, the main-sail of which is attached to a gaff above, to the mast on its foremost edge, and to a long boom below; by which it is occasionally shifted to either quarter.

Sloops, smacks, barges, and lighters, that pass through bridges, have the mast confined in a trunk or wooden cup, above the deck, and fastened in by an iron strap on the aft-side. Some have a strong iron hinge at the heel of the mast, or a bolt through the heel; so that it can be lowered at pleasure, by the stay-tackle easing away the fall by degrees. To raise the mast, the fall is brought to the windlafs, and hove upon, until the mast is up in its place: the fall is then stopped to the windlafs bits.

Dutch sloops are small vessels, used upon the canals in Holland, with one mast, on which are hoisted a sprit-sail and a fore-sail, set close to the stem. There are many fishing-

fishing-boats in Holland, rigged in the same way, with the addition of a bow-sprit and jib, and they are there called "pinks." Their sails are generally tanned.

SLOOP of War, is a name given to the smallest vessels of war, except cutters. They are rigged either as ships or snows. See **RATE** and **SHIP**.

SLOOTEN, or **SLOTEN**, in *Geography*, a town of Holland, in the department of Friesland, capital of Westergoe, near a large lake called Slooter-Meer. Its fortifications, constructed by the confederates, and afterwards destroyed by the Spaniards, have been enlarged by the states of the province, and defended by five bastions. The magistracy is composed of four burgo-masters and three senators; 10 miles E. of Bolswaert. N. lat. $52^{\circ} 55'$. E. long. $5^{\circ} 35'$.

SLOP, STREET, in *Agriculture*, that sort of moist sloppy substance, which is raked, swept, and shovelled up from the streets of large towns, for use as manure. It is a kind of material which is much made use of in this way, in the vicinity of the metropolis, in the neighbourhood of Manchester, and of several other places, where it is collected in large quantities. Near the first of these places the barge-men on the river are said, in the agricultural report of the county, to convey to and deliver the slop of the streets at any distance which is capable of being reached in one tide, at the price of about four guineas for seventeen or eighteen cart-loads, each load consisting of nearly two tons weight. This is called *cold* manure, in contradistinction to that of the stable littery sort, which is denominated *hot* manure, and delivered at the expence of one guinea more.

Slop of this kind is also sent from the different wharfs, by the barges, on the river Lea canal, which carry about thirty tons, or fifteen cart-loads; and delivered, as far as the towns and villages at about thirteen miles distance, for four pounds.

At Manchester, the value of this sort of manure, from almost nothing, has increased to a very considerable sum, in the course of the last twenty-five years.

Most other large towns might afford vast supplies of manure of this nature, and be of great advantage to agriculture; while, at the same time, they would derive an increased revenue from it. At present much neglect takes place in this respect, in many places. See **MANURE**.

SLOPAN, in *Geography*, a town of Poland, in Volhynia; 52 miles N.E. of Lucko.

SLOPE-HOLES, in *Canals*, are holes or marks made in the points E and L (*Plate I. Canals, figs. 14 and 15.*), to direct the navigators, or workmen, where to begin to cut or dig the sides of a canal.

SLOPES, are such parts of the ground as have been dug or left sloping, as GI and KP (*Plate I. Canals, figs. 3 and 6.*) Some also denominate the sides of the canal, as CB and HI, (*figs. 14. and 15.*) the slopes.

SLOPING ALLEY. See **ALLEY**.

SLOPING Banks, in *Rural Economy*, the shelving borders of rivers and sea-shores, which are highly useful and necessary for securing and protecting them against strong floods and tides. The more slow and gradual such slopes are made, the more beneficial they will be in giving safety to such banks. See **RIVER-Banks**, **Securing of**, and **EMBANKMENT**.

SLOP-ROOM, in *Ship-Building*, an apartment on the orlop, appointed for the purser to keep the ship's slops in.

SLOT, in *Agriculture*, a term used to signify any broad, flat, wooden bar.

SLOT, in the *Sportsman's Language*, a term used to express the mark of the foot of a stag, or other creature proper for the chase, in the clay or earth, by which they

are able to guess how long the creature has been gone by, and which way he went. The slot, or treading of the stag, is very nicely studied on this occasion. If the slot be large, deep printed in the ground, and with an open cleft, and, added to these marks, there is a large space between mark and mark, it is certain that the stag is an old one. If there be observed the slots, or treadings of two, the one long, and the other round, and both of one size, the long slot is always that of the larger beast.

There is also another way of knowing the old ones from the young ones by the treading; which is, that the hinder feet of the old ones never reach to their fore-feet, whereas those of the young ones do.

Old stags also are long-jointed, and they never tread double or falsely, as the young ones do, because the tendons, that hold the joints of their feet, are stronger; but the feet of the young ones are sometimes forced, for want of these strong sinews, to turn away double.

It is to be observed also, that there is a great difference between the slot of a stag or hart, and that of a hind; for there is no hart of the second head so young, but that he leaves a larger and wider slot than the hind, excepting when the hinds are big with young, for on that occasion their claws will open as wide as those of the hart.

Another method of knowing the age of a stag is by his fumets, though some general rules are to be known, before any thing can be judged from this article. These are, that in April and May they cast their fumets as it were in cakes; and in June and July they cast them in thin, long, and large crotels; and from thence to the end of August they hold the same form and size; but they are in this last month always hard and knotty. In all these cases, the largest and longest fumets are esteemed to be the marks of the largest and oldest stags. If they have been disturbed, or if they have received any hurt, they usually cast them sharp at one end, and dry. This also is constantly the case, when their new horns are just grown to their hardness, and they rub them against the trees to get off the cracked membranes, which were the velvetings in their first state.

There is always also a difference between the fumets of the morning and those of the evening: those made at night, when they go to relief, are better digested, and consequently moister than those made in the morning; because having taken their rest all day, there is a more perfect digestion made than can be in the night, as they are, during that time, seeking food.

There are also several other ways of judging of the growth and size of a stag, as by his carriage, or bearings, according to the huntsman's phrase; that is, according to the breaking of the tender branches of trees which he makes with his horns in passing through. When the boughs are found bruised and broken very high, and to a good width, there is no doubt of his being an old one; but this judgment is not to be made in the months of March, April, May, and June, because their horns are at that time either wholly wanting, or they are young and velvety. The height of the creature's entries into the woods is also another mark of his size; for the old ones are always proud and stately, and go in erect, but the young ones will creep.

The older the stag is, the sooner he goes to fray, and the larger are the trees he chooses for this use; the young ones go later into it, and always choose the weaker and lower trees. Notwithstanding that, after the sixth year, the age is not certainly known by the horns, as there is, after this time, no increase in the number of their branches; yet a probable guess may be made from their being all thicker and more robust, and the tops more open.

SLOT, *Drawing on the*. See DRAWING.

SLOTH, in *Zoology*. See SLOATH.

SLOUGEA, in *Geography*, a town of Tunis, on the north side of the Mejerdah; 12 miles N.E. of Tuberkfoke.

SLOUGH, a hamlet in the parishes of Upton and Stoke Poges, and hundred of Stoke, county of Buckingham, England, is 21 miles W. from London, and 1 mile N. of Eton. This place is feated on the great western road, and has long been the residence of Dr. Herschel, the celebrated astronomer, who manufactured here some of the largest reflected telescopes ever known. One of these, forty feet in length, still remains in the garden attached to his house; and by the use of this very powerful instrument, the doctor has made several important discoveries in the planetary system. A particular account of this telescope, with eighteen engravings, is published in the *Philosophical Transactions for 1795*. *Beauties of England*, vol. i. by J. Britton and E. W. Brayley, 1801. *Lyfons's Magna Britannia*, vol. i. 4to.

SLOUGH, a deep rut or hole in a road or carriage-way. The cast skin of a snake, the damp of a coal-pit, and the scar of a wound, are also called by the same appellation.

SLOUGH of a wild Boar, is the bed, soil, or mire, in which he wallows, or in which he lies in the day-time.

SLOUGH-Silver, in *Old Writers*, a rent paid in some places in lieu of certain days work in harvest, heretofore reserved to the lord from his tenants.

SLOUTH, or SLOUGHT, in *Hunting*, is used for a company of some sorts of wild beasts: as, a slouth of bears.

SLOW FEVERS. See FEVER.

SLOW Pulse. See PULSE.

SLOW-Worm, the English name of the *cacilia*, or *anguis fragilis* of Linnæus, called also the *blind-worm*, and by some the *deaf adder*, which, in the Linnæan system, is a species of the *anguis* or snake; the *cacilia* being a distinct genus of serpents. See SERPENTES.

It is distinguished from all our snakes by its smallness, and by the shape of its tail, which runs out a great way beyond the anus, and yet is blunt and considerably thick at the end.

The colour of the back is cinerous, marked with small lines composed of minute black specks; the sides are of a reddish cast; the belly dusky; both marked like the back; the tongue is broad and forky; the teeth small, but numerous, and the scales small. It is slow in its motion, and inoffensive in its nature.

These snakes lie torpid in the winter, and are sometimes found in vast numbers twined together.

It resembles the viper in its manner of producing its young, which are brought forth alive.

Dale, from Gesner, gives an account of theriaca being prepared of this serpent and treacle water, for a sudorific in the plague. James.

SLUCH, or SLUTCH, in *Agriculture*, a term often applied to signify a soft liquid muddy sort of material, found in different situations where water stagnates.

SLUCHAU, or TSHLUCHOW, in *Geography*, a town of Prussian Pomerelia; 44 miles S.S.W. of Dantzic.

SLUCK, or SLUCKZ, a town of Lithuania, in the palatinate of Novogrodek, in which are three Greek churches, one for Roman Catholics, one for Lutherans, and one for Calvinists; 68 miles E.S.E. of Novogrodek. N. lat. 52° 50'. E. long. 27° 33'.

SLUDGE, in *Agriculture*. See SLUSS.

SLUDKA, in *Geography*, a town of Russia, in the government of Perm; 8 miles S. of Obvinsk.

SLUDS, a term used by the miners in Cornwall for half-roasted ores.

SLUE, *To*, is to turn any cylindrical or conical piece of timber about its axis, without removing it. This term, in sea-language, is generally applied to the movement by which a mast or boom is turned about, in its cap or boom-iron.

SLUG. See LIMAX.

SLUG, in *Agriculture and Gardening*, a destructive animal of the snail kind, which is highly mischievous in the field, as well as the garden, by eating off the young stems of tender plants. There are several different kinds of these little animals. The white and brown leathery kind often even destroy the strong stems of young cabbage, and other similar plants. The destruction of them has been suggested to be effected by the use of tar-water, sprinkled over the ground; and also by having recourse to lime, in the preparation of the land for such crops. They conceal themselves in the holes and crevices, only making their appearance early in mornings and late in the evenings. The white slug or snail is likewise very destructive to young turnip crops, by riling out of the holes of the soils, on wet and dewy mornings and evenings. Rolling the ground with a heavy implement, before the sun rises, has been advised as a means of destroying them in these cases.

Slugs of this sort are likewise very destructive, in some districts, to the roots of corn crops, during the day-time, in the early spring months, while they lie concealed in the ground, by eating and devouring them; and by coming out in the evenings, and during the night-time, to commit ravages on the blades, and other parts above the ground. Numbers of them are sometimes met with upon the same plant, and they may easily be extirpated and removed from the land by the above practice, while they are at work, especially in moon-light seasons, and any further injury to the crops be guarded against. Warm moist weather is always a great encouragement to their coming out of their hiding-places; and advantage should constantly be taken of it for their extermination, as they suddenly retire under ground during the time of cold.

The strong lands of other places are occasionally much infested with them in the pea, bean, and rye crops and stubbles, as well as clover roots, when a wheat crop is put in upon them. The slugs, in some cases, are of about half an inch in length, having their backs of a blueish cast in the skin part, and their under parts wholly of a white appearance.

A mixture of sulphur and lime, made so as to be conveniently applied, has been found to be highly destructive of slugs in general.

The use of lime-water has lately been advised as an excellent and cheap mode of destroying slugs in gardens, as well as fields, in the second volume of the *Transactions of the Horticultural Society of London*. It is found to be far preferable, in this intention, to quick-lime, which is liable to become too soon saturated with moisture, and rendered ineffectual. The manner of employing the water is after it has been newly made from stone lime, by means of hot water poured upon it, to pour it through the fine rose of a watering-pot over the slugs, which have been collected by means of pea-haulm, or some other similar substance, laid down on the ground in portions, at the distance of about a pole from each other. In proper weather, the slugs soon collect in this way, in great numbers, for shelter as well as to get food. When a boy takes up the substance, and by a gentle shake leaves the whole of the slugs on the ground, another person then pours a small quantity

of lime-water on them, and the boy removes the haulmy material to some intermediate place, in order that the same practice may be repeated. By persevering in this method for a little while, the whole of the slugs may be destroyed, as the least drop of the water speedily kills them. This practice, it is supposed, will be found highly beneficial in the flower-garden, as by watering the edgings of box, thrift, or other kinds, the slugs will be killed with certainty, even when the weather is moist.

The application is considered simple, the effect certain, and the expence trifling, whether in the garden or the field; a few pots only being required, in the latter case, to the acre, which can be made with a very small quantity of lime. And the labour is not of any material consequence, so that the whole charge will not, it is imagined, exceed five shillings the acre.

SLUICE, a frame of timber, stone, or other matter, serving to retain and raise the water of a river, &c. and, on occasion, to let it pass.

Such is the sluice of a mill, which stops and collects the water of a rivulet, &c. to let it fall, at length, in the greater plenty, upon the mill-wheel: such also are those used as vents or drains to discharge water off land. And such are the sluices of Flanders, &c. which serve to prevent the waters of the sea overflowing the lower lands, except when there is occasion to drown them.

Sometimes there is a kind of canal inclosed between two gates or sluices, in artificial navigations, to save the water, and render the passage of boats equally easy and safe, upwards and downwards: as in the sluices of Briare in France, which are a kind of massive walls built parallel to each other, at the distance of twenty or twenty-four feet, closed with strong gates at each end, between which is a kind of canal, or chamber, considerably longer than broad; in which a vessel being inclosed, the water is let out at the first gate, by which the vessel is raised fifteen or sixteen feet, and passed out of this canal into another much higher. By such means a boat is conveyed out of the Loire into the Seine, though the ground between them rise above one hundred and fifty feet higher than either of those rivers.

The sluice of a canal has generally a sliding-board or door, but sometimes folding or double doors moving on hinges, used to stop or let go water at pleasure.

Sluice-gates sometimes signify the lower gates of a lock, from the paddles or sluices that are usually fixed in them.

Sluices are made different ways, according to the use for which they are intended: when they serve for navigation, they are shut with two gates, presenting an angle towards the stream; when they are made near the sea, two pair of gates are made, the one to keep the water out, and the other in, as occasion requires. In this case, the gates towards the sea present an angle that way, and the others the contrary way; and the space inclosed by those gates is called the *chamber*. When sluices are made in the ditches of a fortress, to keep up the water in some parts, instead of gates, shutters are made so as to slide up and down in grooves; and when they are made to raise an inundation, they are then shut by means of square timbers let down in cullises, so as to lie close and firm.

The word sluice is formed of the French *escluse*, which Menage derives from the Latin *exclusa*, found in the Salic law in the same sense. But this is to be restrained to the sluices of mills, &c.; for as to those serving to raise vessels, they were wholly unknown to the ancients.

In *Rural Economy*, a sluice is very convenient in many cases. It ought to be strongly framed in deep waters, particularly where a great height is necessary, so as to stand

firm and immovable against the rushing of heavy bodies; for a small strain makes it leaky, and a small thing will occasion this, unless sufficiently guarded by proper abutments. Larch, green elm, or willow, are the best sorts of timber to be always in water; but heart of oak, for the purpose of standing above it, in wet and dry. The importance of sluices is extremely evident on many occasions, as when a pressing necessity demands the discharge of a great quantity of water, either the expensive mode of engines must be recurred to, the bank cut, or a sluice drawn. If the bank be cut, the passage is interrupted, and there remain the trouble and charge of removing the earth, and re-embanking; but a sluice vents the superfluous water, without the least inconvenience or charge. Their utility in many cases of drainage and embankment, as well as irrigation, is also very great and indispensable.

SLUIDENAIJA KORT, in *Geography*, a town of Russia, in the government of Irkutsk. N. lat. 52° 42'. E. long. 113° 44'.

SLUIN, a town and fortress of Croatia, on the Korrana; 34 miles S. of Carlstadt. N. lat. 45° 15'. E. long. 16° 8'.

SLUIS. See **SLUYS**.

SLUM, a town of Prussia, in Pomerelia; 8 miles S. of Marienburg.

SLUPCA, a town of the duchy of Warsaw; 15 miles S.S.E. of Gnesna.

SLUPE CZ, a town of Poland, in the palatinate of Sandomirz; 16 miles N. of Sandomirz.

SLUPICK, a town of Holland; 3 miles N.E. of Goude.

SLUR, in *Music*, a mark like the arc of a circle, drawn from one note to another, comprehending two or more notes in the same or different degrees. If the notes are in different degrees, it signifies that they are all to be sung to one syllable; for wind instruments, that they are to be made in one continued breath; and for stringed instruments, that are struck with a bow, as a violin, &c. that they are made with one stroke. If the notes are in the same degree, it signifies that it is all one note, to be made as long as the whole notes so connected; and this happens most frequently betwixt the last note of one line, and the first of the next; which is particularly called *syncopation*.

SLUSE, **RENÈ FRANCIS**, in *Biography*, an eminent mathematician, was born of a noble family at Vise, a small town in the bishopric of Liege, in 1622. He was educated for the church, and was canon of St. Lambert in that city, was appointed abbot of Amaz, and grand chancellor and counsellor to the bishop and prince; all which offices he retained with high reputation till his death in 1685, in the 63d year of his age. He was a man of great learning, not only in the particular line of his profession, but in jurisprudence, and even in medicine. He was eminently skilled in the Greek, Hebrew, Arabic, and other Oriental languages; and on that account was employed by the pope, during his residence at Rome, and after his return to Liege, in translating Greek, Armenian, and other writings. He was an excellent mathematician, and furnished some papers for the Transactions of the Royal Society, of which he was elected a member. As an author his principal work is entitled "Mefolabium et Problemata Solida," 4to. In this work M. Sluse rendered great service to the mathematical sciences, by simplifying some parts of the analysis of Des Cartes, which had engaged the attention of many eminent geometers. He is author of a method, by which any solid equation being proposed, it may be constructed in an infinite variety of ways, by means of the circle

circle and any one of the conic sections. He first gave a specimen of this method in the above work, but concealed the analysis till he published the second edition of it in 1688. An account of it is given by Montucla, in his "History of the Mathematics." This author remarks, that Sluse's Geometrical Miscellanies, which appeared in this second edition, do honour to the author, and afford a proof of the great progress he had made in analysis. Besides the work here referred to, he wrote two letters on the superiority of the Latin to the French language, which were translated from the Latin to the French, and published with the letters of M. Le Laboureur, in which a contrary opinion is maintained, under the title of "Avantages de la Langue Françoise sur la Langue Latin." Sluse's Papers in the Philosophical Transactions are, 1. "A short and easy Method of drawing Tangents to all Geometrical Curves," vol. vii. 2. "A Demonstration of the fame," vol. viii. 3. "On the Optic Angle of Alhazen."

SLUSS, or SLUDGE, in *Agriculture*, a word applied to mud or mire. It is sometimes written *slush*.

SLUTCH. See SLUCH.

SLUTER, MATTHEW, in *Biography*, a patrician of Hamburg, was born in that city in 1648. He studied jurisprudence at Jena and Altdorf, and made a tour through Germany and Holland. In 1673 he took the degree of doctor at Rostock. He practised the law in the chancery court of Güttrau, and afterwards visited France, and other places, from which he returned in 1679. He continued his professional labours in his native place, where, in 1701, he became syndic, and in two years afterwards a member of the council. He died in 1719, in the 72d year of his age. Besides various works on jurisprudence, he was author of one entitled "Sciagraphia Bibliothecæ Patrum maximæ," which was added to the "Propylæum Historiæ Christianæ" of his brother Severus Walter. Sluter was a curious observer of the weather, and wrote an illustration of a treatise on Meteorology, published at London in 1690, by William Cock of Edinburgh. In this tract the author endeavours to establish a connection between the changes of the weather and the heavenly bodies; and the object of Sluter in his illustration and commentary was to prove the truth of his theory from experience. The German edition of Cock's Meteorology was published at Hamburg in 1691. Our author likewise published tracts, entitled "Causes of the severe Winter and continual Storms in the Years 1694 and 1695;" and "Indications of the Aspects from the Years 1696 to 1703."

SLUYS, or L'ECLUSE, in *Geography*, a town of France, and principal place of a district, in the department of the Escaut. The place contains 1415, and the canton 4479 inhabitants, on a territory of 92½ kilometres, in 6 communes. This was formerly one of the best ports on the coast of Flanders, and capable of conveniently receiving 500 vessels; but it has been so much deteriorated, that it can now accommodate only small vessels. Its ancient name was "Lammens Vliet." It belonged to the comtes of Nevers, but was obtained in exchange for Bethune of William, comte of Namur, by Philip the Hardy, duke of Burgundy, who surrounded it with walls in 1385. In 1495 Philip de Cleves, lord of Ravenstein, revolted against Philip le Beau, and retired to Sluys, which was besieged by Albert, duke of Saxe, and after four months it surrendered. The city having taken part with the Hollander, was besieged by the prince of Parma in 1587, and the English garrison was compelled to surrender, but upon honourable terms. Until the year 1604 it remained in the possession of Spain; but being besieged by prince Maurice of Nassau, it

was obliged to surrender after a defence of four months. The town is furnished with sluices, by which the whole country may be inundated; and hence it derives its name. After several changes of masters, the garrison was summoned by the French republicans in July 1794; and on the 25th of August, after a gallant defence, became prisoners of war; 18 miles N.E. of Oltend. N. lat. 51° 20'. E. long. 8° 14'.

SLYBZE. See SLEBEZE.

SLYME-HEAD, a cape on the west coast of Ireland, in that part of the county of Galway, called Ballinablincl. N. lat. 53° 24', according to Beaufort, but 53° 29', according to Arrowsmith's late map. W. long. 10° 12'.

SLYPE, a town of France, in the department of the Lys; 5 miles N.N.W. of Menin.

SLYRET, a town of Norway, in the province of Aggerhuus; 80 miles N. of Christiania.

SMACK, is a small vessel only rigged as a sloop, or hoy, and used in the coasting or fishing trade; or as a tender in the king's service. See SLOOP.

SMÅLAND, or SMOLAND, in *Geography*, a province of Sweden, about 100 miles long and 60 broad, formerly governed by its own kings; and, for a considerable time, included in East Gothland, and subject to the same laws. It is said to have derived its name Smaland, *i. e.* small parcels of land, from the circumstance of its having been overspread with woods and wastes, which restricted the culture to a few intervening spots. Smaland is mountainous; nevertheless some parts are so improved by cultivation as to be very fertile, and its pastures in particular are excellent, and of course profitable to the graziers. This province comprehends large forests of beech and other trees; and also silver, copper, and iron mines, a great quantity of iron-ore being found at the bottom of the lakes. A vein of gold-ore has likewise been discovered in Smaland. The chief employment of the inhabitants is agriculture, mining, and grazing. The articles of trade are also planks, beams, masts, tar, pot-ash, iron, grain, cattle, butter, cheese, flesh, bacon, tallow, hops, and fish. In this province are 21 lakes, and its chief towns are Calmar, Wexio, and Jonkioping.

SMALBROKE, RICHARD, in *Biography*, an English prelate, was fellow of Magdalen college, Oxford; and in 1723 he was advanced to the bishopric of St. David's, from whence he was translated, in 1730, to Lichfield and Coventry. He died in 1749. He was distinguished by a vindication of the miracles of Christ against Woolston.

SMALCIUS, VALENTINE, a celebrated writer in favour of Unitarianism, was born in Thuringia, and died at Cracow, in Poland, in 1622. His principal work was "A Treatise on the Divinity of Christ," written in the Latin language, and printed in 1608.

SMALKALDEN, in *Geography*, a river of Germany, which runs into the Werra, 12 miles W. of Smalkalden.

SMALKALDEN, or *Schalkalden*, a large, thriving, and populous town of Germany, in the county of Henneberg, on a river of the same name. In its vicinity are salt-pits, and mines of iron and steel. The Protestant princes have had several meetings in this town, preparatory to the league which was concluded here in 1531, and to their confirmation of the theological articles drawn up by Luther, which have given this town considerable celebrity in ecclesiastical history; 27 miles N.N.E. of Schweinfurt. N. lat. 50° 47'. E. long. 10° 40'.

SMALL of an Anchor, is that part of the shank, next under the square, or anchor.

SMALL-Craft, in *Sea-Language*. See CRAFT.

SMALL Fruits, in *Gardening*, a term applied to those which

which are produced by different plants of a low shrubby growth, as those of the gooseberry, currant, and raspberry kinds, when grown alone, and in a separate state. See *STANDARD Fruit-Trees*.

SMALL Key, in *Geography*, a small island in the East Indian sea. N. lat. $10^{\circ} 37'$. W. long. $247^{\circ} 16'$.

SMALL Oat, in *Agriculture*, a name applied to a particular kind of black grain of this sort, in some places. It is hardy, and capable of being grown with success on poor land of the chalky and other kinds. Other names are also given to it; and there is a sort of oat termed the small short, or small shorts, in the farmer's language. See *OAT*.

SMALL Point, in *Geography*, a cape on the coast of Maine, forming the east point of Casco bay.

SMALL Repeat. See *REPEAT*.

SMALL Sallad Herbs, or *Sallading*, in *Gardening*, are such young tender herbs as are made use of through the year, for the purpose of furnishing sallads. For this use, several young seedling herbs of a warm nature are in request to mix with the larger principal sallad herbs, as lettuces, endive, and celery, in order to improve their flavours and wholesome qualities. The sorts mostly in use are cress, mustard, radish, rape, and turnep; also sometimes cabbage-lettuce for winter and early spring use; all of which, for this use, are in perfection when quite young, that is, while not more than a week, or ten or twelve days old, whilst they remain mostly in the seed-leaf, being then cut up close to the ground for use; for, being mostly of a warm relish, in which consists their chief excellence for winter and spring sallads, if suffered to grow large, and run into the rough leaf, they become of a disagreeable, strong, hot taste; but when used as above, they are exceedingly crisp and tender, with an agreeable warm flavour. For the purpose of sallading, these plants may be obtained young at all times of the year, in the spring and summer in the open ground, and in winter under the shelter of frames and glasses, and occasionally on hot-beds. This sort of sallading is procured by sowing the seeds of the different plants at different times, throughout the whole year.

Winter and Spring Culture.—In the winter and spring it may be raised either in hot-beds, or in the open borders, and, according as it may be required, early or late; but when it is required as early as possible, it must be sown in hot-beds, under frames and lights, &c. or in a bed or border of natural earth under glasses. The sowing should be made on hot-beds any time in December, January, or February; and where a considerable supply is daily required, it may be continued sowing every week or fortnight, in hot-beds, till March, or during the cold weather, for which a moderate hot-bed of dung should be made for one, two, or more garden-frames; but only half a yard or two feet depth of dung, according to the temperature of the season, as the heat is only required to bring up the plants quickly, and forward them a week or two in growth, placing a frame directly thereon, and moulding the bed all over with light rich earth, five or six inches thick, making the surface level and smooth: when, if it is to be forwarded as much as possible, directly sow the seed, which may be done either in drills as shallow as possible, about two or three inches broad, and flat at the bottom, and three inches asunder, sowing the seeds of each sort separately, and very thick, so as almost to cover the ground, only just covering them with earth; or, to make the most of the bed, it may be sown all over the surface, previously smoothing it lightly with the back of the spade, the different sorts separately, and all very thick; and after pressing them all even and

lightly down with the spade, covering them very thinly with earth, by sifting over as much light mould as will only just cover the seed; and as soon as the sowing is performed in either method, putting on the lights. The seeds soon come up, as in two or three days, or less, being careful at this time to give vent to the steam arising in the bed, as well as to indulge the plants with plenty of free air daily, either by tilting the lights in the back or front, according to the temperature of the weather, or by drawing the lights a little down, or taking them quite off occasionally in mild days at first; for the hot-bed being yet new, there will be a considerable steam arising; and the sallading coming up very thick, unless due vent be given to pass off the steam, and admit fresh air, the plants will be apt either to burn or fog, (as the gardeners term it,) and mould off as fast as they come up. Such hot-beds, however, as are not fresh made, do not require this precaution; but in new-made beds it must be strictly observed, till the sallading is all fairly come up, and as long as the strong steam continues. The plants will mostly be fit for use in a week, or ten or twelve days, from the time of sowing the seed.

But in order to have a proper succession, the sowing in the hot-beds should be repeated every week or fortnight during the cold weather; the same hot-bed sometimes retaining its heat, will admit of two sowings, by sowing again as soon as the first crop is gathered: however, to obtain a regular supply daily, it is necessary to continue making fresh hot-beds occasionally. Where only a small quantity may be wanted at a time, and there is the convenience either of cucumber and melon hot-beds, or a hot-house, &c. some seed of each sort may be sown in pots or boxes, and placed in these hot-beds, or the stove, just to bring up the plants fit for use. And where there are not frames and glasses, hand or bell-glasses may be used, or the bed be arched over with low hoop-arches, in order to cover it with mats every night, and in bad weather.

Where, however, there are no hot-beds, in cold weather, early in the spring, part of a warm border, or a bed of light earth in a sunny situation, may be prepared for garden-frames and lights, hand-glasses, &c. raising the ground somewhat to the sun; and having dug it, and raked it fine, sow the seed as above, covering it lightly with earth; and having set on the frames and glasses, the seeds will soon come up, and the sallading be ready a considerable time sooner than in the open ground.

Culture in the full Ground.—From about the end of February, or beginning of March, according to the forwardness or mildness of the season, small sallading may be sown in the open ground, repeating the sowings every week or ten days; the first sowing being performed on a warm border; continuing the sowings in that situation till the beginning or middle of April, when it may be sown in any of the open quarters, and in which the sowings may be repeated weekly, or once a fortnight, as required; but according as the hot weather approaches, sowing in a somewhat shady situation. The ground for each sowing in the different situations should be properly dug, and the surface raked smooth and even.

These sowings are mostly made in shallow drills, which should be drawn with a small hoe, either with the corner, or held edgewise downward, horizontally, drawing the drills along evenly, as shallow as possible, and flat or level at bottom, at three or four inches asunder, in which the seeds should be put evenly all along the bottom, each sort separately, and very thick, covering them in evenly with the finest of the mould, not more than a quarter of an inch deep; or if the smaller seeds are but just covered, it is sufficient;

for when sown very thick, if deeply covered with mould, the plants do not rise regularly. In these early spring sowings, on cold nights, and in all bad weather, it is proper to cover the ground, both before and after the plants begin to rise, with large mats; which will be better, if supported on low hoop-arches, or ranges of pegs stuck in the ground just high enough to support the mats a little from the earth, by which a more effectual as well as forward crop is produced.

But in the latter sowings, when dry warm weather commences, it is proper to give occasional waterings. It is likewise sometimes necessary, where the surface of the ground becomes crusted from wet, &c. as the plants rise thick, to slightly brush over the surface with the hand or a soft broom, so as to reduce the surface mould a little, and promote their coming up.

Summer Sowings.—When the sowings are practised in summer, they should be made more frequently, and the ground be kept watered occasionally, both before and after the plants are come up.

Autumn Sowings.—The sowings may be continued in the open ground all September and October, also occasionally in November, in mild seasons; and until towards the middle of October, they may be made in any open situations; but from the middle or latter end of October, and in November, they must be on warm south borders, performing the sowings as above; and in cold nights, bestowing a covering of mats or hand-glasses, &c. repeating the sowings every week or ten days, or a fortnight, as required.

In gathering young fallading, it should be cut carefully close to the ground, while quite young; in performing which, a large pair of scissors is very convenient.

In order to have good seed, some plants should be preserved annually for the purpose.

SMALL Stones, among *Jewellers*, denote diamonds under the weight of a carat.

SMALL-Work, is used to denote the star and shell-facets of diamonds.

SMALLAGE, in *Botany*, a species of *apium*; which fee.

Smallage grows naturally by the sides of ditches, in many parts of England, and is therefore rarely cultivated in gardens: it is biennial, and flowers in August. Care should be taken to distinguish smallage from the poisonous water-hemlock, which grows naturally in the same places with it; the latter has its leaves deeply divided, quite to the pedicle, into three long narrow sharp-pointed segments; whereas those of smallage are only slightly cut into three roundish obtuse ones.

The root is that part which was formerly used in medicine: it is about the thickness of a thumb, whitish, fibrous, of a warm taste, and a fragrant smell; and was reckoned one of the five greater openers of the shops. It was reputed to be grateful and detergent, to promote urine, and to dislodge gravel; and it was also recommended in disorders of the breast, and for promoting expectoration.

The fresh roots, especially when produced in their native watery places, are supposed to participate, in some degree, of the ill quality of those of the hemlock kind, and to be particularly hurtful to epileptic persons and pregnant women.

Its seed was also of the number of the lesser hot seeds, and was thought to possess greater virtues as a carminative and aperient than the root; its leaves having been given in decoction, or the expressed juice of them in nephritic complaints. The root was greatly recommended against suppressions of the menses, and of the lochia, and was even

said to be alone a remedy for the king's evil; but this wants proof.

Smallage is now wholly exploded from the *materia medica*.

SMALL-POX, in *Medicine*, the *Variola* of authors, a highly contagious and formidable eruptive fever, which occurs in general but once during the life of any individual, and is distinguished by the appearance of pustules on the skin, on the third or fourth day of the fever.

As we have already entered into a brief detail of the little that is known respecting the origin and early propagation of small-pox, (see *INOCULATION*;) it may be sufficient to mention in this place, that it is generally believed that this contagious malady existed in China and Hindoostan, perhaps for some centuries previous to its appearance in Europe; but that there are no very authentic records of its travelling to the west, until the period of the siege of Mecca by the Abyssinians, in the year 572, when it destroyed the invading army. Alexandria being at that time the great mart of Indian commerce, was soon infected with the contagion, and the first description of the disease was given by Ahron, a physician of that city, in the beginning of the following century. From that time it accompanied the Arabs or Saracens in their progressive expeditions, and Europe was contaminated by their invasions of Spain, Sicily, Italy, and France in the eighth century. Previous to this period, it is generally believed that this destructive pestilence was unknown in Europe. This is principally inferred from the silence of all the ancient physicians, Greeks and Romans, who have left us accurate descriptions of many of the diseases, with which we are now familiar, but who have not described the striking and peculiar symptoms which characterize this severe and often fatal malady. Some authors, however, and not without a show of probability, have maintained that such an inference is not strictly deducible from this circumstance. For the ancients were apt to confound every species of fatal fever under the term *pestilence*, and were misled, by their hypothetical doctrines about the four humours, to make no distinctions from a view of the symptoms. Some of the ancient plagues, and particularly that of Athens, described by Thucydides, were manifestly not *the plague* properly so called, but were connected with extensive sores and eruptions on the skin. (See *PLAGUE*.) It has been urged, too, that in a fragment of the works of one Herodotus of Rome, preserved by Aëtius, there is a description of various fevers, accompanied by eruptions, in which the small-pox appears to be distinctly included. It is remarkable, too, that the first Arabian physicians, even Ahron of Alexandria, do not mention the disease as a new malady, but speak of it as one familiarly known; and Rhazes refers to Galen, as having mentioned many of its symptoms. The evidence in support of this opinion is certainly very imperfect, and scarcely sufficient to build a controversy upon; nor is it of any farther importance than as an object of curious inquiry.

All that relates to the history and practice of *inoculation* (which, indeed, should now be superseded by vaccination) has been also detailed in the article already referred to. At present, therefore, our object is to give only the medical history of small-pox, as it occurs in the casual, or, as it is often called, the natural way; describing, first, its symptoms, with the prognostics, and various tendencies of the disease, and afterwards the best methods of treatment.

The term *variola*, which is of modern origin, is supposed to be derived from *vari*, which are small inflamed tumours of the face, occurring about the period of puberty, and noticed first by Celsus under that appellation. The words *pock*, *pocks*, and *pox*, from the Anglo-Saxon *pocca*, signifying a pouch

SMALL-POX.

pouch or pocket, and applicable to any pustule or pustular disease, were appropriated early to this formidable malady; and the epithet *small* was subsequently added to distinguish it from a still more recent disease, the *lues venerea*, to which the same appellation was applied.

Several varieties of the small-pox have been noticed by different writers, but they may be all included under the two principal forms, which were so ably pointed out by Sydenham, and which since his time have been commonly recognized under the appellations of the *distinct* and the *confluent* small-pox. Although originating from the same contagion, and not differing from each other essentially, they exhibit a different series of symptoms, pursue a somewhat different course, and require a different mode of treatment, and therefore it is convenient to treat of them separately.

1. *Of the Distinct Small-Pox:—Variolæ Discretæ.*—In this form of the disease, the eruptive fever is moderate, and not easily distinguished from an ordinary attack of common inflammatory fever. It generally begins about mid-day, with a chilliness and shivering, accompanied by a considerable languor and drowsiness, which are soon followed by a great heat, pains in the head and back, sickness at the stomach, with a foreness or pressure in that part, and in adults, especially if they are kept in bed, with a great disposition to perspiration. In children the sweating does not occur; but they are liable to frequent startings from their slumbers, and on the third day are sometimes affected with one or two fits of convulsion. Sydenham considered this symptom as rather favourable; having observed that it was commonly succeeded by an eruption of a large and mild small-pox. On the evening of the third, or the morning of the fourth day, the eruption appears, and gradually increases during the fourth and fifth days, arising first on the face, and successively on the inferior parts, so as to be completed over the whole body on the last-mentioned day. With the appearance of the eruption, the febrile symptoms abate, and nearly or altogether cease on the following day, with the completion of the eruption. This appears first in small red spots, scarcely eminent, but which, by degrees, rise into minute pimples, which are separate and distinct from each other, and generally not very numerous. The day after their appearance, a small vesicle, containing a clear or slightly whey-coloured fluid, shews itself on each of the spots. For two days these vesicles increase in breadth only, and there is a small depression in their centre. As they extend, they continue to be surrounded with an exactly circular inflamed margin, which, when the pustules are numerous, covers the greater part of the intervening skin, and diffuses somewhat of a damask hue over the spaces between the pustules. Under the touch they are hard, and rather painful, and give the impression of small round seeds under the cuticle to the finger; a circumstance which tends to distinguish them from the vesicles of chicken-pox, which feel like small seeds flattened by pressure.

About the *eighth* day, the eruption is elevated into spheroidal pustules; and if these are numerous, the increase of their size and the fullness of the surrounding parts occasion a considerable swelling of the whole face, and especially of the eyelids, which are so distended as entirely to close the eyes, and often shine like an inflated bladder. Sometimes, where numerous pustules fix upon the eye-lids, the blindness comes on before the eighth day. The eruption now assumes a whiter appearance; for, as the disease proceeds, the matter in the pustules becomes by degrees more opaque, and at length, as the suppuration increases, of a yellowish colour. A similar progress is observed in the hands, but a little later; so that when the face is becoming rough and yellow, the extremities are becoming smoother and whiter. On the *eleventh* day the swelling of

the face is much abated, and the inflammation diminished; the pustules are now at their height, and seem quite full. On the top of each a darker spot appears; and at this place the pustule, on the eleventh day or soon after, is spontaneously broken, and a portion of the matter oozes out; in consequence of which the pustule is shrivelled and subsides, while the matter oozing out dries, and forms a crust upon its surface. Sometimes very little of the matter oozes out, but remains in the pustule, becoming thick, and even forming a hard little scab. After some days, generally about the fourteenth or fifteenth, both the crusts and the hardened pustules fall off, leaving the skin on the points which they covered of a brown red colour; and it is only after many days that these red marks are effaced. The distinct small-pox seldom leaves any pits in the skin; but in some cases, where the matter of the pustules has been more liquid, the crusts formed by it are later in falling off, and the points which they covered undergo some degree of ulceration, which partially destroys the substance of the skin, and produces a small excavation or pit. Sydenham and Cullen ascribe this erroneously to the desquamation which ensues.

As the eruption is successive, so the maturation on the body and extremities follows the same course as above described, but a little later. On the tenth and eleventh days, as the swelling of the face subsides, a swelling arises in the hands and feet, which again subsides, as the pustules come to maturity. In the pustules of the hands and arms, indeed, the matter is frequently absorbed; so that at the height of the disease, these pustules appear as empty vesicles.

When the pustules on the face are numerous, some degree of feverishness appears on the tenth and eleventh days, but it ceases again after the pustules are fully matured, or continues only in a very slight degree till the last pustules on the feet have finished their course. In the distinct small-pox this secondary fever is never considerable, and seldom continues longer than the period just mentioned. Under the same circumstances, an abundant crop of pustules on the face, some uneasiness in the throat, and a hoarseness of voice, occur about the sixth or seventh day, and a thin fluid is poured out from the mouth. These symptoms increase with the swelling of the face; and the discharges from the mouth and throat becoming thicker and more viscid, are more difficultly ejected. Some difficulty of swallowing also occurs; so that liquids taken in to be swallowed are frequently rejected, or thrown out by the nose. But all these affections of the fauces abate as the swelling of the face subsides.

Some varieties of the distinct small-pox have been described by different authors under specific appellations, such as the *contiguous*, the *coherent*, the *warty*, &c. small-pox (see Walker's Inquiry into the Small-pox, chap. viii. and Roe's Treatise on the Natural Small-pox, chap. i.); but these are merely more violent degrees of the disease, partaking more or less of the character of the confluent species, and requiring to be treated accordingly.

2. *Of the Confluent Small-pox.*—This form of the small-pox follows a similar course with the preceding species, but the symptoms of every stage are more violent, and several of the circumstances are also different. The eruptive fever especially is much more violent; the pulse is more frequent, sharp, and contracted; the head-ache, and the pain and anxiety at the præcordia, the sickness and vomiting, are more severe; the coma is more considerable, and there is frequently a delirium. In adults there is less disposition to perspiration than in the other species, and sometimes a diarrhœa occurs; and in children epileptic fits are frequent on the first days of the disease, and sometimes prove fatal before any eruption appears.

SMALL-POX.

appears, or they usher in a very confluent and malignant small-pox.

The eruption appears more early than in the benign small-pox; commonly early on the third day, or on the evening of the second, and scarcely ever so late as the fourth day; except, as Sydenham remarks, in a few rare cases, where it appears to be delayed by some violent symptom, such as an acute pleuritic or rheumatic pain, or a violent pain in the stomach, with sickness and vomiting, which manifestly indicate the confluent and dangerous nature of the forthcoming disease. The eruption too is often preceded by an extensive erythematous efflorescence, like a commencing erysipelas; and sometimes it comes out in little irregular clusters, like the measles, consisting of many crowded red points or pimples. The pimples are always most numerous on the face, and at the same time smaller and less eminent. The little vesicles which form on the tops of the pimples, appear sooner than in the distinct species, and while their diameters extend, they do not retain a circular form, but are of very irregular figures. Many of them run into one another, forming a flat irregular surface, so that the face very often appears to be covered rather with one extended vesicle, than with a number of pustules. And when there is any distinct separation of the pustules, they do not rise to a spheroidal form, but remain flat, and their circumference is not bounded by an inflamed margin, the part of the skin that is free from pustules being commonly pale and flaccid, and not exhibiting the damask hue of the distinct small-pox. The fluid included within the pustules changes about the eighth day from a clear to an opaque appearance, being first whitish and now brownish, but never acquires the yellow colour and thick consistence that appear in the mild species.

In the confluent small-pox, the swelling of the face, which is sometimes absent from the distinct species, but is generally present when the pustules are numerous, never fails to appear, and it comes on more early, and arises to a greater degree, sometimes annihilating every appearance of the features. It abates, however, on the tenth day, and on the eleventh still more. At this time the pustules or vesicles, or rather the extended pellicle, which from the eighth day had become rough and brown, is ruptured; and, shrivelling, pours out a fluid, which concretes into brown or black crusts, which do not fall off for many days, even till after the twentieth day; and, in consequence of the ulceration which takes place under them, pretty certainly leave the surface of the face considerably pitted. On the other parts of the body, and on the extremities, especially the hands and feet, still more than on the trunk, the pustules of confluent small-pox are larger and more distinct than upon the face; but they never acquire the same maturity and consistence of pus as in the properly distinct kind.

The confluent small-pox is attended by two other symptoms of considerable importance, the one in adults, the other in children. The former is salivation, or excessive secretion of saliva, which never fails to accompany the confluent form of the disease in grown persons, and is sometimes seen in a slight degree in the distinct kind. It sometimes begins as soon as the eruptions appear; and sometimes not till a day or two after. The saliva is for some time thin and copious, and easily discharged, having very much the appearance of the ptyalism excited by mercury, except that it does not smell so offensively; but about the eleventh day it becomes thick and more viscid, and is expectorated with great difficulty. The patient is very thirsty, and coughs while he attempts to drink, expelling the liquor through his nostrils. The affection of the throat is also generally aggravated at the same time. The salivation often ceases after the eleventh

day, about which time the hands commonly swell (or at least, Sydenham says, ought to do so); but sometimes, after a complete cessation for a day or two, it returns again.

In children, a diarrhoea occurs frequently in the place of the salivation; but it does not seize them so early as the salivation attacks grown persons. Whenever it begins, however, unless it be checked by art, it attends the disease to its termination.

In the distinct small-pox, as we have already stated, the fever commonly ceases with the completion of the eruption on the fifth day; but it is not so in the confluent species. In the latter, the febrile symptoms only suffer a remission at the time of the eruption, which continues to the period of complete maturation, that is, to the eleventh day, in the latter part of which day it is often renewed with considerable violence, constituting what has been called the *secondary fever*, which is the source of much danger, and is of various duration. The pulse quickens, the heat of the body increases greatly, much thirst, with great anxiety and restlessness, severe head-ache, short and confused slumbers, delirium, and sometimes coma, ensue. These symptoms, indeed, are often so sudden and violent, being accompanied also with suppression of the salivation, and a difficulty of breathing and of deglutition, that, if nothing has been done to alleviate the early inflammatory action, death soon follows. Whence Sydenham speaks so often about the danger of the eleventh day. In other cases, however, this fever is protracted to the fourteenth and seventeenth days, and sometimes even later, and yet terminates fatally. In some instances, these severe forms of confluent small-pox are accompanied by symptoms of great malignancy or putrescency, as it has been called: purple spots, or *petechiæ*, appear in the interstices of the skin between the pustules; and sometimes small black spots, scarcely so large as pins' heads, arise on the top of the eruptions in different places; or a disposition to gangrene under ferous vesicles shews itself; or lastly, various spontaneous hæmorrhages take place from the internal parts, as from the kidneys and bladder, whence bloody urine is discharged; or from the lungs, in bloody expectoration; and sometimes from the intestines, in bloody stools.

From a consideration of the preceding detail of the various circumstances which accompany the different forms and stages of the small-pox, the degree of danger under the various symptoms, and the probable event in particular cases, may be estimated. The following points of prognosis will be obviously inferred. In general, the more exactly the disease retains the form of the distinct kind, it is the safer; and the more it approaches or takes the form of the confluent kind, it is the more dangerous. It is only, indeed, when the distinct kind exhibits a great number of pustules in the face, which are contiguous or coherent, that it is attended with any danger: for it must be observed, that it is chiefly from the crowd of pustules on the face, and not from those on the body, that the danger of the disease is to be apprehended. Particular symptoms will enable us to anticipate particular occurrences. Thus, if the previous or eruptive fever be very violent in its attack, and be accompanied with great prostration of strength, anxiety, and lowness of spirits, with severe head-ache, weeping and redness of the eyes, great pains in the back, a burning heat of skin, and a quick hard pulse;—the occurrence of a confluent eruption may be expected. The more early the eruption, the more danger is to be anticipated; but a retardation of the eruption beyond the fourth day, also implies a probability of a confluent disease. The more gradual the eruption of the pustules, the more favourable; provided

SMALL-POX.

vided the time of their rising be not protracted beyond the usual limits by diarrhœa, pain, or depressing passions. The more distinctly suppuration takes place about the eighth day, and the more rosy the interstices around the pustules, the less danger is to be apprehended. A sudden cessation of the swelling of the face about the eleventh day, and the non-appearance of that swelling about the eighth day, when the pustules are very numerous, are indicative of great danger; as are also a sudden suppression of the salivation in adults, and of the diarrhœa in children, at the former period; especially if the hands and feet have not exhibited any swelling about that time. If, in the distinct small-pox, convulsions occur in children after the eruption is come out, or after incrustation has taken place, death commonly ensues; or, if the patient survives, a paralysis of some of the limbs often remains. The discharge of pale and clear urine, with frequent urging to pass it, in any period of the disease, denotes great danger.

On the other hand, regular gentle sweats, and a free discharge of urine, which deposits a sediment, are favourable symptoms in every species of small-pox. If, in the turn of the confluent small-pox, the pustules, which were before pale and flat, should acquire a redness or damask-rose colour round their bases, and suppuration come on, the patient generally recovers.

When the small-pox attacks women in a state of pregnancy, it is attended with considerable danger, and commonly produces miscarriage or premature labour. It has been a question among pathologists, whether the connection between the child in the womb and the mother was such as to admit of the infection of the former with the small-pox under these circumstances. Whatever hypothetical differences might exist upon this topic, experience has proved that such infection often takes place in the fœtus *in utero*, though not invariably. It would appear, too, that the child is not affected at the same moment with the mother, but soon afterwards by subsequent infection. For, in a case related by Dr. Laird, a woman in the fifth month of her pregnancy passed through a severe small-pox, which commenced about the end of August: she felt the motion of the child till the month of October, on the 28th of which month she was delivered of a child, which was thought to be of six months' growth, and which had been dead some days. "On the back, shoulders, and side, and particularly about the upper part of the thighs, where the integuments were perfectly sound, there were several pustular elevations, with central depressions, strikingly characteristic of the appearances which distinguish small-pox. The fœtus was placed in the museum of Guy's Hospital, and still distinctly exhibits the characters of the eruption." See *Edinburgh Med. and Surg. Journal*, for April, 1807.

A still more extraordinary circumstance, in respect to the infection of the child in the womb, occasionally occurs; namely, the production of small-pox in the child, in consequence of the mother's exposure to the contagion, although the latter may have been prevented from suffering the disease herself, by having previously undergone that disease, or the cow-pox, and therefore escapes the influence of the infection. Dr. Jenner relates the following case, which came under his observation, in the instance of a lady in London. "A few days previous to her confinement, she met a very disgusting object, whose face was covered with the small-pox. The smell and appearance of the poor creature affected her much at the time; and though she mentioned the circumstance on her return home, she had no idea that her infant could suffer from it, having had the small-pox herself when a child. During a few days after its birth the

little one seemed quite well; but on the fifth day it became indisposed, and on the seventh the small-pox appeared. The pustules, which were few in number, matured completely. Dr. Croft, who attended her, being curious to know the effect of inoculation from one of the pustules, put some of the matter into the hands of a gentleman eminently versed in that practice, which produced the disease correctly. Mrs. W. was not sensible of any indisposition herself from this exposure, nor had she any appearance of the small-pox." Another case is mentioned by Dr. Jenner, in which the child *in utero* was infected with small-pox contagion, and born with the eruption upon it, five weeks after the mother had been vaccinated, and a month after she had been exposed to the contagion of small-pox from three of her children. Whence, as Dr. Jenner justly infers, it is obvious, "that the small-pox virus may affect the human frame, even to its inmost recesses, although apparently freed from its effects, and yet give no evidence of its presence by exciting any perceptible disorder." (See *Medico-Chirurgical Transactions*, vol. i. p. 272. Also, Van Swieten, *Comment. ad Aphor.* 1381; and Dr. Mead's *Discourse on Small-pox*, chap. iv.) Dr. Mead states the following analogous fact. "A certain woman, who had formerly had the small-pox, and was now near her reckoning, attended her husband in the distemper. She went her full time, and was delivered of a dead child. It may be needless to observe, that she did not catch it on this occasion; but the dead body of the infant was a horrid sight, being all over covered with the pustules; a manifest sign that it died of the disease before it came into the world."

Though the confluent small-pox should not be immediately fatal, yet the more violent kinds are often followed by a morbid state of the body, under which various disagreeable and dangerous complaints arise. Whether these consequences may be ascribed, with Dr. Cullen, sometimes to an acrid matter, generated by the preceding disease, and deposited in different parts, and sometimes to an inflammatory diathesis produced, and determined to particular organs of the body, is a theoretical inquiry, which we are not disposed to puzzle ourselves and our readers by pursuing. It is manifest, in general, that the constitution is often left in a state of great debility; does not thrive under the ordinary nutrition; and in many cases exhibits a great tendency to scrofulous inflammation, especially of the glandular system, to chronic derangements of the lungs, mesentery, and other viscera, and to various local affections of the skin, membranes, and bones. Another series of evils, which the confluent small-pox is liable to inflict, is the various degrees of injury and destruction which it occasions in the organs of sense, especially in the eyes and ears. Deafness of one or both ears, and the loss of sight in one or both eyes, is no uncommon result of this formidable malady. It appears indeed, from the records of the humane "Institution for the indigent Blind," that a very large proportion of all that claim its protection have been blinded by the small-pox.

Causes of Small-pox, and of its Varieties.—The only exciting cause of small-pox is the specific contagion, generated in the pustules of the disease itself. In what manner, or at what period of time, this great depopulator of the human race was generated, or what physical circumstances concurred to give it existence, history affords us no means of ascertaining. The absurd speculations of the Arabian physicians, respecting the origin of the disease from some contamination of the fœtus with the menstrual impurities of the mother, deserve no notice. The obvious origin of a disease, (so analogous to small-pox, as to supersede the influence of its contagion on man,) from a disease of the skin

SMALL-POX.

of the heels of a horse, of which the cow-pox has recently afforded an example, has led some speculators to the more probable conjecture, that the poison of small-pox may have been communicated to the human from some domesticated animal. The camel has been suggested: but it was forgotten, that, though Arabia was the country from which Europe probably received the contagion; yet that that country appears to have received it from the most eastern nations, by its early commerce, among whom it had previously existed from remote antiquity. (See Moore's interesting "History of the Small-pox," 1815.) At present we can only attend to the operation of this contagion, and investigate its qualities from the effects which it produces.

It is evident, that the contagion of small-pox is capable of being communicated, and of exciting the disease in others, both by the actual contact of the fluid of the pustules, and the dried crusts, and by diffusion in a state of solution in the atmospheric air. It may be also fixed and adherent to various substances, such as woollen, linen, cotton, and other materials of clothing, as well as to wood, and other articles of furniture; from which also it may exhale in a state of vapour. Whence a person may be infected, without actual contact either of the diseased, or of *fomites*, that is, of infected substances. We have already stated, however, at great length, under the article **CONTAGION**, (which see,) the proofs and experiments by which it is rendered manifest, that the influence of this, and probably of most other contagions, by diffusion in the atmosphere, is limited to a very small distance from the source of infection. We refer especially to the experiments of Dr. O'Ryan, of Montpellier, upon that subject, which are related in the article just referred to. See also Dr. Haygarth's Plan for the Extermination of Small-pox in Great Britain.

One property of the contagion of small-pox, which it possesses in common with the contagion of measles, scarlet fever, and chicken-pox, but which does not belong to the contagion of gaol-fever, or typhus, nor to that of the plague, nor to the chronic contagious maladies, syphilis, and scabies, is its power of affecting the constitution *but once during the life of the individual*. The occurrence of the disease, under the mildest or the most severe form, equally renders the body incapable of receiving the disease again. This is the general fact; but in regard to none of these eruptive fevers can it be affirmed, without many exceptions: and the small-pox presents many anomalies in this respect. The extreme rarity of a second attack of small-pox was noticed by the Arabian writers; and their admission of such a fact would scarcely be admitted as a proof of its occurrence, since they deemed the small-pox and measles to be but varieties of the same disease. They attempted to explain the occasional recurrence of the disease upon their absurd theory of its origin, supposing that the whole of the menstrual blood, which contaminates the child, is not thoroughly depurated and expelled by the first attack. Even Boerhaave seems to have believed, that the *distinct* small-pox did not invariably secure the individual from a subsequent attack of the *confluent* form; though the latter effectually prevented a recurrence. (See his *Praxis Medica*, § 1381.) This, however, is not consistent with fact: for some of the most formidable and even fatal attacks of *second* small-pox have occurred in persons previously much pitted and disfigured by the disease. It will not be necessary to enter, in this place, into a very minute detail of the cases of secondary small-pox: it will be sufficient to state the fact, and to refer to some of the authorities on the subject of recent date, since the distinctions between chicken-pox, and the

modifications of small-pox, have been fully established. The celebrated Dr. De Haen has related several very clear instances of second small-pox, which occurred in his own practice. One young man, a student of law, received the contagion twice within three years; the first attack left him pitted, and the second proved fatal. (See his *Ratio Medendi*, p. ix. ch. 7: also his *Epist. Apolog. Responf. ad B. L. Tralles*.) One of the most striking cases of this sort, is that of Mr. Langford, whose countenance was "remarkably pitted and leamed" by a former malignant small-pox, "so as to attract the notice of all who saw him:" yet at the age of fifty, he was attacked again with confluent small-pox, which proved fatal to him, and to another member of his family, five of whom received the infection from him. (See *Memoirs of the Medical Society of London*, vol. iv.) A case of distinct recurrence of small-pox is related by Dr. Laird, in the *Edinburgh Journal*, already referred to; another by Dr. Bateman, in the *Medico-Chirurgical Transactions*, vol. ii. p. 31; and Mr. Ring has collected a great number, to the amount of sixty or seventy, in his *Treatise on Cow-pox*, and in various numbers of the *London Medical and Physical Journal*, especially in volumes 12, 14, and 15. We may add, that the recurrence of measles, in several cases, has been lately authenticated, by the first medical authority now living, (we mean by Dr. Baillie, in a paper published in the third volume of the *Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge*. The scarlet fever appears to be also subject to the same anomalies occasionally. The exceptions, however, are rare in all these eruptive fevers, and the general rule will still hold good. Yet the considerations of these exceptions should remove our surprise, that the cow-pox should not invariably secure the constitution from a subsequent seizure by the small-pox; since its influence on the system is commonly less considerable, than that of the mildest distinct small-pox. We believe, however, that the small-pox, which, under the exceptions, has been occasionally seen to follow the cow-pox, has *always* been much mitigated by the prior operation of the vaccine *virus*, both in the violence and duration of the symptoms, and that it has never, in these cases, terminated fatally.

It appears, from the preceding history of the symptoms, that the safety and danger of the small-pox depends almost entirely upon the smaller or larger number of the pustules: it becomes very important, therefore, both with a view to the prevention and to the treatment of the disease, to investigate the origin of this difference in the eruption, and in the symptoms which accompany it.

From the difference in the appearance, consistence, colour, &c. of the matter produced, as well as in the number and form of the pustules, and from the various degrees of fever, and other symptoms, which accompany the different species of small-pox, it might be readily suspected, that the contagion itself was different. Experience, however, has completely refuted this supposition: for there are innumerable instances of the contagion, arising from a person affected with the mild and distinct small-pox, producing the confluent kind in others; and, on the other hand, it is extremely common to see the distinct kind produced by exposure to the contagion arising from a person affected with the worst confluent small-pox. The practice of inoculation has still farther demonstrated this fact. For the same matter was not unfrequently observed to produce in one person the distinct, and in another the confluent small-pox. And in order that no time should be unnecessarily lost, where persons have been in the most imminent danger from complete

SMALL-POX.

complete exposure to the contagion, inoculation has been immediately performed from a confluent subject; yet the subsequent disease has been distinct and mild. We remember to have heard Dr. Gregory, the able professor of the practice of physic at Edinburgh, assert, in his lectures, that he had once taken matter from the confluent small-pox of a dying child, with which he inoculated two of its brothers: they had both a very mild disease: one of them, however, had previously taken the casual infection, for he sickened in three days from the time of inoculation. Indeed we could state other facts, from the same authority, to prove that matter, taken from the pustules of the dead body, has produced even the mildest form of small-pox. It is manifest, therefore, notwithstanding the prejudices of mankind, that the nature of the original contagion has no influence in modifying the disease which it inflicts: and we must infer, that the various forms which the disease assumes, originate from some particular state of the constitution in the individuals whom it thus variously handles. And this condition of the constitution must be the result of external causes, such as the seasons, and state of the atmosphere; or of internal and personal causes, such as plethora, obesity, irritability, or the contrary, depending on original conformation, or upon indulgence, intemperance, affections of the mind, and so forth. It is not the contagion of small-pox alone, which is variously modified in this way by the existing condition of the constitution; almost all external agents are so modified. The scratch of a thorn will not be felt for an hour by one person; while in another it will inflame and form an abscess, even excite the absorptents, and produce a bubo and fever; or it may run on to gangrene, and occasion death. In like manner, if several people are exposed to cold, by falling into water, for instance, and remaining wet: the effects will be very different individually. Many will escape without inconvenience; some with a common coryza or sore-throat; another will be confined to bed for weeks with an universal rheumatism; another will be attacked with pleurisy, or a spitting of blood, or an inflammation in the bowels. It is precisely the same with the varieties of small-pox: they are not the result of a difference in the cause, but solely of a difference in the state of individual constitutions.

The effect of different seasons upon the human constitution does not admit of very satisfactory explanation. Sydenham and Boerhaave, both able observers of nature, remarked, that the regular and distinct small-pox usually appears about the vernal equinox, when it is epidemic, increasing through the summer, and attaining its height and severity in the autumn, and commonly disappearing with the approach of the winter's cold. They both also observed, that if it commences early, as in January or February, (and Boerhaave adds, more particularly if it has been absent from the place six years,) the following summer will be distinguished by an epidemic of a severe and fatal kind, sparing none who have not previously undergone the disease, and proving extensively destructive.

The internal peculiarities of constitution, which modify the operation of morbid causes in general, and of the contagion of small-pox in particular, are more obvious and intelligible. Various hypotheses about the fermentation excited in the blood, and the free exit or deposition in the skin of the contagious matter, thus multiplied by that process, have been formed to explain this point: and even Dr. Cullen has adopted this absurd humoral notion, and endeavours to point out the circumstances "which determine more or less of the variolous matter to *stick in the skin*, or to pass freely through it." (First Lines, § 598.) But
Vol. XXXIII.

these notions are inconsistent with facts. In the first place, there is no evidence that the contagion acts like leaven upon the blood, "and assimilates a great part of it to its own nature." (Cullen, loc. cit.) The blood, as far as its properties are cognizable by the senses, possesses no qualities which are not common to all inflammatory diseases. There does not appear, indeed, to be any thing analogous to fermentation in the process. The pus that is generated is the result of the inflammatory action of the vessels of the skin, and is generated in the skin only; it is not floating in the mass of circulating fluids, and detained in the skin, as by a sieve. Whatever, therefore, increases the inflammatory action, increases the number of pustules. Thus, parts of the body that are much heated, as by lying upon them, or keeping them in long and close contact, have a greater number of pustules than others; and parts that are covered with plasters, especially those of a stimulant kind, are always more thickly beset with pustules. If we extend this principle to the constitution generally, we shall find, that those persons who are by nature, their period of life, their mode of living, previous indisposition, the season of the year, or other causes of a more irritable and inflammatory habit, will be more liable to suffer severely from the influence of small-pox. An intelligent writer has stated, from his own observation, that persons of a swarthy complexion, of a dry rigid fibre, not much disposed to perspire, with brown or black hair, which is of a strong texture and in great quantity, are more liable to a severe small-pox than those of a fair complexion, with thin, weak, and light hair, and who are moderately fat, but perspire freely. He remarks, too, that "persons afflicted with the palsy, ague, dropsy, and rickets, have commonly a favourable small-pox; and those afflicted with the two former frequently recover from both." (Roe on the Small-Pox, p. 57.) But the natural irritability may be much augmented or diminished by various circumstances, and thus the danger from the attack of small-pox in like manner increased or lessened. Thus, to use the words of the same author, "if a person should live intemperately, use violent exercise, drink much spirituous liquors, or give any occasion whatsoever to inflammation, before the attack of the small-pox, the disease will prove more virulent, although the natural habit be good. On the contrary, if a person be of an indifferent habit, and an unpromising temperament, but live temperately, eat little animal food, and lead a sober and sedentary life, before the disease attacks him, he bids fair for a happy recovery." We may add, that, upon the same principle, the adult age, as more robust and more connected with full living, is more liable to suffer the disease severely than childhood.

It seems, therefore, satisfactorily proved, "that an inflammatory state of the whole system, and more particularly of the skin," is the cause of the multiplication of the pustules, as well as of the other circumstances, which belong to the confluent small-pox, such as the early eruption, the erythematous rash, the continuance of the fever, the effusion of a more ichorous matter, and from thence the peculiar form, hue, incrustation, &c. of the pustules. See Cullen, First Lines, § 600.

Different causes have been assigned for the superior mildness of the disease, when produced by inoculation, over that which occurs in the casual way. Some have supposed that this advantage arose from having the choice of the matter of infection in the former case; and others have imagined that it was owing to the small quantity of matter which was introduced by the lancet. But from what has been said above, it is manifest that the choice of the matter is of

SMALL-POX.

no importance; and we know not how small a quantity is received when infection is communicated in the casual way. But it is very obvious, that, by avoiding the causes of an inflammatory diathesis, by lessening this condition when it exists, by shunning the concurrence of other diseases with the small-pox, and by choosing the proper season and time of life, we gain many advantages; and probably these were the principal advantages which inoculation possessed.

Seat of the Small-pox.—It has been a subject of much dispute, though easily determined by observation, whether the pustules of the small-pox affect the viscera and other internal parts. The most respectable testimony in favour of their existence internally, is that of Wrisberg, in the New Gottingen Commentaries, vol. lxxvi: but some others have also maintained that they had seen the pustules, upon dissection, upon the internal organs. There is no doubt, however, that such observations have originated in mistake. For all the dissections made by recent and more accurate anatomists have demonstrated, that, beyond the extension of the cuticle, no variolous pustules ever arise. Cotunnus, an Italian professor of anatomy, dissected above forty persons, who died of small-pox, for the express purpose of ascertaining what parts or organs were involved with the pustules. These examinations were conducted with great attention and accuracy, and in the presence of a number of students: and the result was, that, though the mouth, tongue, palate, and top of the pharynx, were often full of pustules, and in some few cases the internal membrane of the trachea was inflamed, and exhibited some effusion; yet not the least vestige of pustules was found upon any of the internal parts, even in the œsophagus. “Etenim quod spectat interiores partes,—certè non viscus, non membrana, non glandula, non pars demum interior ulla fuit, quæ in tot exemplis apparuerit pustulata.” (Cotun. de Sedibus Variolarum, § xxxix.) The truth is, as we have already observed, the pustules are little *cutaneous* abscesses, the result of inflammation in the skin alone, and not depositories of contagious matter distilling from the blood.

Diagnosis.—It is not easy, in general, to distinguish the fever, which is about to usher in the small-pox, from common simple fever, or from some other febrile diseases; since its early symptoms are not materially different from these. It may be presumed to be variolous fever, when the small-pox is a prevailing epidemic, provided the individual has not undergone the disease; and especially if he may have been in circumstances which rendered the communication of infection probable, or if his exposure to it were well ascertained. On children, the occurrence of a convulsive fit, on the evening of the second, or on the third day, will lead to a suspicion that the small-pox is about to appear. In all cases, however, this doubt will commonly be cleared up by the fourth day, when the small-pox will have appeared.

It is not easy to confound the eruption of small-pox with any other febrile eruption, except the chicken-pox, which, indeed, has not been demonstrated as a distinct disease more than fifty or sixty years. It had been called *variola spuria*, *bastard* small-pox; and even Dr. Heberden, who has the merit of having given the first clear description of the chicken-pox, (see Medical Transactions of the College of Physicians, vol. i. p. 433.) still applied the term *variola* to it; calling it *variola pusilla*. See his Commentarii de Morbis, cap. 96.

The eruption of small-pox is slower and of longer duration than that of chicken-pox, the latter being commonly completed in three days, and being covered with slight brown scabs on the fifth day, at which time the small-pox is at

the height of suppuration. The inflammation round the chicken-pox is very small, and the contents of them do not seem to be owing to suppuration, as in small-pox, but rather to what is extravasated immediately under the cuticle by the ferous vesicles of the skin, as in a common blister; whence this fluid appears in a vesicle on the second day, and, upon the cuticle being broken, is presently succeeded by a slight scab. On the third and fourth days, the shrivelled or wrinkled state of the vesicles which remain entire, and the radiating furrows of others, the ruptured tops of which have been closed by a slight incrustation, fully characterise the chicken-pox, and distinguish its eruption from the firm and durable pustules of small-pox. Another circumstance is also to be added to the diagnosis of these two diseases. If the whole eruption of chicken-pox on the face, breast, and limbs, be inspected on the fifth or sixth day, every gradation of the progress of the vesicles will appear at the same time, which cannot take place in the slow and regulated progress of the small-pox. (See Willan on Vaccine Inoculation, p. 95.) We have already noticed the difference in the sensation excited by touching the early eruption of the two diseases with the point of the finger, pointed out by the last-named author.

Since the introduction of the practice of vaccination, which may be deemed one of the greatest benefits ever conferred upon mankind by any individual, the diagnosis between small-pox and chicken-pox has, however, been rendered a little more difficult. For in several cases in which the small-pox has occurred in persons who had undergone the cow-pox (and we have seen that even small-pox and measles are not always securities against themselves), a mitigated and modified small-pox has commonly ensued, of a vesicular character, or of a small horny appearance, which has not gone through the usual stages; but, instead of proceeding to full suppuration, has begun to subside and dry away on the sixth day from the commencement of the eruption. It requires considerable attention, therefore, to discriminate between this variety of mitigated small-pox and the chicken-pox; and decision cannot always be obtained without the experiment of inoculation with the matter of the pustules. The impression under the finger, the form, and regular progress of the small-pox, may be generally recognized, however, up to the sixth day, by careful observation.

Treatment of Small-pox.—Until the year 1798, when Dr. Jenner immortalized his name by the announcement of his great discovery of the properties of the cow-pox, no means of prevention could be suggested to any individual, by which he could avoid or protect himself from the small-pox. In all large towns, and especially since the introduction of the practice of inoculation, a constant collection of contagion subsisted, which operated upon every one who visited them, even for a short time, from their more insulated situations in the country, if they remained susceptible of the disease. A preventive, however, is now discovered, and every one may be rendered secure from the influence of this baneful contagion. (See Cow-pox.) At present, however, this valuable preventive is not yet universally adopted, and the small-pox has carried off in this metropolis, during the year which has just terminated (1815), no less than one hundred and twenty-nine persons. We have still, therefore, occasion to study the best mode of treating the disease, under the different forms which it assumes, when it occurs in the casual way.

From a view of the history of the disease, as above detailed, it appears very evident, that the danger and violence of the symptoms are nearly in proportion to the quantity of the eruption; which is again much connected with the degree

gree of fever that accompanies and precedes it. The first indication, therefore, is, to moderate the eruptive fever.

In the case of inoculated small-pox, this process may be commenced in the interval between the insertion of the matter and the beginning of the disorder, that is, several days previous to the origin of the fever; when, by a light and cooling diet, and by the use of laxative medicines, if the habit be full, the body may be brought into a less inflammatory state; and thus rendered less susceptible of violent inflammatory disease. But in the casual small-pox, we have commonly no warning of the malady, until the eruptive fever actually commences; nor, when it has already begun, can we be certain, from any peculiar symptoms, that it is any thing but an ordinary fever; unless it occurs in persons who, not having previously undergone the disease, have been notoriously exposed to the infection. It is fortunate, however, that our inability to distinguish the fever which is about to usher in the small-pox from common inflammatory fever, is of no moment; since the same remedies are the most appropriate in both cases. The older practitioners, indeed, misled by their humoral hypotheses, about a fermentation in the blood, a struggle of the constitution to rid itself of the scum and dregs that were separated, and a salutary effort to discharge them by the skin, which was supposed to be manifest in the pustules, unfortunately took an opposite view of the subject. They thought it necessary to assist and encourage the fever, and very dangerous to repress it; and therefore they excluded the cool air, kept the patient in a hot bed, and administered warm drinks and cordial medicines. The pernicious influence of this practice (which was extended to all febrile complaints) was first detected by the sagacity of our great countryman, Sydenham, in spite of the hypothetical doctrines, in which he had himself been educated; and his prophecy, that, after his death, his opinion and practice would prevail, has been amply verified. In fact it is now universally admitted, that the more the previous fever is moderated, the more all the ensuing symptoms will be mitigated. According to the degree of violence with which the fever commences, the activity of the measures for moderating it will be various. If the symptoms are not severe, the patient may be recommended not to keep his bed, but to remain, according to the advice of Sydenham, in a cool apartment, having the benefit of cool air; and at the same time to discard animal food, and adopt that of a cooling nature, vegetable decoctions, acidulous fruits, and diluent drinks, such as plain cold water, lemonade, whey, &c. All his drinks should be given cold; and the bowels should be freely opened by some cooling purgative, as by the neutral salts, with a little calomel. If these measures are adequate to keep down the fever, and if, at the same time, the eruption appears early, and in small numbers, the safety of the patient may be considered as ascertained; and no farther treatment, except a continuance of the antiphlogistic system, is necessary. The practice of continuing to give purgatives as the eruption declines, appears to be altogether unnecessary, and may in some cases be hurtful; and it seems to be continued rather in compliance with the exploded hypothesis of separating the contagious matter from the blood, than from any rational inference of experience.

Where the fever comes on, however, with great violence, manifesting early its character, by a quick, hard pulse, intense heat, and thirst, a flushed countenance, inflamed eyes, severe head-ache, a quick and oppressed respiration, with delirium, especially in adult persons, and in those of vigorous or plethoric habits, very active measures should be immediately adopted. In persons of the latter description, the

first object would be to let some blood, the quantity of which must be determined by a consideration of the patient's age, constitution, and habits of life, and of the violence of the symptoms. At the same time, although he cannot obey Sydenham's injunction of sitting up, the cooling plan must be adopted to the fullest extent in respect to his apartment, which should be freely ventilated by the admission of the external air, through open windows and doors, and to his bed, which should be a mattress, and as lightly covered as the season and his feelings will permit. If the skin is intensely hot and dry, much benefit will be obtained, in the most expeditious manner, by sponging the surface occasionally with cold water, or even by the use of the cold affusion. We have known several instances, in which this fever, not being suspected to be the variolous fever, was treated by the cold affusion, with the most decided alleviation of the fever, and of the subsequent eruption. The benefits of this practice in scarlet fever, even during the extension of the eruption over the whole skin, are now generally acknowledged by all physicians who have witnessed the salutary and rapid change which it produces, both in the feelings and in the malady of the patient; being, in fact, the most efficacious physical agent, as well as the most expeditious and grateful, that the whole art of medicine is possessed of; and the only expedient fully entitled to the commendation of the ancient empiric, that of curing "*citó, tutó, et jucundé.*" It is, in truth, but the perfection of the cooling system recommended by Sydenham; and when united with cool air, cool drinks, and light coverings, it affords the most certain means of controlling the inflammatory fever.

An active purgative will also contribute to relieve inflammatory action, and should be speedily administered, and repeated according to circumstances. Diaphoretics are also recommended, and if they are not of a stimulating kind, they may be given with advantage: but the most effectual mode of inducing perspiration is by reducing the dry and burning heat of the skin, by cool air and washing.

If, however, these salutary measures have been omitted, or have proved inadequate to prevent a numerous eruption, especially upon the face; if the pustules are not distinct; and particularly, if, on the fifth day, the fever does not suffer a considerable remission; the disease will still require a great deal of attention. It will still be necessary to avoid heat and a heating regimen, and to continue to admit the free access of cool air, although the more active applications of cold, by sponging or affusion with water, need not be continued. The beneficial influence of cool and fresh air, indeed, at all periods of the disease, is very manifest; and in order to impress this truth more strongly, it may not be improper to relate a case or two, from among many that have been recorded, to shew the extent of that influence, even in the later stages. Sir George Baker, in his "*Enquiry into the Merits of a Method for inoculating the Small-pox, &c.*" observes, "*The history recorded by Sydenham, of a young man at Bristol, who owed his recovery to his being laid out on a table, as if dead, is sufficiently known. To this history there is a great resemblance in a case which is mentioned by Dr. Kirkpatrick, as having happened in Carolina. Mr. Benjamin Marych had a violent natural confluent small-pox in the hot weather. His attendants thought him dead; upon which the flashes were immediately set open, and a fresh quantity of air, or possibly a wind, rushing in, produced a fresh respiration and motion in the person who was thought dead. When this was observed, they went to put them down again. The patient who saw it, and was speechless, but sensible of the alteration*

SMALL-POX.

and benefit, beckoned with his hand to prevent them; and by degrees entirely recovered." Another case of the same kind is related by a gentleman of great veracity and experience. "In the year 1736, a man who lived as servant with Mrs. Broderop, one of the daughters of archbishop Wake, in Great Ormond-street, had the confluent small-pox; and on the evening of the fifteenth or sixteenth day, his life was entirely despaired of. On the next morning, when I went rather to enquire after him than to visit him, the nurse's report was, that he had grown worse and worse till two or three o'clock in the morning, at which time he ceased to breathe, became insensible and motionless, and appeared to be absolutely dead. About five or six o'clock, the body was removed and placed on a large table, near an open window, with no covering except only a shirt. No sign of life appeared, but the body continued hotter than is common after death. This heat, however, the nurse attributed to the weather. In this state he had remained about an hour, when the nurse heard a sort of sigh, or faint breathing; and it was observed that he had moved his arm across his stomach. Being raised up with some difficulty, he took a spoonful of a cordial medicine, ordered for him on the preceding day; and as soon as he was able to speak, he said the cold air was very refreshing. Being carried back to the bed, he fell into a sweat, and slept three or four hours. About this time I saw him. His pulse was now equal and strong; his respiration better than it had been for several days before; and his senses perfect. The door and windows were left open, and in a few days the man was quite out of danger." (See sir G. Baker's Essay, above quoted; and Dr. Walker's work on Small-pox.) These facts require no comment. They demonstrate the beneficial influence of cool air at all periods of the disease. It is, however, particularly beneficial at the period of which we are now speaking, when a thick eruption is coming out, and the fever does not remit. At this time the exposure to cool air, with the other antiphlogistic measures, will often greatly lessen the indistinct crowd of pustules that is spreading over the face, and occasion a few regular ones to arise, the head will lose its confusion, and the breathing become less oppressed,

At this period of the disease, too, under the same circumstances, it may be necessary, in adult and plethoric subjects, to take away some blood. This, however, seldom requires to be repeated. But a cooling purgative should be administered and repeated, or aided by a frequent repetition of laxative glysters; and the free use of diluent drinks should be permitted.

Most writers from Sydenham downwards, and Boerhaave and Cullen among the rest, have recommended the administration of an *opiate*, every night, under this febrile condition, that continues after the eruption of confluent small-pox has appeared. Sydenham, however, only gave it to patients whose age exceeded fourteen years: but Boerhaave and Cullen specify the fifth day as the time for the commencement of opiates, and mention no exception. It does not appear, that modern experience has confirmed the views of these great physicians: indeed, when Sydenham speaks of using opium or bleeding to effect the same purpose, we are unable to conjecture what powers he ascribed to the former remedy. "Jam non aliis auxiliis (cum in propinquo mors sit) ægro subveniri posse autumo, quam vel *narcotica* affatim exhibendo, vel *sanguinem* liberaliter *extrahendo*," &c. (Obs. Medicæ, sect. iii. cap. 2.) Dr. Walker has justly animadverted on this practice, which, however it may alleviate restlessness and pain, in slight cases, unaccompanied by acute fever, is well known to accelerate the circulation, to

harden the pulse, to augment the heat and thirst, to increase delirium, to diminish the secretions; in a word, to aggravate all the symptoms of inflammatory fever, while it fails to produce the anticipated rest, or rather banishes it more effectually. Such we know to be the effects of an opiate in all the *phlegmasiæ*, or acute and visceral inflammation; as well as in the active stages of common fever; and we know no circumstance in the early stage of small-pox, which constitutes any exception to this fact, or which modifies the ordinary operation of the medicine. A steady pursuit of the antiphlogistic plan is a much more effectual foothold of the irritation which the patient suffers. Sydenham and other writers urge the impropriety of interfering with the ptyalism, that usually occurs in confluent small-pox soon after the eruption is out, and deem the suppression of it highly dangerous. Yet the tendency of opium to lessen the secretions is well understood: but the principal injury to be apprehended from it is the excitement which it produces. In the later periods of the disease, however, when the febrile excitement is low, and much irritation is kept up by the hardening crusts, the moderate use of opiates is to be recommended.

The antiphlogistic practice, above recommended, should be continued during the progress of the eruption to maturation, unless some particular symptoms of failure of the *vis vite* should ensue. For in every case of small-pox, where the eruption of pustules is numerous, although some abatement of the fever is discernible upon the complete eruption of the spots, yet there is seldom a perfect remission of the fever, the pulse rarely descending below 90 or 100 in the minute. The *secondary fever*, therefore, which occurs about the eleventh day, upon the complete suppuration of the pustules, or at least when these are perfectly fall and stretched to their utmost extent, whatever may be the nature of the fluid which they contain, is rather an augmentation of the existing fever than a new fever. The origin of this fever, in the opinion of Sydenham and most of the writers who followed him, was the re-absorption of the virus of the pustules into the blood, as well as the retention of the ordinary perspirable matter, which could not pass off by the skin. Whence they recommended blood-letting, which, they believed, was the most effectual mode of depurating the blood thus contaminated, as the means of cure for this fever. But not only was their theory very bad, (for surely drawing a few ounces of blood from the circulating mass could have no effect in removing the corruption from that which remained in the vessels,) but their practice was often injurious, by reducing the strength of the patient, at a time when the powers of life were about to fail, and require all possible support. Dr. Freind had the merit of pointing out the superior advantages of gentle purgatives in mitigating the secondary fever. The bowels should be gently but steadily opened, in all cases, at the commencement of this fever, provided no diarrhoea has occurred. According to the state of the pulse, and the appearance of the matter in the eruptions, the strength of the patient, and other symptoms, more or less of a cordial plan of treatment must, however, be combined with the laxatives. Light liquid nourishment, with a little wine and water as drink, should be frequently administered; and a decoction or infusion of cinchona, with the mineral acids and a slight aromatic, will be given with advantage. If the disease put on a more malignant character, with petechiæ and hæmorrhages, the cordial treatment must be increased both in quantity and strength; but the state of the bowels must still be regulated. Under this cordial plan, the petechiæ will sometimes disappear; the empty vesicles will become filled with matter; and the ichorous fluid of others be changed into white thick pus;

pus; the other symptoms of course improving in a similar degree.

Such is the general plan of cure which experience has sanctioned in the small-pox. But in particular cases particular symptoms are very urgent, modifying the character of the disease, and requiring some modification of the method of treatment.

Little can be done to controul effectually the *salivation*, when that discharge is excessive, nor to restore it when it suddenly subsides. In the former case, and when the patient is in danger of suffocation from the viscosity of the saliva, and the difficulty of discharging it, the mouth and throat may be frequently washed or syringed with a gargle containing oxymel, or some of the mineral acids. And, as the saliva often begins to thicken on the eleventh day, Sydenham recommended a blister (which has been often found beneficial) to be applied between the shoulders, on the evening of the tenth day, by way of prevention. The *diarrhœa*, when it occurs spontaneously, being by all writers deemed rather salutary than injurious, should not be interfered with. The *swelling of the head, face, and fauces*, when it is excessive, is highly dangerous, and commonly accompanied by viscosity or suppression of the salivary discharge. The steady pursuit of the antiphlogistic system is the best preventive of this danger, and the free discharge occasioned by laxatives affords the best means of drawing off the determination of the fluids to those parts.

The *head-ache and delirium*, when violent and accompanied with intolerance of light, and other phrenitic symptoms, mark the violence of the fever from the beginning, as well as the too great fulness of the vessels of the head, and therefore demand, not only the most rigid pursuit of the antiphlogistic plan, the free admission of cool air, and active purgation, but also the particular application of cold to the head; the detraction of blood by leeches or cupping from the temples or nucha; or even general blood-letting. The pediluvium is sometimes recommended for the purpose of relieving the head on the principle of revulsion; but we have more than once expressed our doubts both of the truth of the hypothesis and of the advantages of the practice. When the determination to the head is such as to produce actual *coma*, during the eruptive fever, a most dangerous small-pox is to be apprehended; and the cooling evacuating measures just recommended should be carried as far as discretion and experience will justify, and a blister should be applied to the neck.

Inflammation of the throat is a common attendant on all the varieties of small-pox, even the mildest; but in the latter it is slight, and easily relieved by any acidulous and mucilaginous gargle, such as an infusion of figs, acidulated with lemon-juice, apple-tea, or lemonade. But the *angina*, which accompanies the worst kinds of small-pox, is more acute and obstinate, and from extending to the *glottis*, it frequently produces a considerable degree of hoarseness. It is also increased by the general inflammation and tumefaction of the contiguous parts, and continues till these subside. This symptom is moderated by the antiphlogistic regimen, by blood-letting in inflammatory habits, and especially by the early course of laxatives, which contribute to prevent and diminish all the inflammatory symptoms.

Difficulty of breathing is an alarming symptom in small-pox, and seldom occurs except in the worst kinds, and in the last stage of the disease, especially when it is left to nature, or improperly treated in the preceding periods. In cases where the chest is narrow and contracted, or there is a constitutional predisposition to disease in the lungs, this symptom may occur at an earlier stage. Its appearance

implies a threatening or present inflammation or peripneumony, and requires more than any other symptom the free use of blood-letting, as well as the exhibition of cooling purgatives, and the whole antiphlogistic plan.

Some degree of *suppression of urine* not unfrequently takes place in severe cases of small-pox, especially from bad management in the beginning of the disease; it is commonly attended by costiveness, and is most effectually relieved by promoting the intestinal discharge, especially by laxative glysters. An immediate evacuation is sometimes produced, as Sydenham remarked, by taking the patient out of bed, and supporting him exposed to the cool air in his shirt, but still more effectually by placing his feet on a cold floor or hearth, which commonly induces a speedy disposition in the bladder to contract and expel its contents.

It only remains that we allude to the means which have been devised to prevent the deformity which is too often produced by small-pox by the *pits* which it leaves behind. As the pits have been ascribed to the retention of the acrid matter under the cuticle, and the consequent corrosion of the true skin; so it has been proposed to open the pustules, in order to allow the ichor to be discharged. (See Van Swieten, Comment. ad Aph. 1402.) This plan, however, has not proved successful, and the theory is probably erroneous. Others have proposed the covering of the face in the last stage of the disease, to secure it from the air, and the use of fomentations at the same time with warm milk, and unctions with unsalted butter, hog's-lard, or oil. Dr. Walker, in his valuable work already often quoted, adopts a similar method, but at a somewhat earlier period. He maintains that the pits do not originate either from the acrimony of the contained matter, from ulceration, or from any loss of substance of the skin; but that they are, in fact, merely *impressions*, made in the tender skin by the pressure of the hardened and desiccated pustules, or scabs, as a seal impressed melted wax. This, however, may be justly questioned; for the skin, tender as it may be, is probably not capable of receiving any impressions so permanent, and must be partially ulcerated, and lose a portion of its substance by sloughing, under each hardening pustule. It is true, however, that the face is chiefly liable to be pitted, from the greater drying and hardening of the crowd of pustules which cover it, and that this may probably be owing to its greater exposure to the air. Whence the early prevention of such exposure, and the softening of the drying pustules, certainly promise the best security against severe pitting. About the tenth day of the disease, sometimes sooner, according to the kind of small-pox, the apices of the pustules on the face change colour, feel rough, and begin to harden, especially about the mouth and chin, which are more chafed by the bed-clothes. At this time, therefore, Dr. Walker spread over the face a mask, of fine old cambric, thinly smeared with a mild liniment, composed of oil, spermaceti, and a little wax. This mask he renewed three or four times in twenty-four hours, and sometimes oftener, especially when urged by the patient, who generally felt an agreeable and refreshing coolness for some time after each application. On removing the mask, the face was gently touched with a soft cambric handkerchief, and exposed to the air for as short a time as possible. By this expedient, he affirms, the variolous matter is seen through the transparent mask to be preserved in a state of fluidity as long as it remains in that state on other parts of the body, or until it is gradually discharged by oozing out. The mask is to be continued till the pustules are perfectly emptied, which happens in the course of ten, twelve, or fifteen days, and in some kinds of small-pox in a longer time. Dr. Walker

Walker affirms, "in the application of this theory of pits, in the varieties of small-pox that have come under my care, I have constantly found the above mode of treatment to answer my highest expectation, not only in preventing pits in the worst cases of this disease; but must observe an agreeable and unexpected effect, which I have constantly found to accompany it, namely, a preservation of the natural features. Many have experienced such an alteration in the countenances of their friends and children, from the effects of this disease, that they could scarcely know them again. This disagreeable effect has been completely prevented, in every case that I have met with, by the method above directed." (Loc. cit. p. 398.) He adds, however, that the success of this application stands connected with the antiphlogistic and evacuant plan of treatment, which he judiciously recommends, and which accords with that which we have above detailed.

In some constitutions, as we have already stated, the disturbance excited by the small-pox is such as to leave the patients in a state of great predisposition to disease, especially in the glandular system, and all the forms of scrofula are occasionally seen to follow its ravages, as well as some other cachectic conditions. One of the most formidable consequences, however, of confluent small-pox is the loss of sight, which it frequently occasions, and which is so common indeed in this country, that a large majority of the blind who are seen in the streets owe their loss of vision to the small-pox. This, however, is rather the result of the extension of inflammation to the eyes during the attack of the confluent small-pox, than a *sequela* of the disease, and therefore is to be prevented rather by the proper practice during the eruption above detailed, than by any subsequent treatment. With a view to anticipate the morbid consequences, upon the supposition that they arise from the remains or dregs of the contagion still contaminating the blood, it is usual to administer a succession of purgatives, to clear the circulating fluids of these impurities. We do not profess to understand how, by exciting the actions of the exhalents of the intestines, we can draw out of the blood just the impure portion, leaving the rest unpolluted; and consider both the contamination and the purification of the blood as equally gratuitous suppositions. Where the patient comes out of the disease with every appearance of returning health, we do not perceive the necessity of resorting to these hypothetical cleansers, which, if violent, may do harm, and can only be productive of benefit by assisting the digestion and propulsion of the aliments in a gentle way. And where there are appearances of a bad habit of body, or a slow convalescence, more advantages are probably to be obtained by a proper attention to diet and regimen, with a judicious course of alterative and gently tonic medicine, than by the repetition of cathartics. A diet of milk and vegetables, or very light animal fluids, with appropriate exercise, change of air, the tepid bath, and other means which medicine affords of regulating the functions and gradually restoring the strength, should be pursued with diligence, especially where there is a disposition to hectic fever connected with the debility. Some forms of scrofula and cachexia, however, which are more local and unaccompanied by fever, require a more nutritious and cordial plan of treatment, to be determined by the age and other circumstances of the patient.

An able and ingenious project was proposed several years ago by Dr. Haygarth for the extermination of small-pox in Great Britain, turning upon the principle of a general inoculation. (See his *Sketch of a Plan*, &c. in 2 vols. 1793.) It is unnecessary, however, now to enter into any discussion

respecting the efficacy or importance of such a plan; since the discovery of the influence of the cow-pox, by the immortal JENNER, has afforded us an antidote, which requires only a general adoption to supersede altogether that fatal and formidable malady, and to preserve mankind from all the miseries and evils which it has spread over the earth for many centuries past. See COW-POX and INOCULATION.

SMALLS, THE, in *Geography*, rocks in the Irish sea, on which a light-house is erected for the guidance of seamen, about 15 miles S.W. from St. David's Head. N. lat. 51° 44'. W. long. 5° 33'.

SMALRIDGE, GEORGE, in *Biography*, a learned English prelate, was the son of a dyer at Litchfield, in which city he was born in 1663. He was educated at Westminster school, where his fine talents and excellent disposition rendered him a general favourite. In 1682 he was elected to a student's place in Christ's college, Oxford, in which he became in due time a tutor; and his reputation caused him, at an early age, to be selected, with others, as managers of the controversy with Obadiah Walker, master of the University college, a convert to popery. In this connection he published, in 1687, "Animadversions on the Eight Theses laid down, and the Inferences deduced from them, in a Discourse entitled 'Church Government,'" &c. About this period he distinguished himself as a votary of polite literature, of which he gave specimens in the "Musæ Anglicanæ." He entered into holy orders in 1692, and was appointed minister of Tothill-fields chapel, and he also obtained a prebend in the cathedral of Litchfield. In 1700 he took the degree of D.D., and frequently acted as deputy to Dr. Jane, regius professor of divinity at Oxford. On the death of Dr. Jane, in 1707, he was strongly recommended by the university for his successor; but the Whig interest carried it against him. Being now a celebrated preacher, he was chosen, in 1708, lecturer of St. Dunstan's in the West, London, and he was also appointed a member of the lower house of convocation, and exerted himself very much to procure for his friend, Dr. Atterbury, the prolocutor's chair, on which occasion he pronounced an elegant Latin panegyric on his friend, touching with much feeling and delicacy, as an apologist, upon the heat in controversy imputed to him. Dr. Smalridge, though of the party, avoided the animosities too prevalent in its disputes. He held also a friendly correspondence with Dr. Clarke and Whiston, and was extremely useful in moderating the violent proceedings instituted by the convocation against them. He assisted Whiston in his translation of the Apostolical Constitutions. He proposed a conference with Dr. Clarke on the subject of the Trinity, which was held at the seat of Mr. Cartwright, at Aynho, in Northamptonshire, and in which Dr. Smalridge was the advocate of orthodoxy. These connections caused him to be suspected of an inclination towards Arianism, from which he deemed it necessary to vindicate himself by a letter to bishop Trelawny, a short time before his death. In 1711, Dr. Smalridge was made a canon of Christchurch, Oxford, and afterwards dean of Carlisle. When Dr. Atterbury was promoted to the bishopric of Rochester in 1713, his friend succeeded him as dean of Christchurch. In the following year he was raised to the episcopal bench as bishop of Bristol, and very soon after he was nominated lord-almoner to queen Anne. Upon the accession of George I. he refused to sign the declaration made by some of the bishops, on occasion of the rebellion in 1715, because it contained a reflection on some of the clergy who had joined the Jacobites. This step caused the post of almoner to be taken from him, but he possessed the esteem of the princess of Wales, afterwards queen Caroline, with whom he continued in favour till

till his death, which happened in 1719, at Christchurch, where he was interred, and where, some years after, a handsome monument was erected to his memory, with an elegant Latin inscription. He left a widow and two children, who were much befriended by the generosity of the prince of Wales. A collection of 60 of his sermons was printed after his death, which soon came to a second edition. Biog. Brit.

SMALT, the last produce of cobalt, a kind of mineral matter, prepared and purified abroad, and brought hither, sometimes in form of a blue powder, and sometimes in lumps; chiefly used along with starch, to give linens the finer and clearer cast; and best known by the name of powder-blue. See **COBALT**.

The preparation of smalt, as practised in Hermanduria, we find described in the Philosophical Transactions by Dr. Krieg; who tells us, that the matter it is made of is the mineral stone called cobalt, or *cadmia mineralis*; which being pulverized, and the lighter stuff washed away, the remainder is laid on a furnace, and by a fire underneath and aside it, the flames of which are reverberated over it, a matter is separated from it in form of a smoke; which, sticking to the walls, makes what we call arsenic.

When the cobalt has done smoking, it is cooled, mixed with pot-ashes and powder of white flint-stones; the mixture is put in pots, and melted for five or six hours in a furnace. By this means, the matter is formed into a blue glass, which being put in cold water, cracks and grows tender; and is, at length, powdered by an engine, the finest part separated by a sieve, put into a mill, and ground in water into a very fine powder; which, by washing, is still farther separated from the coarser, then dried in warm chambers, barrelled up, and sent away.

There is not a more precarious process in all metallurgy than the preparation of this fine blue glass from cobalt, nor any manufacture in which so expert workmen are necessary. The carrying the heat to too great a degree, in the roasting of the cobalt, is a very mischievous error; and the suffering as much of the arsenic as may be to remain in the earth, is greatly to the advantage of the smalt; and its colour may be greatly heightened by adding common arsenic to it while it is in fusion.

It is always necessary to make careful and repeated experiments on a new ore, or a kind of cobalt which has not been worked before; by trying it with various degrees of heat in the roasting, and with different proportions of the flints and pot-ash in the fusion. On comparing the several products of these experiments, it will easily be seen which yields the finest colour, and this must be always after followed in the great operations.

It is well known, that the beautiful blue glass, called smalt, is prepared from the fixed earth of cobalt; but experiments have proved, that this earth alone will not acquire that fine colour. Dr. Link tried some of it, by keeping it eight hours in the most intense heat; yet on taking it out, it was only a grey glass, excepting that there were a few blue specks in it near the edges of the crucible. These specks make no objection to this doctrine, when properly considered; for they were owing, doubtless, to the same substance which is found necessary to be used, in order to procure the blue colour.

Flints are the necessary addition to cobalt for the making of the blue glass, or smalt; and the crucible being made of earth, might easily contain some particles of sand. Every piece of sand is a small stone, of the nature of flint; that is, a piece of crystal defaced by earth; and these small flints mixing with the glass of the cobalt earth, while in fu-

sion, rendered the small specks, where they were mixed, true smalt, while the rest remained grey and unaltered.

This earth of cobalt evidently contains some portion of copper, though so small in quantity, that it can never be discerned by the common signs, and so intimately blended with the earth, that it can never be procured separate. The lightness of this earth also, in which the copper refides after the sublimation of the arsenic, is a proof that its quantity must be very small; yet that it exists there is evident from the colours it affords.

Copper is well known to yield a green colour with acids, and a fine blue with alkalis. Thus, a solution of this earth in aqua fortis is of a deep green, and its glass, when mixed with the alkali of flints and of pot-ash, is the deep blue smalt: nor is it wonderful, that the vitrified earth of cobalt will never become blue by calcination alone, since, if it owes this colour to copper, it cannot be supposed to shew itself till called forth by an alkali.

Some cobalt yields smalt before roasting, even better than it would afterwards: this is a peculiar kind of cobalt, but is so like the rest, that it cannot be distinguished by the eye; but experiment alone shews this property in it.

Though cobalt in general requires roasting, in order to fit it for yielding the smalt, yet its different kinds require some more, and some less roasting; and the degree can never be judged of by the inspection of the mineral, but is only known by the experienced art in the process. Hence it is, that expert and intelligent persons are necessary in the smalt-works more than in almost any other branch of this sort of business.

The addition of a small quantity of arsenic, or of the arsenical flowers, during the time that the smalt is in fusion, adds greatly to the beauty of the colour: this is a practice kept secret by the workmen of some places; and by this means their smalt is always rendered better than that of their neighbours.

It is easy to see from this, that the roasting of cobalt is the necessary beginning of the smalt-work, not the divesting it of its arsenic, which only happens accidentally in that process; and it would be much better if it did not happen, since we find the arsenic added afterwards exalts the colour. From hence it is evident, that those cobalts which will make smalt without previous roasting, must, as they are found to do, make the very finest smalt, because their arsenic is yet left in them in great part; and from this also appears the necessity of having expert workmen for the smalt-making; since the knowing the degree of fire necessary to the ore is a most essential article, and after the roasting has been carried to a sufficient degree, every moment's heat divesting it of more of its arsenic than was necessary, makes the colour of the smalt to be made afterwards so much the worse. From this also appears the reason why the blue, made by precipitation from a solution of cobalt, is so much superior to the common smalt made by fire; because in this the arsenic is all preserved, whereas, in the common way of preparing it by fire, it is driven off. *Philos. Trans. N^o 396.* See **AZURE** and **ZAFFRE**.

SMAMLEVO, in *Geography*, a town of Russia, in the government of Viatka, on the Kama; 16 miles S. of Sarapul.

SMARA, a name of Kama, the Hindoo cupid. (See **KAMA**.) Smara means the ideal, and in the fanciful mythology of the East, is the reputed son of Maya, or illusion. See **MAYA**.

SMARAGD, *σμαραγδος*, a precious stone of a green colour, very beautiful and brilliant; called also the *emerald*; which see. See also **GEMS**.

SMARAGDUS MONS, in *Ancient Geography*, a mountain of Egypt, on the coast of the Arabic gulf, between Nechofia and Lepte Extrema, according to Ptolemy.

SMARIS, in *Ichthyology*, the name of a small fish caught in the Mediterranean, and common in the markets of Rome, Venice, and elfewhere, and fold to the poorer fort of people at a very small price. This, in the Linnæan fyftem, is a fpecies of the *fparus*; which fee.

It is feldom of more than a finger's length, and of a round, not flattened body, of a dusky blackifh-green on the back and fides, and not marked with any variegations, but having on each fide, near the middle of the body, one large black spot; its gill-fins and tail are of a faint red; the iris of the eyes is of a brownifh-white, and the tail is forked.

SMART, PETER, in *Biography*, a native of Warwickfhire, was educated at Weftminfter fchool, from whence he removed to Oxford, and became a ftudent of Chriftchurch. After entering orders, he obtained a prebend in Durham cathedral, where he diftinguifhed himfelf by his oppofition to the ceremonies in religion, and the removal of the altar from the middle of the choir to the eaft end of the church. He preached and printed fome fermons on the vanity and downfall of fuperftition and popifh ceremonies, for which he was degraded from the miniftry, and imprifoned. He died in 1642. He was likewife author of poems, Latin and Englifh

SMART, CHRISTOPHER, a confiderable poet, born in April, 1722, at Shipbourne, in Kent, was educated at Maidftone and Durham fchools, and at the age of feventeen he was entered at Pembroke Hall, Cambridge. By the death of his father his affairs were embarrassed, but his fpirits were not weighed down by family miffortunes, and while he was the companion of the gay, he cultivated the Mufes, and obtained great credit and feveral academic prizes for his college exercifes. His talents, however, were not adapted to augment the means of fubfiftence, and at length his diftreffes were fo great as to produce a derangement of his mental faculties. He died in 1771, leaving behind him a widow and two daughters, who fettled as bookfellers at Reading. His works confift of fables, fonnets, odes, prize-poems, &c. printed at Reading, in 2 vols. 12mo. 1791. He publifhed a profe tranflation of the works of Horace, and tranflations in verfe of the Pfalms, and of the fables of Phædrus. As a poet, he poffeffed a large fhare of originality; was fometimes very pathetic; and, according to his biographer, he fometimes reached the true fublime.

SMART-Weed, in *Agriculture*, a term applied to the biting or pale-flowered perficaria, or arfmart, which is a troublefome weed in arable land.

SMATCH, in *Ornithology*, a name by which the common oenanthe is called in many parts of England.

SMEAR-DAB, in *Ichthyology*, is a name given to a fpecies of dab among the fifhmongers of London, which is of equal goodnefs with the common dab.

SMEATON, MARK, in *Biography*, a mufician in the fervice of Anna Bullen, and groom of her chamber, whom Henry VIII. in a fit of jealousy, or pretended jealousy, accused of familiarity with his queen. The mufician, in the vain hope of life, was prevailed on to confefs a criminal correpondence with his royal miftrefs; "but even this unfortunate queen's enemies expected little advantage from this confeffion, for they never dared confront him with her." Hume's Hift. Hen. VIII. chap. v.

"The queen faid, he was never in her chamber, but when the king was lalt at Winchefter; and then he came in to play on the virginals. She faid, that fhe never fpoke to him after that, but on Saturday before May day, when fhe

faw him ftanding in the window, and then fhe asked him, why he was fo fad? he faid, it was no matter: fhe answered, you may not look to have me fpeak to you, as if you were a nobleman, fince you are an inferior perfon. No, no, madam, faid he, a look fufficeeth me." BARNET'S Hift. of the Reform. vol. i. book iii. p. 199.

SMEATON, JOHN, an eminent civil engineer, was born on the 28th of May, 1724, at Aulthorpe, near Leeds. The ftrengh of his underftanding, and the originality of his genius, appeared at an early age; his playthings were not the playthings of children, but the tools which men employ; and when he was a mere child, he appeared to take greater pleafure in feeing the operations of workmen, and asking them queftions, than in any thing elfe. Before he was fix years old, he was once difcovered at the top of his father's barn, fixing up what he called a wind-mill of his own conftruction; and at another time, while he was about the fame age, he attended fome men fixing a pump, and obferving them cut off a piece of the bored part, he procured it, and actually made a pump, with which he raifed water. When he was under fifteen years of age, he made an engine for turning, and worked feveral things in ivory and wood, which he prefented to his friends. He made all his own tools for working in wood and metals, and he conftructed a lathe, by which he cut a perpetual fcrew in brafs, a thing but little known, and which was the invention of Mr. Henry Hindley of York, with whom Mr. Smeaton became acquainted, and indeed extremely intimate. Mr. Smeaton, by the time that he was eighteen years of age, acquired, by the ftrengh of his genius and indefatigable induftry, an extenfive fet of tools, and the art of working in moft mechanical trades, without the affiftance of a mafter. A part of every day was ufually occupied in forming fome ingenious piece of mechanism. His father was an attorney, and being defirous to bring up his fon to the fame profeflion, he brought him up to London with him in 1742, and attended the courts in Weftminfter-Hall; but after fome time, finding that the law was not futed to his difpofition, he wrote a ftong memorial to his father on the fubject, who immediately defired the young man to follow the bent of his inclination. In 1751 he began a courfe of experiments to try a machine of his own invention to meafure a fhip's way at fea, and alfo made two voyages, in company with Dr. Knight, to try the effect of it, and alfo for the purpofe of making experiments on a compafs of his own conftruction, which was rendered magnetical by Dr. Knight's artificial magnets. In 1753 he was elected a fellow of the Royal Society; and the number of papers which he publifhed in their Tranfactions, will fhew how highly he deferved the honour of being enrolled a member of that ufeul and important body. In 1759 he received from the council of the Royal Society, by an unanimous vote, their gold medal for his paper, entitled "An experimental Inquiry concerning the natural Powers of Water and Wind to turn Mills and other Machines, depending on a circular Motion." The paper was the refult of experiments made on working models in the years 1752 and 1753, though not communicated to the fociety till 1759; and in the interval he had opportunities of carrying into effect feveral of his inventions and theories, which rendered his paper of much more real value to the fociety and the public at large. In 1755, the EDDYSTONE Light-houfe was burnt down (fee the article), and Mr. Smeaton being recommended to the proprietors of that building as an engineer in every way calculated to rebuild it, he undertook the work, which was completed in 1759, much to the fatisfaction of the parties concerned. Still he was not fully employed as a civil engineer, for in the

year 1764, while he was in Yorkshire, he offered himself as a candidate for the office of receiver to the Derwent water estate; and in the course of the year he obtained the appointment in a manner most flattering to himself, inasmuch as his own merit carried the point in opposition to two other candidates who were strongly recommended and powerfully supported. He was very happy in this appointment, particularly in the assistance which he received from Mr. Walton, the other receiver, who took upon himself the management of the accounts, leaving Mr. Smeaton leisure and opportunity to exert his abilities on public works. In the year 1773, he had so much business as a civil engineer, that he wished to resign this appointment; but his friends prevailed on him to continue in office two years longer. After this, Mr. Smeaton was employed on many works of great public utility. He made the river Calder navigable, a work that required talents of the very first order, owing to the impetuous floods in that river; he planned and attended to the execution of the great canal in Scotland, for conveying the trade of the country either to the Atlantic or German ocean; and as a proof of the disinterestedness of his habits, having brought it to the place originally intended, he declined a handsome yearly salary, in order that he might attend to other business. On the opening of the great arch at London-bridge, the excavation around and under the starlings was so considerable, that the bridge was thought to be in great danger of falling. Mr. Smeaton was then in Yorkshire, and was sent for express, and he arrived without any delay. "I think," says his biographer, "that it was on a Saturday morning when the apprehension of the bridge was so general, that few persons would venture to pass over or under it. Mr. Smeaton applied himself immediately to examine it, and to sound about the starlings as minutely as possible, and the committee being called together, adopted his advice, which was to repurchase the stones that had been taken from the middle pier, then lying in Moorfields, and to throw them into the river to guard the starlings. In this way Mr. Smeaton probably saved London-bridge from falling, and secured it till more effectual methods could be adopted."

Mr. Smeaton was appointed engineer to Ramsgate harbour, and brought it into a state of great utility by various operations, of which he published an account in 1791. The variety of mills which Mr. Smeaton constructed, shews the great uses which he made of his experiments already referred to; for it was a rule with him, from which he never willingly deviated, not to truit to theory in any case, where he could have an opportunity to investigate a subject by real trial. He built a steam-engine at Aulthorpe, and made a vast number of experiments with it to ascertain the power of Newcomen's engine (see STEAM-Engine), which he improved and brought to a far greater degree of perfection, both in its construction and powers, than it was before. Mr. Smeaton, during many years of his life, was a frequent attendant upon parliament, his opinion on various works begun or projected being continually called for. And in these cases the strength of his judgment and perspicuity of expression had full scope. It was his constant custom, when applied to plan or support any measure, to make himself fully master of the subject, to understand its merits and probable defects, before he would engage in it. By this caution, added to the clearness of his expression, and the integrity of his heart, he seldom failed to obtain for the bill which he supported the sanction of an act of parliament. No one was ever heard with more attention, nor had any one ever more confidence placed in his testimony.

In the courts of law he had several compliments paid him from the bench by lord Mansfield and other judges, for the new light that he always threw upon difficult subjects. About the year 1785, the health of this excellent man began to decline, and he took the resolution to avoid all the business he could, in order that he might have leisure to publish an account of his inventions, improvements, and works, by which he conceived he should be doing a public benefit to his country and the world. In September 1792, he had a paralytic seizure, which put a period to his life in about six weeks.

Mr. Smeaton had a warmth of expression that might appear to those who did not know him, to border upon harshness, but those more intimately acquainted with him knew that it arose from the intense application of his mind, which was always in the pursuit of truth, or engaged in some difficult subjects. If he were sometimes apparently hasty and impetuous in his disposition, he would always listen to reason, and yield to the force of argument.

In all the social duties of life he was exemplary: his manners were simple, and his mode of life abstemious. He was singularly moderate in his pecuniary concerns. He was fond of science for its own sake, and spent much of his leisure in cultivating that of astronomy; for which purpose, he fitted up an observatory in his house, furnished with curious contrivances of his own invention. He was a friend and encourager of merit wherever he discerned it, and many persons were indebted to him for important assistance on their entrance into life. Mr. Smeaton was the institutor, in 1771, of a society of civil engineers, which was dissolved at his death, but afterwards renewed; they published, in 1797, a volume of his Reports. For his works in constructing bridges, mills, harbours, engines, &c. see his Reports, in 3 vols. 4to. Of his inventions and improvements of philosophical instruments, an idea may be formed from the list of his writings which is inserted in Hutton's Dictionary.

SMECTIS, in *Natural History*, a name used by several authors for the common fuller's-earth, more commonly called *cimolia purpurascens*.

SMECTYMNUUS, a cant term that made some figure in the time of the civil war, and during the Interregnum. It was formed of the initial letters of the names of five eminent Presbyterian ministers of that time, viz. Stephen Marshal, Edmund Calamy, Thomas Young, Matthew Newcome, and William Spurflow: who, together, wrote a book against episcopacy, in the year 1641, whence they and their retainers were called Smectymnuans.

SMECZNA, in *Geography*, a town of Bohemia, in the circle of Schlan; 3 miles S. of Schlan.

SMEGMA, a kind of wash in use among the ancients. See DETERSORIUM.

SMEGMADERMOS, in *Botany*. See SMEGMARIA.

SMEGMARIA, judiciously abbreviated by Willdenow, from *Smegmadermos*, the name originally given to this genus, by the authors of the *Flora Peruviana*; which, being composed of *σμύγμα*, soap, and *δέρμα*, skin, alludes to the use made of the bark in washing,—"Ruiz et Pavon Prodr. 144. t. 31." Willd. Sp. Pl. v. 4. 1123.—Class and order, *Polygamia Diocia*, Willd. More properly, as we presume, *Decandria Pentagynia*. Nat. Ord. allied to *Rutaceæ* of Jussieu.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coriaceous, downy, in five deep, ovate, equal segments, permanent. *Cor.* Petals five (not six), obovate, the length of the calyx, alternate with its segments; their claws slender. Nectary of five orbicular, smooth, depressed lobes, opposite to, and

lying upon, the segments of the calyx, and about half as long. *Stam.* Filaments ten, awl-shaped, smooth, the length of the calyx, five of them inserted into the receptacle, five into the nectaries; anthers incumbent, nearly orbicular, of two cells bursting in front. *Pist.* Germe superior, small, roundish, villous, in five distinct lobes; styles five, vertical, erect, cylindrical, smooth, shorter than the stamens; stigmas small, obtuse. *Peric.* Capsules five, spreading in the form of a star, obovate, coriaceous, of one cell and two valves. *Seeds* several, winged.

Eff. Ch. Calyx five-cleft. Petals five. Nectary of five orbicular depressed lobes, opposite to the calyx, alternate with the petals, and bearing five of the stamens. Capsules five, superior. Seeds numerous, winged.

1. *S. emarginata.* Chili Soap-bark. (*Smegmadermos emarginatus*; "Raiz et Pavon. Syst. Veg. v. 1. 288. Quillaja fapanaria; Molin. Chil. ed. Germ. 150.")—Native of woods in Chili, about Puchacay, where it is known by the name of *Quillay*. Our specimen was sent by the late abbé Cavanilles. The tree is said to be twenty ells in height, bearing abundance of leafy branches, which are round, much subdivided, knotty, finely downy when young. *Leaves* an inch long, alternate, on short broad stalks, broadly elliptical, obtuse, coriaceous, evergreen, smooth, shining, veiny, entire in our specimen, though reported to be sometimes toothed. *Stipulas* minute, awl-shaped, membranous, in pairs, deciduous. *Flowers* few together, on axillary or terminal, short, downy stalks. *Calyx* expanding more than half an inch, thickly clothed all over with short, dense, white pubescence, as in *Grewia* and *Tilia*, to which we at first suspected this genus might be allied; as perhaps is the case, though it will not answer to Jussieu's definitions of his *Tiliaceæ*, or indeed any other order. The petals are probably white or pink, but of this we have no information. *Capsules* near an inch long, externally downy; their inner coat smooth, cracking transversely with age, but we can discern nothing like the separate elastic tunic of the true *Rutaceæ*.—Nothing but error and inconvenience can result from placing this genus in the class *Polygamia*.

SMELBURG, in *Geography*, a town of the duchy of Warfaw; 50 miles N. of Gnesna.

SMELL, ODOR, with regard to the organ, is an impression made on the nose by little particles continually exhaling from odorous bodies.

SMELL, with regard to the object, is the figure and disposition of odorous effluvia, which, sticking on the organ, excite the sense of smelling.

SMELL, with regard to the soul, is the perception of the impression of the object on the organ; or the affection in the soul resulting from it.

Smell, like taste, consists altogether in the arrangement, composition, and figure of the parts, as appears from the following experiments of Mr. Boyle.

1. From a mixture of two bodies, each of which is, of itself, void of all smell, a very urinous smell may be drawn: this is done by the grinding of quicklime with sal ammoniac.

2. By the admixture of common water, which of itself is void of smell, or inodorous, another inodorous body may be made to emit a very rank smell. Thus, camphor dissolved in oil of vitriol is inodorous, yet mixed with water it immediately exhales a very strong smell.

3. Compound bodies may emit smells, which have no similitude to the smells of the simples of which they consist. Thus, oil of turpentine, mixed with a double quantity of oil of vitriol, and distilled; after distillation, there is no smell but of sulphur; and what is left behind in the retort, be-

ing again urged by a more violent fire, yields a smell like oil of wax.

4. Several smells are only to be drawn forth by motion and agitation. Thus, glass, stones, &c. which, even when heated, yield no smell; yet, when rubbed and agitated in a peculiar manner, emit a strong smell: particularly beechwood, in turning, yields a kind of rosy smell.

5. A body that has a strong smell, by being mixed with an inodorous one, may cease to have any smell at all. Thus, if aqua fortis, not well dephlegmated, be poured on salt of tartar, till it cease to ferment; the liquor, when evaporated, will yield inodorous crystals, much resembling nitre; yet these, when burnt, will yield a most noisome smell.

6. From a mixture of two bodies, one of which smells extremely ill, and the other not well, a very pleasant aromatic odour may be gained, viz. by a mixture of aqua fortis, or spirit of nitre, with an inflammable spirit of wine.

7. Spirits of wine, by mixing with an almost inodorous body, may gain a very pleasant aromatic smell. Thus, inflammable spirits of wine and oil of Dantzic vitriol, mixed in equal portions, then digested, and at last distilled, yield a spirit of a very fragrant smell.

8. A most fragrant body may degenerate into a fetid one, without the admixture of any other body. Thus, if the spirit mentioned in the former experiment be kept in a well-closed receiver, it will soon acquire the rankness of garlic.

9. From two bodies, one of which is inodorous, and the other fetid, a very pleasant smell may arise, much resembling musk, viz. by putting pearls into spirit of vitriol; for, when dissolved, they yield a very agreeable smell. See SMELLING.

SMELL is used as a name for a peculiar sort of wine, of which there are two species; the one sort is very fragrant, muscatelline, and aromatic; this is called simply the *smell-wine*: but the other, which is very rank and offensive to the nose, is called by the Germans *smell-bruntzer*. Many have been the conjectures about the occasion of the rank smell of this wine.

The smell is truly urinous, and is that of a volatile alkali; which not being embodied in, or subdued by the acid of the grape in this imperfect fermentation, vents itself in this rank manner.

It is evident, that the smell is of a volatile nature, for it is often lost in the drawing of the wine several times out of one vessel into another, evaporating during the time of drawing it out.

SMELLIE, WILLIAM, M.D., in *Biography*, an eminent teacher and practitioner of midwifery, was a native of Scotland. After having successively practised this art in a small town of that country for a period of nineteen years, he removed to London, and in 1741 was living in Pall-Mall, where Dr. William Hunter resided with him. This circumstance implies, that he had already risen to considerable eminence in his line, and he was in fact in high repute as a lecturer, being attended by a numerous concourse of pupils of both sexes. This reputation, indeed, he appears to have merited by his talents and assiduity; for he was the first in proposing many of the practical improvements, which modern experience has admitted into the practice of midwifery, and by his mechanical skill he contributed materially to the improvement of the instruments employed to facilitate delivery in difficult cases, and to the disuse of those which were less safe and convenient; and he established some useful rules for their application. He was the first writer, who, by accurately determining the shape and

size of the pelvis, and of the head of the fœtus, and comparing their proportions, and the true position of the fœtus in utero, pointed out clearly the whole progress of the child during parturition: and his opinions were subsequently confirmed, especially by Dr. Hunter, from observations made after death, where parturition had not been completed. The improvement which he made in the forceps, which has since been universally adopted, is well known, and he taught the present manual mode of using them. He abolished many superstitious notions and erroneous customs that prevailed in the management of parturient women and of the children; and he had the satisfaction to see the greater part of his maxims adopted, not only in this island, but by many of the most respectable practitioners in Europe.

In the year 1752, he published the substance of his lectures, in the improvement and correction of which he affirms, that he had spent six years, in one volume 8vo., under the title of "A Treatise on Midwifery;" to which, in 1754, he added a second volume of cases, intended to illustrate the precepts laid down in the former. An additional volume of cases, which he promised in his preface, did not appear till about five years after his death, in 1768. The whole formed the most complete system of the art of midwifery, which had then appeared, and was regarded as the best authority: it was, in fact, the result of an extensive experience of forty years, and contained a very comprehensive view of the various circumstances that usually occur, with instructions respecting the best means of obviating them. In 1754, Dr. Smellie likewise published a set of anatomical plates, of a large folio size, and thirty-six in number, which were intended farther to elucidate the doctrines of his lectures. In eleven of these he acknowledges the assistance of the late professor Cowper. Like other ingenious men of original character, Dr. Smellie was assailed by some critics and opponents, especially by Dr. Burton of York, and by Dr. W. Douglas, with great acrimony; but he ever maintained the character of a man of ingenuity and judgment; he was remarkably candid and modest in his demeanour, and upright and disinterested in all his concerns. His reputation and success were the result of his merit alone; for his awkwardness of person and unpolished manners prevented him from rising to the highest line of practice; but he was much esteemed by his pupils, and by those who employed him. He ultimately retired to Lanark, where he spent the latter years of his life, and died in 1763, at an advanced age. Hutchinso[n] Med. Biog. Gen. Biog.

SMELLING, the act whereby we perceive smells, or by which we become sensible of odorous bodies, by means of certain effluvia, which, striking on the olfactory organ, briskly enough to have their impulse propagated to the brain, excite a sensation of the soul.

The principal organs of smelling are the nostrils and the olfactory nerves; the minute ramifications of which latter are distributed throughout the whole concave of the former. See **NOSE**.

Smelling is performed by the odorous effluvia, floating in the air, being drawn into the nostrils, in inspiration, and struck with such force against the fibrillæ of the olfactory nerves, which the figure of the nose, and the situation of the little bones, render opposite thereto, as to shake them, and give them a vibratory motion; which action, being communicated hence to the common sensory, occasions an idea of a sweet, or fetid, or sour, or an aromatic, or a putrefied object, &c.

The matter in animals, vegetables, fossils, &c. which chiefly affect the sense of smelling, Boerhaave observes, is that

subtile substance, inherent in the oily parts of them, called *Spirits*: because, when this is taken away from the most fragrant bodies, what remains has scarcely any smell at all; but this, poured on the most inodorous bodies, gives them a fragrantcy.

Willis observes, that brutes have, generally, the sense of smelling in much greater perfection than man; as by this alone, they distinguish the virtues and qualities of bodies unknown before; hunt out their food at a great distance, as hounds and birds of prey; or hid among other substances, as ducks, &c.

Man, having other means of judging of his food, &c. did not need so much sagacity in his nose; yet have we instances of a very considerable degree of it, even in man. In the *Histoire des Antilles*, we are assured, there are Negroes, who, by the smelling alone, can distinguish between the footsteps of a Frenchman and a Negro.

It is found that the laminae, with which the upper part of the nostrils is fenced, and which serve to receive the divarications of the olfactory nerves, are always longer, and folded up together in greater numbers, as the animal has this sense more accurate: the various windings and turnings of these laminae detain and fetter more of the odoriferous particles.

The sense of smelling may be diminished or destroyed by diseases; as the moisture, dryness, inflammation or suppuration of the olfactory membrane, the compression of the nerves which supply it, or some fault in the brain itself at their origin. A defect, or too great a degree of solidity of the small spongy bones of the upper jaw, the caverns of the forehead, &c. may likewise impair this sense; and it may be also injured by a collection of fetid matter in these caverns, which is continually exhaling from them, and also by immoderate use of snuff. When the nose abounds with moisture, after gentle evacuations, such things as tend to take off irritation, and coagulate the thin sharp serum, may be applied, as the oil of anise, mixed with fine flour, camphor dissolved in oil of almonds, &c. the vapours of amber, frankincense, gum-mastic, and benjamin, may likewise be received into the nose and mouth. For moistening the mucus when it is too dry, some recommend snuff made of the leaves of marjoram, mixed with oil of amber, marjoram, and aniseed; or a sternutatory of calcined white vitriol, twelve grains of which may be mixed with two ounces of marjoram water, and filtrated. The steam of vinegar upon hot iron, and received up the nostrils, is also of use for softening the mucus, removing obstructions, &c. If there be an ulcer in the nose, it ought to be dressed with some emollient ointment, to which, if the pain be very great, a little laudanum may be added. If it be a venereal ulcer, twelve grains of corrosive sublimate may be dissolved in a pint and a half of brandy, and a table-spoonful of it taken twice a-day. The ulcer ought likewise to be washed with it, and the fumes of cinnabar may be received up the nostrils.

If there be reason to suspect that the nerves, which supply the organs of smelling, are inert, or want stimulating, volatile salts, or strong snuffs, and other things, which occasion sneezing, may be applied to the nose; the forehead may likewise be anointed with balsam of Peru, to which may be added a little oil of amber. See **BRAIN**, **LIFE**, and **NERVOUS System**.

SMELNITZ, or **SZOMOLNOK**, in *Geography*, a town of Hungary; 14 miles S. of Kapisdorf.

SMELT, *Apua Phalerica*, or *Salmo Eperlanus* of Linnaeus, in *Ichthyology*, a fish which is classed, by the generality of writers, among the truttaceous kinds, and is ac-

knowledged to have a general external resemblance to the salmon. See SALMO *Eperlanus*.

It inhabits the seas of the northern parts of Europe, and, Mr. Pennant apprehends, is never found as far south as the Mediterranean.

These fish will live almost any where, but they are very apt to degenerate. They are common in the rivers of New England, and are as large as with us, often weighing two ounces and a half; but a pailful of these being taken from one of their rivers, and put into an adjoining pond, they all degenerated in such a manner, that they were afterwards found so small, that the largest did not weigh more than five pennyweights. Though thus small, however, they are much valued, and are better tasted than the others. Philos. Trans. N^o 374. p. 232.

They are called smelts, because they melt, as it were, or dissolve between the fingers in handling them; or, as others say, on account of their scent, *quasi smell it*. The name *sparling*, by which they are called in Wales and the north of England, is taken from the French *eperlan*: smelts are often sold in the streets of London split and dried, and called *dried sparlings*.

SMELT *Fishing*. See FISHING, *Smelt*.

SMELT, among the fishermen in Yorkshire, and some other parts of England, is also a name given to the salmon, while in its first year. See SALMON.

SMELTING, among *Metallists*, the melting of a metal from the ore in a smelting furnace; in order to separate the metallic parts from the sulphur and arsenic, and the earthy and strong substances of all kinds with which they are combined.

Smelting, in propriety, is restrained to large works, in which ores from the mines are melted down and separated.

In speaking of works in a lesser way, we do not say smelting, but *melting*.

In the more precious metals this is called *refining*; which see. And smelting is most commonly applied to the reduction of iron ores.

The art of smelting the ores of all metallic substances was, probably, at first very imperfect; hence the use of iron has every where been of a more recent date than that of the other metals, because it requires the application of a much stronger fire to smelt the ores of iron than those of any other metal. We have no certain accounts when, or by whom, the several metals were discovered. Wallerius says, that, as far as he knew, Pliny was the first who enumerated the six metals; but they were certainly known long before his age, and were mentioned both by Homer and by Moses, a much more ancient author. (Numb. xxxi. 22.) From this testimony we may certainly infer, that all the metals, anciently mentioned, were known, at least in the country of the Midianites, above fourteen hundred and fifty years before the birth of Christ, or near nine hundred years after the deluge. Moreover, iron and copper were, without doubt, known before the deluge, and probably all the other metals, which are more easily extracted from their ores than the former.

In the time of Abraham, however, gold and silver were esteemed, as they are at present, precious metals (Gen. xxiii. 16. Gen. xiii. 2.); and hence it is reasonable to conclude, that Noah was able to instruct his descendants in the art of smelting metallic ores; this art was afterwards lost among the various colonies, which quitted the plains of Asia in search of settlements; and as the earth, soon after the deluge, and long before it could have been peopled by the posterity of Noah, must have become cover-

ed with wood, and in process of time different countries might have been cleared by setting the wood on fire, which might flux metallic ores contiguous to the surface of the earth, it is not improbable, that the first idea of smelting ores might have been thus suggested to many nations. See Creech's Lucretius, vol. ii. p. 572.

We may hence conjecture, that the first rude process, by which metals were extracted from their ores, was that of putting a quantity of ore upon a heap of wood, and setting the pile on fire, in conformity to the manner, in which ores were smelted during the burning of forests; but as the force of the fire is greatly diminished by the dispersion of its flame, and as the air acts more forcibly in exciting fire, when it rushes upon it with greater velocity, it is likely that the heap of wood and ore would soon be surrounded with a wall of stone, in which sufficient openings would be left for the entrance of the air, and thus a kind of furnace would be constructed.

The Peruvians, we are told, had discovered the art of smelting and refining silver, either by the simple application of fire, or where the ore was more stubborn, and impregnated with foreign substances, by placing it in small ovens or furnaces on high grounds, so artificially constructed, that the draught of air performed the function of a bellows, a machine with which they were totally unacquainted. This method of smelting ores on high grounds, without the assistance of a bellows, or at least of bellows moved by water, seems to have been formerly practised in other countries as well as in Peru. There are several places in Derbyshire, called *boles* by the inhabitants, where lead has been anciently smelted, before the invention of moving bellows by water; these boles were always situated upon high grounds, and mostly upon that side of a hill which faces the west, probably because the wind proceeds most frequently from that quarter.

From a pig of lead, dug up in 1766 at one of these boles near Matlock, and bearing an inscription in relievo, from which it appears to have been smelted in the age of Adrian; many of the boles in Derbyshire seem to be of high antiquity. However, this method of smelting ore by the variable action of the wind, being a very troublesome and precarious process, has been universally disused, and the more regular blast of a bellows has been introduced in its stead.

The invention of the bellows is attributed by Strabo to Anacharsis, the Scythian; but he was probably the improver of this machine; for Homer, who lived long before his time, describes Vulcan as employing twenty pair of bellows at once in the formation of the shield of Achilles. Iliad, lib. xviii. v. 470.

When the art of moving bellows by means of a water-wheel was first discovered, is uncertain; the ancients seem to have been unacquainted with it; but we learn from Agricola (*De Re Metal.* published in 1550, pp. 165. 338.) that it was very generally known, at least among the Germans, in his time; for he speaks of it often, without hinting at its being a recent invention. By this advantageous contrivance, however, the moderns have, in many instances, worked over again, with considerable profit, the heaps of iron and other kinds of slag, from which the metal has been but imperfectly extracted, before the moving of the bellows by water was discovered.

About fifty years ago, the blast, or hearth-furnace, was the only one in use for smelting lead-ore in Derbyshire. In this furnace, ore and charcoal, or ore, and what is called *white coal*, which is wood dried but not charred, being placed, in alternate layers, upon a hearth properly constructed, the fire is raised by the blast of a bellows, moved

SMELTING.

by a water-wheel; the ore is soon smelted by the violence of the fire, and the lead, as it is produced, trickles down a proper channel, into a place contrived for its reception. These ore-hearths are now very rare; though they are frequently applied to the extracting lead from the slag which is produced, either at the ore-hearth, or the cupola furnace, and they are then called *slag-hearths*, and the lead thus obtained is called *slag-lead*; the fire in a slag-hearth is made of the cinder of pit-coal instead of charcoal; the furnace called a *cupol*, or *cupola*, and *reverberatory* furnace, and by the Germans a *wind-furnace*, in which ores are smelted by the flame of pit-coal, is said to have been invented about the year 1698, by a physician named Wright; though Becher may, perhaps, be thought to have a prior claim to its invention, or introduction from Germany. But whoever was the first inventor of the cupola, it is now in general use, not only in Derbyshire and other counties for the smelting of ores of lead, but both at home and abroad, where it is called the *English furnace*, for the smelting of copper ores. This furnace is so contrived, that the ore is melted, not by coming into immediate contact with the fuel, but by the reverberations of the flame upon it. The bottom of the furnace, on which the lead-ore is placed, is somewhat concave, shelving from the sides towards the middle; its roof is low and arched, resembling the roof of a baker's oven: the fire is placed at one end of the furnace, upon an iron grate, to the bottom of which the air has free access; at the other end, opposite to the fire-place, is a high perpendicular chimney; the direction of the flame, when all the apertures in the sides of the furnace are closed up, is necessarily determined, by the stream of air which enters at the grate, towards the chimney, and in tending thither it strikes upon the roof of the furnace, and being reverberated from thence upon the ore soon melts it. This furnace does not require the use of bellows, and may, therefore, be constructed any where. In smelting lead-ore, they generally put into the cupola furnace a ton of ore, previously beat small and dressed, at one time, which quantity they call a *charge*; and they work off three charges of ore in every twenty-four hours. In about six hours from the time of charging, the ore becomes as fluid as milk. In order to obtain the lead free from the slag which swims over it, the smelters usually throw in about a bushel of lime, which dries upon the slag, and prevents its running out with the lead. The slag, thus thickened, is raked up towards the sides of the furnace, and the lead gushes out through a hole in one of the sides of the furnace, which having been properly stopped during the smelting of the ore, is opened for this purpose into an iron pot, from which it is laded into iron moulds, containing what they call a pig of lead; the pigs, when cold, being ordinarily stamped with the maker's name, are sold under the name of *ore-lead*. After the lead has all flowed out of the furnace, they stop up the tap-hole, and drawing down the slag and lime into the middle of the furnace, they raise the fire, till the mixture of slag and lime, which they simply term *slag*, is rendered very liquid; upon this mass they throw another quantity of lime, and proceed as before. When the lead thus obtained, amounting generally to twenty or thirty pounds, is let out of the furnace, a new charge of ore is put in and the operation renewed.

In order to spare the time and expence of fuel, they have, in some furnaces, lately contrived a hole, through which they suffer the main part of the liquid slag to flow out, before they tap the furnace for the lead; upon the little remaining slag they throw a small portion of lime, and draw the mixture out of the furnace without smelting it. This kind of furnace they have nicknamed a *maccaroni*.

Dr. Watson has suggested some improvements in the construction of this furnace, and in the process of smelting above described. He proposes to substitute an horizontal chimney in the place of the perpendicular one now in use, and that the end farthest from the fire should be turned up by a tube of earthen-ware, or otherwise; so that the sulphureous acid, set at liberty during the burning of the sulphur, may issue out in a direction parallel to the flue of the chimney, and at the distance of about one foot and a half above it. Let a number of large globular vessels be made either of glass or lead, each of which must have two necks, so as to be capable of being inserted into one another: let these vessels be placed in the flue of the chimney, the neck of the first being inserted into the above-mentioned tube, and the neck of the last being left open, for fear of injuring the draught of the furnace. Let each of these globular vessels contain a small quantity of water, in which case, he apprehends, that the heat of the flue will raise the water into vapour, and that this watery vapour will be the means of condensing the sulphureous acid vapour, in such a degree as to render the undertaking profitable. When the sulphur is all consumed, the draught of the furnace may be suffered to have its ordinary exit at the end of the horizontal chimney, by a very slight contrivance of a moveable damper.

The same ingenious writer also observes, that very sulphureous ore should be roasted for a long time with a gentle heat. He also proposes to leave as little lead as possible in the slag; for this purpose he suggests, that it might be useful to throw a quantity of charcoal-dust upon the liquid scoria in the cupola furnace, in order that the calcined lead might be converted into lead, by uniting itself to the inflammable principle of the charcoal; and that it might be also useful to flux sulphureous lead-ores in conjunction with the scales or other refuse pieces of iron, or even with some sorts of iron-ore.

The smelter might farther find it worth his while to reduce the slag into a powder by a stamping mill, or to grind it by any other contrivance, and then he may separate the stony part of the slag from the metallic, by washing the whole in water, inasmuch as the metallic part is heavier than the other. Watson's Chem. Ess. vol. iii. p. 253, &c.

The other furnaces used in smelting are supplied with large bellows, moved by the arbor of a wheel, which is turned round by a current of water. These have obtained different names, according to some difference in their construction. Their greater or less height gives occasion also to the distinction of *high furnaces* and *middle furnaces*. The high furnaces are of modern invention; they were first introduced at Mansfeld in 1727, and are now used in almost all countries where ores are smelted, as in Saxony, Bohemia, Hungary, &c. They contribute, by their great height, being above eighteen feet high, which allows the ore to undergo a roasting by different degrees of heat before it is melted, to simplify and diminish the labour. They are chiefly employed for crude fusions, and particularly for the slate copper-ore.

In order to facilitate the extraction of metallic substances from the ores and minerals containing them, some operations, previous to the fusion or smelting of these ores and minerals, are generally necessary. These operations consist of, 1. The *separation* of the ores and metallic matter from the adhering unmetallic earths and stones, by hammers, and other mechanical instruments, or by washing with water. 2. Their *division* or reduction into smaller parts by contusion and trituration, that by another washing with water they may be more perfectly cleansed from extraneous matters, and rendered fitter for the subsequent operations. 3. *Roasting*,

SMELTING.

ing, or calcination, the uses of which operation are to expel the volatile, useless, or noxious substances, as water, vitriolic acid, sulphur, and arsenic; to render the ore more friable and fitter for the subsequent confusion and fusion; and, lastly, to calcine and destroy the viler metals; for instance, the iron copper-ores, by means of the fire, and of the sulphur and arsenic. Stones, as quartz and flints, containing metallic veins or particles, are frequently made red-hot, and then extinguished in cold water, that they may be rendered sufficiently friable and pulverable, to allow the separation of the metallic particles.

Roasting is unnecessary for native metals; for some of the richer gold and silver-ores; for some lead-ores, the sulphur of which may be separated during the fusion; and for many calciform ores, as these do not generally contain any sulphur and arsenic.

In the roasting of ores, the following attentions must be given: 1. To reduce the mineral previously into small lumps, that the surface may be increased; but they must not be so small, nor placed so compactly, as to prevent the passage of the air and flame. 2. The larger pieces must be placed at the bottom of the pile, where the greatest heat is. 3. The heat must be gradually applied, that the sulphur may not be melted, which would greatly retard its expulsion; and that the spars, fluors, and stones, intermixed with the ore, may not crack, fly, and be dispersed. 4. The ores not thoroughly roasted by one operation must be exposed to a second. 5. The fire may be increased towards the end, that the noxious matters more strongly adhering may be expelled. 6. Fuel which yields much flame, as wood and fossil coals free from sulphur, is said to be preferable to charcoal or coaks. Sometimes cold water is thrown on the calcined ore at the end of the operation, while the ore is yet hot, to render it more friable.

No general rule can be given concerning the duration or degree of the fire, these being very various according to the difference of the ores. A roasting during a few hours or days is sufficient for many ores; while some, such as the ore of Rammelsberg, require that it should be continued during several months.

Schlutter enumerates five methods of roasting ores. 1. By constructing a pile of ores and fuel placed in alternate strata, in the open air, without any furnace. 2. By confining such a pile within walls, but without a roof. 3. By placing the pile under a roof, without lateral walls. 4. By placing the pile in a furnace consisting of walls and a roof. 5. By roasting the ore in a reverberatory furnace, in which it must be continually stirred with an iron rod.

Several kinds of *fusions of ores* may be distinguished. 1. When a sulphureous ore is mixed with much earthy matter, from which it cannot be easily separated, by mechanical operations, it is frequently melted, in order to disengage it from these earthy matters, and to concentrate its metallic contents. By this fusion, some of the sulphur is dissipated, and the ore is reduced to a state intermediate betwixt that of ore and of metal. It is then called a *mat* (*lapis sulphureo-metallicus*), and is to be afterwards treated like a pure ore by the second kind of fusion, which is properly the smelting, or extraction of metal by fusion. 2. By this fusion or smelting, the metal is extracted from the ore previously prepared by the above operations, if these be necessary.

The ores of some very fusible metals, as of bismuth, may be smelted by applying a heat sufficient only to melt the metals, which are thereby separated from the adhering extraneous matters. This separation of metals by fusion, without the vitrification of extraneous matters, may be

called *eliquation*. Generally, a complete fusion of the ore and vitrification of the earthy matters are necessary for the perfect separation of the contained metals. By this method, metals are obtained from their ores, sometimes pure, and sometimes mixed with other metallic substances, from which they must be afterwards separated. To procure this separation of metals from ores, these must be so thinly liquefied, that the small metallic particles may disengage themselves from the scoria; but it must not be so thin as to allow the metal to precipitate before it be perfectly disengaged from any adhering extraneous matter, or to pervade and destroy the containing vessels and furnace. Some ores are sufficiently fusible; but others require certain additions, called *fluxes*, to promote their fusion, and the vitrification of their unmetallic parts; and also to render the scoria sufficiently thin to allow of the separation of the metallic particles.

Different fluxes are suitable to different ores, according to the quality of the ore, and of the matrix, or stone adherent to it.

The matrixes of two different ores of the same metal frequently serve as fluxes to each other; as, for instance, an argillaceous matrix with one that is calcareous; these two earths being disposed to vitrification when mixed, though each of them is singly infusible. For this reason, two or more different ores to be smelted are frequently mixed together.

The ores also of different metals require different fluxes. Thus, calcareous earth is found to be best suited to iron ores, and spars and scoria to fusible ores of copper.

The fluxes most frequently employed in the smelting of ores, are calcareous earth, fluors or vitreous spars, quartz, and sand, fusible stones, as slates, basaltes, the several kinds of scoria, and pyrites.

Calcareous earth is used to facilitate the fusion of ores of iron, and of some of the poorer ores of copper, and, in general, of ores mixed with argillaceous earths, or with spar. This earth has been sometimes added with a view of separating the sulphur, to which it very readily unites: but by this union, the sulphur is detained, and a hepar is formed, which readily dissolves iron and other metals, and so firmly adheres to them, that they cannot be separated without more difficulty than they could from the original ore. This addition is therefore not to be made till the sulphur be previously well expelled.

Fluors, or fusible spars, facilitate the fusion of most metallic minerals, and also of calcareous and argillaceous earths, of steatites, asbestos, and of some other infusible stones, but not of siliceous earths without a mixture of calcareous earth.

Quartz is sometimes added in the fusion of ferruginous copper ores, the use of which is said chiefly to be, to enable the ore to receive greater heat, and to give a more perfect vitrification to the ferruginous scoria.

The fusible stones, or slates, basaltes, are so tenacious and thick when fused, that they cannot be considered properly as fluxes, but as matters added to lessen the too great liquidity of some very fusible minerals.

The scoria obtained in the fusion of an ore is frequently useful to facilitate the fusion of an ore of the same metal, and sometimes even of the ores of other metals.

Sulphurated pyrites greatly promotes the fusibility of the scoria of metals, from the sulphur it contains. It is chiefly added to difficultly fusible copper ores, to form the sulphureous compounds called *matts*, that the ores thus brought into fusion, may be separated from the adhering earthy matters, and that the ferruginous matter contained in them may

be destroyed, during the subsequent calcination and fusion, by means of the sulphur.

As in the ores called *calciform*, the metallic matter exists in a calcined state; and as calcination reduces the metals of mineralised ores (excepting the perfect metals) to that state also; therefore all calciform and calcined ores require the addition of some *inflammable substance* to reduce them to a metallic state. In great works, the charcoal or other fuel used to maintain the fire, produces also this effect.

Metals are sometimes added in the fusion of ores of other more valuable metals, to absorb from these sulphur and arsenic. Thus, iron is added to sulphurated cupreous and silver ores. Metals are also added in the fusion of ores of other more valuable metals, to unite with and collect the small particles of these dispersed through much earthy matter, and thus to assist their precipitation. With these intentions, lead is frequently added to ores and minerals containing gold, silver, and copper.

Ores of metals are also sometimes added to assist the precipitation of more valuable metals. Thus, antimony is frequently added to assist the precipitation of gold intermixed with other metallic matters. Macquer's Chem. Dict. Eng. edit. art. *Smelting*, note m. See COPPER, GOLD, IRON, LEAD, SILVER, TIN, &c. See also Schlutter's Treatise on the Smelting of Ores, translated from the German into French by M. Hellot, and Chem. Dict. art. *Smelting*, Eng. ed. notes n, o, p, q.

The following simple method of smelting is practised by the natives of the province of Mekran in Persia; which, although it may, at times, leave a trifling portion of the earth mixed with the metal, is, from its ingenuity, worthy of notice. When a sufficient quantity of the ore is collected, it is placed upon a pile of wood, which is set on fire, and constantly replenished with fresh fuel, until the ore melts and falls to the bottom, when it is separated from the ashes, and found to be considerably clearer than when first taken from the mine. It is then placed in a pit, made of earthen tiles, so constructed as to admit a fire under it. The ore is again melted in this pit, and a considerable quantity of the dross and dirt removed, by skimming the surface. After this process, the metal is lifted out in a liquid state, poured into hollow cylinders of clay, and then sold.

SMELTING-HOUSE, a house where they run and melt the ore into lead: one of these will run a ton in ten or twelve hours; but a fodder is their usual day's work, that is, twenty-two hundred and an half weight.

SMELTZ, in *Geography*, a river of Prussian Lithuania, which runs into the Curish Haff, two miles S. of Memel.

SMENUS, in *Ancient Geography*, a river of the Peloponnesus, in Laconia. It had its source in mount Taigetis, and its mouth on the left of a very elevated promontory, upon which was a temple of Diana Dictymna, according to Pausanias.

SMERWICK, in *Geography*, a small town of the county of Kerry, Ireland, situated on a bay to which it gives name; 7 miles N.W. from Dingle, and 173 S.W. by W. from Dublin.

SMEW, in *Ornithology*, the English name of the common mergus, known among authors by the names of *albellus*, and *mergus cirratus*.

SMICH, in *Geography*, a river that runs into the Danube, 3 miles W. of Sigmaringen.

SMIDARY, a town of Bohemia, in the circle of Koniggratz; 3 miles N. of Biezow.

SMIHANJE, a town of Croatia; 40 miles E. of Bihacs.

SMILA, in *Ancient Geography*, a town of Greece, in

the country of Crofæa, on the confines of Thrace and Macedonia.

SMILACINA, in *Botany*, a name which, with all our respect for its excellent author, professor Desfontaines, we cannot admit, as being fabricated from another existing generic name, *Smilax*, and therefore contrary to sound Linnæan laws, and to right reason. The establishment indeed of the genus itself, which is separated from *Convallaria* merely on account of the deep divisions of the corolla, revives an old question, long ago set at rest, as we presume, by Linnæus. It would be more desirable to discover a character by which the Linnæan *Convallaria*, including the *Polygonatum* and *Smilacina* of other authors, could be clearly distinguished from one or two of its neighbours. See *CONVALLARIA*, the third section of which comprises the *Smilacina* of Desfontaines, Ann. du Mus. d'Hist. Nat. v. 9. 51. Pursh North Amer. v. 1. 232. The essential character is thus given by the author last cited.

Corolla inferior, in six deep spreading segments. Stamens diverging, inserted into the base of each segment. Berry globose, of three cells. Flowers terminal, panicled, or somewhat umbellate.

SMILAU, in *Geography*, a town of Bohemia, in the circle of Czastau; 5 miles N. of Polna.

SMILAX, in *Botany*, *σμιλαξ* of the Greeks, a name originally belonging to the Yew, *Taxus*; but likewise applied by Dioscorides, with different epithets, to some other plants of a climbing nature. One of these he terms *τραχηια*, *rough*, and as the name of *Smilax* remains with this, among modern botanists, De Theis supposes the word to originate from *σμιλον*, a *scraper*. We cannot presume to offer any conjecture respecting its etymology or meaning. The *σμιλαξ* of Dioscorides, simply fo denominated, is stigmatized by him as a most dangerous poison; while his *σμιλαξ τραχηια* is celebrated as an antidote, so powerful, that if given to a new-born infant, he can never be poisoned as long as he lives!—Linn. Gen. 524. Schreb. 692. Willd. Sp. Pl. v. 4. 773. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 387. Sm. Prodr. Fl. Græc. Sibth. v. 2. 259. Pursh 249. Brown Prodr. Nov. Holl. v. 1. 293. Juss. 24. Lamareck Illustr. t. 817. Gærtn. t. 16. (Ripogonum; Forst. Gen. t. 25. Brown Prodr. Nov. Holl. v. 1. 293.)—Class and order, *Dioecia Hexandria*. Nat. Ord. *Sarmentacea*, Linn. *Asparagi*, Juss.

Gen. Ch. Male, *Cal.* Perianth widely bell-shaped, of six oblong leaves, approximated at the base, reflexed and spreading at the extremity. *Cor.* none, unless the calyx be taken for such, (which, from the analogy of *Asparagus*, *Convallaria*, &c. it surely ought to be.) *Stam.* Filaments six, simple; anthers oblong.

Female, *Cal.* as in the male, deciduous. *Cor.* none. *Pist.* Germen superior, ovate; styles three, minute; stigmas oblong, reflexed, downy. *Peric.* Berry globose, of three cells. *Seeds* solitary in each cell, globose, one or two of them generally abortive.

Ess. Ch. Male, Calyx of six leaves. Corolla none.

Female, Calyx of six leaves, inferior, deciduous. Corolla none. Styles three. Berry of three cells. Seeds one, two, or three.

Obs. Mr. Brown defines the calyx *permanens*; we find it, as Linnæus says, *deciduous*. *RIPOGONUM* (see that article) has the stamens and pistils in the same flower.

Of this ample genus, Linnæus in Sp. Pl. has only thirteen species; Willdenow has forty-one. To these, four North American ones are added by Pursh, and Mr. Brown has four from New Holland, exclusive of the second species of *Ripogonum*. They are all climbing perennial plants, with

with simple, alternate, ribbed, entire leaves, with or without tendrils; the stem mostly shrubby, smooth or prickly, round or angular; flowers generally umbellate. The following examples may suffice.

SECT. 1. *Stem prickly, angular.* Fourteen species in Willdenow.

S. aspera. Red-berried Rough Smilax. Linn. Sp. Pl. 1458. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 959, unpublished. Matth. Valgr. v. 2. 551. Ger. Em. 859. (*S. aspera, rutilo fructu*; Cluf. Hist. v. 1. 112.)—Stem angular, very prickly. Leaves oblong-heart-shaped, somewhat hastate, with seven or nine ribs, coriaceous, bordered with spinous teeth.—Native of hedges and thickets, throughout the south of Europe. Dr. Sibthorp found it abundantly in marshy and rough stony ground, in Greece and all the neighbouring islands, flowering late in autumn. The stems climb, by means of tendrils, like our Bryony, and hang in festoons from the tops of hedges. They are woody, perennial, branched, zig-zag, plentifully armed with strong, scattered, hooked prickles, as are likewise the *footstalks* and edges of the evergreen leaves. Flowers white, with a flesh-coloured tint extended to their stalks, in small umbellate tufts, disposed in terminal, zig-zag, smooth clusters. Berries of a dull scarlet red, the size of currants, umbilicated, with three seeds in each.—This is doubtless the *σμίλαξ τραχιὰ* of Dioscorides; the Lofty, or Woody, Bramble of the modern Greeks.

The figure in Plukenet's *Phytographia*, t. 110. f. 3, indicated as a variety, is hardly such, but exhibits nearly the usual form of the leaves; what has been generally taken for *S. aspera* being in fact the following species, whose leaves are always broader.

S. nigra. Black-berried Rough Smilax. Willd. n. 2. Prodr. Fl. Græc. n. 2313, unpublished. (*S. aspera* β; Linn. Sp. Pl. 1458. *S. aspera nigro fructu*; Cluf. Hist. v. 1. 113. *S. aspera lusitanica*; Ger. Em. 860.)—Stem angular, prickly. Leaves oblong-heart-shaped, seven-ribbed, coriaceous, smooth at the edges.—Native of hedges in Spain, Portugal, and the south of France. Dr. Sibthorp observed it about Prusa, in Bithynia. The stems are less prickly than in the former; the leaves broader, not at all dilated at the sides, nor contracted in the middle, so as to approach a hastate form; their edges very slightly, or not at all, prickly; and the berries are black.

S. excelsa. Tall Smilax. Linn. Sp. Pl. 1458. Willd. n. 5. Ait. n. 2. Prodr. Fl. Græc. n. 2314, unpublished. (*S. orientalis, farmentis aculeatis, excelsas arbores scandentibus, foliis non spinosis*; Tourn. Cor. 45. Buxb. Cent. 1. 18. t. 27.)—Stem angular, prickly. Leaves ovate, slightly heart-shaped, with five or seven ribs, and no marginal prickles.—Native of the country near Constantinople. Gathered by Dr. Sibthorp in woods at the village of Belgrad. Buxbaum says it is frequent in hedges about villages in Thrace, as well as in Pontus and Cappadocia, and that it is very useful for fences and shade. The flowers are yellowish-green; the berries red.

Whether *S. aspera*, Alpin. Egypt. 141, cited with doubt by Linnæus, be this plant, is not clear to us. Willdenow thinks it a distinct species, not yet described by systematic writers.

S. Sarsaparilla. Medicinal Smilax, or Sarsaparilla. Linn. Sp. 1459. Willd. n. 9. Ait. n. 4. Pursh n. 5. Woodv. Med. Bot. t. 194. (*S. peruviana, Salsaparilla*; Ger. Em. 859.)—Stem prickly, somewhat quadrangular. Leaves elliptical, pointed, abrupt, three-ribbed; without prickles; slightly glaucous beneath. Common flower-stalk longer than the footstalk.—Common in the hedges and swamps

of North America, flowering in June and July. Pursh. The stem is stout, a little zig-zag, roundish, with about four slight unequal angles, and a few scattered hooked prickles. Full-grown leaves nearly orbicular, two and a half inches broad, abrupt or contracted at each extremity, with a short terminal point; their surface finely reticulated with veins, and marked with three strong ribs, the lateral ribs described by Willdenow hardly deserving to be so denominated. Footstalks short, broad, channelled, each crowned with two tendrils, subsequently deciduous. Flowers yellowish-white, in axillary, solitary, stalked umbels. Berries red, according to Woodville, whose figure, the only one extant, has not been noticed, his work being never quoted by Mr. Aiton, though it surely ranks high as an useful medical book, and the plates, by Mr. Sowerby, are, as far as possible, original. It is much to be wished that what are merely done from dried specimens, or from other authors, had been every where so acknowledged, by which the authority of the publication would have been unimpeachable, and on a par with any whatever. For the history, and medical qualities, of the root, see Sarsaparilla.

S. melastomifolia. Rough-ribbed Smilax.—Stem with many angles, densely and minutely prickly; as well as the seven ribs of the ovate, pointed, slightly heart-shaped, rough-edged leaves.—Gathered by Mr. Menzies, in the Sandwich islands. A fine new species, whose branches are zig-zag, nearly round, with numerous angles, all copiously beset with minute, straight, rigid prickles. Leaves three inches long, and near one and a half broad, with five principal ribs, and a pair of slender, wavy marginal ones. These all bear underneath copious prickles, like those of the branches and footstalks, ranged in several rows on the larger ribs. The reticulated veins are also rough with prickles, so that the leaf altogether resembles that of some species of *Melastoma*. Umbels axillary, stalked, one or more from each leaf, accompanied by large concave, sheathing bracts.

SECT. 2. *Stem prickly, round.* Nine species in Willdenow.

S. australis. Strong-veined New Holland Smilax. Br. n. 1.—Stem round, with copious prickles. Leaves ovate-oblong, acute, five-ribbed, smooth, without prickles. Tendrils in pairs on the footstalks.—Gathered by Mr. Brown, near Port Jackson, New South Wales. We received from Kew garden, in 1798, a specimen in flower of what we presume to be this species. It is distinguished by the copious, strong, straight prickles, of its round, slightly striated, zig-zag branches. The leaves are rigid and coriaceous, smooth, with five ribs, and innumerable prominent reticulated veins; their base somewhat heart-shaped; the footstalks short, broad, channelled, bearing from the middle two long spiral tendrils. Flowers white, numerous, in axillary umbels, whose stalks rather exceed the footstalks.

S. China. Chinese Smilax, or China-root. Linn. Sp. Pl. 1459. Willd. n. 15. Ait. n. 5. Woodv. Med. Bot. t. 236. (*Sankira, vulgò Quaquara*; Smilax minus spinosa, fructu rubicundo, radice virtuosa, China dicta; Kæmpf. Amoen. 781. t. 782. Frutex convolvulaceus spinosus sinicus, &c.; Pluk. Amalth. 101. t. 408. f. 1. China vulgaris officinarum; Ger. Em. 1618.)—Stem roundish, with scattered prickles. Leaves roundish-ovate, acute at each end, with three principal ribs.—Native of China and Japan; said to have been cultivated by Miller, in 1759. The stem is strongly zig-zag. Leaves one and a half or two inches long, and nearly as broad, smooth, with three straight principal ribs, and two wavy, more slight, lateral ones. Footstalks bearing two, or more, long twisted tendrils. Flowers, according to Kæmpfer, greenish-yellow, in umbels,

on slender, solitary, axillary stalks, longer than the footstalks. *Berries* the size of black currants, scarlet, mealy, austere like a medlar, said to contain four, five, or six seeds, a greater number than usual in this genus. We strongly suspect that more than one species is confounded under the history of this species. The Linnæan Chinese specimens have more heart-shaped leaves than any of the figures exhibit, nor is their stem prickly. Very possibly, however, these do not belong to the officinal China-root.

This root was brought into Europe, towards the middle of the 16th century, with strong recommendations of its virtues, as a cure for the venereal disease, as well as for various chronic, cutaneous, or rheumatic disorders. These are neither confirmed by experience, nor rendered probable by the sensible qualities of the root itself, which is farinaceous and nearly insipid.

S. caduca. Deciduous Smilax. Linn. Sp. Pl. 1460. Willd. n. 22. Ait. n. 9. Pursh n. 12.—Stem round, with distant straight prickles; branches angular. Leaves ovate, pointed, five-ribbed. Common flower-stalks hardly longer than the footstalks. Tendrils capillary, much shorter than the leaves.—In dry fields, from Canada to Virginia, flowering in June. *Pursh*. The stem is rather stout, quite round when full-grown, but the branches are decidedly angular, and strongly zig-zag. Prickles distant, stout, tipped with black. Leaves broadly ovate, or slightly heart-shaped, smooth, green on both sides, very finely veined, their lateral ribs often obsolete. Tendrils very small and slender, from the middle of each footstalk. Flowers few, greenish, in solitary umbels.

S. spinulosa. Bristly Smilax.—Stem round, with crowded, capillary, curved prickles; branches somewhat angular. Leaves ovate-oblong, pointed, five-ribbed; glaucous beneath. Tendrils capillary.—Sent from Pennsylvania, by the late Rev. Dr. Muhlenberg, who thought it had been improperly confounded with *S. caduca*. The quantity of fine setaceous prickles, on the stem or branches, seems to be variable; but the more oblong leaves, opaque and glaucous beneath, are very different from the last. We cannot refer this to any of Mr. Pursh's species.

SECT. 3. *Stem without prickles, angular*. Seven species in Willdenow.

S. latifolia. Broad-leaved Smilax. Br. n. 4. Ait. n. 11.—“Stem angular, without prickles. Leaves ovate, five-ribbed, smooth; somewhat heart-shaped or obtuse at the base. Footstalks bearing the tendrils.”—Gathered by Mr. Brown in the tropical part of New Holland. Sent to Kew, in 1791, by Sir Joseph Banks. It is there treated as a greenhouse plant, but has not yet flowered.

S. herbacea. Herbaceous Smilax. Linn. Sp. Pl. 1460. Willd. n. 27. Ait. n. 12. Pursh n. 16. (*S. claviculata hederifolia* tota lævis, e terrâ Marianâ; Pluk. Phyt. t. 225. f. 3, marked 4.)—Stem herbaceous, angular, simple, erect. Leaves oval, seven-ribbed. Tendrils from the base of the long footstalks. Common flower-stalks very long, compressed.—In dry fields, on the edges of woods, from New York to Carolina, flowering in June and July. *Pursh*. The root is perennial. Stems annual, brownish-purple, smooth, with a pair of revolute tendrils to each leaf. Umbels globose, of numerous flowers, on axillary stalks, near six inches long. Berries dark purple, depressed.—Plukenet's figure, if rightly quoted, is a very bad one, the leaves being not sufficiently elliptical, and the footstalks much too short.

SECT. 14. *Stem without prickles, round*. Eleven species in Willdenow.

S. elliptica. Elliptical Smilax. Br. n. 3.—“Stem without prickles; branches round, striated. Leaves elliptic-
Vol. XXXIII.

ovate, somewhat pointed, five-ribbed, smooth; rather acute at the base. Footstalks bearing the tendrils.”—Gathered by Mr. Brown in the tropical part of New Holland.

S. glycyphylla. Sweet-leaved Smilax. Smith in White's Voyage, 230. t. 24. f. A, B. Br. n. 2.—Stem round, without prickles. Leaves ovate-oblong, acute, three-ribbed, smooth, somewhat revolute; glaucous beneath. Footstalks bearing the tendrils.—Sent from the neighbourhood of Port Jackson, New South Wales, among the first communications from thence. The leaves, having a very sweet taste, like liquorice-root, accompanied with some bitterness, were used by the first settlers in that country, to make a sort of tea, which was thought good for the scurvy. The stem is wiry, smooth, and slender. Leaves about two or three inches long, reticulated, coriaceous; broad and rounded at the base, on shortish curved footstalks. Flowers in axillary, stalked umbels.

S. Pseudo-china. Bastard Virginian China-root. Linn. Sp. Pl. 1461. Willd. n. 38. Ait. n. 15. Pursh n. 10, excluding Sloane's synonym. (*S. virginiana, spinis innocuis armata, latis canellæ foliis, radice arundinacæ crassâ et carnosâ*; Pluk. Phyt. t. 110. f. 5. *China spuria nodosa*; Bauh. Pin. 297. *Pseudo-china radix ex Virginia*; Clus. Exot. 83.)—Stem round, without prickles. Leaves ovate, pointed, five-ribbed. Tendrils from the base of the footstalks. Common flower-stalks longer than the leaves.—In sandy fields and dry woods, from New Jersey to Carolina, flowering in May and June. A shrub. The roots very large, searched after by hogs. *Pursh*. The stem is of a purplish-brown, very smooth. Branches long, slender, leafy, climbing by means of slender, not very long, tendrils, springing in pairs from the very base of the angular footstalks. Leaves two inches, or 2½, in length, an inch or more in breadth, slightly heart-shaped at the base, undulated or crisped, but hardly crenate, at the margin, reticulated with veins, which, as well as the ribs, are sometimes rough with minute prickles beneath. Flower-stalks axillary, umbellate, longer than the leaves.—The root of this species is said to have been brought from Virginia for the true China-root, of which we have spoken under the second section. They seem to agree in their farinaceous or starch-like substance, which, it seems, is common to the roots of various other plants of this genus. Sloane describes one under the name of *S. aspera, fructu nigro, radice nodosâ, magnâ, levi, farinacæ, China dictâ*; Sloane Jam. v. 1. 231. t. 143. f. 1. This, he says, has a root as thick as a man's leg, crooked and swelling, with a thin red-brown skin, and a friable light red internal substance, giving a reddish tincture to water. Its qualities are like the real China-root, in the place of which Sloane recommends its use, at least in the West Indies. Linnæus cites this synonym under his *S. Pseudo-china*, with which it has little connection; and he refers also to the *S. aspera, foliis trinerviis oblongis, petiolis biclaviculatis*, Browne's Jamaica, 359, a specimen of which is attached, in the Linnæan herbarium, to the real *S. Pseudo-china*. The leaves of this are elliptical. Common flower-stalks extremely short. Tendrils from the middle of each footstalk. Stem angular; said to be prickly in the lower part. By these latter characters this plant of Browne should belong to the first section; while Sloane's, described with a round and very prickly stem, must be referred to the second. Moreover, Browne's is described with slender branching roots, and we must presume that his *Smilax*, n. 1, is rather Sloane's plant, as Mr. Lunan, in his Hortus Jamaicensis, v. 1. 180, makes it. We do not choose to run the risk of determining these several species, without authentic specimens, more especially as Dr. Swartz has left them untouched. Two more of this tribe are represented in
A 2 Plumier's

Plumier's *Icones*, t. 82 and 84, which cannot be referred to any of the before-mentioned. The latter, indeed, is thus adopted by Willdenow.

S. macrophylla. Large-leaved Smilax. Willd. n. 39.—(China altera, non aculeata, foliis amplioribus; Plum. Ic. 73. t. 84.)—Stem round, without prickles.—Leaves ovate, obtuse, somewhat heart-shaped, seven-ribbed. Tendrils from the middle of the short footstalks.—Native of the West Indies. The leaves nearly agree in size and shape, as well as the footstalks, with *Passiflora alata*. The umbels are axillary, solitary, on stalks twice the length of the footstalks.

SMILAX, in *Gardening*, contains plants of the shrubby, climbing, evergreen kinds, of which the species cultivated are, the rough smilax (*S. aspera*); the tall smilax (*S. excelsa*); the medicinal smilax, or farfaparilla (*S. farfaparilla*); the bay-leaved smilax (*S. laurifolia*); the black bryony-leaved smilax (*S. tamnoides*); the herbaceous smilax (*S. herbacea*); the Chinese smilax (*S. china*); and the bastard Chinese smilax (*S. pseudo-china*.)

In the first sort there is a variety which has the leaves eared at the base.

Method of Culture.—The six first hardy sorts may be increased by slipping the roots, layers, and seed. In the first mode, the stalks arising from the roots should be slipped with roots to each in the autumn, and be planted out either in nursery-rows for a year or two, or, which is better, where they are to grow. In the layer method, the stalks should be laid down in the common manner in autumn, and when well rooted, in the autumn following be taken off and planted out as above. The seed should be obtained from abroad, and be sown in pots filled with fine mould in the spring, being plunged in a hot-bed to forward their coming up; when the plants have attained some growth they should be planted out and managed as the others.

The two last tender sorts may be increased by layers of the young shoots, and dividing the roots, which should be laid down, or planted out in the spring season, in order to have the culture of other woody greenhouse plants of the same nature. The layers will be ready to take off in the spring following.

The first sorts are proper for shady situations, borders, &c. and the latter afford variety in the greenhouse collections, among others of similar growths.

SMILE', in *Surgery*, a lancet.

SMINTHEAN, SMINTHEUS, *σμιθεύς*, in *Antiquity*, an epithet given to Apollo; from the Greek *σμιθῆ*, a rat. There are two different accounts of the origin of this appellation: the first is, that, in the city of Chrysa in Mysia, was a priest of Apollo, called *Crinis*, with whom that god being offended, sent a herd of rats to spoil all his lands; but *Crinis* appeasing the deity, he came in person to his assistance, took up his lodgings with *Crinis's* shepherd, told him who he was, and destroyed all the rats with his arrows; in memory of which *Crinis* built a temple to his deliverer, under the name of *Apollo Smintheus*.

Strabo (l. 13.) says, that in Chrysa was to be seen a statue of Apollo by the hand of Scopas, the celebrated statuary of Paros, with the figure of a rat near his feet; and Heraclides of Pontus asserts, that the rats about that temple were sacred.

Clemens Alexandrinus, in his exhortation to the Greeks, gives us a different story. The Cretans, says he, intending to send out a colony, consulted the oracle of Apollo as to the place: the answer was, that they should fix their colony where those born of the earth should oppose them. Upon their arrival in the Hellespont, the rats, in the night-time, gnawed asunder all the strings of their bows: this

they deemed an accomplishment of the oracle, and there built a city called *Smintha*.

SMINTO, SMINTHIUM, in *Ancient Geography*, a town of Asia Minor, in the Troade, or, as Strabo says, in the territory of Adramyttium. But its true name was *Chrysa*. (See SMINTHEAN.) M. d'Anville has placed Sminthium at a small distance S. of Tros, or Troy: according to Homer, this town was in an island. It gave name to a neighbouring mountain, called "Sminthium Nemus." Steph. Byz.

SMIRIS, in *Natural History*. See EMERY.

SMIRSITZ, in *Geography*, a town of Bohemia, in the circle of Konigingratz; 6 miles N.E. of Konigingratz. N. lat. 50° 14'. E. long. 15° 42'.

SMITH, ADAM, in *Biography*, a distinguished writer in moral and political philosophy, was born in the year 1723, at Kirkaldy, in Fifeshire, where his father held the comptroller-ship of the customs. He received his early education under the care of his mother, then a widow, at the school of Kirkaldy, where he was noticed for an extraordinary passion for reading. At the age of fourteen he was removed to the university of Glasgow, in which he spent three years, attending, among the other lectures, those of the celebrated professor Hutcheson. In 1740 he was sent as a pensioner to Balliol college, Oxford. Here he spent seven years, and it is thought that during this period he employed himself chiefly in acquiring an exact knowledge of the languages, ancient and modern, and in cultivating an English style, by the practice of translating works of high reputation into his own language. Upon quitting the university he abandoned all thoughts of entering into the English church, for which purpose he had been sent thither, and went to Edinburgh, and found a friend and patron in lord Kaimes. In 1751 he was elected professor of logic at Glasgow, from which he was removed, in the following year, to that of moral philosophy. He now felt that he was in a situation accommodated to his talents and disposition, and in later life he was accustomed to speak of his residence and employment at Glasgow as the most useful and happiest portion of his life. His lectures, both logical and moral, were extremely popular; and his manner of delivering them, if not graceful, was said to be highly impressive. In those on moral philosophy were contained the rudiments of his two most celebrated works as an author. Of these, the first is entitled "The Theory of Moral Sentiments," and appeared in the year 1759. The fundamental principle is sympathy, which the author makes the source of our feelings concerning the propriety or impropriety of actions, and their good or ill desert. To this work he afterwards subjoined "A Dissertation on the Origin of Languages." These works were extremely well received, and gave him a place among the best writers of the time. They also made him known to several eminent characters; and it was in consequence of the reputation thus acquired, that he was engaged to accompany the duke of Buccleugh in his travels. He of course resigned his office as professor, and in the beginning of the year 1764, he set out for the continent. He had now an opportunity of comparing the ideas which he had already formed respecting political economy, with those of the ablest men in foreign countries, and also with facts that presented themselves to his observation in the course of his travels. A long residence in France introduced him to the acquaintance of Turgot, Quesnai, Necker, D'Alembert, Helvetius, Marmontel, and others, to whose particular notice he was recommended by his countryman David Hume, with whom he had long been in habits of friendship. He returned to his own country in the autumn of 1766, and the following ten years he passed in retirement with his mother at the obscure town of Kirkaldy. Here he

was habitually employed in reading, the fruits of which were at length given to the world in his celebrated "Inquiry into the Nature and Causes of the Wealth of Nations." This work has long been a standard work, not only in our own country, but throughout Europe. It has been studied and referred to by all who pay attention to the important political topics on which it treats. After the publication of this "Inquiry," he spent a great part of two years in London, where his society was courted by persons of the highest rank in the philosophical and literary world. In the year 1778 he obtained, through the interest of the duke of Buccleugh, the lucrative place of a commissioner of the customs of Scotland, in consequence of which he removed to Edinburgh, which was thenceforth the place of his residence. His mother, who lived to a great age, spent her last days with him here. After the death of his friend, Mr. Hume, he published that philosopher's memoirs of his own life, with some additions, in which he expressed himself so favourably with regard to the character and opinions of the deceased, that it was readily inferred his own sentiments with respect to revealed religion could not be very different from those of his friend, which drew upon him an attack in an anonymous letter, since known to have been from the pen of the late Dr. Horne, afterwards bishop of Norwich. In 1787 he was appointed rector of the university of Glasgow, and in 1790 he died, at the age of sixty-seven. A few days before his death he caused all his papers to be burnt, except a few Essays, which have since been published.

Dr. Smith was a man of great simplicity of character, subject to absence of mind in society, and fitter for speculative than active life. He was much beloved by his friends, and possessed a calm and benignant disposition. Of the originality and comprehensiveness of his views, the extent, variety, and the correctness of his information, and the inexhaustible fertility of his invention, he has left lasting monuments behind him. To his private worth, the most certain of all testimonies may be found in that confidence, respect, and attachment, which followed him through all the various relations of life. When perfectly at ease, and when warmed with conversation, his gestures were animated and not ungraceful; and in the society of those whom he loved, his features were often brightened by a smile of inexpressible benignity.

SMITH, EDWARD, one of the minor English poets, born in 1668, near Tenbury, Worcestershire, was the son of Mr. Neale, a merchant, by the daughter of lord Lechmere. The connection of his parents was dubious, or at least unavowed; for after his father's death, being left to the care of Mr. Smith, who had married his paternal aunt, he assumed his guardian's name, by which he was ever afterwards known. He was indeed, when grown to mature years, acknowledged by his mother as her legitimate son, but he derived no advantage from this declaration. He was educated at Westminster school, under Dr. Busby, who is said to have formed a high opinion of his talents, and, in consequence of this opinion, to have detained him longer than the usual time under his tuition. From Westminster he was elected to Trinity college, Cambridge, but having at the same time an invitation from Christchurch college, Oxford, he preferred the latter, and became a student of that college. Here he distinguished himself by Latin verses, written on some public occasions; and a Latin ode, which he composed in 1691, on the death of Dr. Pococke, the learned Orientalist, obtained for him much celebrity for a poetical imagination. In 1705 he was expelled from his college, on account of his intemperance and licentious conduct. He had, however, previously to this, taken his degree of M.A. He now went to

London, where his wit and convivial powers caused him to be much cared for by persons of eminence, especially of the Whig party; though neither his manners, nor his external appearance, rendered him adapted to good society. In 1708 he published a "Poem to the Memory of Mr. John Phillips," which is said to be the only one of his miscellaneous pieces that merits notice. It has been much admired, because it partakes more of satire than elegy. In the following year he produced his tragedy of Phædra and Hippolitus, which was not very well received. Addison, however, wrote the prologue, and Prior the epilogue; the principal actors took parts in it, and it was patronised by men of high rank, yet it was scarcely heard to the third night. "It has," says the critic, "more poetical than dramatic merit, and is greatly inferior, in point of delicacy, pathos, and conduct, to Racine's tragedy on the same subject." Mr. Smith died in the forty-second year of his age, and his early death was imputed, probably with great justice, to his intemperate habits. He had attained much harmony of versification as a poet, and possessed a certain luxuriance of fancy, but he gives no indication of a higher genius; and did very little for the interests of literature. He was lifted to temporary fame by the efforts of academic partiality, but has now sunk to the level of many who are well nigh forgotten. Johnson's Lives of the Poets.

SMITH, Sir THOMAS, an eminent scholar and statesman of the 15th century, was born at Saffron-Walden, in Essex, in 1524. He was educated for, and sent early to, Queen's college, Cambridge, and by his proficiency in learning obtained a pension as king's scholar. Being chosen fellow of his college, he was appointed, in 1535, to read the public Greek lecture, on which occasion he concurred with Cheke in introducing an improved mode of pronouncing that language. In 1539 he travelled to the continent, for the superior advantages offered by the foreign universities, and at Padua he studied the civil law, in which faculty he graduated. On his return he resumed his residence at Cambridge, where, in 1542, he was admitted to the degree of doctor, and was nominated king's professor in civil law. He pursued with great ardour his scheme of reforming the pronunciation of the Greek, and he likewise attended to the improvement of his native tongue, and published a work concerning its correct orthography and pronunciation. He was a promoter of the principles of the reformation in religion, and did his utmost to shelter those reformers who were exposed to the persecution of the tyrant Henry VIII. He had himself taken orders, possessed a rectory, and also the deanery of Carlisle. On the accession of the virtuous Edward VI., he was taken into favour by the protector Somerset, and raised to several lucrative posts, and in 1548 he was knighted, and appointed secretary of state. On the disgrace of the protector he was deprived of the secretaryship, but was soon replaced in it, and continued during the remainder of the reign in trust and honour. When Mary succeeded to the throne he lost all his offices, and was forbidden to quit the kingdom; but by his caution and prudence he was enabled to flee in safety through the stormy and perilous period. As soon as Elizabeth became queen he was invited to court, and reinstated in the deanery of Carlisle, and employed in various public concerns, particularly in the revision of the Liturgy. He was sent on various embassies to the court of France, and during one of his residences in that country he composed his work "On the Commonwealth of England." Owing to some disappointment he retired to the country, where he spent three years, exercising the duties of a magistrate, and distinguishing himself by his severity against supposed witches. In 1571 he returned to

court, was nominated a privy counsellor, and made assistant to lord Burghley, in his office of secretary of state. In 1572 he was employed to negotiate an alliance with France, and after his return he succeeded lord Burghley, who was advanced to the post of treasurer. He died in 1577, at the age of 63. Sir Thomas Smith is characterised by his eulogist, as "a master of various languages, ancient and modern, and as extremely well versed in several sciences. He was pious, upright, and benevolent, and seems to have been perfectly free from the duplicity and craft which were too frequent in the statesmen of that age." He is chiefly known as a writer by the "Commonwealth of England," already referred to. Several of his letters have been printed in different collections, and four of his orations, on queen Elizabeth's projected marriage, are annexed to his Life by Strype. *Biog. Brit.*

SMITH, THOMAS, a learned writer, was born at London in 1638. He was admitted of Queen's college, Oxford, in 1657, and after taking his degree in arts, was chosen, in 1663, master of the free-school adjoining to Magdalen college. He became fellow of that college in 1666, and was distinguished for his great knowledge in the Oriental languages. He accompanied the English ambassador to Constantinople in 1668, and afterwards lived several years as chaplain with sir Joseph Williamson, secretary of state. He quitted him without any preferment, and was earnestly solicited by several eminent clergymen, his particular friends, who knew his value, to return to the Levant, in order to collect MSS.; but knowing the danger attending such a business, he put a negative on their proposal. He had already made himself known to the learned world by a Latin dissertation on the Chaldee paraphrases, and their versions, another on the Druids, and several sermons on doctrinal points. He had also published some Latin epistles concerning the manners and institutions of the Turks, and the seven churches of Asia; of which he afterwards printed an English translation; and in 1680 he published an account of the Greek church. To these works, relative to what he had observed in the East, may be added some papers communicated by him to the Philosophical Transactions, and others contained in a collection of tracts, entitled "Miscellanea." In 1683 he took his degree of D.D., and was presented to a college-living, which he soon resigned, and continued to reside on his fellowship. When James II., in 1687, sent a mandate to Magdalen college for the admission of a popish fellow, Dr. Smith was one of the few persons who petitioned against the measure, but he was far from steady in his opposition; and when the king signified his determination to be obeyed, Dr. Smith was one of the two fellows who submitted, and in consequence preserved their fellowships, while the others had the honour of being expelled. The doctor, however, did not go far enough to please his sovereign, and was eventually expelled from his office. The succeeding troubles produced his restoration: but in 1692, refusing to take the oaths required by the government of William and Mary, he lost his fellowship and living with which he had been presented. He thenceforth resided chiefly in the family of sir John Cotton, occupied in his studies, and in the composition of a variety of works. Of these, the greater part was of the antiquarian and biographical class. In the latter, his principal publication was entitled "Vitæ quorundam eruditissimorum et illustrium Virorum," containing the lives of archbishop Usher and several other eminent characters. Dr. Smith died in 1710: he is characterised by his biographer as a man of great industry and learning, but he displayed in his writings much party bigotry and illibe-

rality. His Latin style is neither clear nor simple. *Biog. Brit.*

SMITH, CHARLOTTE, daughter of Nicholas Turner, esq. a gentleman of considerable property in the counties of Surry and Suffex, when very young married Mr. Smith, the son of a West India merchant. This match was not the effect of attachment on either side, and was productive of much misery, of which a long account is given in the Monthly Magazine, vol. xxiii. p. 244. The affairs of Mr. Smith not proving prosperous, she, after various persecutions from creditors, and after passing some time in the gloom of a prison with her husband, retired to a convent in Normandy. Here she was reduced to the utmost indigence, yet the exertion of her talents administered to her wants. She wrote several novels, which gained her a comfortable subsistence. She died, after various changes and misfortunes of life, at Thetford, near Farnham, Surry, in the year 1806. Her principal novels are as follow: "The Romance of Real Life;" "Emmeline;" "Ethelinda;" "Celestina;" "Desmond;" and "The Old Manor House." They display great powers of invention; and it is remarkable, that in them all she has contrived to interweave much of her own personal history, and painted in very strong colours the characters of certain rapacious persons, to whose dishonesty she ascribed all, or at least the greater part, of her sorrows. Mrs. Smith was also author of poems, sonnets, and two small volumes, entitled "Conversations introducing Poetry, chiefly on Subjects of Natural History, for the Use of young Persons." Her descriptions are interesting, and her style is elegant. Her sonnets possess great beauty, and all her writings every where display the powers of a fine imagination, correct taste, and strong judgment.

SMITH, GEORGE, a native of Chichester, born in 1714, was, in despite of circumstances in every respect unfavourable, a devotee to the art of painting, particularly in landscape; and by dint of determined perseverance succeeded in producing some works which do honour to his name. He was among the first who rescued the English name, in art, from the odium cast upon it by foreigners, and prepared the way for the brilliant efforts of Wilson. His idea of composition may be eliminated from the print, which Woollett engraved after the picture for which the Society in the Adelphi gave him their highest premium, and which presents a conception almost worthy of Claude: his colouring, indeed, did not keep pace with the design, and his touch was too minute and trifling. There are many prints of his other productions, some etched by himself, but the one we have mentioned is the finest. He died in 1766.

SMITH, ROBERT, LL.D. and D.D., was a contemporary to Barrow. After all our researches, we have not been able to collect any particulars relating to the place of his birth, which was probably in Lincolnshire, and the progress of his early years. It appears, however, that he was admitted A.B. in 1711, A.M. in 1715, LL.D. in 1723, and S.T.P. by royal mandate in 1739. He was first fellow, afterwards professor of astronomy and experimental philosophy, of which he was made Plumean professor in 1716, supplying the place of his cousin, the celebrated Cotes; and he succeeded Dr. Bentley, in 1742, in the mastership of Trinity college, in the university of Cambridge. He had been preceptor to William, duke of Cumberland, and was master of mechanics to the king. In the year 1722 he published, at Cambridge, Cotes's "Harmonia Mensurarum," with additions, in 4to.: in 1738 appeared his "Complete System of Optics, in four books, viz. a popular, a mathematical, a mechanical, and a philosophical treatise," &c. 2 vols.

4to.: in 1747 he published at Cambridge, in 8vo., a second edition of Cotes's "Hydrostatical and Pneumatical Lectures:" and in December 1748, he published his "Harmonics," of which a second edition, much augmented and improved, appeared in October 1758. The inscription over him is H. S. E. Robertus Smith, S. T. P. Hujus Collegii Magister, obiit Aug. 1768, ætatis 79.

Dr. Smith left two annual prizes of 2*l.* to two commencing bachelors of arts, who were to be the best proficient in mathematics and natural philosophy of the year. He also left 2000*l.* towards repairs of Trinity college, and 2500*l.* to the university.

Dr. Smith was a performer on the violoncello, and a curious inquirer into the defects of the musical scale on keyed instruments; which he tried to remedy by many ingenious experiments and calculations. He had a harpsichord made by Kirkman, with quarter-tones, as they are called, with only a single string to each note, by which means the instrument, not being crowded with two or three strings to each, by pedals could make any key perfect, as it allowed of two strings for each of the five short keys, differently tuned, to each note; as F♯ and G♭, G♯ and A♭, A♯ and B♭, &c. which rendered those keys delightful, and which, in the old tuning, were insufferable. But this perfect harmony only suited regular and sober modulation: the compositions of Haydn and Mozart, and their imitators, would want a new scale every two or three bars. Poor Claggett pursued this plan, and by means of multiplied strings and pedals had acquired perfect intonation to all the twenty-four keys. But by additional bridges, and the pressure of so many strings on the belly of the instrument, the tone was injured and enfeebled. This, alas! but confirms the two melancholy reflections, which tell us that "we cannot have every thing;" and that, "il faut souffrir dans ce monde."

The great mathematician, Dr. Smith, had so accustomed himself to perfect harmony, that he neither could bear the throwing of the imperfections of the scale on the *wolf*, or E♭, nor even on two or three short keys seldom used in old church music; but all the compound stops in the organ, such as the sesquialter and cornet, and the single stops of the twelve and the tierce in the chorus, he took out of the fine organ of Trinity college, Cambridge, built by father Smith, and reduced the whole chorus to unisons and octaves, which was thought by many to injure the instrument so much as to bereave it of all its spirit, and render it insipid. And after the decease of Dr. Smith we have been assured, that the excommunicated pipes have been again received into the bosom of the church.

Dr. Smith's "Harmonics," already mentioned, was professedly written to assist organ-builders and tuners to divide the redundancies of the scale equally, or nearly equally, among all the twelve semitones in the octave by a table of *beats*. To give the reader an idea of Dr. Smith's plan, we must refer him to the article BEATS, where this effect, produced by two organ-pipes nearly in tune, is explained. But Dr. Smith's treatise, so far from being intelligible to tuners of organs, and organ-players in general, requires a knowledge in geometry and fluxions, which none but great mathematicians able to read Newton's Principia possess. Yet the book is written in so pleasing and alluring a style, that many peruse as much as they are able of the unscientific part, and give the author credit for the accuracy of his calculations.

SMITH, JOHN CHRISTOPHER, a good musician, and a respectable man. He was the eldest son of the worthy John Christopher Schmidt, Handel's copyist, steward, and confidential countryman, who came over with him from

Germany, and lived an inmate with him to nearly the time of his death. He used to engage and pay the performers in the oratorios carried on by Handel himself; and being a good musician, was the most correct copyist of his time.

His son, John Christian, was a studious and cultivated man, and much esteemed by many of the first people in the kingdom. He was particularly regarded by the late lord Barrington, and all that noble family; and having early in life travelled with a gentleman of fortune, at Geneva he became acquainted with some English gentlemen of learning and talents, among whom were Mr. Price, of Foxley, Herefordshire; Mr. Windham, of Felbrig, Norfolk; Mr. Tate, of Mitcham, Surry; and Mr. Benjamin Stillingfleet, &c. This gave him a taste for, and procured him admission into, good company; so that he formed his character on models of a higher class than that of a mere musician.

In the Monthly Review of a pamphlet published in 1780, entitled "Anecdotes of George Frederick Handel, and of John Christian Smith," there are some passages relating to the venerable Mr. Smith, which we shall transcribe, being certain that they are accurate, from our own knowledge.

"After the period of Mr. Smith's return to England, he mixed very little with his professional brethren, though he continued to compose music, and to teach the harpsichord, till the year 1760; when, being in possession, not only of the *scores* of Handel's oratorios, but of the single vocal and instrumental parts, which had been transcribed for, and used by his numerous bands, Mr. Smith undertook to continue the performance of oratorios in Lent, during eight years, on his own account; and during nine more, jointly with Stanley.

"We have heard, from the first contemporary authority, that there was a shyness between Handel and the younger Smith for several years, which kept them asunder till the great musician lost his sight; but the difference was occasioned by no dignified cause of quarrel. Mr. Smith, early in life, having had some instructions from Handel, though his principal masters were Dr. Pepusch and Roseingrave, when about the year 1739, he published a book of harpsichord lessons, in 4to. Handel took it amiss that his scholar, the son of his copyist, should presume to have a title-page to his lessons engraved exactly in the same form and text-hand with his own first book of "Pieces de Clavecin," the best of all his productions. Mr. Smith's pieces were then perhaps inferior only to those of his model. They consisted, as was then the general fashion, of preludes, fugues, allemandes, corants, and jigs.

"Mr. Smith was certainly an elegant musician, and in his conduct and manners far above the general level of the professors of his art; but we are not certain, that his execution as a practitioner was great, nor that his invention as a composer was original. It is plain, that Mr. Smith's style of composition was that of the day, without an attempt at deviation; a style, which Handel had rendered *à-la-mode*, and to which not only Mr. Smith, but all the English composers, strictly adhered during more than forty years; as is manifest in the works of Green, Boyce, Arne, (in his oratorios,) Worgan, and Stanley. Arne, in his dramatic music, adopted easy and elegant passages from Italian operas; but we must except his *Comus*, in which there is much original melody, as well as in his Vauxhall ballads. Mr. Smith never was a popular composer. His oratorios, though new, and in support of which he had the patronage of several illustrious friends and great families, (particularly that of Barrington,) were not heard and attended so well as those of Handel, which had been in constant use for many years. The Eng-

lish opera of "The Fairies," in which Guadagni and Frafi performed the principal parts, had a considerable run; but it was never revived; nor did the airs penetrate into Vauxhall, Ranelagh, Mary-le-bone, private concerts, or private families, like those of Arne's Comus, or Boyce's Chaplet, after having been heard at the theatres.

SMITH, *Father*, or, as the Germans write his name, *Schmidt*, brought over with him from Germany, of which country he was a native, two nephews, Gerard and Bernard, as assistants; and to distinguish him from these, as well as to express the reverence due to his abilities, which placed him at the head of his profession, he was called *Father Smith*. During the grand rebellion, most of the organs in the kingdom having been destroyed, or stolen out of the churches, at the restoration a sufficient number of workmen for the immediate supply of cathedrals and parish churches, with organs, not being found in our own country, it was thought expedient to invite foreign builders of known abilities to settle among us; and the premiums offered on this occasion brought over the subject of our article and Harris.

The first organ which Smith engaged to build for this country was for the royal chapel at Whitehall, which, being hastily put together, did not quite fulfil the expectations of those who were able to judge of its excellence. An organ is so operose, complicated, and comprehensive a piece of mechanism, that to render it complete in tone, touch, variety, and power, exclusive of the external beauty and majesty of its form and appearance, is perhaps one of the greatest efforts of human ingenuity and contrivance. It was probably from some such early failure, that this admirable workman determined never to engage to build an organ upon short notice, nor for such a price as would oblige him to deliver it in a state of less perfection than he wished. And we have been assured by Snetzler, and by the immediate descendants of those who have conversed with father Smith, and seen him work, that he was so particularly careful in the choice of his wood, as never to use any that had the least knot or flaw in it; and so tender of his reputation, as never to waste his time in trying to mend a bad pipe, either of wood or metal; so that when he came to voice a pipe, if it had any radical defect, he instantly threw it away, and made another. This, in a great measure, accounts for the equality and sweetness of his stops, as well as the soundness of his pipes, to this day.

Smith had not been many months here, before Harris arrived from France, with his son René Rénatus, an ingenious and active young man, to whom he had confided all the secrets of his art. However, they met with but little encouragement at first, as Dallans and Smith had the chief business of the kingdom; but upon the decease of Dallans, who died while he was building an organ for the old church at Greenwich, 1672, and of the elder Harris, who did not long survive him, the younger became a very formidable rival to Smith.

For the contention between these eminent artists, at the time of erecting the admirable organ which still stands in the Temple church, see Burney's *Hist. of Music*, vol. iii. p. 437.

SMITH, THEODORE, a modern and pleasing composer of natural and easy music. He was a native of Germany, and published at Berlin, at 1780, three different sets of sonatas à quatre main, three in each set; and in 1782, six concertos for the harpsichord. Though a native of Germany, he resided so long in England as to be sufficiently acquainted with our language to publish, besides various musical compositions, a *Musical Directory*, printed by Welcker in 1778, an elementary work of considerable merit for its ar-

range and clear explanation of the first rudiments of a player on keyed-instruments.

SMITH, in *Geography*, a county of America, in the district of West Tennessee, containing 11,649 inhabitants.—Also, a township of Pennsylvania, in the county of Washington, containing 1646 inhabitants.

SMITH'S *Inlet*, a bay on the west coast of North America, the entrance of which is nearly closed by rocky isles. From the entrance into the inlet, whose north point lies from its south point N. 20 E. about a league distant, it was found to extend nearly in an east direction about six leagues; here it takes a turn to the N.E., and terminates in N. lat. 51° 24'. E. long. 232° 47½'. About three leagues within the entrance, the rocks and isles terminated, and the inlet contracted to a general breadth of about half a mile, though in some places it was near twice that distance from shore to shore; both of which were formed by high rocky precipices covered with wood. About half way up the canal a village of the natives was discovered, supposed to contain 200 or 240 persons. This was built upon a detached rock, connected with the main by a platform, and constructed for defence. A great number of its inhabitants, in about thirty canoes, visited captain Vancouver's party, and allured them in various ways to visit their habitations. They offered the skins of the sea-otter, and other animals, to barter; and besides promises of refreshment, made signs, not easily misunderstood, that the female part of their society would take pleasure in their company. The entrance is in N. lat. 51° 20'. E. long. 232° 12'.

SMITH'S *Island*, a small island near the east coast of Antigua.—Also, a small island in the Atlantic, near the coast of Virginia; part of a cluster collectively called "Smith's Islands." N. lat. 37° 15'. W. long. 75° 52'.—Also, a large and lofty island in the South Pacific ocean, discovered by lieutenant Ball, commander of the *Supply*, in 1790. S. lat. 9° 44'. E. long. 161° 54'.

SMITH'S *Point*, a cape on the coast of Virginia, forming the southern limit of the Potomack river. N. lat. 37° 54'.

SMITH'S *River*. See STAUNTON.

SMITH'S *Sound*, a bay on the east coast of Newfoundland, bounded by Cape Bonavista.

SMITHERY, a smith's shop; also the art of a smith, by which iron is wrought into any shape by means of fire, hammering, filing, &c.

SMITHFIELD, in *Geography*, a small post-town of Virginia, on Pagan creek, which discharges itself into James river, in the Isle of Wight county; 85 miles S.E. of Richmond. The creek is navigable for vessels of 20 tons.—Also, a post-town, and the capital of Johnson county, in North Carolina, on the east side of Neus river, on a beautiful plain, about 100 miles N.W. of Newburn. In the centre of the town is an Indian burying-place, once in the form of a cone, 16 feet high, 30 feet in diameter, but its height is now reduced to five or six feet.—Also, a town of Jefferson county, in the state of Ohio, containing 1228 inhabitants.—Also, a township of New York, in Madison county, bounded north by Lenox, east by Augusta in Oneida county, south by Eaton and Nelson, and west by Cazenovia; erected in 1807 from Cazenovia, and about 12 miles east and west, and 5 north and south. The principal part of this tract was leased of the Oneida Indians by Peter Smith, 1794, and purchased by the state in 1795. The soil is of a superior quality, and the whole tract is one of the best in the state. It is amply irrigated by small streams, and also by the main branch of the Chenango river, itself a branch of the Susquehanna. This town is principally settled by emigrants from the eastern states, and comprises

comprises the largest part of the tract called New Peterburg. The population in 1810 consisted of 2651 persons. The principal village is Peterboro', situated on the Oneida creek. N. lat. $42^{\circ} 57'$, and W. long. $1^{\circ} 37'$ from New York. —Also, a township of Pennsylvania, in Lycoming county, containing 1084 inhabitants.—Also, a town of Rhode island, in Providence county, containing 3828 inhabitants.

SMITHFIELD, *Lower*, a township of Pennsylvania, in the county of Northampton, containing 1326 inhabitants.

SMITHFIELD, *Upper*, a township of Pennsylvania, in the county of Wayne, containing 520 inhabitants.

SMITHFIELD, *Middle*, a township of Pennsylvania, in the county of Wayne, containing 682 inhabitants.

SMITHIA, in *Botany*, was so named, after the writer of the present article, in the first edition of the *Hortus Kewensis*, of his ever valued and lamented friend the late Mr. William Aiton, published in 1789.—Ait. Hort. Kew. ed. 1. v. 3. 496 and 512. ed. 2. v. 4. 336. Schreb. 809. Willd. Sp. Pl. v. 3. 1161. Mart. Mill. Dict. v. 4. Lamarck Dict. v. 7. 222. Illustr. t. 627.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, two-lipped; the segments ovato-lanceolate, concave, acute, nearly equal. *Cor.* papilionaceous. Standard inversely heart-shaped. Wings oblong, obtuse, rather shorter than the standard. Keel linear-oblong, of one petal, cloven at the base, the length of the wings. *Stam.* Filaments ten, united into two equal sets, combined at the bottom; anthers oblong. *Pist.* Germen superior, embraced by the base of the calyx; style capillary, permanent; stigma simple. *Peric.* Legume included within the calyx, of from four to seven orbicular, single-seeded, distinct, mucicated joints, connected with the permanent folded style, and lying horizontally over each other. *Seeds* solitary, kidney-shaped, compressed, smooth.

Ess. Ch. Stamens in two equal sets. Legume of several horizontal, separate joints, connected by the folded style, and inclosed in the two-lipped, equal calyx.

This genus, though established under the authority of two very eminent botanists, Mr. Dryander and Mr. Salisbury, who thought it peculiarly well marked, has of late been found so nearly to accord with the original species of *Aeschynomene*, as to be scarcely distinguishable therefrom. Mr. Brown, however, who made this discovery, still considers *Smithia* as distinct; the legume of *Aeschynomene* being straight, composed of a series of vertical joints, connected by their edges, and projecting out of the calyx, while the latter is deeply divided. Their habits, and even the sensibility of their foliage, bring them so closely together, that we doubt, at least, the propriety of keeping them separate, though we are content, for the present, to leave them as we find them. Two species only of the genus before us have been observed.

1. *S. sensitiva*. Annual *Smithia*. Ait. Hort. Kew. ed. 1. v. 3. 496. t. 13. ed. 2. n. 1. Willd. n. 1. Salisb. Parad. t. 92.—“Lips of the calyx entire. Clusters stalked, of few flowers.”—Discovered in moist pastures, on the coast of Coromandel, by J. G. Koenig, M.D., by whom seeds were sent in 1785 to Sir Joseph Banks. The plant is annual, and usually kept in a hot-bed, or stove; but, according to Mr. Salisbury, the seeds scattering themselves in favourable situations, will sometimes come up in the open ground, even in dry gravel. The root is tapering. Stems several, spreading, various in luxuriance, more or less branched, round, smooth, leafy. Leaves alternate, abruptly pinnate, of four, five, or six pair of elliptical, obtuse,

entire leaflets, about a quarter of an inch long; oblique at the base; glaucous beneath, their mid-rib and margins especially beset with long, bristly, tawny, close-pressed hairs. *Stipulas* in pairs, lanceolate, membranous, ribbed; auricled and spurred at the base. The leaves fold together when touched, as in the *Mimosa pudica*, but more tardily, unless in a very hot atmosphere. The flowers are yellow, rather small, with a purplish calyx, accompanied by a pair of close bracteas, half its own length. Joints of the legume as small as Red-poppy seed.

2. *S. conferta*. Close-flowered *Smithia*.—Lips of the calyx toothed. Clusters sessile, shorter than the leaves.—Gathered in the tropical part of New Holland, by Sir Joseph Banks, to whom we are obliged for a specimen. This seems likewise to be an annual herbaceous plant. The stems are erect, slender, unbranched, round, smooth. Leaves few, distant, except at the top, where two or three are crowded together; their leaflets much as in the foregoing. *Stipulas* spurred, but scarcely auricled. Clusters axillary, sessile, of a very few flowers, whose petals, in the dried specimen, are of a reddish or tawny hue. By the position of the dried leaves this species seems also sensitive; and perhaps they fold at night over the flowers, like those of the *Lotus tetragonolobus*, celebrated for having first led Linnæus to consider what he afterwards called the Sleep of Plants.

SMITHLAND, in *Geography*, a post-town of Kentucky, in the county of Livingston, containing 99 inhabitants: the county contains 3575.

SMITHTOWN, a post-township of New York, in Suffolk county, Long Island; 92 miles E. of New York; containing 1592 inhabitants, including 72 slaves. This place employs 14 vessels principally in the trade with New York, of 30 to 100 tons burthen.

SMITHVILLE, a town of North Carolina, near the mouth of Cape Fear river; 30 miles S. of Wilmington.—Also, a township of Chenango county, erected from a part of Greene in 1808; 13 miles S.W. of Norwich; containing 995 inhabitants, who manufacture most of their clothing in the household way.

SMITING-LINE, in a *Ship*, is a small rope fastened to the mizen-yard-arm, below at the deck, and is always furled up with the mizen-sail, even to the upper end of the yard, and from thence it comes down to the poop. Its use is to loose the mizen-sail, without striking down the yard, which is easily done, because the mizen-sail is furled up only with rope-yarns; and, therefore, when this rope is pulled hard, it breaks all the rope-yarns, and so the sail falls down of itself. The word of art is, *smite the mizen*, (whence this rope takes its name,) that is, hale by this rope that the sail may fall down.

SMITTL, in *Geography*, a town of Asiatic Turkey, in Caramania; 18 miles E.N.E. of Cogni.

SMOCK, LADY'S, or *Bitter Cresses*, in *Agriculture*, a plant of the weed kind, found in coppices, and on the banks of rivers, which sheep are said sometimes to eat. The common sort is thought by some to be useful in epilepsies.

SMOKE, or SMOAK, *Fumus*, a humid matter, exhaled in form of vapour by the action of heat, either external or internal; or smoke consists of palpable particles, elevated by means of the rarefying heat, or by the force of the ascending current of air, from bodies exposed to heat; and these particles vary much in their properties, according to the substances from which they are produced. See FLAME.

Smoke, Sir Isaac Newton observes, ascends in the chimney by the impulse of the air it floats in: for that air, being rarefied by the fire underneath, has its specific gravity diminished; and thus, being determined to ascend itself, it carries

carries up the smoke along with it. The tail of a comet that great author takes also to ascend from the nucleus, after the same manner. (See COMET.) Smoke of fat unctuous woods, as fir, beech, &c. makes what we call lamp-black.

Smoke, arising from the combustion of vegetables, is a mixture of water, oil, volatile salts, and all the gaseous products which result from the combination of vital air with the several principles of the vegetable.

There are various inventions for preventing and curing smoky chimnies; as the æolipiles of Vitruvius, the ventiducts of Cardan, the windmills of Bernard, the capitals of Serlio, the little drums of Paduanus, and several artifices of De Lorme. See CHIMNEY and FIRE-Places.

In the Philosophical Transactions we have the description of an engine, invented by Monsieur Daleme, which consumes the smoke of all sorts of wood, and that so totally, as the most curious eye cannot discover it in the room, nor the nicest nose to smell it, though the fire be made in the middle of the room. It consists of several iron hoops, four or five inches in diameter, which shut into one another, and is placed on a trevet. A brand taken out of the fire smokes instantly, but ceases as soon as returned: the most fetid things, as a coal steeped in cat's piss, which stinks abominably when taken out of the fire, yet in it makes not the least ill scent; no more than red-herrings broiled, &c.

SMOKE-Jack. See JACK.

SMOKE-Farthings were the pentecostal or customary oblations offered by the inhabitants within any diocese, when they made their processions to the cathedral church; which came, by degrees, into an annual standing rent, called smoke-farthings. See PENTECOSTALS.

SMOKE-Silver, in our *Old Writers*. Lands were held in some places by the payment of the sum of six-pence yearly to the sheriff, called smoke-silver.

Smoke-silver and smoke-penny are to be paid to the ministers of divers parishes as a modus, in lieu of tithewood; and in some manors, formerly belonging to religious houses, there is still paid, as appendant to the said manors, the ancient Peter-pence, by the name of smoke-money.

SMOKEY BAY, in *Geography*, a large bay on the west coast of the entrance into Cook's river, between Cape Douglas and Point Banks.

SMOLEN, an island in the North sea, on the coast of Norway, 25 miles in circumference. N. lat. 63° 24'. E. long. 8° 26'.

SMOLENSK, a town of Russia, and capital of a government, situated on the Dnieper; the residence of a governor, and a bishop's see, with very considerable commerce. The possession of it has been often disputed between the Poles and the Russians. It is built on two hills, between which are a valley and river, and surrounded with walls, 30 feet high and 15 thick, the lower part being stone, and the upper brick, which trace the course of the hills, and enclose a space of about five miles. At every angle towers are erected. The houses of the common people are mostly constructed of wood: the number of inhabitants is said to exceed 4000. The chief articles of trade are flax, hemp, timber, masts, planks, honey, wax, hides, hogs' bristles, and Siberian furs; 420 miles E.N.E. of Warsaw. N. lat. 54° 40'. E. long. 32° 18'.

SMOLENSK, a government of Russia, bounded on the north by Plovskoe and Tverskoe, on the east by Moscovkaia and Kaluzskoe, on the south by Orlovskoe and Novgorod Sieverskoe, and on the west by Polotzkoe and Mogilevskoe; at its greatest length 180 miles from N. to S., and 160 from E. to W. This government contains White Russia, pro-

perly so called, and was ceded by Poland to Russia, as a duchy, by a treaty, concluded in the year 1667, and confirmed in 1686. Its capital is Smolensk. N. lat. 53° 20' to 56° 15'. E. long. 31° to 36°.

SMOLIN, a town of Hungary; 22 miles N.N.E. of Presburg.—Alfo, a mountain of Bosnia; 32 miles S.S.W. of Zwoornick.

SMOLLET, TOBIAS, in *Biography*, a writer of considerable reputation, was born, in 1720, at Dalquhurn, in Dumbartonshire. After a common education he was put apprentice to a surgeon in Glasgow, and at the same time he availed himself of the opportunity of attending medical lectures at the university. At this early period he composed a tragedy. In his nineteenth year he quitted Scotland for London, where he quickly obtained the situation of surgeon's mate in the navy. He failed in the expedition fitted out against Carthage, under admiral Vernon and general Wentworth; and during the voyage he displayed his powers of observation, as well as his satirical turn, by the account he drew up of that ill-conducted and unsuccessful enterprise. He was soon disgusted with the service in which he had engaged, and quitted it in the West Indies. It had, however, been of great service, by introducing him to that acquaintance with the manners and language of sailors, of which he made the most amusing exhibitions in his novels. The savage cruelties used by the king's troops after the battle of Culloden called forth Smollet's warmest feelings, and occasioned his poem entitled "The Tears of Scotland," which by its spirit and elegance placed the author high in the rank of minor poets. It was followed by two satires, a species of composition to which the natural irritability of temper gave him a propensity. He married, in 1747, a lady, with whom he expected a good fortune, of which, however, he received very little, and the expensive style in which he set out in life brought him very soon into serious difficulties. In this emergency he had recourse to his pen, and in 1748 he produced his first novel, entitled "Roderick Random," which had no doubt strong allusions to his own history, and became extremely popular. "A trip to Paris, in 1750, enlarged his knowledge of the world, and gave rise to his "Adventures of Peregrine Pickle," in which he exerted all the powers of humorous invention and delineation, though often at the expence of delicacy and morality. He now determined to pursue his profession, and commenced physician at Bath, but he met with so little success that he soon abandoned it, and resumed writing as a profession. His next publication was "Adventures of Ferdinand Count Fathom," which was followed by a new translation of Don Quixote. In 1756 he undertook the management of a new Review, under the title of the "Critical," which, after undergoing a number of changes, still exists. His satirical and acrimonious spirit soon broke out in this journal, and involved him in a quarrel with admiral Knowles, on whose conduct in the expedition to Rochefort he had spoken with great severity. Smollet was prosecuted and convicted of a libel, and suffered the punishment of the law, viz. fine and imprisonment.

After this he wrote for the theatre an after-piece, entitled the "Reprisal, or the Tars of Old England;" this was acted at Drury-lane in 1757; and in the following year he published a hastily written "Complete History of England, from the Descent of Julius Cæsar to the Treaty of Aix-la-Chapelle," in two vols. 4to. About the same period he published a novel, entitled "The Adventures of Sir Launcelot Greaves," and he is supposed to have written the histories of France, Italy, and Germany, in the modern part of the Universal History. In 1761 he began to publish his

"Continuation of the History of England," taken up at the Revolution, where Hume left it, and brought down to the year 1765.

At the beginning of the present reign, Dr. Smollet was an advocate in defence of the measures adopted by the administration, at the head of which was lord Bute, and in connection with others he published a weekly paper, called "The Briton," which was encountered by the more famous one entitled "The North Briton," set on foot by the well-known John Wilkes. The rancour displayed on both sides dissolved the friendship which had long subsisted between these two political champions. Smollet, from some domestic afflictions, determined to visit the continent, whither he went in 1763, and he spent two years in a tour through France and Italy. After his return he published, in 1766, his "Travels" in these countries, in a series of letters, in two vols. 8vo. which contained many lively and sensible remarks, but which were deeply tinged with the gloomy temper of mind, which rendered him dissatisfied and out of humour with almost every thing he saw. In 1769 he published a sort of political romance, entitled "The Adventures of an Atom," intended to ridicule different administrations, but especially that of the earl of Chatham.

Increasing ill-health induced him, in the year 1770, to pay another visit to Italy, accompanied by his wife, and during his last voyage he wrote his last novel, "The Expedition of Humphry Clinker," which some critics regard as the best of all his novels. He died in the neighbourhood of Leghorn, in October 1771, in the fifty-first year of his age. "Dr. Smollet," says the author of the article in the General Biography, "was undoubtedly a man of talents and great variety of powers, though he did not attain the highest rank in any thing. He is best known as a novelist, and they who read those compositions for amusement only, without much nicety of taste, seldom fail of being entertained by him. Yet his portraits are often caricatures, his scenes of humour coarse and extravagant, and his jests borrowed. As an historian, he has attained more credit for the elegance and animation of his style, than for the higher qualities of judgment, accuracy, and impartiality; and though his continuation is annexed to Hume's History, the two writers will bear no comparison." His poetic powers were considerable. His "Tears of Scotland," "Ode to Leven Water," and some other short pieces, are polished, tender, and picturesque. His "Ode to Independence" is a loftier flight, and has perhaps few superiors in the lyric strain. His satires are vigorous, but violent and disgusting.

SMOLNITZ, in *Geography*, a town of Bohemia, in the circle of Schlan; 12 miles W.N.W. of Schlan.

SMORGONIE, a town of Russian Lithuania, in the palatinate of Wilna.

SMORZATO, in *Italian Music*, for the violin family, implies that the bow should be drawn or pressed to its full length, not with the same force throughout, but lighter by degrees, till scarcely any sound is heard. This term seems now superseded by *diminuendo* and *perdendosi*.

SMOSTRIE, in *Geography*, a town of Poland, in Polandia; 15 miles N. of Kaminiac.

SMOTHER-FLY, in *Agriculture*, a provincial term applied to the bean aphid.

SMOTRZICZ, in *Geography*, a river of Poland, which runs into the Dniester, 8 miles S. of Kaminiac.

SMRDOW, a town of Bohemia, in the circle of Czafslau; 9 miles S. of Czafslau.

SMUGGLING, a cant term for the running of goods, or the offence of importing them without paying the duties
VOL. XXXIII.

imposed thereon by the laws of the *customs* and *excise*. See each of these articles.

This is restrained by a great variety of statutes, which inflict pecuniary penalties, and seizure of the goods, for clandestine smuggling; and affix the guilt of felony, with transportation for seven years, upon more open, daring, and avowed practices: but the last of them (19 Geo. II. c. 34.) is for this purpose *instar omnium*; for it makes all forcible acts of smuggling, carried on in defiance of the laws, or even in disguise to evade them, felony without benefit of clergy. For the chief provisions of this act, which was at first temporary, but made perpetual by 43 Geo. III. c. 15, see CUSTOMS.

SMUSH-POT, amongst *Painters*, is the vessel into which they rub off the paint from the pencils, and put the scrapings of the pallet.

SMUT, or USTILAGO, in *Agriculture*, a disease in corn, and which, according to M. Duhamel, exhibits the following marks or appearances. 1. This distemper destroys entirely the germ and substance of the grain. 2. It affects not only the ear, but also, in some degree, the whole plant, when it has made a great progress. 3. It very seldom happens, but that when one stalk is smutty, all the ears of the other stalks from the same root are so too. 4. So early as in March or April, upon opening carefully the hood or blades which cover the ear, and examining the young ear, then not above the sixth part of an inch in length; and almost close to the roots, he found this embryo already black, and attacked with this distemper. Perhaps it may not always seize the plant so early. 5. When the distempered ear comes out of its covering formed by the blades, it looks lank and meagre: the common, and immediate coverings of the grains, are in this case so very slight and thin, that the black powder is seen through them: and from this time nothing is found in lieu of grain, but a black powder, which has a fetid smell, and no consistency. As this powder, of which the constituent particles have but very little cohesion, and of which the coverings are destroyed, is easily blown off by wind, or washed away by rain; the husbandman, in housing these plants, houses only skeletons of the ears. If any impression of this powder remains, it is easily taken off by sifting; but he has not experienced it to be contagious, like that of burnt grain. And Mr. Tillet, it is remarked, has observed that these corrupted ears are often found to be vitiated even in the hood, though this last looks as green and perfect as if nothing ailed the corn within. The upper part of the stalk of a smutty plant is not commonly quite straight, from within about half an inch below the ear. If such a stalk is squeezed there, it scarcely yields at all to the pressure. If it be cut asunder at about a sixth part, or a quarter of an inch below the ear, it will be found to be almost entirely filled with pith, in such a manner that only a very small opening can be perceived in the heart of the stalk, instead of the large pipe that is in healthy stems. He concludes from hence, that the circulation of the juices is obstructed in the upper part of the stalks of smutty plants. Bearded wheat is apt to be smutty, as well as that which is not bearded; but neither Mr. Tillet nor he ever met with a smutty ear of rye.

And in respect to the causes of smut, it is observed, that the smuttiness of corn cannot be owing to a want of fecundation, as many have hitherto mistakenly imagined, since it affects and destroys the organs of both sexes, long before the time of that fecundation:—that it cannot be imputed to the setting of wet upon the ears, or to fogs, or to a violent impression of the sun; since we have seen the ears
B b smutty

smutty long before they ceased to be covered with the blades, which continue green till the distemper has made great progress:—that the same observations refute absolutely the opinion of those who suppose the cause of the smut to be in the grains after they are formed, and before they are past their milky state:—that the smut of corn has been also ascribed to the moisture of the earth; but we do not see more smutty plants in the lowest, and consequently wettest parts of a field, than in the highest and most dry. Besides, why should there be a single smutty plant in the midst of numbers of found ones? However, as it appears that corn is more frequently attacked with this distemper in wet years than when the seasons are dry, too much moisture may perhaps, without being the immediate cause of the smut, favour its progress more than drought would do.

Some naturalists have ascribed this distemper to insects. Our author, if he is not authorized absolutely to deny this, can at least assert, that, after having been of this opinion for some time, all his endeavours to establish it by facts have proved ineffectual. Some observers have indeed shewn him different insects in smutty grains; but as he found the very same kinds likewise in found ears, he believes, with Mr. Tillet, that they are not in any manner the cause of this distemper. We know that the corn-caterpillar devours the mealy substance of the grain; but it does not occasion smut. Numbers of flies lay their eggs upon these seeds, and the worms and maggots which proceed from them eat the seeds; but this does not occasion any thing like smut. The Rev. Dr. Hales, to satisfy himself whether the smut of corn might not proceed from the seeds being bruised by the flail, took a number of grains, of different sizes, and bruised them with a hammer. Thus his own experience convinced him that he had conceived a wrong idea of the cause of this distemper.

Several cultivators have thought that pigeons' dung and that of sheep render corn smutty: but this is a groundless notion. We have large pigeon-houses, the dung of which is strewed upon our wheat-lands; yet we do not find that these fields are more affected with smut than others. This allegation is, therefore, absolutely destitute of proof. It is added, that Wolfius was of opinion that the smut of corn proceeded from a monstrosity of the embryo; but M. Almen has refuted that supposition, by shewing, that the male flowers of certain kinds of plants are attacked with this distemper: now the flowers have not any embryo.

And this last philosopher has judiciously observed, that the smut of corn cannot derive its origin from a defect in the sap; as all the parts of the plant, except the ear, look healthy, and there are plants whose roots are perennial, which appear vigorous, though their feeds are smutty every year. He is of opinion, that whatever weakens the plant is apt to bring on the smut, and instances as a proof of this, that it is a frequent custom in his country, to cut rye as soon as it spindles, for food for their cattle; and that this rye generally produces other ears, which seldom contain any but distempered grain: to which he adds, that seed-corn which had been pricked or run through with a needle, or which is not thoroughly ripe, and that which produces lateral or second ears, is subject to the smut. And he afterwards, from other trials, seems disposed to ascribe this disease to mouldiness.

But in the "Memoirs of the Bath Agricultural Society," it is said to be a disease that only occurs when the weather is wet, during the period of the flowering of the plants, in which the anthers may burst and the farina be washed way. It is supposed not to be produced by any infectious material, or the *ova* of insects that may adhere to the grain, as

smutty ears and found ones are found proceeding from the same root; and, in some instances, both smutty and found grains to be contained in the same ear; some of the corns having even one end smutty and the other found, consequently to arise from the want of due impregnation, from the farina fecundans being faulty or imperfect, and that putrefaction takes place on the death of the corn. And this supposition is supported by the experiments of the Italian philosopher Spallanzani, who found that the seed is produced in the plants long anterior to impregnation, which cannot be performed until the flower is open, and the dust of the anther fully in a state of maturity. And Dr. Darwin, on these principles, conceives, that for want of impregnation, or the vivifying principle, the wheat-corn may putrefy, as is the case with addle eggs of oviparous animals. However, the inquiries of other writers seem to lead to the opinion that the affection is produced by the attacks of an insect, and that, though certainly infectious, it may be prevented or cured by the use of different kinds of pickles.

Further, a variety of facts and reflections have been offered on this subject by Mr. R. Somerville, in the second volume of "Communications to the Board of Agriculture;" who begins by remarking, that some years ago, he collected a quantity of smutted ears from one field of wheat, in which they were very numerous, and a number of healthy well-filled ears from another field, in which there was no smut. The grains were rubbed out of both, intimately mixed, and kept in a box for two months, at the end of which time they were rubbed between the hands in such a manner as to break the whole of the smut-ball. The parcel was then divided into two equal parts, one of which was three or four times washed with pure water, and well rubbed between the hands at each washing, and afterwards sown in a drill in his garden; the other half was sown in another drill without any washing or preparation whatever, the soil and every other circumstance being equal. Both parcels vegetated at the same time, and for about two months thereafter there was no visible difference in their appearance; about that period, he however observed, that many of the plants in the drill that had been sown without being washed, were of a darker colour than the others; these, when narrowly examined, were of a dirty-green. The plants in the drill that had been washed were all of one colour, and seemingly healthy; as the season advanced, the difference in colour became more striking, and continued to increase till the grain was fairly out of the blade: about this time many of the dirty-green ears began to exhibit symptoms of decay. As soon as the ear was fairly shot out, the whole of those in the unwashed drill, that had the dirty-green appearance above described, were found to contain nothing but smut; and these smutted ears were in the proportion of more than six to one of the healthy ones; while, on the contrary, the drill in which the washed grains had been sown, and which consisted of several hundred grains, had hardly a smutted or unhealthy ear in it. The same experiment was repeated the following season, and with nearly the same result. Satisfied with knowing that complete washing would be found a remedy for the disease, he made no farther inquiry upon the subject till last autumn, when he was employed in making observations upon the blight, in the course of which he met with a good deal of smut in many fields; and being at the time possessed of some excellent glasses, he carefully examined some of the smutted plants. This at first was done more as a matter of amusement, than from any expectation of discovering any thing that might contribute to throw light upon the subject.

subject. Upon a near inspection with the glass, he found that the dirty-green colour of the blades of the smutted ears was owing to a number of spots infinitely small, and bearing a near resemblance to those upon blighted ears: his observations were continued throughout the whole period of the ripening, in the course of which he made no additional discovery, except observing, that the leaves and stalks of the smutted ears decayed sooner than such as were healthy. About the end of autumn, however, having one day brought home some smutted ears of rather an unusual appearance, he examined them very narrowly, and observed that the balls were perforated in many places with small round holes, a thing he had not before observed in any that he had met with: this he ascribed to vermin; and upon sticking one of the grains upon a pin, and placing it under the glass in a very bright sun, he could distinctly observe several small transparent specks upon the beard, or downy part of it. He examined several more, and met with exactly the same appearance; but upon being called hastily away upon business, he was under the necessity of leaving them upon the table, without being able to ascertain whether the objects he had seen were eggs or insects. In the evening, when he came home, he resumed the investigation by *candle-light*; in the course of which, as he was under the necessity of holding them very near the candle, the heat soon relieved him from his embarrassment, by putting them in motion, and he then discovered that the specks above-mentioned were real insects, resembling wood-lice in shape. Next day he repeated the same trials by sun-light with new smut-balls, and discovered the same appearances, but without being able to make any of the insects stir. Disappointed and vexed at not being able to see them in motion with the sun-light, and recollecting the heat of the candle, he threw the concentrated rays of the sun upon them with a burning-glass, which completely answered his purpose of putting them in motion, and shewing them in every different point of view. To describe minutely an insect so small as not to be distinguishable by the naked eye, would, he thinks, be no easy matter; it is sufficient to say, that its general appearance is very similar to the wood-louse, though infinitely smaller. As soon as he had clearly ascertained the existence of this insect, his mind was perfectly at ease with regard to the cause of the distemper; but though he could very readily conceive that vermin, in the early stages of the growth of a plant, might so injure the stamina as to render it unfit to produce any thing but smut, he could not so well understand how it was possible for the mere touch of the black earth contained in the smut-balls to produce the same effect. It is well known, that in the animal body, certain infections are communicated merely by the contact of the sound and unsound parts; but that in every instance where this happens, the injury can be distinctly traced to an absorption of the virulent matter, by the vessels of the healthy subject.

And we are now, he thinks, so well acquainted with vegetation, as to know that plants have a circulating system as well as animals; and that while they are in a growing state, poison as well as nourishment may enter their vessels, and do infinite mischief. If this reasoning is sanctioned by experience, and there can be no doubt of it, and if there is the slightest analogy between animal and vegetable life, it will at once appear, that no bad effect could possibly arise from smutted and healthy ears coming in contact, either in the stack or the barn, as at that time they are in a state of rest, and no circulation going on. It may be argued in answer to this, that while the plants are green, the shaking of the wind may bring the smutted and the healthy ears

into contact, and that the acrimony of the smut may corrode and destroy the healthy wheat, so as to produce the disease. This idea he knows is entertained by many very good farmers: it is, however, clearly disproved by the experiment above recited, by which it appears that a simple washing in water, provided it is properly performed, is a very effectual cure for the distemper: common sense will inform us, that had the stamina, or germ of the grains so washed, been injured by any thing of a corrosive nature, even in the slightest degree, no ablation whatever could possibly have repaired the mischief. And the same reasoning, he supposes, applies with equal justice to the other causes assigned, with the single exception of insects; for if either the grain was naturally weak, or had been sprung in harvest, or was deficient in its male organs, as is ridiculously supposed, nothing but the highest degree of weakness and credulity could make any person believe, that either the washing with water, or indeed any other preparation, could cure such defects.

It is, therefore, his opinion, that the smut is occasioned by the small insect above described, as seen by the glass in the downy part of the grain; and that when the balls are either broken in the operation of thrashing, or come in contact with clean healthy grains, the insects leave the smutted grains, and, adhering to such as are healthy, are sown with them, and wound the tender stem in such a manner as to render the plant incapable of producing any thing but smut. It is not an easy matter to account for the manner in which this takes place; but a little attention to the circumstances he is now to mention will perhaps throw some light upon it. It is known that plants of very opposite natures and qualities will grow and produce abundantly upon the same soil, where the nourishment is seemingly the same. This effect is also known to be owing to the structure of their vessels, by the action of which the juices that circulate through them are differently prepared in every different plant. From this striking difference, owing confessedly to organization, is it not, he asks, presumable that the smut in wheat is produced by the insects wounding the vessels of the plant in such a manner as to render them incapable of taking up any other principle from the soil, but the smut contained in the balls, which, upon examination, seems to have no quality different from the finest vegetable earth? This opinion, he thinks, is strongly supported from the circumstance of certain pickles being found a cure for the malady. The effect of these pickles is, however, completely misunderstood; for, in place of supposing, as is erroneously done, that they operate by strengthening the grain, and thereby removing that debility which has been long considered the cause of smut, their benefit depends upon the powers they possess of destroying the insects above described: but to shew the absurdity of the commonly received opinion in a more striking point of view, it is only necessary, he adds, to state, that many of these preparations, which are supposed to be so friendly to vegetation, are in fact inimical to it, unless they are used with the utmost caution; even stale urine, which has long been considered as a safe and innocent remedy, is, under certain circumstances, highly pernicious. After he had discovered the insect, he made trial of all the substances commonly used, and found all of them, when properly applied, destructive to it. Is it not, therefore, he contends, more agreeable to plain common sense to suppose, that the virtue of these preparations consists more in the power they have of destroying vermin, than in any strengthening quality they possess?

The following opinion has been offered on this vegetable

SMUT.

table affection by sir John Call, who supposes, that the smut is occasioned by certain animalcula deposited in the husks of the ear, when the wheat is in blossom, which are fed and brought to perfection by devouring the milky juice, and observes, that were the disease radical in the original grain of the feed-wheat, or infectious from the juice arising through the pores and tubes of the stalk, there could not be in the same ear, grains, some decayed and others quite perfect. But to bring the matter to the test of experiment, he collected a quantity of smutted ears of wheat, in some of which were two or more grains apparently perfect, all which he caused to be rubbed out with the hand in a bag, smut and altogether; the fresh grains found in the bag were then sown in a particular ridge amongst other wheat, in a field under tillage. Their growth from the first was similar to the rest of the wheat; and from a certificate of respectable farmers, it appears their produce was as free from smut, as that of the field in general. And hence the conclusion is drawn, that washing or pickling wheat, as a remedy against the smut, is unnecessary and useless; and that as blights and other diseases of plants are more prevalent from circumstances in some seasons than in others, so the smut is an accident of a like nature, which mankind can neither foresee nor prevent. The general

experience of farmers is, however, in opposition to this supposition. And whether this vegetable disease may be produced by insects, or be the effect of some other cause, to many of which it has been ascribed by different philosophical inquirers; the most general practice of farmers has been that of preparing their seed by the means of some sort of washing or brining. The following is a tabular view of the results of trials made with different steepes, in order to ascertain their utility in this intention, as well as in promoting the growth of the grain, as given by Mr. Bevan, in the 9th volume of the "Agricultural Magazine." It contains twelve samples of smutty wheat, and the same number of sound good wheat, steeped in twelve different solutions of the most common acids and alkalies, and salts, most readily procured. The wheat was sown at Leighton, Bedfordshire, on a sandy soil. The solutions were all made cold, and the samples continued about twenty-four hours in steep. The columns marked A are the results from the good wheat, and those marked B are from the smutty samples. It may be observed, that neither of the samples steeped in the solutions of nitric acid came up, excepting a single corn in the good sample, and which produced above 1200 corns from it.

Kinds of Substances used.	Specific Gravity of the Solution.	Number of smutty Ears in Three Sheaves.		Bushels of good Wheat, per Acre.		Cwts. of Straw, per Acre.	
		A.	B.	A.	B.	A.	B.

But M. de Lignerolle contends, that the surest means of avoiding smut, and that which he has long practised with success on upwards of three hundred acres of land, is to change the seed every year, to be very careful that the feed-corn be well dried and thoroughly ripe, and that it be not smutty, nor have any smutty powder sticking to it. He then pours boiling-water on quick-lime, in a large tub; and after the ebullition is over, as much cold water as there was hot, and stirs it all strongly together, in order to dissolve and thoroughly mix the lime. The quantity of wheat intended to be sown is sprinkled with this ley, and then well stirred with a shovel, and laid in as high a heap as possible. It is best, he supposes, to keep the grain for a week after this preparation, turning it every day; for otherwise it would heat so as to destroy the germ. By these means he has not had any smut, when the fields around him have been infected with that distemper. And Mr. Donat, near Rochelle, has used the following with success: take quick-lime and pigeons' dung, of each twenty-five pounds, forty pounds of wood-ashes, and twenty-five pounds of sea-salt, or salt-

petre. Put all these into a tub large enough to hold half a hog-shead of common water, which should be added to them. Stir them all well with a stick, till the lime is quite dissolved. This ley will keep some time without spoiling. It must be stirred just before the corn is steeped in it. The grain is then put into a basket, and plunged into the ley, where it remains till it has thoroughly imbibed it; after which it is taken out, and laid in a heap till it is quite drained of all its moisture: or, which is a still better way, take a mashing-tub, fill it with grain to within four inches of the brim, and then pour in the ley well stirred before-hand. When the tub is full, let the ley run out at the bottom into some other vessel, in order to use it again for more corn. Let the grain be then taken out and laid in a heap to drain; and continue in this manner to steep all the feed-corn. The wheat, thus prepared, may be sown the next day, and must not be kept above five or six days, for fear of its heating. This quantity of ley will serve to prepare more than twenty bushels of wheat. Mr. Tull has also long since observed, that brining and changing the feed are the general remedies for

for smut. Likewise a very intelligent writer in the eleventh volume of the Agricultural Magazine says, that he can truly state, that in the course of long and extensive practice, he has never discovered the produce of any good and properly prepared feed-wheat smutted, while that of his unprepared escaped. On the contrary, whenever he has sown any in the latter state, he has always observed much smut in the crops raised from it; and refers his readers to the following account of an accurate comparative statement. On the 15th of March last he sowed two contiguous ridges (in the middle of a very large field,) equal in soil, condition, and exposure, with wheat of the same variety, raised on the same kind of soil, in precisely the same mode of management, and thoroughly mixed. The seed contained a very small quantity of smut, perhaps one black ball to a quart; but the other grains were not at all discoloured. The ridges were set out in an east and west direction, each eighty yards long and nine broad. On the west half of the northern ridge he sowed the seed without any preparation whatever; and on the east, after being well washed in clean river-water. On the west half of the other ridge the wheat was sown after having been wet with old chamber-ley; and on the east half, after being prepared (provincially pickled) in the usual manner, with old chamber-ley and lime in fine powder. All the land was ploughed and sown broad-cast on the same day, without any variation of weather, and equally well harrowed. We had a calm, dry, and tolerably warm blooming season. Some time after the ears were out he examined the crop very minutely. That after the unprepared seed, the washed seed, and the wheat wet with chamber-ley, contained a great, and that from the seed which received the chamber-ley and lime, a very small, quantity of smut. The straw of this appeared as good as that of the sound wheat. Upon every piece of ground he found ears partly smutted and partly sound. In part of these ears he found some rows of grain containing sound wheat near the middle of the row, and smut both above and below it. With a view of finding the proportion (at harvest) with some degree of precision, he took four sheaves from the middle of the crop raised from the pickled seed, mixed them thoroughly, reduced them to an equal size, viz. to the circumference of twenty-four inches, and then carefully picked out and counted the number of smutted ears they contained. He pursued precisely the same mode with the crops upon the other pieces of ground, and the results were as under:

	Smutted Ears.
The four sheaves after the pickled seed contained	165
The four do. from the seed which was washed in clean water	1212
The four do. from the seed wet with chamber-ley	723
The four do. from the seed which received no wash- ing or preparation	1270

It is supposed that it is stated in some of our agricultural publications, that one of the strong acids, much diluted with water, has been successfully used in preparing feed-wheat, with a view of preventing smut; a disease which has been improperly confounded with blight or mildew. The latter remedy he never tried; he has, however, on several occasions, used sea-water (so strongly impregnated with salt, that an egg would swim on it) and lime, and also the drainings of fold-yards and lime, and is of opinion that these mixtures are not nearly so efficacious as the latter article and strong chamber-ley. The best mode of preparation is, he thinks, to immerse the wheat in the chamber-ley, stirring it well

(about five or ten minutes), and skimming off the light grains, &c. The chamber-ley should be let out by a tap, and the wheat spread on a floor, and so well mixed with the lime that every grain may receive a part of it. If this mode be carefully practised with seed free from smut, he can, from experience, assure the husbandman that he will never suffer, in any considerable degree, from that disease. As the lime and chamber-ley will soon destroy the vegetative principle of the grain, if it be suffered to remain in a heap, or in bags, it should be committed to the ground within six or eight hours after it has been thus prepared. He has sometimes known it considerably injured after being kept twenty-four hours thinly spread out upon a well aired floor. And as, when the seed is in a very moist state, it will not pass regularly through the drill-machine, it is necessary on that account to have it drier in the drill than the broad-cast husbandry.

When the wheat used in the above experiment was prepared, a proper vessel was not at hand, and therefore the chamber-ley was sprinkled upon it. This, however, is not a good method, for we lose the chamber-ley, and the advantage of skimming off the light grains, black balls, &c.; and notwithstanding frequent turnings, it sometimes happens that all the grains do not receive a sufficient quantity of the liquid. A proper vessel should therefore be constantly had recourse to for this purpose.

But on the supposition of this diseased state of grain being produced by an insect, the following method of kiln-drying has been proposed in the third volume of the Farmer's Magazine. Let the wheat be laid upon the kiln about three or four inches thick, the kiln being heated middlingly strong with blind coal; the wheat to continue on the kiln for twenty-four hours, but turned frequently. After taking it off the kiln, it must be allowed twenty-four hours to cool, during which time it must be frequently turned, and then put through the fanners once or twice. After the wheat has lain a few hours on the kiln, and the fire begins to have effect, a great number of very small worms, formerly undiscovered by the eye, appear on the top of the grain, and are soon destroyed by the heat. These come from blacked wheat or other corns that could not be suspected to be indifferent; or may lie in, or on good wheat, which worms continuing, (when not thus killed,) might consume the corn after it is thrown into the earth, thereby checking the growth entirely, or preventing it from having the strength it otherwise would have, to bring forth a strong productive stalk. It is added, that the first farmer in Clackmannanshire who tried the kiln-drying of wheat, instead of pickling it, learnt it about twenty-five years ago (and he has continued the practice ever since) from an Irishman, who had been appointed by the Board of Trustees to stamp the linens, &c. manufactured in the village of Alva, who asserted that it was practised in his part of Ireland; but at this distance of time, the farmer has forgot what part of Ireland the man said he came from. See PICKLE and STEEPING.

Further, with the view of cleaning smutty grain; various methods have been proposed; as by agitating it with different substances, as sand, and lime made from floue, or white or grey chalk, which, when used, should be finely sifted, and then well blended with the wheat in proportion to the state of the smut, as from one to two bushels for a load of five quarters, which should then be passed through a machine one or more times, according to the purpose for which the wheat is intended. And for common purposes, it is supposed that the smut in wheat may be removed by a machine with brushes, invented for the purpose; but that if it be for feed, it should be put in a trough, or wicker receiver, under the spout of a pump, or the fall of a stream, and be briskly stirred

stirred about, until the injurious substance floats away, or can be skimmed off from the surface. When intended for flour, after this washing, it must be dried on a malt-kiln for the space of eighteen hours, but heated so as not to exceed 85° of Fahrenheit's thermometer. The representation of a machine contrived for this use, may be seen in the Corrected Agricultural Report of Berkshire.

M. Chantran presented a memoir to the French National Institute in 1799, on the smut in wheat, and its acid. After remarking, that stalks which bear charred ears do not differ from others, and that these ears often contain good and bad grains, he thought himself authorized to advance, that this disease does not exist, as generally believed, in the germ of the seed from which they sprung. However, he does not consider liming the seed as useless; he thinks that it destroys the animalculæ attached to the seeds, and that the reason of its not entirely extirpating the smut, is because it cannot act on those small insects which occasion it, and which happen to be scattered in the ground.

Having analysed forty-six grains of smut, he found in this substance an acid easy to be demonstrated. For this purpose, boiling water being infused over it, gave a strong tinge of red to tincture of turnsole, while the remainder of this tincture retained its former character. Smut, deprived of the acid, and calcined in the open air, emitted the odour of burnt corn, and gave a residuum six times as large as the same quantity of the farina of wheat treated in the same manner. This, joined to microscopic observations, says Chantran, proves the animal nature of this substance, and a difference between it and the farina of wheat greater than could arise merely from disease. The acid of smut is not volatile, and may be concentrated by distillation. With lime and with ammonia it proves an insoluble salt; and this distinguishes it from the phosphoric acid. Combined with potash it gave a salt crystallized in small deliquescent needles of a bitter taste. It decomposes carbonate of lime.

SMUT, or *Blacks*, in oats, a sort of vegetable disease that often occurs or takes place in crops of this kind, in much the same manner as that of smut in wheat, in many of the country districts. It is said by some to affect the whole of the ear of the grain, being occasionally met with in different stages of its progress in the standing crops, as well as at the time of threshing out the corn, as in those of a soft unctuous state, in the state of a ball, and in a powdery state, or that of a fine dust, which disperses itself in threshing, and fixes upon different parts of the faces of the men who thresh, rendering them quite black. But others, probably without sufficient observation or knowledge of the fact, suppose it to be a plant growing separately among the oats.

It is an affection of this sort of grain which happens frequently on the eastern side of the county of Lancaster, in the life of Man, and in several other situations. It is found to prevail less among the potatoe oat crops than those of any other sorts of that grain, and to be much more prevalent in some years than in others.

No effectual method of preventing it has yet been discovered, but it is found to be much lessened by the good cultivation and management of the land on which this sort of crop is grown. The oat crops, where it exists to any considerable extent, are much less productive than in other circumstances, and the quality of the produce is probably not so good. But the diseased substance is so light in its nature, that it is readily blown away in dressing or cleaning the grain without its doing much mischief to it.

SMUT-Balls, the small balls of smutty matter which are found among diseased wheat and other crops. These balls, as well as the diseased parts of the crops, appear now, from

actual experience, to be constantly of a very infectious nature, and should, of course, be as much guarded against, and cautiously avoided, in preparing the seed of the crops for sowing, as possible; as it is not improbable, but that the disease may sometimes be communicated and propagated in this way, without the farmer being in the least aware of it. See *STEEPING Seed-Grains and Seeds*.

SMYNHUSEN, in *Geography*, a town of the duchy of Holstein; 6 miles E. of Lunden.

SMYRHIZA, in *Botany*, a name used by Pliny, and some other old authors, for the common myrrhis, or chervil.

SMYRNA, in *Ancient Geography*, one of the Ionian towns of Asia Minor, situated towards the northern part of the isthmus of the peninsula of Colophon, upon a gulf bearing the name of the town. This town is very ancient, and is said to have been founded by the Smyrnæans, who inhabited a quarter of Ephesus called "Smyrna," from whom it derived this name. Being expelled by the Æolians, they retired to Colophon; but the Colophonians having been obliged to expatriate themselves on account of sedition, found an asylum among the inhabitants of Smyrna. Some time afterwards, finding that the Smyrnæans celebrated without their city a feast in honour of Bacchus, they shut the gates and took possession of the town. The Æolians came to their succour; but it was at length determined, by common consent, that they should leave the Ionians in possession of the town, and withdraw themselves with all their moveable effects. The Smyrnæans having accepted this condition, they distributed themselves into eleven other Æolian cities, where they obtained the right of citizenship. At a subsequent period the Lydians took possession of Smyrna under Ardys; and having destroyed it, the inhabitants dispersed themselves into different districts. Four hundred years afterwards, Alexander rebuilt it about twenty stadia from its ancient site. Strabo, however, attributes its re-establishment to Antigonus and Lyfimachus, without mentioning Alexander. Nor does Arrian, in his history of this province, take notice of this circumstance. Hence it is natural to conclude, that Alexander only formed a design of rebuilding it, or that he partially executed his project; that it was continued by Antigonus, and completed by Lyfimachus. This town was destroyed by an earthquake A.D. 180, according to Eusebius, but according to Dion Cassius, two or three years sooner. The Chronicon Pascale dates it A.D. 178. Marcus Aurelius re-established it. The river Meles ran by its walls, and near its source was another, where it has been said that Homer wrote his poems. Hence it was that Tibullus (l. iv. c. 1.) called these poems "Meletere Carmen," but Smyrna arrogates to itself the honour of having given birth to Homer. At Smyrna there was a quadrangular portico, with a temple of Homer and his statue. The Smyrnæans had also a bronze coin, which they called "Homerium." This town was built partly on the brow of a hill and partly on a plain; and towards its front and the gymnasium was the temple of the Mother of the Gods. The streets were paved, and intersected one another at right angles. It had several grand porticoes of a square form, ranges of buildings, and a fine library. In process of time Smyrna became the centre of the commerce of Asia. Luxury drew hither the arts; and it was decorated by superb edifices, and crowded by a multitude of strangers. At Smyrna there were none of those tyrants who oppressed many other cities of Asia, and even the Romans respected the happy state of this town, and left it the shadow of liberty. This city has retained a very considerable degree of its ancient celebrity. See the next article.

SMYRNA, or *Ismir*, in *Geography*, a city and sea-port of Asiatic

Asiatic Turkey, in the province of Natolia, situated on a gulf of the Mediterranean, which is capable of containing the largest navy in the world. On account of the extent and convenience of its harbour, it is become the common rendezvous of merchants from the four parts of the world, and the staple of their commerce; so that it is the first port for trade in the Turkish dominions. Its situation is delightful; and approaching it by sea, it has the appearance of a capacious amphitheatre, crowned at the summits with the ruins of an ancient castle. The bay is extensive, the anchorage excellent, and the water so deep, that ships of considerable burden may anchor close by the wharf. Many English merchants reside here, and they have a consul to protect them. The trade is conducted by Jew brokers, who are wealthy, and live handsomely and even splendidly. The whole town is a continual bazar, or fair, abounding with every thing that serves for clothing, sustenance, and pleasure; all the best commodities of Europe and Asia being brought hither for sale.

The adjacent territory is very fertile, abounding with fine olive-trees and vines; and it affords excellent wine. The European consul lives here in great state and magnificence. The population of Smyrna consists of about 130,000 persons: of these, about 70,000 are Turks, 30,000 Greeks, 15,000 Armenians, 10,000 Jews, and 5000 strangers and Franks. The governor is appointed by the Porte, who manages the civil concerns in the city; but in all criminal cases is subject to the mollah or cadi, who is judge of his district. The salary of the governor, or muselim, is estimated at nearly 300,000 piastres, or about 17,000*l.* sterling.

In the environs are several fine villages, to which the Franks and wealthy inhabitants resort in summer, particularly Bournabat, at the distance of about half an hour's ride, standing on the banks of the Melica, and at the foot of several mountains. Other villages are Cucklueiah, where the imperial consul has a palace; Bugiah, where the British consul has a good house; and Sadig, where the Dutch consul resides.

The total value of goods from Smyrna to London amounted, on an average of the years 1785, 1786, and 1787, to 463,349*l.* sterling, and from London to Smyrna to 423,548*l.* In 1790, 1791, and 1792, the exports to London amounted to 779,610*l.*, and the imports from thence to 848,240*l.* This city suffered very much by a fire on the 6th of August, 1763, which destroyed many of the best houses, factories, and magazines, and occasioned very extensive desolation. The loss sustained was reckoned at 200,000*l.* sterling; 176 miles S.S.W. of Constantinople. N. lat. 38° 28'. E. long. 27° 8'.

SMYRNA, a post-township of America, in the state of New York, and county of Chenango; 105 miles W. of Albany, bounded N. by Lebanon in Madison county, E. by Sherburne, S. by Plymouth, and W. by German. It is six miles square, and its streams supply grain-mills, saw-mills, and a fulling-mill. It has also a small furnace for casting of iron. Its vallies are rich and productive, and a great part of the hilly land is either arable, fit for meadow, or good for grazing. Hemp is cultivated on the rich mould of the vallies, and the timber is principally maple, beech, elm, bals-wood, and hemlock. The first settler here was Porter, in 1792, and a post-office was established in 1808. The whole population, in 1810, consisted of 1344 persons.

SMYRNA, *New*, a town of East Florida, inhabited by a colony of Greeks and Minorquins, established by Dr. Turnbull, on a branch of the Mosquito river. N. lat. 28°.

SMYRNIUM, in *Botany*, indubitably the *σμυρνιον* of Dioscorides, whose ample description is peculiarly appli-

cable to one of the species, *S. perfoliatum*. By his account of the sensible qualities of the seed, being so like Myrrh, the origin of the name from *σμυρρα*, *myrrh*, is sufficiently apparent.—Linn. Gen. 144. Schreb. 194. Willd. Sp. Pl. v. 1. 1467. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 328. Prodr. Fl. Græc. Sibth. v. 1. 202. Ait. Hort. Kew. v. 2. 157. Pursh v. 1. 196. Juss. 219. Tourn. t. 168. Lamarek Illustr. t. 204. Gærtn. t. 22.—Class and order, *Pentandria Digynia*. Nat. Ord. *Umbellatæ*.

Gen. Ch. *General umbel* unequal, increasing daily in size; *partial erect*. *General* as well as *partial involucrem* wanting. *Perianth* scarcely discernible. *Cor. Universal* uniform; the flowers of the disk abortive; *partial* of five lanceolate, keeled, slightly inflexed petals. *Stam.* Filaments five, simple, the length of the corolla; anthers simple. *Pist.* Germen inferior, styles two, simple; stigmas two, simple. *Peric.* Fruit oblong, striated, separable into two parts. *Seeds* two, crescent-shaped, convex on the outer side, and marked with three angles; flat on the other.

Ess. Ch. *Involucrem* neither general nor partial. Fruit oblong, with angular ribs. Petals pointed, keeled, incurved.

1. *S. perfoliatum*. Perfoliate Alexanders. Linn. Sp. Pl. 376. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 289, unpublished. (*S. creticum*; Matth. Valgr. v. 2. 131. Ger. Em. 1024. An Hippocelinum; Column. Ecphr. v. 2. 21.)—Stem-leaves simple, clasping the stem with their heart-shaped base, all serrated and alternate.—Native of Italy and the Levant. Common in the hilly parts of Greece, as well as in Crete and Cyprus. *Sibthorp*. A hardy biennial plant, one of the handsomest of its tribe, naturalized, in a manner, on rock-work, neglected banks, or open borders, in Chelsea garden, flowering in May. This answers most precisely to the *σμυρριον* of Dioscorides, inasmuch that we can only wonder at the doubts of any of his commentators. “*Παραφυρδας εχουσα πολλας*,” surely alludes to the abundance of very peculiar leaves surrounding the stem, which are contrasted, in the next sentence, with the broader foliage, springing from the root. That expression, therefore, is improperly rendered by the word *folioles*, offsets or seyons, of which there are no traces. The root is brown, fleshy, tuberous, with thick fibres. Stem two feet high, much branched, with dilated membranous angles, especially in the branches. *Radical leaves* stalked, twice or thrice ternate; their leaflets stalked, smooth, shining, ovate or wedge-shaped, notched, three-cleft, or variously lobed; *stem-leaves* sessile, simple, roundish-heart-shaped, crenate, smooth, reticulated with veins, either mere or less obtuse, or acute and elongated, embracing the stem with their broad, rounded base, one of whose lobes folds over the other; their colour becomes a rich golden yellow as the *flowers* advance toward perfection; the upper ones are gradually smaller, more coloured, and closer together. *Umbels* yellow, of many rays. *Seeds* black, globose, angular, scarcely ribbed, about the size of cabbage seed, of a hot, pungent, aromatic flavour, like the rest of the plant. The *petals* are really heart-shaped, with inflexed points.

2. *S. ægyptiacum*. Egyptian Alexanders. Linn. Sp. Pl. 376. Amoen. Acad. v. 4. 270. Willd. n. 2.—Floral leaves opposite, heart-shaped, entire.—Gathered in Egypt by Hasselquist. Of this there is no figure. By the Linnaean specimen, which consists of the top of the plant only, it appears nearly akin to the preceding; but differs essentially in having the *branches* opposite, or three together, not alternate, the *floral leaves* being also disposed in the same manner, and nearly, if not absolutely, entire.

SMYRNIUM.

3. *S. laterale*. Cape Alexanders. Thunb. Prodr. 51. Willd. n. 3.—Stem-leaves ternate, cut and serrated. Umbels lateral, sessile.—Gathered by Thunberg, at the Cape of Good Hope.

4. *S. Olusatrum*. Common Alexanders. Linn. Sp. Pl. 376. Willd. n. 4. Fl. Brit. n. 1. Engl. Bot. t. 230. (Smyrniac; Matth. Valgr. v. 2. 130. Hippofelinum; Ger. Em. 1019. Petroselinon Alexandrinum; Trag. Hist. 436.)—Stem-leaves ternate, stalked, serrated. Umbels terminal.—Native of rocks near the sea, the borders of marshes, or the neighbourhood of ancient buildings, in Britain, France, Spain, Holland, Cyprus, Greece, and Asia Minor, flowering in spring. The root is fleshy, usually biennial, but we have observed it to live several years in a situation where it could not produce flowers. Whole plant smooth, light green, shining, bushy, three feet high, of an aromatic and sweetish flavour. Stem round, pale, furrowed, hollow. Lower leaves thrice ternate, with broad, deeply serrated, variously shaped leaflets, ovate or wedge-shaped at the base. Footstalks dilated, concave, ribbed, and membranous. Umbels numerous, greenish-white, globose, of many general and partial rays; very rarely accompanied by a few small, awl-shaped leaves of a general involucre, but this is accidental, and occurs now and then in other genera that, like this plant, have never any partial involucre. The fruit is black, composed of two aromatic, acrid, bitter, three-ribbed seeds, as big as those of the garden *Tropaeolum*, or Nasturtium. There can be no more doubt of this being the *σμυρνιεύου* of Dioscorides, than there is respecting his synonym for our first species. The old name of *Olus atrum*, or Black Pot-herb, probably alludes to the colour of the seeds, which are remarkably large and conspicuous. Our English one was perhaps introduced from Germany, where, as well as in Italy, Ray says the plant is called *Herba Alexandrina*. Were it not for this information, we might suspect Alexanders, or Alifanders, (as the word sometimes is written,) to be a corruption of *Olusatrum* pronounced with a broad foreign twang. The root and young herbage formerly served those purposes in salads and broths, which are now better answered by the more delicately flavoured Celery.

5. *S. apiifolium*. Smallage-leaved Alexanders. Willd. n. 5. Ait. n. 3. (*S. creticum*, paludapii folio; Tourn. Cor. 22.)—"Stem-leaves wedge-shaped, obtuse, three-cleft, toothed."—Gathered in Crete, by Tournefort, from one of whose specimens, consisting of a branch with umbels in seed, Willdenow adopted this species. He informs us there was no general or partial involucre. We have seen nothing answering to the above account.

6. *S. cordatum*. Heart-leaved Alexanders. Walt. Carolin. 114. Pursh n. 1. (*Thapsia trifoliata*; Linn. Sp. Pl. 366. Willd. Sp. Pl. v. 1. 1465. Ait. Hort. Kew. v. 2. 156. *Sium folio infimo cordato, caulinis ternatis, omnibus crenatis*; Gron. Virg. 43.)—Radical leaves roundish-heart-shaped, crenate, simple; those of the stem ternate, stalked, acute, serrated. Ribs of the seeds prominent, compressed.—In woods, frequently on the mountains, from New England to Carolina, flowering in June and July. Root perennial. Flowers yellow. Pursh. The habit of the whole plant, and, if we mistake not, the character of the seeds, both agree with the present genus, but not at all with *Thapsia*; yet it is to be wished that Walter, in transferring this species hither, had not needlessly changed the specific name. The herb is smooth, slender, erect, slightly branched. Leaves light-green; the radical ones simple, shaped like those of a violet, on long stalks; the rest ternate, more ovate and acute. Umbels

small, dense, terminal, solitary. Walter says the flowers are white; and so they appear rather than yellow, in Kalm's specimen. The seeds are small, oval, brown, with three prominent, rounded, thick-edged, flat ribs to each.

7. *S. aureum*. Golden Alexanders. Linn. Sp. Pl. 377. Willd. n. 6. Ait. n. 4. (*Angelica acadensis*, flore luteo; Dodart Mem. ed. Amsterd. 557. t. 1.)—Leaves twice ternate; the middle division often pinnate; leaflets ovato-lanceolate, strongly serrated. Seeds elliptical, furrowed.—On the mountains and hills, near banks of rivers, from Pennsylvania to Carolina, flowering in June and July. Pursh. Root perennial, black, tufted. Stems numerous, erect, hollow, a foot and a half high, angular, furrowed, smooth like every other part of the plant, except at the origin of the footstalks. Lower leaves on long stalks, spreading; their leaflets an inch or more in length, coarsely serrated, acute, but not pointed. Umbels small, dense, yellow. Seed brown, not unlike Caraway seeds. The whole plant is said by Dodart to be acrid, bitter, and aromatic, "very different in flavour from common *Angelica*." We have, from the Rev. Dr. Muhlenberg, a variety of this, with much narrower, sharper, more finely serrated leaflets.

8. *S. acuminatum*. Pointed-leaved Alexanders. (*S. aureum* β; Linn. Sp. Pl. 377. Willd. n. 6. *S. foliis caulinis decompositis acuminatis*; Gron. Virg. 44.)—Leaves twice ternate; the middle division pinnate; leaflets ovate, taper-pointed, copiously and sharply serrated. Rays of the umbel elongated.—Native of Virginia; sent by Gronovius to Linnæus, who confounded it improperly with the last. The whole plant appears to be much larger. Stalks of the radical leaves at least a foot long; leaflets two inches or more in length, with very numerous, close, acute, rather unequal serratures, and taper points; stem-leaves smaller, less compound. Umbels solitary, on long terminal stalks; the general rays above an inch long, while in flower, accompanied, in our solitary specimen, with a serrated accessory leaf, which cannot be supposed a general involucre, though a few of the partial umbels are each also furnished with a single entire lanceolate leaf, more indicative of a partial involucre. The flowers seem to be yellow. We have no knowledge of the seeds, and the genus of this plant must therefore remain doubtful.

9. *S. atropurpureum*. Dark-purple-flowered Alexanders. Lamarck Dict. v. 3. 667. Pursh n. 3.—"Leaves all ternate; leaflets ovate, acute, serrated."—On dry slate hills in Virginia and Carolina, flowering from May to July. Pursh. Root perennial. Stem a foot or more in height, slightly branched, angular, smooth. Leaflets ovate, more or less elongated, pointed, smooth, rather fleshy, finely and regularly serrated, and somewhat cartilaginous at the edges, green on both sides. Umbels small, terminal, stalked, of a very dark purple; the partial ones having sometimes a very short involucre. Desfrouseaux (in Lamarck).

10. *S. integerrimum*. Entire-leaved Virginian Alexanders. Linn. Sp. Pl. 377. Willd. n. 7. Ait. n. 5. Pursh n. 4.—Leaves glaucous, twice or thrice ternate; leaflets oval, entire. Rays of the umbel elongated. Central flowers abortive. Seeds ovate, angular.—On dry hills, from New England to Carolina, but scarce; flowering in June. Root perennial. Pursh. The whole plant is smooth; and glaucous in some degree. Stem round, somewhat branched, leafy. Leaflets about an inch long. Common footstalk of the stem-leaves concave, dilated, membranous; partial ones long and slender. Umbels without any general or partial involucre; the general rays long and slender; partial ones short. Flowers yellowish; the central ones male,

male, or abortive. *Fruit* the size of mustard-seed, blackish, obscurely angular in Kaln's dried specimen, agreeing much with some kinds of *Ligusticum*, to which genus this plant is closely allied in habit; see *LIGUSTICUM*. The *seeds* of these genera are, in some cases, nearly akin; which circumstance has led a learned botanical traveller, Marschall von Bieberstein, to name a plant of mount Caucasus *Smyrniium nudicaule*, which is no other than *Ligusticum cornubiense*, according to a specimen from Dr. Fischer. This is the more surprising, as the same able botanist had previously described *Danaa* of Allioni, which is the very same species, for a *Pimpinella*. See Sims and König's Ann. of Bot. v. 2. 433. The presence of a general and partial involucre, and especially the small, not capitate, *stigmas*, prove it, nevertheless, to be no *Pimpinella*; nor do the *seeds* themselves answer to that genus.

11. *S. nudicaule*. Naked-stalked Alexanders. Pursh n. 5.—“Leaves radical, ternate; leaflets with a few unequal teeth. Flower-stalk radical. Rays of the umbel elongated, with scarcely any general or partial involucre.”—Gathered by governor Lewis, on the Columbia river, flowering in April and May. *Root* perennial. The natives eat the tops of this plant, and boil it in their soups, as we use celery. *Pursh*.

SMYRNIUM, in *Gardeining*, contains a plant of the herbaceous esculent kind, of which the species cultivated is the common alexanders (*S. olusatrum*).

Method of Culture.—These plants are raised from seeds, which should be sown in the spring, in any light soil and open situation, in shallow drills, fifteen or eighteen inches asunder; and when the plants are come up two or three inches high, be thinned out to six or eight inches distance in the rows, to give them room to shoot up strong; when earth must be drawn up about them gradually, in order to blanch or whiten them a little below, that they may be more crisp and tender for autumn and winter use; but as in the spring following they shoot out again vigorously, some earth should be hoed up close about each plant, and in three or four weeks they will be blanched fit for use.

This is used as a culinary plant, when blanched, in the same manner as celery, and is of a warm aromatic quality.

SMYRUS, in *Ichthyology*, a name sometimes given by Pliny to the fish called by authors *myrus*, the *Muraena myrus* of Linnæus, and by Willughby the *sea-serpent*, with a compressed tail.

It is a species of the *muraena* according to Artedi, and is distinguished from all the others by that author, under the name of the *muraena* with a sharp snout, variegated with white spots, and with the edge of the back-fin black.

SMYTHAM, in *Mineralogy*, lead-ore stamped and pounded down, like powder or sand, to cleanse the stones and earth from the ore.

SNAASEN, in *Geography*, a lake of Norway, in the province of Drontheim, 24 miles long and three wide; 54 miles N.N.E. of Drontheim.

SNACKENBURG, a town of Westphalia, in the principality of Lunenburg-Zelle; 52 miles E.S.E. of Lunenburg.

SNÆFELL'S SYSSEL, a district of Iceland, about six miles to the west of Miklaholt, which is a village situated on a small eminence, completely surrounded by morasses, and consists of a church, the priest's house, and a few cottages. This Syffel forms the extremity of the peninsula, terminated by the Snæfell Jökul. The central part of this peninsula, through its whole length, is occupied by a lofty range of mountains, between which and the sea, on the

southern side, an extensive tract of flat land intervenes. Beyond Miklaholt, this plain narrows considerably, becoming not more than three or four miles in width. Some part of this extent is sandy, and appears to have been left by the sea. The greatest part, however, is boggy; and the whole is covered with an abundance of fine grass, on which numbers of cattle and sheep are seen grazing. Here and there are small elevations. See *STADERSTAD*.

The height of Snæfell Jökul was ascertained by calculation to be 4558 feet; which estimate differs no more than a few feet from the measurement of the Danish officers, who at this time (1810) were employed in surveying the coasts of Iceland. Nevertheless, Eghert Olafsoo, one of the most eminent naturalists in modern times, asserts that, by barometrical measurement, he found the height of this mountain to be not less than 7000 feet; a calculation that certainly differs widely from the truth. This mountain is volcanic, as part of it has discharged lava, which has flowed into the sea; but this lava is very ancient; as no eruptions have taken place, either from the Snæfell Jökul, or from any part of the adjacent mountains, since the island first became inhabited. This mountain was ascended by the travellers whose report we are now citing, and they have described the progress of their ascent, which was a very adventurous undertaking, on account of the chasms and precipices occasioned by the snow that covers the summit and sides of it.

Snæfell Syffel is situated on the western coast (see *SYSSEL*), and contains 270 farms, 652 families, and 3541 inhabitants. Mackenzie's Travels in Iceland.

SNAFELSNESS, a promontory on the west coast of Iceland, 45 miles long, and five broad.

SNAFFEN, a town of Norway, in the province of Drontheim; 46 miles N.E. of Drontheim.

SNAPPLE, in the *Manege*, a well-known kind of bridle. The snaffle, after the English fashion, is a very slender bit-mouth, without any branches; they are much used in England instead of true bridles, which are only employed in the service of war. The French call them *bridoas*, by way of distinction from *brides*, i. e. *bridles*.

The snaffle, or small watering-bit, is commonly a scatch-mouth, accoutred with two little very straight branches, and a curb, and mounted with a head-stall, and two long reins of Hungary leather. See *BRIDLE*.

The snaffle is much recommended by Mr. Berenger in his History and Art of Horsemanship, vol. ii. p. 225, &c.

SNAFIELD, in *Geography*, the highest mountain in the Isle of Man; its height, observed by an exact barometer, the mercury of which subsided 2 $\frac{1}{2}$ inches, being about 580 yards. The summit of this mountain affords a prospect of England, Scotland, Ireland, and Wales.

SNAG-GREET. See *SNAIL-COD*.

SNAIL, in *Ichthyology*. See *LIPARIS Nestras*.

SNAIL, *Helix*, in *Natural History*. See *HELIX*.

The *gardea snail*, or *helix lucorum* of Pultney, is a well-known species: it abounds with a viscid slimy juice, which it readily gives out by boiling to milk or water, so as to render them thick and glutinous. The decoctions in milk are apparently very nutritious and demulcent, and have been recommended in a thin acrimonious state of the humours, in consumptive cases and emaciations. See *HELIX Hortensis*.

The *exotic snail*, or *pomatia helix* of Linnæus, is also celebrated on account of its naturalization in this country, by sir Kenelm Digby, and its use, as a food, in several parts of Europe during Lent. See *POMATIA* and *HELIX Pomatia*.

Perrault doubts of snails having eyes, and Dr. Brown denies it;

it; but according to Dr. Porterfield, a good microscope shews them distinctly.

The eyes of snails are lodged in their horns, one at the end of each horn, which they can retract at pleasure. Med. Ess. Edin. vol. iii. art. 12.

The manner of examining these eyes, which are four in number, is this; when the horns are out, cut off nimbly the extremity of one of them, and placing it before the microscope, you may discover the black spot at the end to be a really semiglobular eye.

The dissection of this animal is very curious; for by this means the microscope not only discovers the heart beating just against the round hole near the neck, which seems the place of respiration, but also the liver, spleen, stomach, and intestines, with the veins, arteries, mouth, and teeth, are plainly observable; the guts of this creature are green, from its eating of herbs, and are branched all over with fine capillary white veins; the mouth is like a hare's or rabbit's, with four or six needle-teeth, resembling those of leeches, and of a substance like horn.

Snails are said to couple three times at the distance of about fifteen days from each other, nature producing a new spear for each time of copulation, which lasts ten or twelve hours; at the end of about eighteen days they bring forth their eggs, by the aperture of their neck. Baker's Microscope, p. 217. Mem. Roy. Ac. Abr. vol. iii. p. 85.

So small an animal as the snail is not free from the plague of supporting other small animals on its body; and as in other animals we find these secondary ones either living only on their surface, as lice, &c. or only in the intestines, as worms; it is very remarkable that this creature infests the snail in both these manners, being found sometimes on the surface of its body; and sometimes within its intestines.

There is a part of the common garden snail, and of other of the like kinds, commonly called the *collar*; this surrounds the neck of the snail, and is considerably thick, being the only part that is visible when the animal is retired quietly into its shell. In this state of the animal, these insects, which infest it, are usually seen in considerable numbers, marching about very nimbly on this part: besides, the snail, every time it has occasion to open its anus, gives them a place by which to enter into its intestines, and they often seize the opportunity. Mem. Roy. Ac. Abr. vol. iii. p. 377, &c.

Snails are great destroyers of fruit in our gardens, especially the better sorts of wall-fruit. Lime and ashes sprinkled on the ground where they most resort, will drive them away, and destroy the young brood of them: it is a common practice to pull off the fruit they have bitten, but this should never be done, for they will eat no other till they have wholly eat up this, if it be left for them.

Aristotle and the old Greeks had no idea of the generation of these insects in the manner of other animals, but supposed them produced spontaneously; but the Romans shew, by many passages in their writings, that they have got over this error; and even seem, by the preference they gave to the neck of this animal in this intention, to have understood the hermaphrodite structure of this insect, which much later ages have pretended to make a new discovery.

The eastern nations at present run much into the opinions of the Romans of old, as to provocatives; they use, as the others did, every thing that serves to the purposes of generation in other animals, and every thing that has but the resemblance of the external figure of the parts subservient to it.

SNAIL, *Ear*. See SHELLS.

SNAIL, *Naked, Limax*. See SLUG and LIMAX.

SNAIL, *Oat*, a name given by Dr. Litter, in the Philosophical Transactions, to a small snail, which he observed under the loose bark of old willows, elms, and other trees, and which is of a very singular structure; the shell resembling an oat-corn, whence the name, and its volutæ, or wreaths, running contrary to the direction of them in other snails, that is, east and west, as the philosophers express it, referring it to the motion of the sun; but these shells, to use that language, have the turns west and east, or more plainly, they have the turns running from the right hand to the left, not from the left to the right, as other snails. Phil. Trans. N^o 250.

SNAIL is also the name of the animal inhabiting many kinds of shells, as the patella, cochlea, nerite, buccinum, turbo, trochus, voluta, murex, purpura, lyra, and concha Veneris. See PATELLA, COCHLEA, &c.

SNAIL-*Cod*, in *Agriculture*, a name given by Mr. Worlidge to a species of manure found at the bottom of deep rivers. It is a kind of mud or sludge, very soft, full of wrinkles, and intermixed with many little shells and snails, to which it is thought to owe a great part of its richness. It is sometimes called *snag-greet*.

SNAIL-*Flower*, in *Botany*. See PHASEOLUS.

SNAIL-*Horned*, in *Rural Economy*, a term applied to the horns of such cattle as have them short and down-hanging, with blunt points, and somewhat bent, in the common form of the snail.

SNAIL-*Shell, Medic or Trefoil*, in *Agriculture*, a plant of the artificial grass kind, often known by the name of heart clover or trefoil. It was introduced into Berkshire, according to the agricultural report of that district, by captain Vancouver, on his return from his voyage round the world, though a native of that country, under the notion of the seeds being those of some more important plant from the South Sea islands. It has since been cultivated there, it is said, with success, producing a luxuriant herbage, of which cattle are extremely fond. It stands the winter well, and a crop may at any time be produced. It is asserted to have the advantage of lucerne, in not being easily choaked, and in growing on a light soil, though it without doubt produces the most abundantly in good soils. The cultivators have hitherto sown it in the broad-cast method, and are, it is said, determined to persevere, having now collected a sufficient quantity of its seed to enable them to extend their trials to some acres of land.

It would seem to be deserving of trials in other counties, where herbage is scarce and not easily raised.

SNAIL-*Trefoil*, in *Botany*. See MEDICAGO.

SNATH, in *Geography*, a market-town in a parish of the same name, lower division of the wapentake of Osgoldcross, liberty of the honor of Pontefract, and West Riding of Yorkshire, England, is situated at the distance of 22 miles S. by E. from York, and 174 miles N. by W. from London. The site of this town is a gentle eminence, which rises from the southern bank of the river Aire, and overlooks a flat and fertile district of country. The market-day here is Thursday, weekly; and there are fairs on the first Friday in April, 10th of August, and first Friday in September, for horned cattle, sheep, woollen cloth, linen, and cheese. The church is an ancient building, in the pointed style; remarkable only as the burial-place of the ancestors of lord viscount Down, who has a seat at Cowick, about a mile S.E. from Snath. Carlton, two miles to the N.E., is the seat of the family of Stapleton, whose ancestors distinguished

guished themselves by their bravery and loyalty during the civil wars between king Charles I. and his parliament.

According to the parliamentary returns of 1811, Snaith parish includes eleven townships, viz. Armin, Baln, Cowick, Goole, Hick, Henfall, Hooke, Follington, Rawcliff, and Snaith, which united contain 1133 houses, and 5095 inhabitants, of whom about 743 reside in the town of Snaith. Beauties of England and Wales, vol. xvi. by John Bigland, 8vo. 1812. Carlisle's Topographical Dictionary of England, 4to. 1808.

SNAKE, ANGUIS, in the Linnæan *System of Zoology*, is a genus of serpents, the characters of which are, that the animals belonging to this genus have abdominal and sub-caudal scales. Here we may observe, that Linnæus has distinguished the small scales, with which the back and sides of the animals belonging to the class of serpents are covered, by the name of *squamæ*; and the oblong, narrow, transverse plates, with which the bellies of some of them are covered, by the denomination of *scuta*. Those that have both *squamæ* and *scuta*, he distributes under the genus of *coluber*; those that have only *squamæ*, under the appellation of *anguis*. In conformity to this distribution, he has ranked the common snake, as well as the viper, &c. under the genus of *coluber* (which see); and classed sixteen different species, as the four-footed Javan snake, the common slow-worm, &c. under that of *anguis*. See SERPENTES.

SNAKE, Annulated. See AMPHISBÆNA and SERPENTES.

SNAKE, Argus. See COLUBER *Argus*.

SNAKE, Australasian. See COLUBER *Australasia*.

SNAKE, Black. See COLUBER *Constrictor*.

SNAKE, Black and Red. See COLUBER *Torquatus*.

SNAKE, Blood, Hamorrhous, the name of a peculiar species of serpent, so called, because it was supposed, that on a person's being bit by it, the blood flowed out of every part of the body.

It is a small serpent, seldom arriving to more than a foot long; its eyes are remarkably vivid, bright, and sparkling; its skin is very glossy, and its back variegated with a great number of black and white spots; its neck is very slender; its tail extremely sharp, and it has a sort of small horns placed over its eyes. It is found in Egypt.

There is also an American kind of this, found in the southern parts, and called by the natives *abucyalli*, which is larger than the other, and resembles the rattle-snake in many particulars, but wants the distinguishing character in the tail.

SNAKE, Boaform. See COLUBER *Boaformis*.

SNAKE, Brazilian. See COLUBER.

SNAKE, Bull-headed. See COLUBER *Bucephalus*.

SNAKE, Coach-whip. See COLUBER *Flagellum*.

SNAKE, Common, or Ringed, Coluber Natrix of Linnæus. See NATRIX and COLUBER *Natrix*.

The following account of an easy method of preserving snakes may not be unacceptable. When the snake is killed, it must be washed clean, and put into a glass of a proper size, the tail first, and afterwards the rest of the body, winding it in spiral ascending circles, and disposing the back, which is always the most beautiful, outwardly. A thread connected with a small bead is then, by a needle, to be passed through the upper jaw from within outwardly, and then through the cork of the bottle, where it must be fastened: by this means the head will be drawn into a natural posture, and the mouth kept open by the bead, by which the teeth, &c. will be discovered. The glass is then to be filled with rum, and the cork sealed down. In this manner the snake may be preserved for many years; nor will the spirits impair or change the lustre of its colour.

SNAKE, Daboya. See COLUBER.

SNAKE, Hooded. See COLUBER *Naja*.

SNAKE, Horned. See CERASTES and COLUBER *Cerastes*.

SNAKE, Javan. See COLUBER *Javanicus*.

SNAKE, Oak. See DRYINAS and CROTALUS.

SNAKE, Panther. See COLUBER.

SNAKE, Rattle, a very dreadful genus of serpents. See CROTALUS.

SNAKE, Ruffelian. See COLUBER *Ruffelli*.

SNAKE, Sand, the English name of a kind of serpent found in Lybia, and some parts of Italy. See AMMO-DYTES.

SNAKE, Sea, Serpens Marinus, the name of a fish of the eel-kind, being the cylindric *muræna* (which see), with the tail naked and acute, usually of five or six feet in length, and a furrowed body, continuing all the way of the same thickness, till near the tail. Its back is of a dusky yellow, and its belly a shining blue; its snout is long, slender, and pointed, and the opening of its mouth extremely large; near the end of the under jaw it has four or five large sharp teeth, which bend backwards; the rest of the teeth are very small, and stand close together; at the very extremity of the upper jaw it has four very large teeth, and all the rest are small, and like those in the under one; but the largest teeth of all are placed in a row, in the middle of the palate; it has only one pair of fins, which are placed near the gills; the opening of the gills is at a considerable distance from the head, and it is marked with dotted lines down its sides. It is common in the Mediterranean, and its flesh is very fine tailed, but full of small bones. Willughby, Hist. Pisc. p. 108.

Bishop Pontopiddan mentions (in his Hist. of Norway, vol. ii. p. 195, &c.) a sea-snake of a very prodigious size; for the particulars of its dimensions, &c. we must refer to the testimonies which he has recorded. These animals, some of which are said to be no less than six hundred feet long, are dangerous to navigators, as they throw themselves over vessels of some hundred tons burthen, and sink them to the bottom by their weight. The preservative against them is castor, the smell of which they are said to avoid. The bishop apprehends, that this creature, which inhabits the North sea, is the leviathan mentioned in the scripture. Isaiah, xxvii. 1. Job, xxvi. 13.

SNAKE, Sleep. See HYPNOTICUS *Serpens*.

SNAKE, Spectacle. See COBRAS *de Capello* and COLUBER.

SNAKE, Triangular-headed. See COLUBER.

SNAKE-Gourd, in Botany. See TRICOSANTHES.

SNAKE-Root, Serpentaria, the root of a species of aristolochia. See ARISTOLOCHIA *Serpentaria*.

The ancients were only acquainted with two kinds of serpentaria, the great and the small: but since the discovery of America, botanists have added several others; as the serpentaria Virginiana, or Virginian snake-root; besides that of Canada, and that of Brasil.

They were supposed to be alexipharmics, or counter-poisons; and as such were ingredients in the Venice treacle.

The herb dragon is also called, by some writers, the great serpentaria; by the ancients, *draunculus major*. This has its stem very straight, smooth, and marked with red spots, like the skin of a serpent; whence, probably, as much as from its virtues, it is that it takes its name. Its root is big, round, and white, covered with a thin skin. The smaller serpentaria, of this kind, has its stalk much like that of the larger, only its leaves are like those of ivy, whereas those of the larger are digitated, after the manner of bastard hellebore. Its root is round and bulbous.

The serpentaria of Virginia, called also colubrina Virginiana, asarum Virginianum, serpentaria nigra, and the contrayerva of Virginia, has its leaves green and large, almost in figure of a heart; its fruit round, and its root, which is of a very strong aromatic smell, has, at bottom, an infinite number of long small filaments, representing a kind of beard, of a brownish colour on the outside, and paler or yellowish within.

It was first brought into Europe from Virginia by the English; and is by the Americans esteemed a sovereign antidote against the bite of the rattle-snake.

We are told by travellers, that this root not only cures the bite of a rattle-snake, but that that animal flies the very smell of it; for which reason the Indians, and other travellers, always carry it with them on the end of a staff, by way of a preservative from that creature.

The dried serpentaria root is imported into this country in bales, each containing from two to five hundred weight. The dried root has an aromatic odour, not unlike that of valerian; and a sharp, warm, bitter taste, resembling in some degree that of camphor. Water extracts all the sensible qualities of the root, affording a yellowish-brown infusion, which is not altered by sulphate of iron or zinc, the nitrate of silver, oxymuriate of mercury, tartarized antimony, the mineral acids, and the alkalies; nor is it precipitated by gelatine or tannin. The superacetate of lead throws down a flocculent precipitate, which is not soluble in acetic acid, shewing the presence of mucus. With alcohol it affords a bright greenish tincture, which is rendered turbid by the addition of water. The active principles of serpentaria, therefore, appear to reside in a bitter resin; and perhaps camphor, and essential oil.

For medical purposes, serpentaria, or Virginian snake-root, is reckoned a stimulating diaphoretic and tonic. It is beneficially employed in typhoid and putrid fevers, whether idiopathic, or accompanying the exanthemata, to excite diaphoresis, and support the powers of the system; and is found frequently to increase the efficacy of cinchona in removing protracted intermittents. It is also an excellent remedy in dyspepsia, particularly when the skin is dry and parched; and is sometimes used as a gargle in putrid sore-throat. On account of its stimulant properties, it is contraindicated when the inflammatory diathesis is present; and previous to its exhibition, the bowels should be well evacuated.

It may be given in substance, or in infusion made by macerating ziv of the bruised root in $\text{f}\text{z}\text{xij}$ of boiling water, in a covered vessel for two hours, and straining. Decoction is a bad form of giving serpentaria, as the boiling dissipates the essential oil, on which the virtues of the remedy chiefly depend. The dose of the powdered root is grs. x , or grs. xx , increased to zss ; that of the infusion $\text{f}\text{z}\text{ss}$ to $\text{f}\text{z}\text{ij}$, every fourth hour.

The official preparations are as follow: viz. the "tinctura serpentariæ," the "tinctura cinchonæ composita," and the "electuarium opiatum." The "tincture of snake-root" of the Lond. and Dub. pharmacopœias is prepared by macerating for fourteen days (seven days, Dub.) three ounces of snake-root (cut and bruised, Dub.) in two pints of proof spirit, and filtering. The "tinctura arilolochiæ serpentariæ," or "tincture of snake-root," of the Edinb. Ph., is obtained by digesting for seven days two ounces of snake-root bruised, a drachm of cochineal in powder, in two pounds and a half of proof spirit, and filtering through paper. This tincture is an useful addition to infusion of cinchona in typhoid and putrid fevers, gout, and periodic head-ache. The dose is from $\text{f}\text{z}\text{ss}$ to $\text{f}\text{z}\text{ij}$; or when taken

in water, as much as can be taken without any injury from the operation of the spirit.

The "tinctura cinchonæ composita," or "compound tincture of cinchona," of the Lond. and Dub. Ph., is prepared by taking of lance-leaved cinchona bark, powdered, two ounces; dried orange-peel, an ounce and a half (half an ounce, Dub.); Virginian snake-root bruised, three drachms; saffron, one drachm; cochineal in powder, two scruples; macerating for fourteen days in twenty fluid-ounces of proof spirit, and filtering. This tincture is more grateful than the official tincture of cinchona, and though it contains less cinchona, yet the addition of the other ingredients renders it more useful both as a stomachic and a febrifuge. It is the same as the celebrated tincture of Huxham, who generally gave it in intermittents and low nervous fevers, in diluted wine or any proper vehicle, with ten or fifteen drops of elixir of vitriol (aromatic sulphuric acid, Edinb.) The dose is from fzj to $\text{f}\text{z}\text{ij}$, or more, in intermittents. For an account of the "electuarium opiatum," see OPIUM. Thomson's Lond. Disp.

Snake-Root, Rattle. See POLYGALA Senega.

Snake-Root, Rattle, in the *Materia Medica*. See SENEGA.

Snake-Stone, in *Mineralogy*. See AMMONITE.

Snake-Weed Knot-Grass, in *Agriculture*, a common grass by way-fides, which, if cultivated, the seeds are found to answer the same purposes as those of buck-wheat. It is annual, or at most biennial, in its growth.

Snake-Wood, in the *Materia Medica*, is the wood or root of the tree which affords the nux vomica, or of other trees of the same genus. It is brought from the East Indies under the name of lignum colubrinum, in pieces about the thickness of a man's arm, covered with a rusty-coloured bark, internally of a yellow colour, with whitish streaks. This wood, in rasping or scraping, emits a faint but not disagreeable smell; and when chewed for some time, discovers a very bitter taste.

From the experiments of Cartheuser, water appears to be the proper menstruum of its active matter. It has been recommended, in small doses, not exceeding half a drachm, as an anthelmintic, and in obstinate quartans, jaundices, cachexies, and other chronic disorders. It is said to operate most commonly by sweat, sometimes by stool, and sometimes by vomit. It appears, however, to be possessed, in a lower degree, of the same ill qualities with the nux vomica. Lewis.

Snake Creek, in *Geography*, a river of Louisiana, on the north-east side of the Missouri, in N. lat. 38° , 18 yards wide.

Snake Islands, a cluster of small islands in the Indian sea, near the coast of Africa. S. lat. $5^{\circ} 20'$.

Snake Indians, a tribe of Indians in Louisiana, on the south-west side of the Missouri river, near the heads of the Arkansas, Platte, and Yellow-stone rivers. The number of warriors is 200, and of inhabitants 5500. They trade with New Mexico. These Indians, though a very numerous race, are badly armed, and much at the mercy of the other Indians, by whom they are made slaves, when taken prisoners. They are also called Ayuten bands, and Camanches. They wander about the heads of the Platte, and in the vast plains bordering on New Mexico and New Spain, south of the Arkansas; and are divided into many bands. One of these bands is probably that denominated Paunch Indians, who wander along the Rocky mountains, and sometimes venture across. The Snake Indians possess a very great number of horses, asses, and mules. Mr. Brackenridge, in his "Views of Louisiana," observes, that these Indians were different,

different, both in language and appearance, from any whom he had ever seen; and he thinks, that the found of the language bears a considerable resemblance to those of Africa which he had heard. We shall here subjoin a brief account of the river, near which these Indians are settled. The Arkansas, next to the Missouri, is the most considerable tributary of the Mississippi. It is nearly 2500 miles in length, and navigable at proper seasons through nearly the whole distance. The chief rivers which fall into it are the Verdigris, the Negracka, Canadian river, Grand river, &c. Several are much impregnated with salt, and the Arkansas, at certain seasons, is also brackish. The lands on this river, for 600 or 800 miles upwards, are described as very fine, and capable of affording settlements, though principally untimbered. There is a remarkable communication between the Arkansas and White river, by a channel connecting the two rivers, with a current setting alternately out of the one or the other, as the flood in either happens to predominate. The Platte is the longest and largest of the rivers which discharge themselves into the Missouri, being little short of 2000 miles, and yet it can hardly be reckoned a navigable stream; the channel being very wide, and the quicksands, with which it abounds, ever varying. Several fine navigable rivers, however, discharge themselves into it; such are the Elk Horn, the Wolf river, and the Padonca Fork.

The Yellow-stone, or Roche Jaune, much resembles the Missouri in extent and difficulty of navigation, and is a very considerable river. After the junction, the Missouri undergoes a very perceptible change. In seasons of high water, it is more properly a flood, and indeed the descriptions of its rapidity are almost incredible. It enters the Missouri 1880 miles up. Its principal branches are Big Horn, Tongue river, and Clark's river.

SNAKENBURG, a town of Brandenburg, in the Old Mark, on the Elbe; 10 miles N. of Sechaufen.

SNAKING, in the *Practice of Rigging*, a sort of fastening to confine the outer turns of seizings, &c. with the same size rope, line, spun-yarn, &c. by passing it across and under the outer turns at angles; so that one part may remain perfect and independent, if the other should be shot away.

SNAP-DRAGON, or *Calf's-Snout*, in *Botany*. See ANTIRRHINUM.

The least sort of this plant is sometimes a troublesome weed in corn-fields, but it is annual in its growth, and, of course, with care, easily and readily destroyed by preventing its flowering and producing seeds.

SNAP-DRAGON of *America*. See RUELLIA and BARLERIA.

SNAPE, in *Anchor-Making*, denotes the sudden diminution of any part.

SNAPPERTUNA, in *Geography*, a town of Sweden, in the province of Nyland; 7 miles E.N.E. of Eknas.

SNAP-TREE, in *Botany*. See JUSTICIA.

SNARES, in *Geography*, a cluster of craggy islands in the South Pacific ocean, discovered by Capt. Vancouver, on the 24th of November, 1791, and appearing without verdure. The north-eastermost, which is the largest, he apprehended to be equal in extent to all the rest; it is about 9 miles in circuit, and may be seen 8 or 9 leagues off. It is situated in S. lat. 48° 3'. E. long. 166° 20'. Mr. Broughton also discovered these islands on the 23d of the same month, and in passing through them, called the largest "Knight's Island;" which see.

SNARNVIER, a town of Asiatic Turkey, in the province of Sivas, anciently called "Synoria," and once the place where Mithridates kept his treasures; 25 miles S.S.W. of Arabkir.

SNATCH-BLOCKS, in *Block-Making*. See BLOCKS.

SNATHE, in *Agriculture*, a term applied to the handle of a scythe.

SNAYERS, PETER, in *Biography*, a painter of very considerable merit in almost every branch, but particularly in battles, huntings, and landscapes. He was born at Antwerp in 1593, and was a disciple of Henry van Balen. He was held in great estimation by the archduke Albert, who patronized him, appointed him his painter, and sent several of his pictures into Spain. Besides this superior encouragement, he was employed for many of the churches in the Netherlands, and his battle-pieces are to be found in all the most choice collections of that country. Rubens and Vandyck honoured them with their approbation; and the latter painted the portrait of Snayers among the eminent artists of the day. He died in 1670, aged 77.

SNEATH, or SNEYTH, in *Agriculture*, a term applied to the shaft of a scythe in some places.

SNECK, in *Rural Economy*, provincially the latch of a door or gate.

SNECKEN, in *Geography*, a town of Prussian Lithuania; 8 miles W.S.W. of Tilsit.

SNEECK, a town of Holland, in the province of Friesland, situated in the country of Westergoo, called by the natives "Snitz." The town is well-built, and encompassed by ditches and ramparts. Several learned men have been educated in the Latin school of this town; 38 miles W.S.W. of Groningen. N. lat. 53° 4'. E. long. 5° 35'.

SNEEZE-WORT, in *Botany*, a species of *Achillea*; which see.

SNEEZE-WORT, *Austrian*, a species of *Xeranthemum*; which see.

SNEEZING, in *Medicine*, *Sternutatio*, a violent convulsive motion of the muscles of respiration, which is preceded by a deep inspiration filling the lungs, then forces the air violently through the nose, while the lower jaw is at the same moment closed, and shakes the head and whole body. See LUNGS.

Sneezing is always excited by some irritation affecting the inner membrane of the nose; and the air, therefore, which in coughing is expelled through the mouth, is vehemently driven through the nostrils in sneezing, for the purpose of expelling that irritation. When a person is about to sneeze, he perceives a sort of gentle and agreeable tickling in the nose, and sometimes there is also a similar sensation about the præcordia: when one or both these are felt, the person is obliged to suspend all the bodily actions and wait the event; the whole effort of the body appears to be centered in the convulsion which ensues, and the expulsion of the air through the nostrils is accompanied by the peculiar noise so well known. In general, one or two of these convulsive efforts effects the purpose of removing the irritating cause; but cases are recorded, in which the repetition and violence of the convulsion have been increased to the extent of becoming a disease; and, in persons of an apoplectic disposition, it is even said to have induced that disease, and thus to have proved fatal. (See a case related by Morgagni, De Sed. et Caus. Morborum, Epist. xiv. art. 27.) It is clearly demonstrable, indeed, as Van Swieten has shewn, that continued paroxysms of sneezing tend to load the vessels of the head with blood: for the violent contraction of the chest impedes for the time the passage of the blood through the lungs, and therefore obstructs the return of the venous blood from the head, the vessels of which necessarily become distended. That this is actually the case is evident from the appearances; because, on a repetition of sneezing, the face swells and looks redder, the eyes water and appear full and distended,

distended, and the nose drops from the increased secretion into its cavities. (Van Swieten Comment. ad Aph. 271.) Its occasional dangerous violence is said to have been the cause of the benediction, so universally bestowed on those who sneeze, of which we shall say more presently.

The causes of sneezing are various, and consist not only of irritating matters immediately stimulating the lining membrane of the nose, but of sympathetic irritations from neighbouring, or even from distant parts. Any extraneous body brought into contact with the pituitary membrane, such as instruments, and especially irritating powders, such as snuff, or even its own mucous fluids, under particular states, will excite sneezing. As a direct communication exists between the eyes and the nostrils, into which the tears are constantly passing through the lacrymal ducts, a reverse sympathy is excited in many people by irritations of the eye, so that the membrane of the nose is at the same time titillated; whence, in such persons, sneezing is immediately excited by sudden exposure to a strong light, as by passing from a shade into a bright sun-shine, especially where that is strongly reflected from snow or a white pavement. Other sympathies have been mentioned by medical authors, especially irritations in the lungs, and also in the stomach and bowels, as the causes of sneezing. Thus it has been produced by carbonic acid gas, by fermenting beer, by eating shell-fish, by worms in the alimentary canal, by a leaden ball remaining in the region of the diaphragm, and even by more distant irritations, as by the distention of the gravid uterus in pregnancy, diseases of the head, &c. See Richter's Bibliotheca, vi. 730. See also Sauvages Nosol. Method. who makes seven species of *sternutatio* from these various causes.

It is only in these rare cases in which sneezing, being connected with some other disease, becomes the object of medical treatment; and then of course it can only be remedied by curing the disease, or removing the distant irritations, from which it originates. Like other spasmodic affections, however, it may be alleviated by opiates, with camphor and ether, and similar antispasmodics. It would be fruitless to mention many of the inert remedies that have been proposed; such as bags, filled with aromatic substances, fixed to the vertex, rubbing the gums, &c.

The custom of *bleffing* persons when they sneeze is derived from very ancient times, and its origin has been variously accounted for. Several writers affirm that it commenced in the year 750, under pope Gregory the Great, when a pestilence occurred, in which those who sneezed died; whence this pontiff appointed a form of prayer and a wish to be said to persons sneezing, for averting this fatality from them. But the custom is of much more ancient date. It was accounted very ancient in the time of Aristotle, who in his problems has endeavoured to account for it. It is alluded to in the Greek Anthology in an epigram, in which the salutation of *salve Jupiter, Ζευ σπρωμι*, is given as a familiar phrase addressed to sneezers. Pliny also questions "cur sternutantes salutantur?" (Nat. Hist. lib. 28. cap. 2. Anthol. Lips. 1794. tom. iii. p. 95.); and Cælius Rhodoginus has an example of it among the Greeks in the time of Cyrus the younger. In Alexander Ross's appendix to Arcana Microscopi, p. 222, it is said, "Prometheus was the first that wished well to the sneezer, when the man, which he had made of clay, fell into a fit of sternutation, upon the approach of that celestial fire which he stole from the sun. This gave original to that custom among the Gentiles, in saluting the sneezer. They used also to worship the head in sternutation, as being a divine part, and seat of the senses and cogitation." For many other passages relating to this subject, see Brand's Observations on Popular Antiquities,

edited by H. Ellis, vol. ii. p. 456, et seq. These testimonies are sufficient to shew the antiquity of this custom, and the obscurity of its origin. It may be added, that sneezing has been from ancient times also considered as an *omen*; respecting which Pliny has some observations in the chapter just quoted. It is noticed as such in the eighteenth Idyllium of Theocritus; and by Aristotle, who has a problem, "why sneezing from noon to midnight was good, but from night to noon unlucky."

SNEGACIUS, CYRIACUS, in *Biography*, in 1590 published at Erford, a tract upon "Harmony, or the Use of the Monochord, an Instrument for measuring and ascertaining the Proportion of Sounds by a single String;" of which he ascribes the invention to the Arabians; the only new idea which we could find in the book, which is written in Latin, and of which the original title is, "Nova et exquisita Monochordi dimensio."

The same author published likewise, in 1590, an elementary tract, entitled "Isagoges Musicae," in two books, the chief merit of which seems to consist in the definitions of musical terms, with short examples in notation.

SNEIRNE, in *Geography*, a town of Persia, in the province of Irac.

SNELL, RODOLPH, in *Biography*, a respectable Dutch philosopher, was born at Oudenwater in the year 1546. After having occupied the situation of professor of Hebrew and mathematics at Leyden for some time, he died in 1613, at the age of 67 years. He was a writer of several works on geometry, and various parts of philosophy.

SNELL, WILLEBRORD, the son of the preceding professor, and an excellent mathematician, was born at Leyden in the year 1591, where he succeeded his father in the professorial chair in 1613, and where he died in 1626, at the premature age of 35 years. He was the author of several valuable works and discoveries. To him we owe the first discovery of the true law of the refraction of the rays of light; and this discovery was made, as Huygens assures us, before it was announced by Des Cartes. Snellius undertook also to measure the earth; and this operation he effected by observing the interval between Alcaer and Bergen-op-Zoom, corresponding to a difference of latitude of $1^{\circ} 11' 30''$. He also determined the distance between Alcaer and Leyden; and from a mean of these measurements, he made a degree to consist of 55,021 French toises or fathoms. These measures were afterwards repeated and corrected by Muschenbroeck, who then found the degree to contain 57,033 toises. His works were numerous, and the principal of them are enumerated in Hutton's Dictionary.

SNELLINCKS, JOHN, was born at Mechlin in 1544. He painted in history and still-life; but he derives his principal renown from his skill in representing battles, particularly attacks of cavalry, which were regarded as pre-eminent among works of that kind. He was honoured by the patronage of the archduke and dukes, and most of the nobility of his day in the Netherlands, and enjoyed all the gratifications which employment and applause are calculated to afford. His taste in grouping is judicious, and he knew how to take advantage of the circumstances of a battle to display his knowledge of chiaro-scuro with great effect. Vandyck appears to have honoured him with his approbation, and has painted his portrait among the distinguished artists of his day, and also etched a plate of it. He died in 1638, aged 94.

SNET, among *Sportsmen*, the fat of all kinds of deer. Dict. Russ.

SNEYDERS, or SNYDERS, FRANCIS, in *Biography*. This ingenious painter was born at Antwerp in 1579, and was

was a disciple of Henry van Balen. At the beginning of his practice he confined himself to fruits, flowers, and other objects of still-life; but he soon advanced to the imitation of animated nature, and in the representation of animals in all the vigour of life and action, in scenes of huntings and fightings, if he has had any rival, he has not been surpassed for freedom, truth, and energy.

Though Rubens was excellent in subjects of this nature himself, yet he frequently employed Sneyders to introduce animals into his pictures: and such was his excellence in colouring and execution, that in this dread competition he rose to a level with his great compeer; and produced an union of spirit and effect, which has rarely occurred where two artists have been engaged upon one canvas. Sometimes Rubens, and Jordaens also, returned the compliment, and painted figures in Sneyders' assemblages of beasts, dead game, fish, vegetables, &c. Of these combined labours, we have many excellent examples in this country; and as Sneyders lived to the age of 78, and was an industrious man, they are not thinly scattered on the continent. It is impossible not to be struck with the astonishing facility with which his works are completed; or with the delicacies of drawing, the correctness and fullness of expression, he has given to his animals, their ferocity or their alarm, even their affection for their young or their benefactor. Vandyck painted an excellent portrait of Sneyders, which was in the Orleans collection, and is engraved in the set of his heads. He himself handled the point, and has left several etchings of various animals. They are now become scarce. He died in 1657.

SNEYDSBOROUGH, in *Geography*, a town of America, in Amson county, North Carolina, on the Great Pedee; 120 miles above George-Town.—Also, a post-town in Richmond county, North Carolina, 418 miles from Washington.

SNIADYN, a town of Lithuania, in the palatinate of Brzesc; 88 miles E. of Pinsk.

SNIATYN, a town of Austrian Poland, in Galicia, on the Pruth; 96 miles N. of Lemberg. N. lat. $48^{\circ} 33'$. E. long. $25^{\circ} 52'$.

SNID-SKARON, a small island in the gulf of Bothnia. N. lat. $65^{\circ} 25'$.

SNIEGULKA, in *Natural History*, the name given by the common people of Poland to a bird of passage, that only comes to them in the colder months.

The name signifies the *snow-bird*; and Rzaczinski, in his History of Poland, calls it *nivalis avis*. The people preface from its coming, the mildness or severity of their winter.

SNIGGLING, a method of fishing for eels, chiefly used in the day-time, when they are found to abscond themselves near weirs, mills, or flood-gates; it is performed thus; take a strong line and hook, baited with a lob or garden-worm, and observing the holes where the eels lie hid, thrust your bait into them by the help of a stick, and if there be any, you shall be sure to have a bite; and may, if your tackling hold, get the largest eels.

SNIPE, *Gallinago Minor*, or *Scolopax Gallinago* of Linnæus, in *Ornithology*, a bird well known among the sportsmen, and which, though in general a bird of passage, yet sometimes remains with us the whole year, and builds and breeds here. Its young are so often found in England, that Mr. Pennant doubts whether it ever entirely leaves this island. It lives in marshy places, and builds among reeds in winter, but in the summer is found in our highest mountains as well as low moors; it lays four or five eggs at a time, of a dirty olive colour, marked with dusky spots.

When snipes are much disturbed, particularly in the breeding season, they soar to a great height, making a peculiar bleating noise, and when they descend, dart down with great rapidity. The cock is observed (while his mate sits on her eggs) to poise himself on his wings, making sometimes a whistling and sometimes a drumming noise. Their food is the same with that of the woodcock, and they are found in every quarter of the globe, and in all climates. See *SCOLOPAX Gallinago*.

These birds are easily taken, by means of lime-twigs in this manner: take fifty or sixty birchen twigs, and lime them all very well together; take these out into places where there are snipes, and having found the places which they most frequent, which may be seen by their dung, set the twigs in these places, at about a yard distance one from another. Other places are those where the water lies open in hard frost and snowy weather; in these places also, and wherever they are suspected to come to feed, let more lime twigs be placed in the same manner. The twigs are not to be placed perpendicularly in the ground, but sloping, some one way, some another; the sportsman is then to retire to a distance, and watch the coming of the birds to these places. When they fly to them, they naturally take a sweep round the earth, and by this means they will almost always be caught by one or other of the twigs. When the first snipe is taken, the sportsman is not to run to take it up, for it will feed with the twig under its wings, and this will be a means of bringing down more of them to the place. When three or four are taken, they may be taken up, only leaving one fast to entice others; and thus the sport may be continued as long as there are any birds of this kind about the place. It may be very proper, when the twigs are planted, to go about, and beat all the open and watery places near, that they may be raised from thence, and fly to those places where the twigs are placed to receive them. The snipe, and also the woodcock, are by a late act comprehended under the class of **GAME**.

SNIPE, *Great*, a species very rarely found in England. See *SCOLOPAX Major*.

SNIPE, *Minor*. See **BITTERN**.

SNIPE, *Jack*. See **JACK Snipe**, and *SCOLOPAX Gallinula*.

SNIPE-Bills, in *Maritime Affairs*, a kind of hooks for falleting the axle-tree of chain-pumps to the bits.

SNISNITZA, in *Geography*, a mountain of Bosnia; 8 miles W. of Bosna.

SNIZORT, a town of the island of Skye. N. lat. $57^{\circ} 27'$. W. long. $6^{\circ} 20'$.

SNORING, in *Medicine, *stertor*, *ronchus*, a sound produced by sleeping persons in particular positions, apparently occasioned by the vibrations of the palate in a state of relaxation, when the respiration is performed by inspiring and expiring the air through the mouth and the nose at the same time. The founder the sleep, and the more completely therefore the parts are relaxed, the louder and more constant the snoring. In the profound coma, which constitutes the sleep of apoplexy, snoring is a characteristic symptom; but the apoplectic stertor is also commonly accompanied by an additional noise, arising from the saliva and mucus, which are not swallowed, being forced through the nostrils, and still more impeding the respiration. A similar stertor likewise occurs in the profound coma produced by an over-dose of opium, or of wine and spirits, which indeed is not always easily distinguishable from common apoplexy, except by the knowledge of the cause.*

This snoring is very different from the noisy respiration, or rattling in the throat, denominated *cerchnos* or *cerchon*, which

which is made in the larynx and windpipe, by the passing of the air through an accumulating fluid, as in cases of asthma, or in the last struggles of exhausted life; of the termination of which, in the latter instance, this rattling sound is marked by the attendants as an unerring sign.

SNORT, in the *Manege*, called in French *elrouer*, denotes a certain sound which a horse of fire makes by breathing through his nostrils; as if he had a mind to expel something that was in his nose, and hindered him to take breath.

This noise or sound is performed by means of a cartilage within the nostrils, called in French *fouris*. Horses of much metal snort, when you offer to keep them in. See **SOURIS**.

SNOTTER, in *Rigging*, a short rope spliced together at the ends, and served with spun-yarn, or covered with hide: it is seized to the size of the mast, leaving a bight, wherein is fitted the lower end of the sprit, which confines it to the mast.

SNOV, in *Geography*, a river of Russia, which runs into the Desna, near Beriezin, in the government of Tchernigov.

SNOW, VALENTINE, in *Biography*, an admirable performer on the trumpet, whose exquisite tone and fine shake must be well remembered by many persons now living, who have heard him at Vauxhall, or in Handel's oratorios.

In 1753 he succeeded Shore as serjeant-trumpet, a place of 500*l.* a-year; after which promotion he ceased to perform in public, which was a serious loss to the frequenters of Vauxhall, where his silver tones, having room to expand in the open air, never arrived at the ears of the audience in a manner too loud or piercing.

SNOW, Nix, a meteor formed in the middle region of the air, of vapour raised by the action of the sun, or subterraneous fire; there congealed, its parts condensed, its specific gravity increased, and thus returned to the earth in form of little white villi, or flakes.

The snow we receive, may properly enough be ascribed to the coldness of the atmosphere through which it falls. When the atmosphere is warm enough to dissolve the snow before it arrives at us, we call it *rain*; if it preserves itself undissolved, it makes what we call *snow*. See **EVAPORATION**.

Dr. Grew, in a discourse of the nature of snow, observes, that many parts of it are of a regular figure, for the most part so many little rowels, or stars of six points; and are perfect and transparent ice, as we see on a pond, &c. Upon each of these points are those collateral points, set at the same angles as the main points themselves; among which there are divers other irregular ones, which are chiefly broken points, and fragments of the regular ones: others, also, by various winds, seem to have been thawed, and frozen again into irregular clusters; so that it seems as if the whole body of snow were an infinite mass of icicles irregularly figured. A cloud of vapours being gathered into drops, the said drops forthwith descend; upon which descent, meeting with a freezing air as they pass through a colder region, each drop is immediately frozen into an icicle, shooting itself forth into several points; but these still continuing their descent, and meeting with some intermitting gales of warmer air, or, in their continual wastage to and fro, touching upon each other, some of them are a little thawed, blunted, and again frozen into clusters, or entangled, so as to fall down in what we call flakes.

Clouds of snow, signior Beccaria observes, differ in nothing from clouds of rain, (see **RAIN**;) but in the circumstance of cold, which freezes them. Both the regular diffusion of snow, and the regularity in the structure of the

parts of which it consists, (particularly some figures of snow or hail, which he calls *rosette*, and which fall about Turin,) shew the clouds of snow to be actuated by some uniform cause, like electricity. He even endeavours, very particularly, to shew in what manner certain configurations of snow are made, by the uniform action of electricity. He adds, that his apparatus never failed to be electrified by snow, as well as by rain; and that a more intense electricity unites the particles of hail (see **HAIL**) more closely than the more moderate electricity does those of snow. Lett. dell' Ellettricismo, p. 520, &c. Priestley's Hist. &c. of Electricity, vol. i. p. 432.

The lightness of snow, although it is firm ice, is owing to the excess of its surface, in comparison to the matter contained under it; as gold itself may be extended in surface till it will ride upon the least breath of air.

The uses of snow must be very great, if all be true that Bartholine has said in its behalf, in an express treatise "De Nivis Usu Medico." He there shews, that it fructifies the earth (which, indeed, is a very old and general opinion); and that it preserves from the plague, cures fevers, colics, tooth-aches, sore-eyes, and pleurisies, (for which last use, his countrymen of Denmark usually keep snow-water gathered in March). He adds, that it contributes to the prolongation of life; giving instances of people in the Alpine mountains that live to great ages: and to the preserving of dead bodies; instances of which he gives in persons buried under the snow in passing the Alps, which have been found uncorrupted in the summer, when the snow is melted.

He observes, that, in Norway, snow-water is not only their sole drink in the winter; but snow even serves for food; people having been known to live several days without any other sustenance.

Indeed, the generality of the medicinal effects of snow are not to be ascribed to any specific virtue in snow, but to other causes.

It fructifies the ground, for instance, by guarding the corn, or other vegetables, from the intenser cold of the air, especially from the cold piercing winds; and it preserves dead bodies, by condensing and binding up the parts, and thus preventing all such fermentations, or internal conflicts of their particles, as would produce putrefaction.

It has been a vulgar opinion, very generally received, that snow fertilizes the lands upon which it falls more than rain, in consequence of the nitrous salts which it is supposed to acquire by freezing. But it appears from the experiments of Margraaf, in the year 1751, that the chemical difference between rain and snow-water is exceedingly small, and that the latter, however, is somewhat less nitrous, and contains a somewhat less proportion of earth than the former; but neither of them contain either earth or any kind of salt in any quantity, which can be sensibly efficacious in promoting vegetation. Allowing, therefore, that nitre is a fertilizer of land, which many are, upon good grounds, disposed utterly to deny, yet so very small is the quantity of it contained in snow, that it cannot be supposed to promote the vegetation of plants upon which the snow has fallen.

The peculiar agency of snow as a fertilizer, in preference to rain, may, without recurring to nitrous salts, erroneously supposed to be contained in it, be rationally ascribed to its furnishing a covering for the roots of vegetables, by which they are guarded from the influence of the atmospherical cold, and the internal heat of the earth is prevented from escaping. Snow may also fertilize the earth, agreeably to the hypothesis of those who make oil the food of plants, by means of the oily particles which

which it contains: besides, snow, in melting, moistens and pulverizes the soil which had been bound up by the frost, and thus fits it for the absorption of the vernal dews and rain; and as its water has a tendency to putrefaction, it seems, on many accounts, without admitting it to contain any nitre, to be admirably adapted to promote vegetation. *Watson's Chem. Ess.* vol. ii. p. 77, &c.

It is supposed by Dr. Darwin, that it may be true, that snows of long duration in our winters may be less injurious to vegetation than great rains and shorter frost. First, because great rains carry down many thousand pounds worth of the best manure into the sea; whereas snow dissolves gradually, the upper surface, as it thaws, sliding over the under part, which remains frozen, and thence carries away less from the land into the rivers; whence a snow flood may be distinguished from a rain flood by the transparency of the water. Secondly, snow protects vegetables from the severity of the frost; since it is generally in a state of thaw where it is in contact with the earth; as the earth's heat is 48° , and that of thawing snow 32° . The plants between them are generally kept in a degree of heat about 40° , by which many of them are preserved. On this account, some plants from Siberia were said to perish by the frosts at Upsal; because the snows did not commence at the same time as in the colder climate from which they were brought. And thus, says he, the lichen *rangiferinus*, coral moss, vegetates beneath the snow in Siberia, where the degree of heat is always about 40° ; that is, in the middle between the freezing point and the common heat of the earth. And as this vegetable is, for many months of the winter, the sole food of the rein-deer, who digs furrows in the snow to find it; and as the milk and flesh of this animal are almost the only sustenance which can be procured by the natives during the long winters of those higher latitudes, this moss may be said to support some millions of mankind. And it is added, that snow protects vegetables, that are covered by it, from cold, both because it is a bad conductor of heat itself, and contains much air in its pores. When living animals are buried in snow, as sheep, or hares, the water which their warmth produces, becomes absorbed into the surrounding snow by capillary attraction, and the creatures are not moistened by its dropping on them; but the cavity enlarges, as the snow dissolves, affording them both a dry and a warm habitation. If this was generally known, many cold and weary travellers in snowy nights might be saved by covering themselves with snow, instead of endeavouring to proceed. It should be added, he says, that Haënsfratz has endeavoured to shew, by ingenious chemical experiments, that rain-water and snow contain both of them a redundancy of oxygen, compared with river-water, which they may have acquired in their descent through the atmosphere; and that as oxygen is shewn by the experiments of Ingenhousz and Senebier, to promote the growth of seeds and of plants, he concludes that rain-water and snow promote vegetation in a much greater degree than river-water and ice, which seems to accord with the popular observations on this subject.

Deep and drifting snows are often very dangerous and troublesome on sheep-farms, and the elevated tracts on which they are kept during the winter season, so as to require and demand much attention in the shepherd to prevent their fatal effects and consequences.

It is a popular error, that the first snow that falls in the year has particular virtues. In Italy they cool their wines all the summer with snow-water.

Snow may be preserved by ramming it down in a dry place under ground, and covering it well with chaff. At Leghorn they use barley chaff for this purpose.

Snow and ice are also preserved with straw or reeds. Mr. Boyle has described the manner in his experimental history of cold. See ICE and ICE-HOUSE.

It is usual in hot countries to mix snow and ice with their wine. Hence Pliny says, "Hi nives, illi glaciem potant, pœnasque montium in voluptatem gulæ vertunt."

Signior Sarotti, in the Philosophical Transactions, mentions a red, or bloody snow, which fell on the mountains La Langhe, near Genoa, on St. Joseph's day. This snow, when squeezed, yielded a liquor of the same red colour.

Snow of a very bright red colour has sometimes been found on the summits of the highest mountains. The matter which colours it burns with a smell similar to that of a great many vegetable substances. Saussure, who often collected such snow on the Alps, was induced by this property, as well as by its being found in summer, and in places where many plants were in flower, to consider the colouring matter as the farina of some plant. C. Ramond, who found this dust on the snow of the Pyrenees, remarked, that it is heavier than water, and hence suspected it to be of mineral origin; and he, indeed, found that it arises from the decomposition of certain micas. This decomposition requires, without doubt, the conditions mentioned by Saussure; for C. Ramond found, that they are necessary on the Pyrenees, as well as on the Alps.

Snow, in *Sea Language*, is generally the largest of all two-masted vessels employed by Europeans, and the most convenient for navigation. The sails and rigging on the main-mast and fore-mast of a snow are exactly similar to those on the same masts in a ship, only that there is a small mast behind the main-mast of the former, which carries a sail nearly resembling the mizen of a ship. The foot of this mast is fixed in a block of wood on the quarter-deck, abaft the main-mast, and the head of it is attached to the after-part of the main-top. The sail, which is called the try-sail, is extended from its mast towards the stern of the vessel. When floops of war are rigged as snows, they are furnished with a horse (see HORSE), which answers the purpose of the try-sail-mast, the fore-part of the sail being attached by rings to the said horse, in different parts of its height. Falconer.

Snow-Ball Tree, in Botany, a species of *Viburnum*; which see.

Snow-Berry. See CHIOCOCCA.

Snow-Berry Bush, a species of *Lonicera*; which see.

Snow-Bird, in Ornithology, the *EMBERIZA Nivalis* of Linnæus; which see.

These birds are called in Scotland *snow-flakes*, because they appear in hard weather and in deep snows. Some few breed in the Highlands, on the summits of the highest hills, but the greatest number migrate from the extreme north. Their appearance is a certain forerunner of hard weather and storms of snow, being driven by the cold from their common retreats. Their progress southward is probably thus: Spitzbergen and Greenland, Hudson's Bay, the Lapland Alps, Scandinavia, Iceland, the Ferro isles, Shetland, Orkneys, Scotland, and the Cheviot hills. They visit, at that season, all parts of the northern hemisphere, Prussia, Austria, and Siberia. They arrive lean and return fat. In their flight they keep close to each other, and sing themselves collectively into the form of a ball, at which instant the fowler makes great havoc among them. Pennant.

Snow-Drop, in Botany. See GALANTHUS.

Snow-Drop, Great. See LEUCOIUM.

Snow-Drop Tree. See CHIONANTHUS.

Snow-Maill, in Sheep Farming, a term usually applied by the

the farmers in the northern parts of the island, to the sum of money paid to any person who may be in possession of low grounds, for permitting their sheep to feed thereon in times of deep snows.

Snow-Plough, in *Rural Economy*, a contrivance made use of in Sweden, and other northern countries, for the purpose of clearing roads from snow; and which might probably be employed here with advantage in the same intention. It consists of a shaft, to which the horses are yoked, usually two abreast, and one before. The sleds are constructed of three or four deals, well jointed and nailed together, having more or less height, according as the snow is more or less deep, as from three to four feet. The length is usually about fifteen feet, and two iron bars are nailed to the bottom, to make it slide with greater facility. It has also a box for the purpose of being loaded, to keep it down. It may have any breadth, from fifteen to twenty feet, according as the snow may want clearing. There is a representation of an implement of this kind in the first volume of *Communications to the Board of Agriculture*.

Snow-Stone, in *Natural History*, a name given by some to a very beautiful stone found in America; of which the Spaniards are very fond, making it into tables, and other ornaments, in their houses. Alonso Barba, who had seen much of it, tells us, that it is found in the province of Atacama, usually in pieces of four feet long, and four or five inches broad; so that they are forced to join them in the working. Its general thickness is about two inches. It has a great variety of colours, which form clouds and variegations of a very beautiful kind. The principal colours are red, yellow, green, black, and white. The white is generally formed into spots on the very blackest parts of the mass, and is so beautifully disposed, that it represents snow falling in all its whiteness upon a jetty surface.

Snow Mountains, in *Geography*, a range of lofty mountains, which forms an extensive district in Southern Africa, near the Cape of Good Hope. The whole range of hills which is included under this name forms a large group, of which the two great parallel chains from the west, with another not less extensive chain from the north-east, and a smaller from the south, are all united. The name, in itself, indicates a pretty considerable height; and, in fact, the highest point, called the "Compass-Hill," is, according to the calculations of colonel Gordon, about 300 feet higher than the summit of the "Kamberg," and, consequently, 6500 feet above the level of the sea. This hill is distinguished more particularly from all others in Southern Africa, by being less insulated; or, in other words, it is surrounded every way by hills of a constantly decreasing elevation, till they are lost at length in the plain. On all sides, the slopes are gradual from the summit, so that the traveller may be constantly ascending for several days together, by tolerably commodious paths, without encountering any dangerous steeps, any deep chasms, or rugged precipices. The heights are all rounded like domes; the valleys are spacious and open; and even considerable plains stretch in some places between one ascent and the next. The aspect of the whole mountain is rather naked and uniform than wild and majestic: on account of the gentleness of the acclivity, and the level nature of the valleys, the water does not rush down in torrents, or form deep channels, but rather sinks into the earth; and to this circumstance the fertility of these mountains is to be principally ascribed. In its marshy hollows, the horned cattle find excellent pasture, and the ridges and heights being scattered over with small aromatic plants, the sheep are furnished with an abundant supply of the most salutary nourishment. The climate in the higher parts is cold

in winter, and deep snows fall, which continue to lie upon the ground for many weeks. Nevertheless, the greater part of the country is habitable; the inhabitants of the other parts that are not so, descend into some of the lower parts, where they have a "legplaats," or winter habitation, during the short period in which they are obliged to quit their more elevated situation. In this respect the Snow mountains have a very decided preference over the Roggeveld; and, besides, the weather, in winter, though cold, is clear and bright, whereas, in the Roggeveld, there are often thick fogs, which are very injurious to the cattle.

Three considerable rivers have their sources in the Snow mountains, which are constantly supplied with water through the whole year, from the melted snows and the rain-water. Towards the S. flows the Zondag's river; towards the E. several small streams, which at last unite to form the great Fish river; and at the foot of the mountains on the N. side, rises the Sea-Cow river, which flows into the Orange river, which latter, subsequent to this union, continues its course for more than 100 miles, when it falls into the sea on the western coast. Both the other rivers run in a southerly direction.

The upper stratum of the Snow mountains consists of a large-grained sand-stone, intermingled at intervals with quartz. Lower down they consist of a schist, varying in different parts, both in thickness and colour; but no granite is found here. The soil throughout is a soft argile, which, as well as the sand-stone, is in many parts very much oxidated. The ground is almost every where strewed with loose stones, which very much contribute to keep it cool in summer, and also assist in promoting the vegetation of the plants. Here is no want of springs, and therefore the country is tolerably populous; it is very favourable to the breeding of cattle, and most of the inhabitants are in easy circumstances. But through the country the springs, though constantly flowing, do not yield such an abundance of water as to allow of sufficiently watering the fields for agricultural purposes. On these hills no tree grows; and it is justly observed by Mr. Barrow, that here are people, who in their whole lives never saw a wood, or even a copse. The want of wood prevents a supply of fuel, so that people are obliged to burn the dung of their cattle dried. The bleak wind of winter is particularly adverse to the cultivation of nut or fruit-trees, and even the oak will not thrive. The locusts in this country are very numerous, and very destructive. Game is abundant, but the lions and leopards do great mischief among the flocks and herds. But of all the enemies which this country has to dread, the Bosjesmans are the most formidable, whose maraudings occasion annually a loss of five out of every hundred of the sheep and oxen. The breeding of sheep is the most important occupation of the colonists in these parts. The sheep of this country and of the Roggeveld are the most weighty of any in the colony, and their flesh is reckoned the best flavoured. Some farmers have flocks to the amount of 6000 or 7000, and few have less than 3000. The cattle are not less profitable. The cows give rich milk in abundance, more so than in other parts; and great quantities of butter are carried to Cape Town. Mr. Barrow reckons that a herd of 50 cows will produce at least 100 pounds of butter in a week. The inhabitants of the Snow mountains are a vigorous and cheerful race. Mr. Barrow, it is said, associated with some of the most worthy and respectable people of the colony, and seems to have entertained too favourable an opinion of their general character, as others have found them less friendly and hospitable. It is observed, that without such dogs as this country affords, it would be absolutely uninhabitable. By these the inhabitants are

are defended, not only from their four-footed enemies, but also from the Bosjesmans. Nothing can be compared to their watchfulness; the leopard, the jackal, even the lion himself, are terrified with the barking of the faithful troop, and hasten to retreat.

SNOW-BIRD LAKE, a lake of North America, W. of Hudfon's bay; 12 miles wide from E. to W., but from N. to S. much more extensive.

SNOWDON MOUNTAINS, a cluster or ridge of lofty hills in the county of Caernarvon, North Wales, are situated to the S.E. of the county-town, stretching to the confines of Merionethshire. They are called by the Welsh the mountains of Eryri, and according to an ancient proverb, mentioned by Giraldus, were considered to be so extensive and productive, as to be capable of affording sufficient pasture for all the herds in Wales, if collected together. The same author informs us, that there were two lakes on the high part of these hills, one of which was remarkable for a floating island, and the other for three kinds of fish, *viz.* eels, trout, and perch, which had "only one eye, the left being wanting." The highest summit of this ridge is called by the inhabitants Y Wyddfa, or the Conspicuous, and by the English, specially Snowdon. Though confessedly the highest mountain in Wales, being, according to Pennant, 3567 feet above the level of the sea, it is by no means the most picturesque in its form; for Cadair Idris, Moelwyn, and Arran, in North Wales, and the Cadair Arthur, near Brecknock, in South Wales, present a far bolder outline. Camden remarks of these mountains, that they may be very properly termed the British Alps; "for besides that they are the highest of all the island, they are also no less inaccessible by reason of the steepness of their rocks than the Alps themselves; and they all encompass one hill, which far exceeding the rest in height, does so tower its head aloft, that it seems, I shall not say to threaten the sky, but to thrust its summit into it. It harbours snow continually, being throughout the year covered with it, or rather with a hardened crust of snow, and hence the British name of Craig Eryri, and the English one of Snowdon."

Snowdon was held as sacred by the ancient Britons, as Parnassus was by the Greeks, and Ida by the Cretans. It is still said, "that whosoever slept upon Snowdon would wake inspired, as much as if he had taken a nap on the hill of Apollo." The Welsh also have always had the strongest attachment to the tract of Snowdon. It was, say they, the appurtenance of the principality of Wales, which the prince and his predecessors held from the days of Brute. One of the titles of the prince was that of lord of Snowdon: and, indeed, such was the importance attached to this strong region, that when Llewellyn was at his last extremity, he rejected "the proposal of Edward, of a thousand a-year, and some honourable county in England, to give it up, well knowing that his principality must terminate with the cession." When the English monarch afterwards effected the complete conquest of Wales, he held a triumphal fair upon this mountain, and adjourned to finish the joy of his victory, by solemn tournaments on the plains of Nevin. After this event the tract of Snowdon was annexed to the crown of England, and continued to be a royal forest as late as the reign of queen Elizabeth. Leland informs us, that in his days stags were found here in such numbers, as to destroy the little corn the farmers attempted to sow; but these, Pennant tells us, were extirpated before the year 1626. The same author adds, "Snowdon being a royal forest, warrants were issued for the killing of the deer. I have seen one from the duke of Suffolk, dated April 30, 1552, and

another in the first year of queen Elizabeth, signed by Robert Tounesend; and a third, in 1561, by Henry Sydney. The second was addressed to the master of the game, ranger, and keeper of the queen's highness forest of Snowdon, in the county of Carnarvon. The last extended the forest into the counties of Meirionydd and Anglesea, with the view of gratifying the rapacity of the favourite, Dudley, earl of Leicester, who had by letters patent been appointed chief ranger." Pennant's Tour in Wales, vol. ii. 4to. The Itinerary of Archbishop Baldwin through Wales, A.D. 1188, by Giraldus de Barri, translated by sir R. C. Hoare, bart. 4to. 1806. Aikin's Tour in Wales, 8vo. Wyndham's Tour in North Wales, 4to. Hutton's Remarks on North Wales, being the Result of Sixteen Tours, 8vo. 1803. Bingley's Tour round North Wales, 2 vols. 8vo. 1800. Caernarvonshire, or some Account of its Antiquities, Mountains, and Productions, 8vo. 1792.

SNOW-HILL, a sea-port of Maryland, and capital of Worcester county, situated on the S.E. side of Pokomoke river, containing about 60 houses, a court-house and gaol; the inhabitants of which deal principally in lumber and corn; 158 miles from Washington. N. lat. 38° 11'. W. long. 75° 30'.

SNOWSWICK Pine-Apple Cheese, in *Rural Economy*, a particular sort of cheese made about that place in Berkshire, which are of the pine-apple shape and external appearance. They are principally made upon the farm of a Mr. Pike, and some others, in the parish of Buscot, which are famous for them. They sell considerably higher than those cheeses which are made in the common forms, and they are justly entitled to the distinction and increase of price, in consequence of their peculiar richness, and the delicacy of their flavour. When kept to the proper age, they are, perhaps, not inferior to any cheese in the kingdom.

In regard to the method of making them, the first part of the process is exactly the same as for the common sort. The curds are then well worked and broken down with the hands, after which the whole is pressed into a wooden mould, contrived in the shape of a flower-pot, being afterwards hung up and suspended from beams, rafters, or pegs, in an airy apartment, in a net, the meshes of which mark and indent the surface in the manner of the pine-apple. Salt is then rubbed into and over them, or they are steeped in a suitable brine made from that substance. On the above person's farm, the first of these methods is thought to be the most proper and adviseable. No sort of continued pressure is employed, and yet in firmness, it is said, when dry, these cheeses cannot be distinguished from those which have undergone the force of pressure in cheese-presses.

One of these pine-apple cheeses, for the most part, weighs about five pounds, and in good years, it is said, that two tons of them are made on the farm already noticed alone. It is, indeed, scarcely known that they are manufactured any where else.

Some cheeses are made in other parts of this district, as about Stanford, in the Vale, in the fanciful shape of a hare sitting in her form. These are likewise sometimes coloured with sage. See CHEESE and DAIRYING.

SNUFF, a preparation of tobacco, made by reducing it into a powder, fit to be taken in at the nose, in order to purge or clear the head of pituita.

Ordinarily, tobacco is the basis of snuff; other matters being only added to give it a more agreeable scent, &c. The kinds of snuff, and their several names, are infinite; and new ones are daily invented; so that it would be difficult, not to say impossible, to give a detail of them. We shall only say, that there are three principal sorts: the first granulated

nulated; the second an impalpable powder; and the third the bran, or coarse part remaining after sifting the second fort.

The many mischiefs attending the unnatural practice of taking this powder of tobacco at the nostrils, have been described by the writers in general on these subjects, since this pernicious custom has reigned in the world; but one of the most remarkable accidents, occasioned by it, is related in the *Acta Eruditorum*, which was the forming of a polypus in the œsophagus, that killed the patient, by starving him, from an inability of swallowing. *Act. Erudit. an. 1715, p. 475.* See *PICA Nafi.*

SNUFF, or *Snuffler*, in the *Manege*. See *SNORT*.

SNUG BAY, in *Geography*, a bay in the Straits of Magellan, N.N.W. of Cape Froward.

SNUG Bay Point, a cape in the Straits of Magellan; 8 miles N.N.W. of Cape Froward.

SNUG Corner Cove, a bay of the North Pacific ocean, on the E. side of Prince William's sound, on the W. coast of North America. N. lat. 60° 50'. W. long. 146° 30'.

SNYING, in *Ship-Building*, a term applied to those planks, whose edges curve or round upwards. The great injury occasioned in full bows or buttocks is only to be prevented by introducing steelers. See *STEELERS*.

SNYTE, in *Geography*, a river of England, which runs into the Dean, in Nottinghamshire.

SOA, a town of the island of Cuba; 60 miles N. of St. Yago.

SOA, a small island of the Hebrides, or Western islands of Scotland, situated near the celebrated isle of St. Kilda. It is about a mile in circumference.

SOACA, in *Ancient Geography*, a town situated in the interior of Arabia Felix, according to Ptolemy.

SOAGGIO, in *Ichthyology*, the name of a fish common in the markets of Rome and of Venice, and of the turbot kind. See *LUG-a-leaf*.

SOAID, in *Geography*. See *SAIDOU*.

SOAK, or *SOVIAK*, a town of Arabia, in the province of Mascat, on the E. coast; 5 miles N.W. of Burka.

SOAKAGE, in *Agriculture*, a term applied to the water that drains through the banks or other parts, in fen and other moist districts. It is very considerable and troublesome in some instances, so as to cause much expence. See *EMBANKMENT*.

SOAL, or *SOLE*, in *Ichthyology*, the English name of the fish, called by the generality of authors the *buglossus*, by some *solea*, and the *PLEURONECTES Solea* of Linnæus, which see. Some authors call it the *linguacula*.

The foal is found on all our coasts, but those on the western shores are much larger than those of the north. They are usually taken in a trawl-net; they keep much at the bottom, and feed on small shell-fish. The small foals are much superior in goodness to the large ones.

Soals may be taken at any time of the year, but they must not be under seven inches from the eye to the end of the tail. 1 & 2 *Geo. I. cap. 18.*

SOAL, *Smooth*, from its transparency called the *lantern-fish*. See *PLEURONECTES Arnoglossus*.

SOALTERPOUR, in *Geography*, a town of Bengal; 20 miles E. of Rangamatty.

SOAMUS, (*Tjhamou*), in *Ancient Geography*, a river of India, on this side of the Ganges. Its source was in mount Emodus, S. of the Hydaspes, into which it discharged itself N.E. of Bucephala.

SOANA, a river of Asiatic Sarmatia, the mouth of which is placed by Ptolemy on the western coast of the Caspian sea, above the town of Telcha.—Also, a river of

the island of Taprobana, so called by Ptolemy, who places its mouth on the western coast, between the promontory of Andrasimundum and the town Sindocanda.—Also, a town of Italy, in Etruria, N.W. of the Volturni.

SOANA, in *Geography*, a town of Etruria, the see of a bishop, suffragan of Siena; 24 miles N.E. of Orbitello.

SOANA, a mountain of France; 10 miles S. of Aosta.

SOANDA, or *SOANDUS*, in *Ancient Geography*, a town of Cappadocia, between Therma and Sacæna, according to the Itinerary of Antonine.

SOANE, in *Geography*, a river of Hindoostan, which rises in the country of Allahabad, about 30 miles S.E. from Sohagepour, and runs into the Ganges, near Patna.

SOANEN, JOHN, in *Biography*, a French prelate, was born at Rioms in 1647. His father was an attorney in the presidial court of that city; his mother was niece of the learned Jesuit Sirmont. In 1661 he entered the congregation of the Oratory at Paris, where he took for his confessor the celebrated father Quesnel. After teaching the languages and rhetoric in several of the seminaries of the society, he devoted himself to pulpit services, and with so much success, that he became one of the four distinguished preachers of the congregation, who were popularly denominated the four evangelists. Fenelon joined him with Massillon as models of pulpit eloquence. In 1695 he was placed in the see of Seneza, a bishopric of small revenue, but which, being in a retired situation, required little of the parade of office, and permitted him to expend the greatest share of his income in charity. To his various virtues as a Christian pastor, he united a firmness which enabled him to sustain the part of a martyr to principle. On the publication of the bull *Unigenitus*, which contained a condemnation of Quesnel's opinions, he appealed against it to a future council, and published a pastoral letter, in which he controverted its positions with great force of argument. Cardinal Fleury, resolving to make an example of a disobedient prelate, selected Soanen for a victim; and in 1727, assembling the council of Embrun, procured a condemnation of the licentious bishop, who was suspended from his priestly and episcopal functions, and exiled. In his retreat he had numerous visitors, who paid him the respect due to his virtue and integrity. He died in the year 1740, at the age of 92, revered by the Jansenists as a saint, and condemned by the Molinists as a rebel. He was author of "Pastoral Instructions," "Charges," and "Letters," which were printed, with his "Life," in 2 vols. 4to. and 8 vols. 12mo.

SOANES, in *Ancient Geography*, a people of Asia, in the Colchide, being of the number of those who were in the general assembly of Dioscurias, and who inhabited the summits of mount Caucasus, above the town of Dioscurias, according to Strabo.

SOANGUR, in *Geography*, a town of Hindoostan, in Guzerat; 50 miles S. of Surat. N. lat. 21° 10'. E. long. 73° 33'.

SOANK, a town of Hindoostan, in Bahar; 45 miles S.S.E. of Bahar.—Also, a river of Hindoostan, which rises near Burwah, in Bahar, and runs into the Bramnee, near Khoud, in Orissa.

SOAP, in *Chemistry*, is a name for those bodies which are compounds of the alkalies with fat and the fixed oils. The earths and the other metallic oxyds also combine with fat and oils, forming neutral compounds. The former have been called earthy, and the latter metallic soaps.

The soaps formed by the alkalies have the distinguishing character of being soluble in water and alcohol. The earthy soaps

soaps are perfectly insoluble. And since any of the earths have a stronger attraction for oil than the alkalies, the alkaline soaps are always decomposed by the earths. This occasions the curdy appearance when soap is used with water containing any earthy or metallic salt. It is from this quality that waters are said to be hard.

The earthy soaps are of a greyish-white colour, of a curdy appearance. The metallic soaps are of different colours. Both these and the earthy soaps are formed by adding a solution of an alkaline soap to a solution of an earthy or metallic salt. A precipitate is formed, which is the soap to be obtained. With a solution of iron containing the red oxyd, the soap is of an orange-red colour. It has the consistency of a salve or plaster, but by exposure to the air it becomes dry and friable, but may be softened by heat. When a similar solution of soap is added to a solution of sulphate of copper, a green soap is formed, which is a fluxible mass like wax. Corrosive sublimate, treated in this manner, gives a red soap. All the metallic oxyds may be combined with fat or oil in a similar way.

SOAP, in the *Manufactures* and *Domestic Economy*. This is confined to soaps made with the fixed alkalies, combined with different kinds of fat and oil. These, in the manufacture of soap, are divided into two principal varieties, *viz.* hard and soft.

1. *Hard Soap*.—The alkali employed for hard soap is soda, generally obtained from the different sea vegetables, and called by different names, according to the name of the plant in different countries. Most of the *algæ*, but particularly the *fucus* and *salsola*, afford soda by burning. The vegetables are first dried, and then burnt in pits formed with loose stones. The earthy matter and the soda, with some neutral salts, fuse into a crude mass, in which state it is sold. This substance is furnished in great abundance from the Highlands of Scotland, under the name of *kelp*, and from Alicant in Spain, under the name of *barilla*. In France it is known by the name of *varec*; this being the name of the plant from which it is generally produced there.

It is commonly, however, in this state that it comes to the soap-maker, varying frequently in its value, and often occasioning much uncertainty in its employment. It should be the first business, therefore, of the manufacturer, to assay the substance from which he gets his alkali, even before he purchases it. For this purpose a given quantity should be dried and weighed. After reducing it to powder, it must be treated with hot rain-water, till the water coming from it has no taste, reserving all the portions of water added from time to time. Concentrate this liquid by evaporation, till the quantity of liquid is not more than three times the weight of the quantity taken to be assayed. Now weigh out a quantity of sulphuric acid, say half the weight of the assay. From this quantity take small portions at a time, and add them to the solution above-mentioned, stirring it at the same time with a wooden rod. When the escape of gas begins to diminish on the addition of fresh acid, let the additional portions be very small. Now take bits of paper stained blue with litmus: on dipping one into the liquid, if more acid is wanting, the paper will not be changed, but the moment the paper is turned red by the liquid, cease to add sulphuric acid. Let the remaining acid be now weighed, in order to know what has been used, and note this down. Now take pure sal soda (carbonate of soda) in well-formed crystals, exactly of the same weight with the first assay, and dissolve it in three times its weight of pure water. Weigh out the same quantity of sulphuric acid as before, and just follow the same steps as above directed, till the litmus paper just turns red, then weigh the remaining acid, to obtain the quan-

tity used, and note down as before. Then say, as the acid consumed by the sal soda is to that consumed by the assay, so is 100 to a number which will give the *per centage* of carbonate of soda contained in the crude alkali. Thirty *per cent.* of the carbonate of soda so indicated will be real soda, the only substance which combines with the fat to form soap. When the exact value of the alkali is known, it is then to be treated as follows, to prepare it for mixing with the fat.

The kelp or barilla is first to be pounded, and then mixed with one-fifth its weight of quicklime, in a large vat. These vats are generally three or four in number to each boiler. They are frequently made with brick-work, from four to five-feet cubes, but sometimes of cast-iron. Besides these vats for the infusion of crude alkali, each of these has a similar cavity under it. The bottom of the vat is even with the ground, the under vat being sunk below, and is intended to receive the liquor which runs from a plug-hole in the upper vat, when the infusion has gone on to a certain extent. One of these vats, with its under reservoir, is sufficient for one boiling, but they are generally all at work, in order to give time for the solution of the alkali from the crude mass.

In charging a vat, the barilla, kelp, or potash, and sometimes mixtures of these, are first coarsely powdered, and mixed with quicklime also coarsely powdered; some water is then thrown upon these to slake the lime. In the side of the vat some straw is first placed about the plug-hole, to prevent bits from passing through. The vat is now charged, and water poured upon the materials till it stands considerably above the solid mass. After standing several hours the plug is withdrawn, to let out the solution into the lower reservoir. The plug is now returned, and fresh water poured upon the materials. Some or all the first ley is now removed into one of the other lower reservoirs before the second infusion is drawn off. This is done, that the soap-boiler may always have at command two leys of different degrees of strength, as in the course of every boiling he finds it necessary to use sometimes the weak and at other times the strong.

The number of waters to be added to the materials depends upon the judgment of the workman, who by his taste can tell when the water has dissolved the whole of the alkali. The times of charging the vats are irregular with respect to the times of charging the boiler. Some one of the vats is constantly employed, in order to insure a constant supply of the ley.

The boilers are made to hold from about 20 to 25 cwt. of soap; they are made in two parts, the lower part being about three feet in diameter, and the same in length: under the bottom of this the fire acts. The top part has a flange, to which the upper part is screwed. The latter is nearly an hemisphere, rising above the floor just sufficient to allow the workman to stir the soap when he stands up.

The ley being ready to lade out of the reservoir, which is near to the boiler, the tallow or oil first weighed is put in. When it is sufficiently melted, the workman begins by adding the ley, and stirring the mixture. The alkali and the oil soon begin to unite, forming a milky fluid. As more ley is added, and the stirring continued, the liquid thickens. This is continued generally for 30 hours, and frequently more, till small portions of the soap, taken out from time to time, assume a proper consistence, which the workman by constant experience understands. He now adds a quantity of common salt, which has the effect of separating the watery part from the soap, which contains a portion of neutral salts, that existed in the crude alkali, and sometimes also free alkali, especially when more than enough has been added. The fire is now to be withdrawn, and the mass left to cool. The watery part will be found at the bottom, and
requires

SOAP.

requires to be pumped out by a pump, which is a fixture on the side of the boiler. When this has been removed the fire is rekindled, and if the mass does not melt freely, a little water is added. As soon as the whole becomes liquid, and is made uniform by agitation with wooden poles, the fire is again withdrawn, and the mass allowed to assume a proper consistence for lading. It is laded into square moulds: these are composed of a number of strata lying one upon another, so that when the soap has become solid, each layer of frame-work can be removed, beginning at the top, and the soap is cut into cakes with a piece of small brass wire at every interval: these cakes are afterwards cut into square prismatic pieces, in which state they are sold.

Some manufacturers proceed in a different manner in boiling the soap. In the method above described, and which is practised by a judicious soap-boiler in Derby, the watery part, or what is called the spent ley, is not separated till all the ley is added. This method is called close working, because the liquid is of an uniform thickness all the time, till the salt is added: it then assumes what is called the granular form, in which the watery part is separated from the soap, like the whey and the curd in making cheese. This arises from the soap being insoluble in salt-water. In this state the soap is said to be open, to distinguish it from the state in which it exists before the salt is added, and in which the soap is said to be closed. In the open working the common salt is added at several intervals, in order to keep the soap separated from the water. The fire is also withdrawn several times, and as many times the spent leys are pumped off. After each time, except the last, fresh ley is added and the stirring repeated. The proper state for the soap is known by the appearance of the bubbles. The very hard soap, or that which is made with all soda, is not the most convenient for practice; it is neither so fit for washing the hands, nor so easily reducible to a pulpy state for the different manufactures in which it is employed. The hard white soap, produced in the manufactory above alluded to, is in great repute from its whiteness and its proper consistency. This soap is formed with tallow and a mixture of soda and potash. The boiler holds from about 25 to 27 cwt. of soap. The following are the average proportions of the materials employed; 13 cwt. 2 qr. 16 lbs. of tallow, 5 cwt. 3 qr. 12 lbs. barilla, 3 cwt. 2 qr. 6 lbs. American potash, 4 cwt. 2 qr. 7 lbs. quicklime, and 3 qr. 16 lbs. common salt (muriate of soda.) These materials produce 1 ton 4 cwt. 0 qr. 1 lb. of white soap. The lime, the barilla, and the potash, are mixed together, and placed in the vat already described. In order to furnish the ley which is added to the melted tallow, the lime is employed merely to rob the potash and soda of their carbonic acid, and of course does not enter into the composition of the soap. The neutral salts, which both the barilla and potash contain, are pumped out with the spent leys with a portion of uncombined alkali: of this we shall say something hereafter.

Hence it will appear, that the soap is a compound of pure alkali, with the fat, and a portion of water.

In the making of soap, as in all other chemical combinations, the proportions appear to be definite. Every soap-boiler knows, that where too much ley is added to the fat, the excess will be found in the watery part under the soap; and that if the fat were in excess, the soap would be greasy to the feel, and would otherwise shew the presence of uncombined fat. Hence it will be found on analysis, that the proportions will be uniform, because they are definite. The quantity of soda which combines with olive-oil and tallow,

is about 30 of the former to 212 of the latter; and since an atom of potash is to that of soda as 29.25 to 44.5, 45 of potash will combine with 212 of oil or tallow.

The following is an analysis of soap by Darcet, Lelievre, and Pelletier:

Oil	-	-	-	60.94
Soda	-	-	-	8.56
Water	-	-	-	30.5
				100

If the alkali were potash instead of soda, then the proportions would be,

Oil	-	-	-	58.4
Potash	-	-	-	12.3
Water	-	-	-	29.3
				100

In the first of these analyses, the soda is to the oil as 85 to 609, or as 1 to 7.28 nearly. In the second, the potash is to the oil as 12.3 to 58.4, or as 1 to 4.6 nearly. The specimen of soap before alluded to contains a mixture of potash and soda. The 3 cwt. 2 qr. 6 lbs. of American potash, according to the average value of that article, ought to give 2 cwt. 2 qr. of pure potash. By the above analysis, the 1 ton 4 cwt. 0 qr. 1 lb. of soap ought to contain 7 cwt. 1 qr. 7 lbs. of water. There ought to be therefore only 16 cwt. 3 qr. 21 lbs. of the alkali and tallow. It appears, that in forming this specimen of soap, 100 lbs. of common salt were added, which gives to the soap 55.5 lbs. of soda, and takes away from it 83.25 lbs. of potash. Hence, the alkali resulting from the potash in this soap will be 1 cwt. 3 qr., and 55.5 lbs. of soda derived from the common salt, or 2 qr. 4 lbs. nearly. In order to know what soda is derived from the barilla, we must subtract the tallow and the alkali from the whole; that is (16 cwt. 2 qr. 27 lbs.) 1 cwt. 3 qr. of potash, 2 qr. of soda, and 13 cwt. 2 qr. 16 lbs. of tallow, will leave 3 qr. 6 lbs. of soda derived from the barilla.

The proportions of the soap in question will, therefore, be, in 2689 lbs. of soap,

Tallow	-	-	-	1528	or 57
Soda	-	-	-	146	5.4
Potash	-	-	-	196	7.3
Water	-	-	-	819	30.3
				2689	100

This result, although it contains a little too much of the mixed alkali to correspond with theory, is strikingly near the truth. We may therefore conclude, that soap, in general, contains from 8 to 12 per cent. of alkali, as more or less of each prevails, and about 30 per cent. of water. The hardest white soap made with soda would contain 8 per cent.; and the soft soap, in which potash alone is used, would be a little more than 12 per cent.

In the above specimen of hard soap, it will be seen that 398 lbs. of crude potash furnish 280 lbs. of real alkali, which is seven-tenths of the whole. With this were employed 656 lbs. of barilla, which furnish 90 lbs. of real alkali. Now 192 lbs. of American potash will produce 135 lbs. of pure potash, and this will disengage from 126 lbs. of muriate of soda, or common salt, 90 lbs. of pure soda. Hence 192 lbs. of American potash and 126 lbs. of salt will produce as much soda as 656 lbs. of barilla.

This

SOAP.

This weight of barilla, at the present price, costs 10*l.* 5*s.*: 192 lbs. of potash will now cost 6*l.* 17*s.*; and 126 lbs. of common salt, 1*l.* 17*s.* These two sums are 8*l.* 14*s.* The saving, therefore, in employing potash and common salt, in making even the best hard white soap, instead of barilla, is nearly 5 per cent. But if the two alkalies are to be contained in equal proportions, then about half the common salt only need be used, and the saving will be very considerable. It will also appear evident, that soap may be made of any degree of hardness, by using more or less of common salt with the potash; and that if no salt at all be used, the soap will be soft.

The difference of price between barilla and potash is often much more than at present in favour of using potash: this will make the saving above mentioned more conspicuous.

It must also be remembered, that some salt is always used for the purpose of separating the spent leys from the soap. This has been stated at about three-quarters of a cwt. to 24 cwt. of soap. It seems that a solution of salt of this strength does not dissolve soap.

Hard Soap, Yellow.—This soap is formed of similar proportions of soda and tallow with the last; but it also contains rosin, and sometimes palm oil.

The following are the average proportions of the materials for making yellow soap, which may be relied upon.

Tallow.	Rosin.	Palm Oil.	Barilla.	Potash.	Lime.	Soap produced.
Cwt. qr. lb.						
13 0 11	3 2 18	1 0 0	6 2 14	1 0 16	5 0 9	26 1 21

The whole weight of the materials, exclusive of the lime and the refuse of the potash and barilla, is equal to 24 cwt. 0 qr. 1 lb.; the soap, independent of the water it contains, is 18 cwt. 0 qr. 25 lbs.: this, taken from 24 cwt. 0 qr. 1 lb. leaves 5 cwt. 3 qr. 4 lbs. for the refuse of the tallow, rosin, and palm oil. That the tallow must make much waste will be easily conceived, from the most inferior kind being used. The rosin and oil must also yield much refuse. This refuse is found all together at the bottom of the pan after boiling, and is known in the manufactories under the name of *nigre*.

In boiling the yellow soap, the rosin, oil, and tallow are put into the boiler first. The ley is prepared in a similar vat, and managed in other respects in the same mode as in forming the white soap.

The manner too of adding the ley from time to time, and the stirring, are just kept up in a similar way, till the fatty matter is fully saturated. The time required for boiling the quantity of soap stated above, is sometimes as much as three weeks, during which time it is kept in what is called the open state, that is, the watery part is completely separated from the soap. It would appear that this soap requires merely the presence of the neutral salts in ley to keep it in the open state. This arises probably from this being a less perfect soap, and less soluble in water. The soap appears in small lumps, perfectly detached from the fluid. At the end of every day the soap is allowed to cool, when the thin part sinks to the bottom: this is spent ley, and is pumped off every morning. The fire is again raised, and fresh leys added: the boiling and stirring go on again. This action is repeated till the fat is said to be killed. This, as we have observed, takes sometimes fifteen or twenty days. When this change is complete the fire is withdrawn, and the mass allowed to cool: the last ley is pumped out. The addition of a little water, and the fire being raised, allow the soap

to be dissolved, and the refuse, which is principally the substance we have called *nigre*, is left at the bottom, perfectly distinct from the soap. When the soap is of a proper consistency for caking, it is transferred to the moulds, where it is treated in a manner similar to that already described in the white soap.

It is a question, whether making this inferior soap is so profitable to the manufacturer as is supposed. It has appeared, that in making the quantity of soap above stated, which is 26 cwt. 0 qr. 21 lbs., there are 5 cwt. 3 qr. 4 lbs. of refuse, which is principally in the *nigre*. This refuse will be found very trifling in the white soap; we think not more than $\frac{1}{17}$ th of the weight of the soap. It will be evident, that in making the yellow soap, a great quantity of matter is used which never combines. Would it not be more economical to purify these materials before hand?

Soft Soap.—This differs in its composition from hard, containing no alkali, but potash. We have seen that hard soap may be made not only with pure soda, as is the case in the manufactories in the south of France, but that a tolerably hard soap, much better fitted for practice, is made with about equal portions of potash and soda.

Soft soap made with colourless fat, such as tallow, is a white unctuous substance, about the consistency of lard. If the fat be coloured, the soap partakes of the same. In France and other parts of the continent, it is generally coloured, sometimes with metallic oxyds. Those made with yellow oil are sometimes coloured with indigo, which gives them a green colour. The oils employed are seldom olive-oil, but the cheaper oils, such as rape-oil, the oil of hempseed, lint-feed, and others.

In Holland it was made with whale-oil. This oil was forbidden on some parts of the continent, on account of its disagreeable smell. In this country, however, all the soft soaps are made with whale-oil, which gives a transparent mass of a yellow colour. In commerce, however, we do not find it uniform in its colour. Besides the yellow part, it appears interspersed with white spots, giving the whole a strong resemblance to the inside of a dried fig.

The proportions of potash and oil, for forming soft soap, will be easily inferred from what has been observed in the proportions of the other soaps. The white specks are produced by adding a portion of tallow to the oil, when the boiler is charged. This addition does not improve the soap, but habit in commerce has rendered it indispensable. The ley is prepared by adding to the potash about three-fourths its weight of quicklime, and the process is continued as directed in making the hard soap, using the same apparatus. The ley, when prepared, is to be added to the oil and tallow in the boiler at intervals, similar to those in making the hard soap, and the stirring kept up in the same way, till the mass assumes a proper consistency. The experienced soap-maker will judge, when the materials are in proper proportions, by the appearance of the soap when boiling; hence he knows when to cease to add more ley. Should a stranger to the process of making either kind of soap have to perform the task, he would require to know the proportions in which the alkali ought to bear to the oil. He would weigh his oil or tallow when he put it into the boiler; he will assay his ley by the method laid down in the commencement of this article, and by that means know how much real alkali is contained in a given measure of his ley. He will by this means know nearly when he had added a sufficient quantity of ley to saturate the oil or fat. In the soap made with soda, the real alkali must be to the oil as 1 to 7.28, and that with all potash must be as 1 to 5.1 nearly. This of course will be the proportion for soft soap. When the soft soap is

of a proper consistency for caking, it is poured into barrels, in which it is sold.

Soaps, particularly the hard, are frequently reduced in their value, by the fraudulent practice of keeping them wet. The common or proper state is when they contain about 30 *per cent.* of water; but they may, by a nefarious management, be made to contain 60 *per cent.* which is a great imposition. This fraud, like many others, is detected when it is too late. It is found to lose weight rapidly by exposure to the air.

Before we close this article, we may point out some means of economizing the use of the alkali in soap-making, which, in very extensive manufactories, is worth attending to. In the first place, it should be observed, that the spent leys always contain free alkali, and it is generally added a second time, in order that as much as possible of it may be taken up. It is found, however, by experience, that some will still be found in solution, which the fat will never take up. This is owing to the same liquid containing several neutral salts in solution. If this liquor be evaporated to a certain extent, and set to cool in shallow vessels, the neutral salts will crystallize and separate from the liquid to a certain extent. The liquid part may then be evaporated a second time, and again crystallized. The liquid, after these salts have been separated, may now be added to the fat, and the alkali will combine with it. If barilla or kelp is the alkali, then the liquid ought to have a little lime added, which evaporating, serves to take the carbonic acid from the soda. Without this precaution the carbonate of soda would crystallize with the other salts. With potash this precaution is unnecessary.

The salts which are separated from barilla and kelp are chiefly muriate and sulphate of soda. The former may be used as a substitute for salt in the last part of the process of boiling. The sulphate of soda may be fused with sawdust or powdered coal in a reverberatory-furnace. The sulphuret of soda is produced, from which the alkali may be recovered. Perfumed soaps are easily formed by adding the different essential oils while the soap is in a liquid form, but not while very hot, because the perfume would evaporate. The saponaceous liquid, called milk of roses, is formed by mixing the liquid obtained by exposing potash to the air with rose-water, and then adding this to oil of almonds, till the mixture becomes milky without being greasy.

Ball Soap, commonly used in the North, is made with lees from ashes and tallow. The lees are put into the copper, and boiled till the watery part is quite gone, and there remains nothing in the copper but a sort of saline matter (the very strength or essence of the ley); to this the tallow is put, and the copper is kept boiling and stirring for above half an hour, in which time the soap is made; and then it is put out of the copper into tubs, or baskets, with sheets in them, and immediately (while soft) made into balls. Note, it requires nearly twenty-four hours, in this process, to boil away the watery part of the ley.

The simplest, and upon the whole the most beautiful, soap, is the fine white soap prepared from olive-oil and soda, extracted from the best barilla, which is manufactured largely in the countries where the olive grows; particularly in the south of France, for which Marseilles is the most celebrated, in some parts of Italy, and in Tripoli. A similar, but more expensive soap, is made of soda and oil of almonds for medicinal purposes. (See *SAPO Amygdalinus.*) What is called in our country "Windfor soap" is of this kind, prepared with either of the above-mentioned oils. Common soap is manufactured principally by our soap-boilers from tallow or any other fat; and the alkali em-

ployed is either barilla or pearl-ash, or a mixture of the two, according to the price and the practice of the manufacturer. But in order to obtain a stiff salt, recourse is had to the action of common salt, as we have already mentioned. The olive-oil, or Marseilles and other soaps, are sometimes artistically "marbled," or streaked throughout their whole substance with red or blue veins. This soap is harder than the white soap of the same materials, because it requires to be dried to a greater degree in order to take the marbling. This is performed, by adding to the soap, as soon as it is completely made and separated from the spent ley, a fresh quantity of ley, and immediately afterwards a solution of sulphate of iron. A decomposition between the two takes place, and a black oxyd of iron is separated, which is entangled within the liquid soap. The boiler is then cooled, and the ley which settles is drawn off; after which the soap is again melted. A workman then stands over the boiler, and stirs the soap with a wooden instrument, while another throws in at intervals a quantity of colcothar, or brown-red oxyd of iron, ground up with water into a uniform liquid. This diffuses both the oxyds through the soap, which is then cooled and framed. This process requires some manual dexterity, so that the ingredients may be stirred together, and the marbling sufficiently diffused through the whole mass, without mixing it completely.

Soap is much used in washing and whitening linens, cleansing woollen cloths from oil, whitening silk, and freeing it from the resinous varnish with which it is naturally covered; and for various other purposes, by the dyers, perfumers, hatters, fullers, &c.

The alkaline lixiviums, being capable of dissolving oils more effectually than soap, might be employed for the same purposes; but when this activity is not mitigated by oil, as it is in soap, they are capable of altering, and even destroying entirely, by their causticity, most substances, especially animal matters, as silk, wool, and others; whereas soap cleanses from oil almost as effectually as pure alkali, without danger of altering or destroying, which renders it very useful.

The manufacture of soap in London, first began in the year 1524; before which time this city was served with white soap from foreign countries, and with grey soap, speckled with white, from Bristol, and sold for a penny a pound, and also black soap for a halfpenny the pound.

SOAP, in the *Materia Medica*. Soaps, both hard and soft, have been applied to medical use. Well made hard soap, fit for medical use, has very little odour, and a nauseous alkalescent taste; is white, and of a firm consistency; does not feel greasy, and is devoid of any saline efflorescence on the surface. With water it forms a milky opaque solution; and with alcohol a nearly transparent, somewhat gelatinous, solution. It is decomposed by all the acids, and by many neutral salts, which combine with the alkali and form new compounds; hence hard water which contains sulphate of lime does not properly dissolve soap. According to the experiments of Darcet, Lelievre, and Pelletier, (stated in the preceding article,) 100 parts of newly made soap consist of 60.94 oil, 8.56 alkali, and 0.503 water: but part of the water is lost by keeping, and the soap becomes lighter.

Hard soap, triturated with vegetable resins and thick balsams, incorporates with them into a compound; soluble, like the soap itself, in watery liquors; hence it proves an useful ingredient in resinous pills, which of themselves are apt to pass entire through the intestines, but by the admixture of soap become dissoluble in the stomach. It renders unctuous

unctuous and thick animal matters dissoluble in like manner in aqueous fluids, and hence may be presumed to act as a menstruum for these kinds of substances in the body, that is, to attenuate viscid juices and resolve obstructions: such, in effect, are the virtues which it appears to exert in cachectic, hydroptic, and icteric cases, in which last, particularly, its aperient and resolvent powers have been often experienced. Solutions of it have been likewise found to dissolve certain animal concretions of the harder kind, as the filaments which are sometimes seen floating in the urine of rheumatic and arthritic persons, the matter secreted in gouty joints, and the more compact urinary calculus; on these substances (at least in the latter), though soap of itself acts more languidly than lime-water, yet, when joined to that menstruum, it remarkably increases its activity; the dissolving power of a composition of the two being, according to Dr. Whytt's experiments, considerably greater than that of the soap and lime-water unmixed: of the good effects of these medicines in calculous cases there are several instances; but what their effects may be in gouty and rheumatic ones is not yet well known. See LITHONTRIPTICS, STEPHENS'S *Medicine*, &c. and STONE.

Soap is regarded, in the materia medica, as purgative and lithontriptic; externally applied it is stimulant and detergent. For internal use the hard soap only is employed. It is occasionally ordered in habitual costiveness, and in jaundice, combined with rhubarb, or some bitter extract; but its power as a purgative is very limited, and it cannot act in any other way in relieving jaundice. It is more useful in calculous habits, in which, however, its action is altogether confined to the stomach; for as soap is decomposed by the weakest acids, its alkaline base corrects the acidity so prevalent in the stomachs of calculous patients, and thus at least assists in checking the increase of the disease. Soap is also beneficial in decomposing metallic poisons when taken into the stomach; and, as it is the antidote which can most readily be procured, should always be early resorted to. It is necessary in this latter case to give it in solution; of which a teacupful should be drunk at short intervals, till the effects expected from it be produced. In other cases it is preferable to give it in substance. The dose may be from grs. v to ʒs, made into pills.

As an external remedy, soap is efficaciously used in frictions to sprains and bruises; and much benefit has been derived from rubbing the tumid bellies of children labouring under mesenteric fever, with a strong lather of soap every morning and evening.

From the properties of soap we may know, that it must be a very effectual and convenient anti-acid. It absorbs acids as powerfully as pure alkalies and absorbent earths, without having the causticity of the former, and without oppressing the stomach by its weight, like the latter. Soap is also one of the best antidotes to stop quickly, and with the least inconvenience, the bad effects of acid corrosive poisons, as aqua fortis, corrosive sublimate, &c.

Soap is employed externally for discussing rheumatic pains, arthritic tumours, the humours stagnating after sprains, &c. Some pretend that the indurated tophaceous concretions in arthritic joints, have been resolved by the external use of soapy cataplasms. Several compositions for external purposes are prepared in the shops.

The official preparations of soap are as follow: *viz.* "Pills of soap with opium," of Lond. Ph.; "Pills of compound squill;" "Aloetic pills" of Ed. Ph.; "Pills of aloes and assafoetida." (See PILLS.) "Pills of aloes and ginger," of the Dub. Ph. are compounded of ʒi. of hepatic aloes, ʒi. dr. of ginger-root in powder, ʒi. oz.

of soap, and ½ dr. of essential oil of peppermint: let the aloes and ginger be rubbed together to a powder; then add the soap and the oil so as to form a mass. This is an useful pill, and used with advantage for obviating the habitual costiveness of the sedentary, and of leucophlegmatic habits. The dose is from grs. x to grs. xv, or more:—"Soap plaster." (See EMPLASTRUM Saponis, and SOAP PLASTER.) "Cerate of soap," of the Lond. Ph. is composed of 8 oz. of hard soap, 10 oz. of yellow wax, 1 lb. of semivitreous oxyd of lead powdered, a pint of olive-oil, and a gallon of vinegar. Boil the vinegar on the oxyd of lead over a slow fire, stirring diligently till they incorporate; then add the soap, and boil again in a similar manner, until the moisture be entirely evaporated; and, lastly, mix with the oil the wax previously melted. This cerate is occasionally used as a cooling dressing. For the "compound soap liniment" of the Lond. Ph. see LINIMENT. The "Tincture of soap," commonly called "Liniment of soap," of the Ed. Ph., is prepared by digesting 4 oz. of soap sliced in 2 lbs. of alcohol for three days, and then adding 2 oz. of camphor, and ½ oz. of the volatile oil of rosemary, frequently shaking the mixture. These preparations are stimulant and anodyne, and may be beneficially applied against local pains, and in bruises, rubbed upon the parts. "The tincture of soap and opium" of Ed. Ph., commonly called "Anodyne liniment," is made in the same manner, and from the same ingredients as the other tincture of soap, only adding, at the beginning of the process, one ounce of opium. The addition of the opium to the soap liniment renders it, in many cases of rheumatism and local pains, more useful than the simple liniment.

The anodyne balsam, commonly called Bates's balsam, is prepared by digesting two ounces of soap and half an ounce of opium, in a gentle sand-heat, for three days, with eighteen ounces of rectified spirit of wine, and then adding six drachms of camphor and one drachm of oil of rosemary to the strained liquor. This composition, with the addition of opium, is supposed to be more effectual for allaying violent pains than the common opodeldoc: it is also given internally in nervous colics, jaundices, &c.

Soft soap is considerably more acrid than the hard soap, and it is, therefore, employed only for some external purposes: a mixture of equal parts of our common soft soap and quicklime is used as a mild caustic. Lewis's *Mat. Med.* Thomson's *Lond. Disp.*

SOAP, *Almond.* See SAPO *Amygdalinus*, and SOAP, *supra.*

SOAP, *Ammoniacal*, a white saponaceous compound, readily made by shaking any oil with liquid ammonia, which is much used medicinally as a stimulating application; but the union between these two is much weaker than between the fixed alkalies and oil, so that this will not harden; and by keeping for some time, the ingredients will partly separate. In order to effect a more intimate union between them, muriated ammonia must be added to common soap.

SOAP-LEES. See LIXIVIUM *Saponarium*.

The term *soap-les* is sometimes used technically to denote the "spent ley," which is pumped out of the vat or cistern, after the soap has separated; and which, being more or less alkaline, is reserved either to be used again, or to be evaporated, so that the residue may be calcined for extracting the alkali.

SOAP, *Starkey's*, is a combination of fixed vegetable alkali with essential oil of turpentine. It is so called from its inventor, who combined salt of tartar (carbonate of potash) with this oil, and obtained a saponaceous compound, to

which many medicinal virtues have been ascribed. It enters also into the composition of pills, named also from Starkey. As fixed alkalies are very difficultly made to unite with essential oils, Starkey found no other expedient for the preparation of his soap, than time and patience. His method consists in putting dry alkali into a matras, and pouring upon it essential oil of turpentine to a height equal to the breadth of two or three fingers: in five or six months part of the alkali and oil will be thus combined together, and form a soap, which must be separated from the mixture, and more of it will be afterwards formed in the same manner. The most commodious method, says Dr. Lewis, of obtaining the combination, is by throwing the salt, red-hot, into a heated mortar, immediately reducing it to powder; then pouring on it, whilst hot, by little at a time, an equal quantity, or more, of the oil, and continuing to grind them together, so as to form a smooth soft mass. Stahl, Rouelle, Beaumé, &c. have published processes for this combination. Mr. Beaumé says, that it may be made in a few hours by triturating, during a long time, alkaline salt upon a porphyry, and adding to this salt, during the trituration, oil of turpentine. This medicine, which has an acrid alkaline taste, and is very apt to deliquate on being exposed to air, was formerly celebrated, under the denomination of soap of tartar, universal corrector, &c. as a diuretic in nephritic complaints, and as a corrector of certain vegetables, particularly of opium: its virtues have not been fully determined by experience, nor does the present practice pay any regard to it.

SOAP, *Volatile*, is of three kinds, viz. one composed of fixed alkalies and volatile oils; another of volatile alkalies and oils of the grosser or more fixed kind; and the third, in which both the alkali and the oil are volatile. Of the first kind is Starkey's soap: those of the second sort are obtained more readily. (See *LINIMENTUM Volatile*, and *EPITHEM Volatile*.) Combinations of the latter kind, in a liquid form, have been described under *SALTS*; and compositions of the same kinds may be obtained in a solid state, by mixing the salt with the oil, and subliming them together.

SOAP, *Laws relating to*. By 17 Geo. III. c. 52. no person, within the limits of the head office of excise in London, shall be permitted to make any soap, unless he occupy a tenement of 10*l.* a year, and be assessed to, and pay the parish rates; or elsewhere, unless he be assessed to, and pay to church and poor. By 24 Geo. III. c. 41. and 43 Geo. III. c. 69. every soap-maker shall annually take out a licence, for which he shall pay 2*l.* By 43 Geo. III. c. 68. sched. (A), certain duties are laid on soap imported, as therein stated; and upon the exportation of soap made in Great Britain, and which hath paid the duties, the same shall be drawn back, by 43 Geo. III. c. 69. sched. (C): but no drawback shall be allowed on the exportation of foreign soap imported. (27 Geo. II. c. 21.) By 43 Geo. III. c. 69. sched. (A), certain duties are imposed on soap made in Great Britain; and certain allowances shall be made for soap used in the manufactures of Great Britain, sched. (C). Places of making are to be entered on pain of 200*l.* (10 Ann. c. 19. 47 Geo. III. sess. 2. c. 30.); and covers and locks to be provided under a forfeiture of 100*l.* (5 Geo. III. c. 43. 12 Geo. III. c. 40.) The furnace-door of every utensil used in the manufacture of soap shall be locked by the excise officer, as soon as the fire is damped or drawn out, and fastenings provided; and opening or damaging such fastening incurs a penalty of 100*l.* (17 Geo. III. c. 52. 24 Geo. III. c. 48. sess. 2.) Officers are required to enter and survey at all times, by day or night, and the penalty of obstructing is 50*l.*; and they

may unlock and examine every copper, &c. between the hours of five in the morning and eleven in the evening, and the penalty of obstructing is 100*l.* No soap-maker shall have any private pipe or conveyance, on pain of 200*l.*; and the penalty of obstructing an officer who searches for it is 100*l.* No maker shall have more than one moveable pump, on penalty of 500*l.* Every maker of soap, before he begins any making, if within the bills of mortality, shall give twelve hours, if elsewhere, twenty-four hours' notice, in writing, to the officer, of the time when he intends to begin, on pain of 100*l.* No maker shall remove any soap unfurveyed, on pain of 20*l.*, without giving proper notice of his intention. And if any maker shall conceal any soap or materials, he shall forfeit the same, and also 500*l.* (1 Geo. III. stat. 2. c. 36.) And the penalty of privately making soap is forfeiture of the soap and materials, and 100*l.* (5 Geo. III. c. 43.) Persons assisting in making soap privately shall forfeit, for the first offence, 20*l.*; for the second, 40*l.* or be liable to four months' imprisonment till it be paid. (47 Geo. III. sess. 2. c. 30.) Owners or renters of houses where soap shall be privately made forfeit 200*l.* Every barrel of soap shall contain 256 lbs. avoirdupois, half-barrel 128 lbs., firkin 64 lbs., half-firkin 32 lbs., besides the weight or tare of each cask; and all soap, excepting hard cake soap and ball soap, shall be put into such casks and no other, on pain of forfeiture and 5*l.* (10 Ann. c. 19. 12 Ann. st. 2. c. 9.) The maker shall weekly enter in writing at the next office the soap made by him in each week, with the weight and quantity at each boiling, on pain of 50*l.*; and within one week after entry clear off the duties, on pain of double duty. (17 Geo. III. c. 52.) Cockets granted for shipping soap to be conveyed to any other part of the kingdom, shall express the quality, quantity, and weight, the mark of the package, by whom made and sold, and where consigned, under penalty of forfeiture and seizure of the same and package. (23 Geo. II. c. 21.) No soap shall be imported, otherwise than in some package, containing at least 224 pounds of hard soap, on pain of seizure and forfeiture, and also package; and the master of the vessel shall forfeit 50*l.* If any person shall knowingly harbour or conceal any soap, unlawfully imported, or reloaded after shipping for exportation upon debenture, he shall forfeit 50*l.* for every hundred weight, together with the goods and package. The maker shall keep just scales and weights, where he makes his soap, and permit and assist the officer to use them, on pain of 10*l.* (10 Ann. c. 19.) And by 10 Geo. III. c. 44. for insufficient scales and weights, he shall forfeit 100*l.*

SOAP-*Ashes*, in *Agriculture*, the refuse of soap-boilers, sometimes termed soapers' ashes. See *ASHES*.

SOAP *Refuse*, the compounds of oil, tallow, and other substances, with lime and pot-ash, which are often met with and used as manures. Most sorts of soapy mixtures are found to have much effect in promoting vegetation.

Soap-suds, or the washings of this sort which are left and thrown away from large mills and manufactories, such as those of the silk and other similar kinds, are found highly beneficial as manures themselves, or for being mixed and blended up with other matters in this intention. The farmers, in some places, collect them by the hoghead, at the rate of from 6*d.* to 1*s.*, and mix them up with earthy materials, so as to form rich composts, in consequence of their containing portions of animal matter, gum, and alkali, especially when taken from silk works. And the common soap-suds, which are generally wasted and thrown away, are said to have been found of great utility in cold moist meadows; and would probably be more so, if employed in combination

bination with rich earthy substances. All the various refuse matters of this sort should be collected, as they are capable of being used in this way with advantage to the farmer. See *SALINE Manures*.

SOAP-Stone, in *Mineralogy*, a variety of steatite. (See *STEATITE*.) The name is derived from the colour, and the peculiar unctuous feel, which resembles that of white soap. It is sometimes striped and mottled with veins and spots of a dull purple. When first quarried it is very soft, and yields to the nail; but gradually grows harder by exposure to the air, though it never loses the soapy feel by which it is characterized. The only part of England where soap-stone is procured is at the promontory of the Lizard, in Cornwall: it occurs in veins in serpentine, to which rock it seems nearly allied. A large quantity of this stone is used in the china manufacture at Worcester. Its value arises from its great infusibility, and its property of preserving its whiteness in the furnace. The former it derives from the absence of lime, or the alkalis; the latter from the absence of metallic matter, of which a very small portion only can be traced by chemical analysis. The fracture of soap-stone is uneven and splintery; it is translucent in minute fragments; it cracks and falls to powder in hot water.

SOAP-Earth, Smyrna. See *FLOS Afiz*, *NATRON*, and *SAPONACEA Terra*.

SOAPBERRY-TREE, in *Botany*. See *SAPINDUS*.

The skin or pulp of the berries of the soapberry-tree is used as soap: they are of the size of a musket-ball, with winged leaves, and are used in washing without any admixture of salt or oil. They perform the office of soap very well, as to the cleansing of the linen, but being of a very acid nature, they rot it in time.

The Negroes in general use them for their coarse apparel, which bears them much better than the finer linen worn by the Europeans.

It is said, that this fruit is a medicine of singular and specific virtue in chloroses, and that a tincture or extract is preferable to the berry in substance; whence it may be presumed, that the soapy matter is dissoluble in spirit. Its medicinal virtue was first published by Marloe, in a letter to Mr. Boyle; but it is unknown in practice, and in the shops. Lewis.

SOAPERS' WASTE, in *Agriculture*, the waste materials of soap manufactories, and of other places where works of this nature are carried on, which are useful as manure. These waste matters have been recommended in this intention, mostly on the supposition, that their effects principally depended upon the different saline matters which they contained; but it has been found, that the quantity of such substances in them is very small indeed, and that it principally consists of mild lime and quicklime. It is said that lime, when made wet with salt-water, yields more of this waste than in other cases, and is capable of being employed as manure, in certain cases, with greater benefit than that of lime in its ordinary state. This is a material which is very extensively made use of in some districts.

SOAPEY ROCK, in *Geography*, a rock in the English Channel, close to the Cornish coast; 4 miles N.W. of Lizard Point.

SOAPWORT, in *Botany*, &c. See *SAPONARIA*.

SOAR, or *Sour*, anciently *Leire*, in *Geography*, a river of England, which rises about five miles from Lutterworth, passes by Leicester, &c. and runs into the Trent on the borders of Nottinghamshire, about three miles N.N.E. of Kegworth.

SOAR, a fort of Hindoostan, in Bahar; 23 miles N. of Durbunga. N. lat. $26^{\circ} 30'$. E. long. $86^{\circ} 5'$.

SOAR-Hawk. See *FALCON*.

SOARA, in *Ancient Geography*, a river of India, on this side of the Ganges. Ptolemy.

SOASTUS, a river of India, which ran into the Cophas, according to Arrian.

SOATRIS, a town of Lower Mæsia, upon the Euxine sea, between Marcianopolis and Anchiale, according to the Itinerary of Antonine.

SOATTO. See *SOAGGIO*.

SOAVE, Ital. was a musical term, formerly, for singing or playing in a sweet and pleasing manner; but *dolce* has long supplied its place; which see.

SOAVO, in *Geography*, a town of Italy, in the Veronese; 10 miles E. of Verona.

SOAY, a small island on the coast of Sutherlandshire, near the entrance of Loch Inver. It affords good pasturage for sheep. N. lat. $56^{\circ} 29'$. W. long. $6^{\circ} 27'$.

SOB, a river of Russia, which runs into the Oby; 32 miles S.W. of Obdorskoi.

SOBALA, in *Ancient Geography*, a town of Asia Minor, in Caria. Steph. Byz.

SOBALASSARA, a town of India, on this side of the Ganges, which Ptolemy attributes to the Caspiræi.

SOBANNUS, a river of India, on this side of the Ganges, the mouth of which is placed by Ptolemy between Pagrafa and Pithonobaste.

SOBATZ, in *Geography*, a town of Slavonia, on the river Save; 30 miles W.S.W. of Belgrade.

SOBERNHEIM, a town of France, in the department of the Rhine and Moselle; 10 miles W.S.W. of Creutznach. N. lat. $49^{\circ} 45'$. E. long. $7^{\circ} 45'$.

SOBHA, in *Hindoo Mythology*, is a personification of beauty, and the name of a nymph celebrated in the annals of the East for her amours with *Krishna*; which see. See also *RADHA*, for the translation of a passage wherein she is mentioned.

SOBIESKI'S SHIELD, in *Astronomy*. See *SCUTUM Sobieski*.

SOBIESKY, in *Biography*. See *JOHN*, king of Poland.

SOBIESLAU, in *Geography*, a town of Bohemia, in the circle of Bechin; 10 miles E. of Bechin. N. lat. $49^{\circ} 18'$. E. long. $14^{\circ} 34'$.

SOBINKA, a town of Bohemia, in the circle of Boleslau; 5 miles S.W. of Jung Buntzel.

SOBOTALE, in *Ancient Geography*, a town of Arabia Felix, which, according to Pliny, was the capital of the Atramites.

SOBOTKA, in *Geography*, a town of Bohemia, in the circle of Boleslau; 11 miles E.S.E. of Jung Buntzel. N. lat. $50^{\circ} 24'$. E. long. $15^{\circ} 11'$.

SOBRADA, a town of Spain, in Galicia; 9 miles E.S.E. of Lugo.

SOBRADILLO, a town of Spain, in the province of Leon; 24 miles N.N.W. of Ciudad Rodrigo.

SOBRALIA, in *Botany*, a genus dedicated, in the *Flora Peruviana*, p. 109, to the honour of Don Francis Martin Sobral, a distinguished Spanish botanist. *De Theis*.

SOBRARVA, in *Geography*, a district and principality of Spain, included in Aragon, W. of Ribagorga, anciently a small kingdom.

SOBRE BUENA, a name given by the Spaniards in America to a species of vanilla, which is greatly superior to all the other kinds.

The pods of this are of the same shape with those of the common vanilla, but are nearly twice as large. A bundle of about fifty of these usually weighs five ounces, and such a bundle of the sibre buena kind often weighs eight. These are full of a blackish balsamic liquor, in which are contained a number of small seeds.

SOBREYRA, in *Botany*, a genus named in honour of John Sobreyra, a Spanish monk and a naturalist. *De Theis*.

SOC, **SOK**, or *Soka*, in *Law*, denotes jurisdiction; or a power or privilege to administer justice, and execute laws.

The word is also used for the shire, circuit, or territory, in which such power is exercised by him endued with such jurisdiction.

Hence, also, the law Latin *foca*, used for a feignory or lordship enfranchised by the king, with liberty of holding a court of his *soc-men* or *socagers*, that is, his tenants; whose tenure is hence called *focage*.

This kind of liberty still subsists in several parts of England, under the name of *foke* or *foken*. Skene defines *foce* to be, *señal de hominibus suis in curia secundum consuetudinem regni*. Brady makes mention of these liberties: *soc, sac, tol, team, insangthes*, and *usangthes*.

In the laws of Henry I. *foca* is also used as synonymous with franchise, for a privileged place, refuge, asylum, or sanctuary, &c. from the Saxon *foen*, or *foene*.

SOCAGE, or **SOCCAGE**, in its most extensive signification, seems to denote a tenure by any certain and determinate service. And thus, our ancient writers constantly put it in opposition to chivalry, or knight-service, where the render was uncertain.

Thus Bracton, if a man holds by a rent in money, without any escheage or serjeanty, *id tenementum dici potest focagium*. Littleton also defines it to be, where the tenant holds his tenement of the lord by any certain service in lieu of all other services, so that they be not services of chivalry, or knight-service: therefore, he tells us, that whatsoever is not tenure of chivalry is tenure in focage. The service must therefore be certain, in order to denominate it focage; as to hold by fealty and 20s. rent; or by homage, fealty, and 20s. rent; or by homage and fealty, without rent; or by fealty and certain corporal services, as ploughing the lord's land for three days; or by fealty only, without any other service; for all these are tenures in focage.

Socage is of two sorts; *viz.* *free focage*, where the services are not only certain but honourable; and *villein focage*, where the services, though certain, are of a baser nature. See **VILLENAGE**.

Such as hold by the former tenure are called, in Glanvil, and other subsequent authors, by the name of *liberi fokemanni*, or tenants in free focage. This, in the nature of its service, and the fruits and consequences appertaining to it, was always much the most free and independent species of any. On this account, the learned judge Blackstone assents to Mr. Somner's etymology of the word; who derives it from the Saxon appellation *foce*, which signifies *liberty* or *privilege*, and, being joined to a usual termination, is called *focage*, signifying by it a free or privileged tenure. This etymology, he says, seems to be much more just than that of our common lawyers in general, who derive it from *foca*, a *plough*; because in ancient time their focage-tenure consisted in nothing else, but services of husbandry, which the tenant was bound to do to his lord, as to plough, sow, or reap for him; but that in process of time, this service was changed into an annual rent by consent of all parties,

and that, in reference to its original, it still retains the name of focage, or plough-service. But this by no means agrees with what Littleton himself tells us, that to hold by fealty only, without paying any rent, is tenure in focage; for here is plainly no commutation for plough-service. Besides, even services, confessedly of a military nature and original, the instant they were reduced to a certainty, changed both their name and nature, and were called focage. It was the *certainty*, therefore, that denominated it a focage-tenure; and nothing surely could be a greater liberty or privilege, than to have the service ascertained, and not left to the arbitrary calls of the lord, as in the tenure of chivalry. Wherefore also Britton, who describes focage-tenure under the name of *fraunke ferme*, tells us, that they are lands and tenements, of which the nature of the fee is changed by feoffment out of chivalry for certain yearly services, and in respect of which, neither homage, ward, marriage, nor relief, can be demanded. Moreover, if focage-tenures were of such base and servile original, it is hard to account for the very great immunities, which the tenants of them always enjoyed; so highly superior to those of the tenants by chivalry, that it was thought, in the reigns of both Edward I. and Charles II. a point of the utmost importance and value to the tenants, to reduce the tenants by knight-service to *fraunke ferme*, or tenure by focage. It seems probable, therefore, that the focage-tenures were the relics of Saxon liberty, retained by such persons as had neither forfeited them to the king, nor been obliged to exchange their tenure for the more honourable, as it was called, but at the same time more burthensome tenure of knight-service. This is peculiarly remarkable in the tenure called gavel-kind, which is generally acknowledged to be a species of focage-tenure; the preservation of which inviolate from the innovations of the Norman conqueror, is a fact universally known. And those who thus preferred their liberties were said to hold in *free* and *common* focage. This tenure will, therefore, include all other methods of holding free-lands by certain and invariable rents and duties; and, in particular, petit serjeanty, tenure in burgage, and gavel-kind. Blackst. Comm. book ii. cap. 6. Lord Littleton's Hist. of Hen. II. vol. iii. p. 158. 8vo.

Skene defines *focage*, a tenure of lands, by which a man is infeoffed freely, without wardship and marriage, paying to his lord some small rents, &c. which is called *free focage*, &c. Several divisions of focage are met with in law-writers, as *focage in capite*, &c. But by stat. 12 Car. II. it is ordained, that all tenures from and after the 24th of February, 1645, shall be adjudged and taken for ever, to be turned into free and common focage.

SOCAGE, *Guardian in*. See **GUARDIAN**.

SOCAGERS, in our *Old Writers*, such tenants as held by the tenure called *focage*. They were otherwise called *soc-men*.

SOCANDAGO, in *Geography*. See **SAGENDAGO**.

SOCCELLI, among the *Romans*, were swaths or bands, which covered the leg down to the foccus.

SOCCUS, **SOCK**, in *Antiquity*, a kind of high shoe, reaching above the ankle, worn by the actors in the ancient drama, in the representation of comic characters.

The foccus was much lower than the cothurnus, and was the distinguishing wear of the comedians; as the cothurnus was of the tragedians; hence foccus is frequently used for comedy itself. Comedy, says M. Fenelon, must talk in a humbler style than tragedy; the sock is lower than the buskin.

SOCCUS, in *Botany*. See **ARTOCARPUS**.

SOCERGA,

SOCERGA, in *Geography*, a town of Istria; 7 miles S.E. of Capo d'Istria.

SOCHAN. See **ZACHAN**.

SOCHATSCHOW, a town of the duchy of Warfaw; 30 miles N. of Rava.

SOCHIAVO, a town of Italy, in the Bellunese; 5 miles W. of Belluno.

SOCHOS, in *Ancient Geography*, a town of Asia, in Syria, situated on the bank of the river Singas, in the southern part of the town of Samosata.

SOCIAL WAR, in *Roman History*, commenced A.U.C. 663, on the following occasion. M. Livius Drusus, tribune of the people, influenced by a view to the public welfare, formed a scheme to reconcile all orders of men, and put an end to all discontents, which he foresaw would in process of time, if not removed, produce a general insurrection. With this view he proposed a law for investing the Italian allies with all the privileges of Roman citizens. They remonstrated that they paid considerable taxes; that, in time of war, their countries raised double the number of forces that were raised in Rome; that the commonwealth owed greatly to their valour that prodigious power which she had acquired; and that it was but just they should share the honour of a state, which they had helped to aggrandize both with their arms and treasures. But this law of Drusus in their favour was opposed with great violence, not only by the senators and knights, but even by the people, who could not bear the thoughts of making those their fellow-citizens, whom they looked upon as their subjects. In the mean time the Italian allies flocked to Rome from all parts to support their protector, and determined to effect by force what they could not gain by favour. The death of Drusus, who was basely assassinated for attempting to procure for them the right of citizenship, provoked the allies to such a degree, that they recurred to arms, in order to do themselves justice. The Marsi, Peligni, Samnites, Campanians, and Lucanians, and in short all the provinces from the Liris to the Adriatic, revolted at once. Rome had never engaged more formidable enemies. As they had all served in the same armies of the republic, they were as well disciplined as her legions, and their leaders had learned the art of war under her most famous commanders. It is said of the Marsi in particular, that Rome had never gained a victory in which they had not a great share. The first step they took in their revolt, was to erect themselves into a republic in opposition to that of Rome. After many alternate successes and defeats, the consul, Julius Cæsar, desirous to put an end to the war, drew up a law, which was confirmed by the senate, and enacted, that all the nations in Italy, whose alliance with Rome was indisputable, should enjoy the rights of Roman citizens. This law, called the Julian law, much abated the ardour of the enemy, and drew off several nations from the confederacy. The tribune, M. Plautius Sylvanus, in conjunction with Caius Papirius Carbo, one of his colleagues, put the last hand to the Julian law in favour of the allies, and got it confirmed by the people, and published in the following words: all the citizens of the allied cities, who shall be in Italy at the time of the promulgation of this law, shall be deemed citizens of Rome, provided they register their names with one of the three prætors within sixty days. This brought the Italians to Rome in such numbers, that the new citizens became more numerous than the old; but, lest this should make strangers matters of the elections, and consequently of the republic, the censors did not incorporate them in the thirty-five Roman tribes, but formed them into new tribes, who were to vote last. By this means all matters were determined by a majority of voices, before the new

tribes gave their suffrages. The allies were sensible of this artifice, but dissembled their dissatisfaction, being resolved, when an opportunity offered, to put themselves upon a level with the old inhabitants of Rome. The tribune, Sulpicius, proposed a law, that all the inhabitants of Italy, who had lately obtained the right of citizenship, should be incorporated into thirty-five tribes, and consequently have the same right of voting, each in his tribe, as others had, without any distinction, and got it passed. But when Sylla prevailed, all the laws of Sulpicius were declared void and null.

SOCIETY, **SOCIETAS**, an assemblage or union of several persons in the same place, for their mutual assistance, security, interest, or entertainment.

Societies of men united together to procure their mutual safety and advantage, by means of their union compose nations or states. Men are led to associate for this purpose by the affections and instincts implanted in their nature, and by the wants and weaknesses inseparable from the constitution of both their bodies and minds, and from the condition they are appointed to occupy. They also possess the faculties of reason and of speech, which render them capable of mutual intercourse for their mutual advantage. Hence we may deduce that natural society which is established among mankind; and the general law of this society is, that each should do for others whatever their necessities require, and they are capable of doing, without neglecting what they owe to themselves. This law ought to be observed by all the individuals of the human race, in order to live agreeably to their nature, and in conformity to the design of their common Creator: nor can it be neglected or violated, consistently with a due regard to our own safety and happiness.

Thus we see that the universal society of the human race is an institution of nature, and that it necessarily results from the nature of man: and, therefore, all men, whatsoever be their station, are obliged to cultivate and discharge its duties. They cannot dispense with it by any convention or private association. When they unite in civil society, in order to form a separate state, or nation, they may justly enter into particular engagements, towards those with whom they associate; but they are still under the obligation of performing their duty to the rest of the human species.

As the end of the natural society established between all mankind is that of their affording assistance towards their own perfection, as well as that of the state; and as the nations, considered as so many free persons who live together in a state of nature, are obliged to cultivate between each other this intercourse of humanity; the end of the great society established by nature between all nations is also a mutual assistance for the improvement of themselves and their state. Accordingly, the first general law which the very end of the society of nations discovers, is, that each nation ought to contribute all in its power to the happiness and perfection of others: but the duties which we owe to ourselves having a claim in our preference to those which are incumbent upon us with respect to others, a nation ought, in the first place, to do whatever it can to promote its own happiness and perfection. Moreover, as nations are free and independent of each other, in the same manner as men are naturally free and independent, the second general law of their society is, that such nation ought to be left in the peaceable enjoyment of that liberty which it has derived from nature. From this liberty and independence it follows, that every nation is to judge of what its conscience demands, of what it can or cannot do, of what is proper or improper to be done; and, consequently, to examine and determine whether it can perform any office for another, without

without being wanting in what it owes to itself. Since men are naturally equal, and their rights and obligations are the same, as equally proceeding from nature, nations composed of men considered as so many free persons, living together in a state of nature, are naturally equal, and receive from nature the same obligations and rights; and hence we conclude, that what is permitted to one nation is permitted to all, and what is not permitted to one is not permitted to any other. The effect of all this is the producing, at least externally, and among men, a perfect equality of rights between nations, in the administration of their affairs, and the pursuit of their pretensions, without regard to the intrinsic justice of their conduct, of which others have no right to form a definitive judgment; so that what is permitted in one is also permitted in the other; and they ought to be considered in human society as having an equal right. It is, therefore, necessary, on many occasions, that nations should suffer certain things to be done that are very unjust and blameable in their own nature, because they cannot oppose it by open force, without violating the liberty of some particular state, and destroying the foundation of natural society. The rules that flow from this principle form what Mr. Wolff calls "the voluntary law of nations." Hence it follows, that all nations have a right to repel by force what openly violates the law of the society which nature has established among them, or that directly attacks the welfare and safety of that society. At the same time, care must be taken not to extend this law to the prejudice of the liberty of nations. The general and common law of nations, with respect to the conduct of all sovereign states, ought to be measured by the end of the association that subsists between them. The several engagements into which nations may enter produce a new head of the law of nations, called "conventional," or "of treaties." Besides, certain maxims, and customs consecrated by long use, and observed by nations between each other as a kind of law, form the "customary law of nations," or, "the custom of nations." These three kinds of the law of nations, "voluntary," "conventional," and "customary," together compose the "positive law of nations." For they all proceed from the volition of nations; the "voluntary law," from their presumed consent; the "conventional law," from an express covenant; and the "customary law," from a tacit consent. See *LAW of Nations, STATE, and GOVERNMENT.*

Of societies we have a great many kinds, distinguished by the different ends proposed by them: *civil societies, trading societies, religious societies, literary societies, &c.*

SOCIETY, in *Trade*, is a contract or agreement between two or more persons, by which they bind themselves together for a certain time, and agree to share equally in the profits or losses which shall accrue in the affairs for which the society or copartnership is contracted.

We have several very considerable societies of this kind; as the Merchant Adventurers, the Turkey, East India, Muscovy, Eastland, Greenland, Spanish, African, South Sea, and Hudson's Bay, companies; the institutions, policies, &c. of which, see under the article *COMPANY.*

By the Roman law, the social contract needs no other solemnity but the sole consent of parties, without any writing at all; but among us, articles of copartnership are required. There is no contract in which probity is more required than in society; inasmuch as the laws pronounce those null that are made contrary to equity, and with design to deceive.

The French distinguish three kinds of mercantile society; *ordinary society*, called also *collective* and *general*; *society in commendam* or *commandity*; and *anonymous society*, called also *momentary* and *inconnué*.

The first is, where several merchants act alike in the affairs of the society, and do all under their collective names, which are public, and known to every body.

Society in commendam, &c. is that between two persons, one of whom only puts his money into stock, without doing any other office of a copartner; the other, who is called the *complementary* of the society, dispatching all the business under his own name.

Anonymous society, is that where all the members are employed, each particularly in the common interest, and each is accountable for profits, &c. to the rest, but without the public's being informed of them; so that the seller has only an action against the particular buyer, no other name appearing.

It is also called *momentary*, because frequently made on particular occasions, and ceasing with them: as in the making a purchase, selling any commodity, &c.

Of this they distinguish four kinds: *society by participation*, which is usually formed by letters from one city to another, where a merchandize is to be bought or sold. The second is, when two or three persons go together to fairs to buy goods. The third, when two or three persons agree to buy up the whole of some commodity in any country to sell it again at their own price. And the fourth is, when three or four persons make a journey together to buy and sell the same commodity. Beside merchants, people of quality, &c. are admitted into these anonymous societies.

SOCIETIES, *Religious*, are parties of persons formed either to live regularly together, or to promote the interest of religion, or to cultivate it in themselves.

Of the first kind are all congregations of religious; particularly the Jesuits (see *JESUITS*), who are called the society of Jesus; though they more usually call themselves the company of Jesus; the society of the Sorbonne; the society of St. Thomas de Villeneuve, instituted in 1660, by F. Ange le Proust; the society of St. Joseph, instituted in 1638; the society of Bretagne, a reform of Benedictines, in 1606; and the society of Jesus, a religious military order, instituted by Pius II.; the society of the Cord. See *CORD.*

Of the second kind are, the

SOCIETY for the Reformation of Manners, and putting in execution the laws against immorality and prophaneness. A society of this kind was set on foot about the time of the Revolution, by five or six private persons in London, and was afterwards exceedingly increased by a number of members of all denominations.

Societies for this purpose have been occasionally established, not only in London, but in other principal towns, in a later period.

SOCIETIES, *Friendly*. See *FRIENDLY Societies.*

SOCIETIES, *Friendly*, in reference to *Agriculture*, such as are established for the purpose of relieving the labouring classes during the periods of sickness, or when incapable of working. Many societies of this nature have been formed in different parts of the kingdom within these few years, with much success. And it has been remarked by Mr. Curwen, that to encourage the people to provide means of support for themselves, in cases of sickness and misfortune, is highly desirable, both as to the effect it produces in making them more respectable members of the community, and in exempting parishes from the most enormous weight of poor rates.

On this subject it has been suggested by a late writer, after observing that such establishments would certainly be attended with very beneficial consequences, that it might be highly proper to frame a law, whereby labourers of all descriptions should be *compelled* to assign a portion of the fruits

of their labour, during the time of their health and strength, for the establishing of a fund for their relief when overtaken by misfortunes. The forming of provident societies or clubs, by which, during the time the members are in health and the vigour of life, they may, by small constant weekly payments, make a suitable provision, from the produce of their own industry, against the period when sickness, misfortune, old age, or infirmity may reach them, is, he thinks, a measure which, the more it is known, the more it will meet with the approbation of the public. And though, by some, such societies may be thought very remotely, if at all, connected with the subject of agriculture; to the more intelligent, the best means of providing for the industrious peasantry, whose 'rough laborious hand' allows the wealthy to live in indolence and ease, will always be an interesting subject. The more so it must prove, as the suggesting of proper measures for that effect, if attended to, will infallibly remove, in a great degree, the load of poor rates, which hangs like a mill-stone about the neck of the English farmer; a load which, if effectual measures be not in a short time adopted to remove, must necessarily be attended with consequences of the most alarming nature, as its weight is increasing with such rapidity, that in a few years it must become altogether insupportable.

And it has been well remarked by Dr. Anderson, that friendly societies, voluntarily entered into by the industrious poor, have relieved many a worthy character in the time of their sickness, infirmities, misfortunes, and old age, in a more ample and comfortable manner than they would have been provided for by the parish levies. Why, he asks, may not all the poorer sort in their youth be compelled to provide, out of their industry, for their old age and infirmities? Why may not the poor of every parish be by law created into friendly societies? Suppose the master of every servant and labourer was obliged to retain, out of the wages of each, three-pence a-week, and pay the same in the respective names of such servants and labourers into the parish stock. When a servant or labourer removes from one parish to another, he might be entitled to a certificate from the parish he leaves, where he has drawn no pay of the amount of the sum total he has contributed; and when he has gained a settlement in another parish, that parish might be entitled to draw on the first for the money the pauper has paid; so that every man may draw his fortune after him, which may prevent many a litigation respecting the settlement of the poor, and be a great spur to industry.

In the rural economy of the west of England, it has been stated by Mr. Marshall, that several of these valuable institutions have existed in Devonshire for about thirty years; and that their good effects are so evident, that the encouragement of them ought to become a national object of the first magnitude; not more with a view to lessen the present heavy burdens of the poor rates, than to instil into the lower classes of society a principle of frugality, and a sense of social duties, which these meetings, under suitable regulations, cannot fail of producing.

The following is the plan laid down by Mr. Pew, who has paid much attention to the subject, and who observes, that if the collection of a small but voluntary tax upon the sober and industrious citizen, for his own use when in distress, be in some degree beneficial, he conceives that the collection of a still smaller, though compulsory, tax upon all ranks of men, the idle, the improvident, and the irresolute, as well as the industrious citizen, for the same purpose, would be a measure as much more beneficial as it is more extensive. This he conceives to be capable of being effected in this way. 1. That a proper officer be

appointed for such an extent of district as he may be supposed conveniently to superintend, to take a list of the names and places of abode of all males and females above the age of seventeen years, in the same manner as the list is made out for the militia. 2. That every such male pay two-pence *per week*, and every such female three farthings or one penny *per week*, into the hands of the above officer, for the purposes hereafter to be specified. 3. That the above officer shall be empowered to furnish employment for all such as are willing to work, and who cannot find it for themselves. Whether this officer should be chosen annually in rotation, after the manner of an overseer, or whether he should be a permanent officer upon an adequate salary, will be a matter of future consideration; but if the latter, he should be paid by the community and not out of the fund. 4. That all the poor being thus sure of employment, the master or mistress for whom they work should be justified in retaining these sums respectively out of their wages; and whether they do so or not, they should (in default of the individual) be answerable to the officer for its payment. All masters and mistresses of families should in like manner be answerable for their servants; and all keepers of lodgings, &c. for their inmates. 5. That these sums should be carried weekly to the general treasurer of the division, who should give sufficient security for the same. 6. That out of this fund every male who is really incapable of labour, should (by virtue of a certificate from the above officer) have a right to demand from the treasurer five shillings *per week* for the first six months, should his illness last so long, and four shillings *per week* after that period, until he again become capable of labour. And that every female should have a right to demand two shillings and six-pence *per week* for the first six months, and afterwards two shillings *per week*, until she be again able to work: she should also be entitled to four weeks full pay at every lying-in. Every male above the age of sixty-five years, whether capable of labour or not, should be entitled to four shillings *per week* during life. Every female, after the same age, two shillings. 7. Any person having three children under nine years of age, should be entitled to one shilling and six-pence *per week*, until the eldest should have attained the age of nine years; and if he has more than three under that age, he should be entitled to one shilling and six-pence *per week* for each above that number; and if any one or more of his children should happen to be idiotic, insane, or otherwise so far disabled, either in body or mind, as to be utterly incapable of labour, each of them should still be considered as under the age of nine years, and paid for accordingly.

If a mother should be left a widow, with three children under nine years of age, she should be entitled to receive five shillings; if with two children, three shillings; and if with one child, one shilling and six-pence *per week*; if with more than three under that age, one shilling *per week* for each above that number; it being admitted that all her time is taken up by three, and allowance made for it, but that she is capable of looking after, and taking care of, a greater number. The wives of men serving in the militia, and in the army or navy, should, during the absence of their husbands, be considered and provided for in all respects as widows.

If a child should be left an orphan, under nine years of age, two shillings *per week* should be allowed from the fund for its maintenance; if more than one of the same family, one shilling and six-pence *per week* for each above that number. As there is probably no less friendship amongst the lower than amongst the higher orders of society, it would generally happen that some friend or relation of the deceased

deceas'd would gladly take charge of the children, provided they could do so without essential loss to themselves. This regulation would effectually prevent that loss; and to compensate in some degree for the want of parental affection, six-pence *per* week more is allowed for the maintenance of an orphan, or a family of orphans, than for a child, or a family of children, who still retain their mother. If, however, any beings should be so uncommonly unfortunate as not to be thus adopted, the officer above-mentioned should be obliged to provide a receptacle for them, which he will always be able to do for the sum or sums above-mentioned. 8. All children above nine years of age, if in health, should, if they have no parents, or their parents are not able to provide for them, be put out after the manner of parish apprentices. 9. All persons neglecting or refusing to pay their contribution, should be committed to the house of correction for the space of ————. 10. If the fund should at any time fall short of the necessary demands upon it, the deficiency should be made up by a parish rate, collected in the same manner as at present; but without any sense of obligation on the part of the multitude, (for there would be no poor,) who should, in all cases, receive their relief in the nature of a demand. 11. If the fund (as most probably would happen) should increase beyond the necessary demands upon it, the surplus should, on no occasion, be diverted to any other purpose than the benefit of the subscribers; but when the price of grain exceeded that which brings it easily within the reach of the multitude (suppose six shillings or six shillings and six-pence the Winchester bushel), every person who had three children or more under nine years of age, should have a right to demand such a sum as, in proportion to the number of his family, would reduce the various necessary articles of life (taking wheat as the standard) to a moderate price; and, indeed, he thinks, in all cases, when the price of grain exceeds that proportion at which the industrious labourer can afford to come to market, sound policy, as well as common humanity, requires that all large families should be entitled to receive such a sum as above specified, although it should be necessary to collect a rate for the purpose.

He need not perhaps add, that every officer intrusted with money should give ample security for his integrity, and the faithful discharge of his duty; that due checks should be established to prevent embezzlement; and that all accounts should be made up and balanced so frequently as to prevent the probability of mistakes. And still more effectually to secure the complete execution of the plan, it would perhaps be necessary to appoint a general inspector of the funds, who, with the assistance of a few subordinate officers, would probably be able to attend the whole kingdom.

And it is supposed by Mr. Donaldson, that if this plan was carried into execution by the legislature, it must in its consequences promote essentially the well-being of the great body of the people, as well as the interests of those concerned in the commerce, manufactures, and agriculture of the country. But though the establishment of friendly or provident societies has, in numerous instances, been found productive of the most salutary effects; and would, if well supported and countenanced in every part of the kingdom by the contributions of the rich proprietors, render compulsory acts of parliament unnecessary; yet as such a mode, however desirable, could probably never be generally adopted, it would certainly be the most effectual method to have an act of parliament for the purpose framed on the above principles: without this or some similar regulation, such societies will probably never, he thinks, become sufficiently general to fully answer the intention. The great

beneficial effects that have resulted from these societies, in those instances in which they have been established in parishes, have been shewn in various statements of them, and should promote their adoption in others, which may easily be done by the principal proprietors in such places taking the lead in forwarding such institutions. In the use of all such regulations, or those of any other similar kinds, they should constantly be brought forward and well adapted to the states, conditions, and circumstances of the situations, places, and times, in which, and at which, they are employed, in order that the best effects may be produced from them.

SOCIETY for propagating the Gospel in foreign Parts was instituted by king William III. in 1701, for securing a maintenance for an orthodox clergy, and making other provisions for the propagation of the gospel in the plantations, colonies, factories, &c.: to that end he incorporated the archbishops, several bishops, and others of the nobility, gentry, and clergy, to the number of ninety, into a body, with privilege to purchase two thousand pounds a-year inheritance, and estates for lives or years, with other goods, to any value.

They are directed by their charter to meet yearly, on the third Friday in February, to choose a president, vice-president, and other officers; and the third Friday in every month, to transact business, depute fit persons to take subscriptions for the said uses, and of all monies so received to give account to the lord chancellor, &c. Of this society there is a standing committee at St. Paul's Chapter-house, who prepare matters for the monthly meeting, which is held at St. Martin's library. They are trustees of Codrington college, in Barbadoes, supported by plantations in that island.

SOCIETY for promoting Christian Knowledge was begun in 1699, by some persons of worth, &c. Its original design was to propagate religion in the plantations, to secure the pious education of the poor at home, and to reclaim those that err in the fundamentals of Christianity.

In the year 1701, they had procured considerable charities, and had transmitted the same to the plantations, in libraries, bibles, catechisms, &c. with a voluntary maintenance for the several ministers to be employed in the plantations. But the society for propagating the gospel in foreign parts being then instituted, they were incorporated, by charter, into the same: and thus discharged, as a particular society, from the farther pursuit of that branch of their original design, which comprehended the appointment and payment of missionaries, as well as the distribution of books; whereupon they wholly turned themselves to the other, and became very considerable, by great accessions from among the clergy and laity.

The members of the society for promoting Christian knowledge meet weekly, at the society's office in Bartlett's Buildings, Holborn, to concert measures for raising charity for the education of poor children, and setting up schools for that purpose; as also for the more regular disposal of pious books and catechisms, for instruction of the ignorant, erroneous, &c. By the assistance of members of other religious societies, they have procured subscriptions for the education of above three thousand children, who are placed out in schools about London, and taught reading, writing, psalmody, &c. They have dispersed great numbers of books among the poor, in the fleet, army, &c. and have procured several to be translated into Welsh, and other foreign languages, and dispersed accordingly. This society for promoting Christian knowledge is supported exclusively by members of the church of England. They have three treasurers,

urers, a secretary, an assistant, a clerk and collector, with two assistants.

SOCIETY, New England, was first incorporated by an ordinance of parliament in 1649, by the name of the "President and Society for the Propagation of the Gospel in New England;" and empowered to receive and dispose of monies in such manner as should best conduce to the preaching and propagation of the gospel among the natives, and for the maintenance of schools for the education of their children; for which purpose a general collection was to be made in all the counties, cities, towns, and parishes of England and Wales. With the sum of money thus collected, the society was enabled to purchase an estate in land of between 500*l.* and 600*l.* a year. But upon the restoration of king Charles II. the charter became void, and colonel Bedingsfield, a papist, who had sold an estate of 322*l.* per annum, which had been settled for the uses of this society, repollesed himself of it, and refused to pay back the money which he had received for it. However, the corporation being revived, in 1661, by an express charter, which ordained, that there be for ever within the kingdom of England, a "Society or Company for the Propagation of the Gospel in New England and the Parts adjacent in America," the estate which had been detained by Bedingsfield was restored by the chancellor's decree. The members of this society are not to exceed forty-five; these and their successors, to be chosen by the society, are constituted one body corporate, with the powers and privileges usual in such cases; and a power is likewise given them to appoint commissioners residing in New England to transact their business in those parts. The honourable Mr. Boyle was appointed by charter the first governor of this company. See a copy of the charter in the Appendix to Dr. Birch's Life of Mr. Boyle.

SOCIETY of the Sons of the Clergy, was incorporated by king Charles II. in 1678, by the name of "The Governors of the Charity for Relief of the poor Widows and Children of Clergymen." This society is under the direction and management of a president and vice-president, three treasurers, and a court of assistants composed of forty members. Several hundreds of widows and children of the clergy have annually received considerable relief from this useful charity. See *Corporation of the Sons of the CLERGY*.

SOCIETY of Stewards and Subscribers for maintaining and educating poor Orphans of Clergymen till of Age to be put Apprentice, an establishment formed in the year 1749, which has attained a considerable degree of prosperity, and which has received into its school more than 700 children of both sexes, most of whom have been apprenticed or otherwise provided for. This society was incorporated by an act of parliament in the 48th year of Geo. III., and it is under the management of a president, vice-president, treasurer, secretary, and committee, elected annually, at a general meeting in February. The committee consists of the principal officers, a secretary, and of 20 other members, any eight of whom shall be deemed a board, who meet every month. See **CLERGY**.

SOCIETY for the Sons of the Clergy of the established Church of Scotland, was instituted at Edinburgh in February 1790, and was constituted a body corporate by his majesty's royal charter in 1792. The views of this society have been limited only to the sons of clergymen, conceiving that its funds will be thus most advantageously employed, and proposing other plans of beneficence which shall also comprehend the daughters of the clergy, as its funds increase.

SOCIETY for promoting religious Knowledge among the Poor commenced in the year 1750, for the purpose of giving

bibles, testaments, and other good books, to those who most needed them, and who were most likely to improve them. This society is supported by an annual subscription of the members, together with the donations and legacies of other contributors; and each subscriber is entitled to a nomination of books in turn, corresponding to the amount of his subscription. The society meets every month.

SOCIETY for promoting Christian Knowledge in the Highlands and Islands of Scotland, was first begun by the allocation of private contributors at Edinburgh, about the year 1701; their design was approved and encouraged by queen Anne, who, in 1708, issued her royal proclamation for this purpose: and, in 1709, she granted a patent, constituting a certain number of the subscribers a society, or body politic, with full powers to receive donations and purchase lands, &c. not exceeding 2000*l.* a year, and with the profits of the same to erect and maintain schools, &c. Accordingly the lords of session, under her majesty's commission, nominated eighty-two subscribers to be the first members of this society, who chose a president, treasurer, secretary, and other officers. They also chose a committee of fifteen, who were to meet every month, or oftener, as occasion required. There is a general meeting of the whole society every three months, when they admit members, make general regulations, give orders to the committee, and settle their accounts. In 1710 the society began to settle schools. In 1738 the king granted a new patent, to cause such children as were found proper to be instructed in husbandry, housewifery, and manufactures; in pursuance of which the society erected several working schools. The society's first charter extends to popish and infidel countries beyond the seas, and four missionaries have been maintained for converting the native Indians in America to the Christian faith. The society has several corresponding members in London, who meet every quarter, to receive subscriptions, donations, &c. These form the Corresponding Board, which was established in the year 1729; and which, after remaining long inactive, began, in 1773, to co-operate more cordially with their brethren in Scotland. Since that period an annual sermon has been preached in commendation of the charity; and the preachers have been selected from various religious denominations with advantage to the charity.

There is also a charitable society in London, corresponding with the incorporated society in Dublin, for promoting the English Protestant charter-schools in Ireland; under the management of a treasurer, a standing committee of fifteen, and secretary, who meet once a month.

SOCIETY for promoting Christianity among the Jews, London, was instituted in August 1808, and it has been conducted under the management of a committee, consisting of eighteen members, besides the treasurer and secretary, five of whom are a quorum; who meet on the first Friday in every month at the Jews' chapel in Spitalfields. The object of this society being to relieve the temporal distresses of the Jews, as well as to promote their spiritual welfare, the committee are empowered, from time to time, to adopt such measures for any such purposes as the majority of the members present may approve. General meetings are held twice in the year, for receiving the reports of the committee; and two collection sermons are preached at each of the half-yearly meetings, for the benefit of the society, one in the established church, and the other among the Dissenters. A sermon is addressed to the Jews every Lord's day evening, and a regular course of lectures is delivered every Wednesday evening. Divine service is performed in the morning and afternoon of every Sunday.

SOCIETY.

SOCIETY for promoting the Discovery of the interior Parts of Africa. See AFRICAN Association and AFRICA.

Of the third kind are divers religious societies, very properly so called: these were first set on foot in London about the year 1678, by a few young men, who agreed to meet weekly, for prayer, psalmody, and spiritual conference. These afterwards increased to forty distinct bodies, who set up public prayers in many churches where they were not before frequent, procured frequent administrations of the sacrament, and maintained lectures on that subject, in one church or another, almost on every Sunday evening.

SOCIETY, *Marine*, was founded, principally, by the late Jonas Hanway, who convened a meeting of merchants and owners of ships, and proposed their forming themselves into a society for giving clothing to landmen and boys for the sea-service. A regular society was formed, and a proper committee and other officers were appointed. By the registers of the society it appeared, that from the 24th of July, 1756, the date of the commencement of this society, to the 1st of February, 1772, it had clothed and fitted out 5451 men, and 6306 boys: and the total number to the 31st of December, 1808, amounted to 20,315 men, and 30,857 boys. By 12 Geo. III. c. 67, A.D. 1772, fifty-two governors were incorporated, from which number are appointed a president, six vice-presidents, a treasurer, and twenty-four (in 1808 the number was sixty) assistants, vested with full powers to carry the designs of the society into execution. Boys serving out their apprenticeships at sea, not being for a less time than four years, are entitled to the liberty of setting up and exercising trade or business in any place in Great Britain or Ireland. No such apprentice is liable to be impressed into the king's service till after the age of eighteen years. Seven governors constitute a general court, which is held four times in every year. The first local residence of this society was in an office over the Royal Exchange; but it has since erected a convenient building in Bishopsgate-street. Among the ornaments and decorations of this building, we may reckon the mausoleum of the late captain Thomas Hanway, presented to the corporation by his brother, Jonas Hanway, esq. on the 1st of September, 1774. An annual subscription of two guineas qualifies a governor for that year; two guineas *per annum*, paid during eight years successively, or a donation of twelve guineas, qualifies a governor for life.

SOCIETY of *St. Patrick, Benevolent*, was established on the 17th of March, 1784, by a considerable number of noblemen and gentlemen, either natives of Ireland or variously connected with it, for the purpose of imparting comfort to persons of that kingdom in distress: one of their objects was the education of children born of Irish parents, residing in or near London. The duke of Kent is patron of this society. The union of this society with the Irish charitable society, instituted in the year 1704, which continued its distributions till the year 1756, when it ceased to meet, was effected by the marquis of Buckingham and a committee, which settled a plan for this purpose. Twenty guineas constitute a governor for life, and three guineas an annual governor. The encouragement which this society has met with has induced it to engage a piece of ground in St. George's Fields, for the purpose of erecting a suitable building by subscription, where the children may by degrees be taken wholly under its own care. The sub-committee meet every month, and the grand committee four times in the year. Its officers are, a patron, president, seven vice-presidents, three auditors, &c. a treasurer, physician, surgeon, and secretary.

SOCIETY, *Philanthropic*, commenced at a small house on

Cambridge-Heath, near Hackney; but as it prospered, buildings have been erected in St. George's Fields, to which a chapel has been lately added. The institution takes its date in the year 1788, and was formed for the prevention of crimes, and the reform of the criminal poor, by the encouragement of industry, and the culture of good morals among those children who were training in vicious courses, public plunder, infamy, and ruin. In December 1789, the number of wards for both sexes under the society's care was sixty. The fund of the society is employed as a manufacturing capital, the instruction for which will serve at any future time to afford the children employment when they are capable of being journeymen. The age of admission is limited to the ages of seven and fourteen, and the children taken under the care of the society are either the offspring of convicted felons, or such as have themselves been engaged in criminal practices. Those of the first class are orphans; and those of the second class are such as in many cases have been guilty of offences at an age which saves them from legal punishment. Objects are admitted by the committee at its weekly meetings; and they are seldom taken younger than eight or nine, or older than twelve. After admission, boys that have been delinquents are sent in the first instance to the "Reform," a house at Bermondsey so called; where the system is framed with a view to the amendment of the moral character by instruction: out of school-hours they are set to pick oakum, that by remaining unemployed they may not acquire habits of idleness. When any of them appear, by the reports of the chaplain, to be sufficiently reformed, they are transferred to the manufactory in St. George's Fields, and placed on the same footing with the rest of the boys in that situation. The sons of convicts, not having been themselves criminal, are sent at once to the manufactory, which contains, besides accommodations for lodging about 100 boys, workshops for carrying on the following trades, *viz.* printing, copper-plate printing, book-binding, shoe-making, tailor's work, ropemaking, and twine-spinning. The profits of the trades are carried to the account of the society, a portion being appropriated, by way of reward, to such of the boys as are industrious, partly paid to them immediately, and partly reserved for their use when they cease to belong to the society. The girls are placed in a building contiguous to the manufactory; but all intercourse between them and the boys is effectually prevented by a wall of considerable height. The girls are brought up for menial servants: they make their own clothing, and shirts for the boys, and wash and mend for the manufactory: besides which, their earnings in plain work are considerable. When of proper age, they are placed out, at low wages, in reputable families, and receive rewards for good behaviour at the end of the first and third years of their service, *viz.* one guinea at each period. A chapel has been erected for the convenience of their attending public worship.

Every general court must consist of seven members at least; and the committee, which consists of twenty-four members, together with the principal officers, visitors, and auditors, meet once a week, and three of them are competent to proceed to business. They appoint sub-committees. A number of boys having served a regular apprenticeship in the society's manufactory, and received certificates of their honesty and industry during the latter part of their service, are now employed in town as journeymen to respectable masters; and many of the girls are in service, and have received the pecuniary rewards assigned them. The present officers are his royal highness the duke of York, president, twelve vice-presidents, a treasurer, four visitors, three auditors,

ditors, a chaplain, reader at the chapel and secretary, two preachers, a physician, surgeon, apothecary, superintendent, and steward.

SOCIETY, *Philological*, comprehends a school for general instruction and clothing of the sons of poor clergymen, naval and military officers, reduced tradesmen, and mechanics. It was instituted in the year 1792, under the patronage of the duke of York, by Mr. Thomas Collingwood of Upper Titchfield-street, Mary-le-bone. This society has adopted a plan of education more liberal than is usually provided for in common schools of charitable institutions. The school is established at Lillón Green, Paddington. The committee, consisting of five members, meet every month, and a general court is held once a year. The officers are his royal highness the duke of York, a president, eleven vice-presidents, three trustees, a committee of twenty, a secretary, several masters, a solicitor, physician, surgeon, apothecary, and collector.

SOCIETY, called the *African Institution*, was established for the important object of attempting the civilization of Africa, and of educating Africans. See *AFRICAN INSTITUTION*.

SOCIETY of Friends, for American Indian Civilization, was instituted by the Friends in the year 1795, and the object of it has been prosecuted with their customary assiduity and perseverance, and with such success, that the northern tribes of American Indians have been considerably influenced to adopt the arts of cultivation, as a prelude to their being capable of receiving the truths and blessings of religion. The whole fraternity of Quakers interest themselves in the promotion of these objects.

SOCIETY, British and Foreign Bible. This society, which has been extremely successful in promoting the circulation of the holy scriptures, was established in the year 1804; and almost as soon as it was embodied, lord Teignmouth became the president, and the bishops of London, Durham, Salisbury, and St. David's, with several noblemen and gentlemen of high respectability, accepted the office of vice-presidents. Thus constituted and patronized, from the popularity of its plan, and the exertions of its conductors, it obtained a rapid establishment in the world, and may be considered as possessing a larger and more efficient operation than was ever acquired by an institution for charitable purposes to be met with on the page of history. Upon its appearance before the public, Wales and Scotland distinguished themselves by individual, congregational, and associated contributions to its funds; and rivalled each other, and their fellow-citizens in England, by the promptitude of their support. Ireland also joined in the work. The continent of Europe felt the impulse which London had excited, and evinced the effects of it in local associations for prosecuting the same common purpose. Asia displayed a similar spirit, and Calcutta became the seat of a corresponding committee, professing, in the name and chiefly by the funds of the society in London, to aid and encourage translations of the scriptures into all the vernacular dialects of the East. In some parts of America there was a similar union of Christians upon kindred principles, and with the same object in view. Several of these associations have been assisted by voluntary donations from the British and Foreign Bible Society. "Thus," says the historian of this institution, "the flame which was kindled in London has been propagated generally over more than three-fourths of the world, and is on its way for a still more extensive and particular diffusion."

The seat and centre of this institution is London: its larger component parts are to be traced in auxiliary societies, formed under its encouragement, and contributory to its

object and operation, in several of the most considerable towns throughout the united kingdom, in all the villages about the metropolis, and in conspicuous stations throughout the other portions of the world, already enumerated. Its auxiliaries within the united kingdom are more than 150, and they comprehend some of the most important and commanding positions. On the continent it has three auxiliaries of great activity, and acting under very respectable patronage, in Stockholm, Berlin, and Basle. These stations, from their local situation, and the conveniencies with which they abound, are peculiarly favourable to the object of supplying the inhabitants of Europe with the scriptures, in their several languages. The Calcutta society, consisting of Christians of different denominations, and patronized, in a measure, by the existing government, will be able in time to furnish bibles to the native Christians, said to amount to a million in number, and to produce correct versions of the scriptures in the various languages of the East, and to open channels for their circulation among millions of people who have never yet heard of the divine mission of Jesus Christ. In America the society is assisted in the prosecution of its object by the Bible Societies of Philadelphia, New York, Connecticut, Massachusetts, New Jersey, &c.; all produced by the example of the London society, aided by its funds, and acting in avowed communication and harmony with it. "In addition to these regular and organized bodies, the society has correspondents of various descriptions in different parts of the world, actively engaged in promoting its designs, by dispersing, at its expence, the sacred oracles of divine truth to men of every nation under heaven."

In the first six years of the existence of this society it had issued from its depository in London more than 325,000 copies of the scriptures, independently of those which had been printed under its auspices, beyond the limits of the united kingdom. In England it has printed the scriptures, at its own expence, in the English, Welsh, Gaelic, French, Spanish, Portuguese, Italian, Dutch, Danish, Mohawk, Equimaux, Modern Greek, Manks, and native Irish languages. On the continent it has largely aided the printing of them in nearly twenty different languages. In Asia it has promoted, by liberal contributions, the translation and publication of them in a great variety of languages and dialects.

The object of this society, which has already expended several hundred thousand pounds, is distinctly and exclusively to promote, in the largest practicable extent, the circulation of the holy scriptures, without note or comment, both at home and abroad. By a fundamental law and regulation of the society, the copies circulated in the language of the united kingdom are those of the authorized version only. The constitution of the society comprehends all denominations of Christians, who profess to regard the holy scriptures as the proper standard of religious truth. The members of the society, be their subscriptions what they may, provided they are not less than one guinea annually, are entitled to purchase bibles and testaments at reduced prices, to five times the amount of their annual subscription. For a farther account of this society, we refer our readers to its annual reports, which are now grown to the size of a moderate octavo volume.

Ten guineas constitute a member for life, and one guinea an annual member, five guineas an annual governor, and fifty pounds a governor for life. Its officers are a president, treasurer, assistant secretary, collector, and bookseller.

An auxiliary *Bible Society* was established for the county of Surrey in 1812. Its officers are a president, twelve vice-presidents, a treasurer, and two secretaries.

SOCIETY.

SOCIETY, Sunday School, was established, in 1796, for promoting free and Sunday schools in Wales, under the patronage of the prince of Wales. Its officers are a president, vice-president, treasurer and vice-treasurer, and secretary.

Society for promoting Sunday schools throughout the British dominions was instituted in 1785. See SCHOOLS.

SOCIETY for the Suppression of Vice, was established in Essex-street, in the Strand, in 1802. Its officers are a president, twelve vice-presidents, a treasurer, a secretary, and collector.

SOCIETY, National, for promoting the education of the poor in the principles of the established church, in England and Wales, was instituted in 1811. The prince of Wales is patron, and the archbishop of Canterbury president: it has a great number of vice-presidents, including all the bishops, a treasurer, and secretary.

SOCIETY, Naval and Military Bible, was instituted in 1780, for the purpose of distributing bibles among the soldiers and sailors of the army and navy. One guinea constitutes a governor, and ten guineas a governor for life.

SOCIETY or Fund for the Support of decayed Musicians and their Families, was established in 1738, and incorporated in 1790.

This institution had always been patronized by many of the first families in the kingdom, as honorary subscribers; and the public in general eagerly attended the annual benefits, which, with the subscriptions of the professional members and gratuitous performance, produced a considerable sum. But the benevolent spirit of the establishment was narrowed, and insufficient to furnish means of comfort to the claimants already on their list, and consequently precluded the augmentation of their number, till after that memorable event, the Commemoration of Handel in 1784, by which 6000*l.* were added to their fund, enabled the governors to enlarge and extend their bounty, by a more considerable allowance to the decayed claimants and their families already on their list, and to be less scrupulous in the admission of new members.

Their majesties and the royal family having been graciously pleased to countenance this establishment, and honour it with their presence, not only at all the commemoration performances, but at every subsequent annual benefit for its support, increased its importance, and excited an ambition in the members to be under the immediate protection of his majesty; which wish was most graciously complied with in 1790, by a permission to incorporate themselves under the title of the "Royal Society of Musicians," till which period the institution went under the title of "The Fund for the Support of decayed Musicians and their Families."

SOCIETY for bettering the Condition of the Poor, was founded in 1796. Its object was to examine the cause of individual distress, to remove difficulties in the way of parochial relief, to facilitate the distribution of charitable benefactors, to inspect workhouses and charitable institutions, in order to suggest improvements, and so aid the important cause of religious instruction to the mature and to the young.

SOCIETY for abolishing the Method of sweeping Chimnies by climbing Boys, was instituted in 1802. Ten guineas constitute a perpetual, and one guinea an annual governor.

SOCIETY for the Discharge and Relief of Persons imprisoned for small Debts, was instituted in February, 1772. The debts, or composition for them, of the persons that are relieved must not exceed 10*l.*; and the aged and infirm are preferred, as well as those that have the largest families, and others who have lost their liberty by unavoidable misfortunes, and not by fraud, vice, or extravagance. No debtor

can be relieved a second time. The annual subscriptions are two guineas, and those for life are twenty guineas. Similar in its object is the "Philanthropic Society" at Mile-End; the annual subscription being only twelve shillings, and five guineas constituting a life-governor.

SOCIETY of Friends of Foreigners in Distress, was instituted A.D. 1806, to relieve the destitute in a strange land, by pecuniary, medical, legal, and religious aid. One guinea constitutes an annual governor, and ten guineas a governor for life.

SOCIETY, Hibernian, was instituted A.D. 1806, for the purpose of providing every poor family in Ireland with a copy of the holy scriptures, especially of the New Testament, to increase the number of their Sunday schools, to circulate religious tracts, and to give encouragement to preachers of approved characters. One guinea constitutes an annual member, and ten guineas a member for life.

SOCIETY, Royal Humane, was established A.D. 1774, by Dr. Cogan and Dr. Hawes, for the recovery of the apparently dead by drowning, or by any other causes of suffocation. One guinea constitutes an annual member, and ten guineas a member for life. See DROWNING.

SOCIETY for teaching the indigent Blind. See BLINDNESS.

SOCIETY for the Relief and Instruction of the Deaf and Dumb. See DEAFNESS.

SOCIETY for the Establishment of a literary Fund was instituted A.D. 1790, for the relief of authors in distress, whose claims, stated in writing to the committee, are duly considered by them, and admitted, if proper, at their discretion, whilst the names of the applicants are not disclosed. The annual subscription is one guinea, and that for life is ten guineas. The society's house is in Gerard-street, Soho.

SOCIETY for the Relief of Widows and Orphans of Medical Men in London and its Vicinity, grants to a widow, provided that her income does not exceed 30*l.*, and if she has children, they have not more than 10*l.* per annum each, an annuity, and a sum towards an apprentice fee when the children are fourteen years of age. Any orphan whose father was a member of the society at his death, who has not more than 15*l.* per annum, also receives an annuity; and relief is granted to medical men themselves, rendered incapable of attending to their business. Twenty guineas constitute a member for life, and one guinea an annual subscriber; and a subscriber of two guineas for fifteen years becomes afterwards a governor.

SOCIETY for Relief and Support of disabled Seamen, their Widows and Children, in the Merchant Seamen's Service, was incorporated by statute 20 Geo. II. to provide relief by pensions for seamen incapable of future service by sickness, wounds, or old age, and for the widows and children of those that have been killed or wounded, provided they be under fifteen years of age, or, above that age, incapable of earning a subsistence by some infirmity. Relief is restricted to those who have contributed 6*d.* per month out of his wages to this fund. Fifty pounds constitute a governor. The affairs of the society are conducted at the merchant seamen's office, Royal Exchange, London.

SOCIETY, Missionary, was instituted in the year 1795, for the purpose of spreading the gospel in foreign parts.

SOCIETY for Missions to Africa and the East, was established by voluntary subscription in the year 1799, for the conversion of the African and Eastern tribes. The missionaries fixed their station at Sierra Leone, also on the Rio Pongas and Bassia, where they have opened schools, and worship on the Lord's day; and as the slave-trade declines, or is abolished, they flatter themselves with success. Many

Maroons

Maroons and others are said to have been converted, children baptized, and the civilization of the heathens, and their conversion to Christianity, which must ever concur, are effected. The annual subscription is one guinea, and a life-subscription twenty guineas.

SOCIETY, *Naval Charitable*, was established in 1791, for the relief of indigent orphans, widows, and children of sea-officers, and also sea-officers reduced by misfortunes to indigence. A *modus* has been settled for the subscription; *viz.* by admirals 3*l.* 3*s.*, vice-admirals 2*l.* 2*s.*, rear-admirals 1*l.* 1*s.*, captains 10*s.* 6*d.*, lieutenants 5*s.*, physicians 10*s.*, surgeons 5*s.*, mellers 5*s.*, purfers 5*s.* The sum given to each applicant is limited to 20*l.* A similar charity was established at the Admiralty in 1792.

SOCIETY for the Conversion of Negroes, was instituted by the zeal of the late bishop Porteus, and was chartered in 1795 for the conversion, instruction, and education of the Negro slaves of the British West India islands: for which purpose clergymen are employed as assistants to the parochial clergy there. The bishop, highly to his honour, indulged the consoling hope, "that the same beneficent spirit which by degrees extinguished Pagan slavery, will also gradually, and without injury to any one, relieve mankind from the prellure of this and every other species of personal and perpetual slavery." The subsequent Abolition of the SLAVE-TRADE (which see) has verified this expectation. The funds arise from the rents of estates vested in the corporation of London, under decree of the court of chancery, upon the will of the honourable Robert Boyle.

SOCIETY, *Religious Tract*, began to circulate its small useful tracts in the year 1799; and of these many have been translated into the Danish, Portuguese, French, and Spanish languages, and have been dispersed amongst the prisoners of war, and other foreigners in this country. Auxiliary societies have been founded in several other countries. A donation of ten guineas constitutes a governor for life, and of half-a-guinea an annual governor.

SOCIETY, *Endeavour*, was instituted in 1794, for promoting the principles and duties of the established church, by forming a library of orthodox divinity, and the distribution of books; the occasional relief of indigence, with medical assistance, including midwifery, and inoculation. It is divided into two departments, *viz.* the eastern and the western.

SOCIETY of Schoolmasters was founded in 1798, in order to establish a fund for the benefit of their widows and orphans, and for relief of schoolmasters and ushers become necessitous through age, infirmity, or misfortune. The fund consists of joint stock, which constitutes a benefit society, and the charitable fund, which is supported by contributions of the members of five guineas entrance money, and one guinea annually: benefactions are received from any other person, 2*l.* for life. The joint stock is shared among widows and children of decayed members in certain proportions, and this is disposable property: the charitable fund is employed in relieving members and their widows, educating their orphans, assisting decayed schoolmasters in general and their widows, and helping others who become necessitous.

SOCIETY called the Scots Corporation. See Scots Hospital.

SOCIETY for rewarding Servants, British, commenced in 1792, with a view of offering a reward for meritorious service, either by a commutation of their probable future advantages for a present pecuniary consideration, or by the immediate possession of half the contingent annuity. Subscribers of one guinea may nominate one male or female

hired domestic servant, not exceeding fifty years of age, to be registered for such future rewards. Subscribers of fifteen guineas have the same nomination. If servants have served any subscriber three years whilst registered, they will be entitled to 5*l.* per annum; if more than three years, 6*l.*, to be increased in proportion of 3*l.* for every three years' faithful service to the same subscriber during the registry. In this manner debentures have been granted to 1151 servants.

SOCIETY of the Stock-Exchange Fund. See STOCK-EXCHANGE.

SOCIETY of the Stranger's Friend was constituted to relieve distress wherever it is found, and especially when out of the reach of other assistance, and to give such religious instruction as may be suitable to the persons visited at their own habitations. For this purpose the visitors divide the town into districts, and personally attend and relieve the objects of their compassion.

SOCIETY, *Unitarian*, was instituted in 1791 for promoting Christian knowledge and the practice of virtue, by distributing books selected and approved by its members. The annual subscription is one guinea, and ten guineas constitute a governor for life, who is entitled to a proportional allowance of books.

SOCIETY, *American Philosophical*, was established at Philadelphia in the year 1769, by the union of two societies which had formerly subsisted in that city, for promoting useful knowledge, under the direction of one patron, one president, three vice-presidents, one treasurer, four secretaries, and three curators, who are annually chosen by ballot. The ordinary meetings of this society are held on the first and third Fridays of every month, from October to May inclusive. The society was incorporated by charter 15th March, 1780, and has published several volumes of its Transactions, containing many ingenious papers on general literature and the sciences, as well as respecting those subjects that are peculiar to America.

A society of a similar kind, under the title of the "Academy of Arts and Sciences, &c." has been also established at Boston. See ACADEMY.

A Royal Society of Sciences was instituted at Upsal about the year 1720: the meetings are monthly, and the Transactions are published quarterly, in 4to.

There is also another society at Gottenburg, called the Royal Society of Sciences and Belles Lettres.

The Society of Natural Historians at Berlin was founded by Dr. Martini; in which place there is also a philosophical society.

The Royal Society of Gottingen was instituted by king George II. in 1751.

In France there have been several institutions of this kind for the improvement of science, recounted under ACADEMY; see also INSTITUTE.

For other institutions of a similar nature, and their literary productions, see ACADEMY, JOURNAL, and TRANSACTIONS.

SOCIETY, *Edinburgh, Philosophical*, a society which succeeded the Medical Society, and formed upon the plan of including all the different branches of natural knowledge and the antiquities of Scotland. Its rise and progress towards its present state are as follow.

In the year 1718, a literary society was established at Edinburgh by the learned Ruddiman and others, which, in 1731, was succeeded by another for the improvement of medical knowledge. In the year 1739, the celebrated MacLaurin conceived the idea of enlarging the plan of this society, by extending it to subjects of philosophy and literature.

ration. The institution was accordingly new-modelled by a printed set of laws and regulations, the number of members was increased, and they were distinguished from that time by the title of "The Society for improving Arts and Sciences," or more generally by the title of "The Philosophical Society of Edinburgh." The meetings of this society, interrupted in 1745, were revived in 1752; and, in 1754, the first volume of their collection was published, under the title of "Essays or Observations, Physical and Literary," which has been succeeded by other volumes. This society, in consequence of the suggestion of the professors of the university, and particularly of the principal, the Rev. Dr. Robertson, and the concurrence of the members of the society, was incorporated by royal charter, on the 29th of March, 1783, under the name of "The Royal Society of Edinburgh," instituted for the advancement of learning and useful knowledge. The first meeting was held on the first Monday of August, 1783; when were chosen a president, two vice-presidents, a secretary, treasurer, and a council of twelve persons, who are chosen by ballot annually on the last Monday of November, and by whom the business of the society is conducted. The society consists of ordinary and honorary members, the latter being restricted to persons residing out of Great Britain and Ireland. The election of new members is made at two stated general meetings, held on the fourth Monday of January, and the fourth Monday of June. A candidate for the place of an ordinary member must signify, by a letter addressed to one of the members, his wish to be received into the society; and he must then be publicly proposed at least a month before the day of election. If the proposal be seconded by two of the members present, his name is to be inserted in the list of candidates, and hung up in the ordinary place of meeting. The election is made by ballot, and is determined in favour of a candidate, if he shall have the votes of two-thirds of those present, in a meeting consisting of at least twenty-one members.

The members are divided into two classes, which meet and deliberate separately: one of these classes is denominated the "Physical class," and comprehends within its department the sciences of mathematics, natural philosophy, chemistry, medicine, natural history, and whatever relates to the improvement of arts and manufactures. The other, denominated the "Literary class," has for its department literature, philology, history, antiquities, and speculative philosophy. Each of the classes has four presidents and two secretaries, who officiate by turns. At the meetings of these classes the written essays and observations of the members of the society, or their correspondents, are read publicly, and become the subjects of conversation. The ordinary members, who usually reside in the city of Edinburgh or its vicinity, are expected to attend regularly the monthly meetings, and are required to defray, by an annual contribution, the current expences of the institution. The members who reside at such a distance from Edinburgh, that they cannot enjoy the advantages arising from a regular attendance on the meetings of the society, are not subjected to any contribution for defraying its expences, but have a right to attend those meetings when they are occasionally in Edinburgh, and to take part in all their proceedings. This society has published several volumes of its Transactions, bearing ample testimony to the learning and ingenious researches and observations of their various authors.

SOCIETY, Royal. See *ROYAL Society.*

There is also an Experimental Society at Dublin, for promoting natural knowledge, which was instituted in 1777; the members meet once every week, and distribute three hono-

rary gold medals annually for the most approved discovery, invention, or essay, on any mathematical or philosophical subject. The society is under the direction of a president, two vice-presidents, and a secretary.

A Literary and Philosophical Society, of considerable reputation, has been lately established at Manchester, under the direction of two presidents, four vice-presidents, and two secretaries. The number of members is limited to fifty; besides whom there are several honorary members, all of whom are elected by ballot; and the officers are chosen annually in April. Several valuable essays have been already read at the meetings of this society, and several volumes have been published.

SOCIETY of Antiquaries. See *ANTIQUARY.*

SOCIETY for the Encouragement of Arts, Manufactures, and Commerce, was instituted in the year 1754, in pursuance of a plan formed in 1753, for the purpose of exciting emulation and industry in the improvement of ingenious and commercial arts, the various branches of agriculture, &c. by honourable and pecuniary rewards. It was set on foot by lord Falkstone, lord Romney, Mr. Shipley, Dr. Hales, and a few other gentlemen; but its importance and utility soon gained a very considerable accession of members and subscribers. This society, according to its present constitution, is under the direction and management of one president, sixteen vice-presidents, the chairmen of the several committees of accounts, correspondence, polite arts, agriculture, manufactures, mechanics, chemistry, colonies, and trade; in each of which department there are two, a principal secretary, an assistant secretary, register, collector, and messenger. The office is in the Adelphi.

Every person, desiring to be a member, must be proposed by some member at one meeting, and ballotted for at a succeeding meeting, and if he be chosen by two-thirds of the members present, he is deemed a perpetual member on payment of twenty guineas, or else a subscribing member on payment of any yearly sum not less than two guineas.

The proceedings of the society are regulated by a body of rules and orders established for this purpose; all questions are determined by holding up of hands or ballot, and no matter can be confirmed without the assent of the majority at two meetings. They invite the public in general to propose subjects for encouragement, and whatever is deemed deserving attention is referred to the consideration of a committee, which makes a report to the whole society, where it is approved, rejected, or altered. Their premiums, which have been very extensively bestowed, are either sums of money, or the society's medals in gold or silver.

Their meetings are every Wednesday evening, from the second Wednesday in November to the end of May, and at other times on the first and third Wednesday in every month.

In the Memoirs of Agriculture, and other economical arts, by Mr. Dossie, Bailey's machines of the Society of Arts, and the Transactions of the Society, of which they have published a great number of volumes, we may see how various, extensive, and liberal the plan, which this society has adopted and pursued.

Similar societies, particularly with a view to the improvement of agriculture, have been established in different parts of the kingdom.

The Society instituted at Bath, in the year 1777, for the encouragement of agriculture, arts, manufactures, and commerce, deserves particular mention. The Transactions published by this society contain many valuable experiments and observations, particularly relating to agriculture, which merit

merit the attention of all agriculturalists and farmers in the kingdom.

SOCIETY or *Board of Agriculture*, a society or board of this kind, which was established at London, under the authority of government, for the purpose of promoting agriculture and the internal improvement of the country. It was instituted in or about the year 1793, and consists, according to the charter of its incorporation, of a president, of such several members, by virtue of their different offices, as are therein mentioned, and of thirty ordinary members, mostly members of parliament: besides which, of so many honorary members as they may think proper, and of such a number of corresponding members, natives or foreigners, as may be necessary for the purposes of the institution, the former of whom have the right of being present at all deliberations of the society, but not the latter. Neither of them, however, have the power of voting upon any question.

The president, and a part of the ordinary members, to the number of five, may and are capable of being changed annually on the twenty-fifth day of March. The four vice-presidents may likewise be annually changed, and new ones named and appointed at the same time, as well as the treasurer, and secretary. But the under secretary, the clerk or clerks, with the surveyors, &c. are not subject to annual change.

It cannot be doubted or disputed, that the plans and objects which this establishment has in view, are extremely important, diversified, and comprehensive, as they relate not only to the improvement of the agriculture itself, but to the whole of the internal economy and management of the country. They will probably, however, be best understood by consulting the small tract, which contains an account of the origin of the establishment and its progress for three years afterwards, published in 1796, by its first president, sir John Sinclair.

The consequence and utility of such an institution as this, when under judicious and able management, must obviously be very great, not only to this nation, and the community at large, but also in its example to others, where no similar establishments have yet taken place.

Under such sort of regulation and management, it is unquestionably capable of promoting improvements in many different ways, and with many different designs and intentions, so as to be of the utmost beneficial consequence to the general interests of the country as a whole. Its means are now likewise much more ample and sufficient for accomplishing such purposes, than they were on its first foundation, as they have been, in some measure, increased since that period.

It may in short, by the combination of ingenuity and talent which it affords, be the means of promoting and extending a better, more full, and wider cultivation of the soil and territory of the country, somewhat in proportion to the increasing population, wealth, luxury, and wants of the community; of collecting and embodying the numerous useful scattered facts and practices on the subject, which have been spread throughout the different districts of the kingdom; and of providing and dispersing a more full and correct body of information on all parts of the subject, so as to render the nature of the land, the objects of cultivation, and the modes of performing it, more clearly understood, and approach nearer to the state of perfection. In these ways, it may also be the cause of exciting and drawing a greater and more careful attention to all matters of the agricultural kind, than has hitherto been the case, in all those who either possess rank, property, or talents, in

the different classes of society, all through the country; which, by operating upon the vast mass of knowledge that has been drawn together, must have the effect of giving rise to an almost boundless variety of interesting improvements in the profession, both as a science, and an useful practical art. Some, indeed, have been so much persuaded of this, that they have indulged the notion and supposition of the institution becoming of the greatest advantage and importance to the country. Its utility and benefits must, however, require some length of time, before they can fully display themselves, as is the case in all similar establishments.

SOCIETIES, *County Agricultural*, the various societies of this nature, which are formed and established in different counties and parts of the country, for the purpose of improving and bettering the state of the agriculture and rural management of them. These kinds of societies are now instituted in almost every part of the kingdom, and must have considerable effect in rendering the local modes of managing lands in such situations more perfect and beneficial, as well as in spreading and diffusing the knowledge of the improvements, which are progressively made in the art of cultivation, in a more full, complete, and extensive manner. Though some, who are by no means deficient in intelligence or information, may have doubted of the utility and advantage of these institutions, there can be no reason, on the whole, for supposing that they have not been beneficial to the interests of the nation. As there is probably nothing which is more conducive to general improvement, than a rational spirit of inquiry, investigation, and experiment, the establishment of these kinds of societies would seem to have had a direct disposition and tendency to excite and bring forth such a spirit, as well as to extend it, which has been of the utmost advantage in guiding and directing the attentions and exertions of practical farmers to those methods and objects of management, which are the most suitable and likely not only to be beneficial to themselves, but to the whole nation and community at large.

It is not improbable, however, but by having more regard in respect to their regulations and the general objects of their consideration, as well as to the various local circumstances which are connected with them, they may be rendered a great deal more useful and efficient than they are at present, by producing a much greater competition among the smaller classes of cultivators, and by contributing to a far more exact knowledge of the nature of soils, the dimensions of farms, and the real profits and benefits to be derived from them.

In short, the utility and expediency of institutions of this sort must always be, in some measure, in proportion to the increase of population, and the general wants of the country, in so far as food is required.

Most of the societies of this description, which have been established in this country, comprehend, besides the various local regulations, which relate particularly to themselves, the whole or a great part of the plan and objects which are comprised in the different county reports on the state of agriculture, which have been published by the Board. See *Surveys of the Board of Agriculture*.

Many of these societies existed long before the Society or Board of Agriculture was established.

These societies, besides being useful in promoting and disseminating all sorts of valuable improvements in the local rural managements and practices of the particular districts to which they belong, such as in fencing, draining, tilling, ploughing, sowing, harrowing, cutting, securing, watering, pasturing, flocking, and feeding different kinds of land or soil;

soil; also in breeding, rearing, improving, and encouraging the various sorts of live-stock, in furthering planting in different modes, in bettering the tools and machinery of the art, in distinguishing and encouraging good labourers and servants, in regulating and suiting leases, in establishing necessary and convenient fairs and markets, and in promoting any other beneficial undertakings of the same kind; may be highly important, and of great utility, in circulating and diffusing more extensively the information and instruction collected and brought into order by the Society or Board of Agriculture.

There are many other ways in which such societies may also contribute in benefiting the agricultural interests of the nation.

SOCIETY, *Horticultural, of London*, was instituted in 1804, under a president, a council, three treasurers, and secretary.

SOCIETY, *Asiatic*, an institution planned by the late illustrious sir William Jones, and actually formed at Calcutta, on the 15th of January, 1784, for the purpose of tracing the history, antiquities, arts, sciences, and literature, of the immense continent of Asia. As it was resolved to follow as nearly as possible the plan of the Royal Society of London, of which the king is patron, the patronage of the Asiatic Society was offered to the governor-general and council, as the executive power in the territories of the company. By their acceptance of this offer, Mr. Hastings, as governor-general, appeared among the patrons of the new society; "but he seemed in his private station as the first liberal promoter of useful knowledge in Bengal, and especially as the great encourager of Persian and Sanscrit literature, to deserve a particular mark of distinction;" he was requested, therefore, to accept the honorary title of president. This was handsomely declined in a letter from Mr. Hastings, in which he requested "to yield his pretensions to the gentleman whose genius planned the institution, and was most capable of conducting it to the attainment of the great and splendid purposes of its formation." On the receipt of this letter, sir William Jones was nominated president of the society; and we cannot give the reader a view of the object of the institution in clearer language than that which he employed in his first discourse from the chair.

"It is your design, I conceive (said the president), to take an ample space for your learned investigations, bounding them only by the geographical limits of Asia; so that, considering Hindoostan as a centre, and turning your eyes in idea to the north, you have on your right many important kingdoms in the Eastern peninsula, the ancient and wonderful empire of China, with all her Tartarian dependencies, and that of Japan, with the cluster of precious islands, in which many singular curiosities have too long been concealed: before you lies that prodigious chain of mountains, which formerly perhaps were a barrier against the violence of the sea, and beyond them the very interesting country of Tibet, and the vast regions of Tartary, from which, as from the Trojan horse of the poets, have issued so many consummate warriors, whose domain has extended at least from the banks of the Ilyssus to the mouths of the Ganges: on your left are the beautiful and celebrated provinces of Iran, or Persia, the unmeasured, and perhaps unmeasurable deserts of Arabia, and the once flourishing kingdom of Yemen, with the pleasant isles that the Arabs have subdued or colonized; and farther westward, the Asiatic dominions of the Turkish sultans, whose moon seems approaching rapidly to its wane. By this great circumference the field of your useful researches will be enclosed; but since Egypt had unquestionably an old connection with this

country, if not with China, since the language and literature of the Abyssinians bear a manifest affinity to those of Asia, since the Arabian arms prevailed along the African coast of the Mediterranean, and even erected a powerful dynasty on the continent of Europe, you may not be displeased occasionally to follow the streams of Asiatic learning a little beyond its natural boundary; and, if it be necessary or convenient that a short name or epithet be given to our society, in order to distinguish it in the world, that of *Asiatic* appears both classical and proper, whether we consider the place or the object of the institution, and preferable to *Oriental*, which is in truth a word merely relative, and though commonly used in Europe, conveys no very distinct idea.

"If now it be asked, What are the intended objects of our inquiries within these spacious limits? we answer, *Man* and *Nature*; whatever is performed by the *one*, or produced by the *other*. Human knowledge has been elegantly analysed according to the three great faculties of the mind, *memory*, *reason*, and *imagination*, which we constantly find employed in arranging and retaining, comparing and distinguishing, combining and diversifying, the ideas which we receive through our senses, or acquire by reflection: hence the three main branches of learning are, *history*, *science*, and *art*; the first comprehends either an account of natural productions, or the genuine records of empires and states; the second embraces the whole circle of pure and mixed mathematics, together with ethics and law, as far as they depend on the reasoning faculty; and the third includes all the beauties of imagery and the charms of invention, displayed in modulated language, or represented by colour, figure, or sound.

"Agreeably to this analysis, you will investigate whatever is rare in the stupendous fabric of nature, will correct the geography of Asia by new observations and discoveries; will trace the annals and even traditions of those nations who from time to time have peopled or desolated it; and will bring to light their various forms of government, with their institutions civil and religious; you will examine their improvements and methods in arithmetic and geometry; in trigonometry, mensuration, mechanics, optics, astronomy, and general physics; their systems of morality, grammar, rhetoric, and dialectic; their skill in chirurgery and medicine; and their advancement, whatever it may be, in anatomy and chemistry. To this you will add researches into their agriculture, manufactures, and trade; and whilst you inquire with pleasure into their music, architecture, painting, and poetry, will not neglect those inferior arts by which the comforts and even elegancies of social life are supplied or improved. You may observe that I have omitted their languages, the diversity and difficulty of which are a sad obstacle to the progress of useful knowledge; but I have ever considered languages as the mere instruments of real learning, and think them improperly confounded with learning itself: the attainment of them is, however, indispensably necessary; and if to the Persian, Armenian, Turkish, and Arabic, could be added not only the Sanscrit, the treasures of which we may now hope to see unlocked, but even the Chinese, Tartarian, Japanese, and the various insular dialects, an immense mine would then be open, in which we might labour with equal delight and advantage."

Of this society eleven volumes of the Transactions have been published, which are replete with information in a high degree curious and important; and we hope that the European world will soon be favoured with another. The much-to-be lamented death of the accomplished president may indeed damp the spirit of investigation among the members;

bers; for to conquer difficulties so great as they must meet with, a portion seems to be necessary of that enthusiasm which accompanied all the pursuits of sir William Jones; but his successors will, we trust, use their utmost endeavours to have the plan completed of which sir William gave the outlines.

SOCIETY for working Mines, an association not long ago formed on the continent of Europe. This institution originated at an accidental meeting of several mineralogists at Skleno, near Schemnitz, in Hungary, collected to examine a new method of amalgamation. The object of the society is physical geography; mineralogy founded on chemistry; the management of ore in the different operations which it undergoes; subterraneous geometry; the history of mining; founderies, and the processes for the extraction of the metals from the ores, either by fusion or amalgamation, in every instance applied to practice. The end of this institution is to collect, in the most extensive sense, every thing that can assist the operations of the miner, and to communicate it to the different members, that they may employ it for the public good, in their respective countries. Each member must consider himself as bound to lend to the society every thing which will contribute to the end of its institution; to point out, with precision, the several facts and observations; to communicate every experiment which occurs, even the unsuccessful ones, if the relation may seem to be advantageous to the public; to communicate to the society their examination of schemes, and their opinions on questions proposed by it; and to pay annually two ducats (about 18s. 6d.) to the direction every Easter. The society, on the other hand, is bound to publish every novelty that shall be communicated to it; to communicate to each member, at the member's expence, the memoirs, designs, models, productions, and every thing connected with the institution; to answer all the necessary demands made, relating in any respect to mining; and to give its opinion on every plan or project communicated through the medium of an honorary member.

The great centre of all intelligence is to be at Zellerfeld, in Hartz, Brunswick: but the society is not fixed to any one spot: for every particular state some practical mineralogist is nominated as director. Among these are the names of baron Born, M. Pallas, M. Charpentier, M. Prebra, and M. Henkel. Their office is to propose the members; to take care that the views of the society are pursued in the different countries where they reside; to answer the requests of the members of their country who are qualified to make them; in case of the death of a director, to choose another; and the majority is to determine where the archives and the strong box is to be placed.

All the eminent mineralogists in Europe are members of this society. It is erected on so liberal and so extensive a plan, that we entertain the highest hopes of its success; and have only to add, that we wish much to see the study of several other sciences pursued in the same manner.

SOCIETY, British, for extending the Fisheries, and improving the Sea-Coasts of this Kingdom, was instituted in 1786. The end and design of this society will best appear from their charter, of which we present an abstract.

The preamble states, "the great want of improvement in fisheries, agriculture, and manufactures, in the Highlands and islands of North Britain; the prevalence of emigration, from the want of employment in those parts; the prospect of a new nursery of seamen, by the establishment of fishing towns and villages in that quarter. The act therefore declares, that the persons therein named, and every other person or persons who shall thereafter become proprietors of the joint stock mentioned therein, shall be a distinct and

separate body politic and corporate, by the name of "The British Society for extending the Fisheries and improving the Sea-Coasts of this Kingdom:"—that the said society may raise a capital joint stock, not exceeding 150,000*l.*, to be applied to purchasing, or otherwise acquiring, lands and tenements in perpetuity, for the building thereon, and on no other land whatever, free towns, villages, and fishing stations:—that the joint stock shall be divided into shares of 40*l.* each:—that no one person shall, in his or her name, possess more than ten shares, or 500*l.*:—that the society shall not borrow any sum or sums of money whatsoever:—that the sums to be advanced for this undertaking, and the profits arising therefrom, shall be divided proportionably to the sum subscribed; and that no person shall be liable for a larger sum than he or she shall have respectively subscribed:—that one or two shares shall entitle to one vote and no more in person or by proxy, at all meetings of proprietors; three or four shares to two votes; five, six, or seven shares, to three votes; eight or nine shares to four votes; and ten shares to five votes, and no more:—that more persons than one inclining to hold in their joint names one or more shares, shall be entitled to vote, by one of such persons, according to the priority of their names, or by proxy:—that bodies corporate shall vote by proxy under their seal:—that all persons holding proxies shall be proprietors, and that no one person shall hold more than five votes by proxy:—that the affairs of the society shall be managed by a governor, deputy-governor, and thirteen other directors, to be elected annually on the 25th of March, from among the proprietors of the society, holding at least one full share, by signed lists of their names, to be transmitted by the proprietors to the secretary of the society:—that five proprietors, not being governor, director, or other officer, shall be in like manner annually elected to audit the accounts of the society:—that there shall be one general meeting of the proprietors annually, on the 25th of March:—that occasional general meetings shall be called, on the request of nine or more proprietors:—that the general meetings of the proprietors shall make all bye-laws and constitutions for the government of the society, and for the good and orderly carrying on of the business of the same:—that no transfer shall be made of the stock of the society for three years from the 10th of August 1786:—that the cash of the society shall be lodged in the bank of England, bank of Scotland, or the royal bank of Scotland:—that no director, proprietor, agent, or officer of the society, shall retain any sum or sums of money in his hands beyond the space of thirty days, on any account whatsoever:—that all payments by the society shall be made by drafts on the said banks, under the hands of the governor or deputy-governor, countersigned by the secretary or his deputy, and two or more directors:—and that the books in which the accounts of the society shall be kept shall be open to all the proprietors."

The institution of this public-spirited society was in a great measure owing to the exertions of the patriotic John Knox; who, in the course of twenty-three years, traversed and explored the Highlands of Scotland no less than sixteen times, and expended several thousand pounds of his own fortune in pursuing his patriotic designs.

SOCIETY, British Wool. See *British Wool Society*.

SOCIETY, Geological, was instituted in 1811, under a president, four vice-presidents, treasurer, two secretaries, and a foreign secretary.

SOCIETY, Mineralogical, was instituted in 1799; but it is now incorporated with the former.

SOCIETY, Entomological, of London, instituted in 1806,

has a president, vice-president, treasurer, and secretary, several fellows, and a printer.

SOCIETY, Linnæan, was founded in 1788, and incorporated in 1802. Its president is Sir James Edward Smith; it has a council, a treasurer, secretary, and librarian. Its house is in Gerard-street, Soho. It has already (1816) published eleven volumes of its Transactions.

SOCIETY, Mathematical, in Crispin-street, Spitalfields, was established in 1717. It is under the conduct of a president, treasurer, and secretary.

SOCIETY for the Improvement of Naval Architecture, was founded in 1791. The object of it is to encourage every useful invention and discovery relating to naval architecture, as far as shall be in their power, both by honorary and pecuniary rewards. They have in view particularly to improve the theories of floating bodies, and of the resistance of fluids; to procure drafts and models of different vessels, together with calculations of their capacity, centre of gravity, tonnage, &c.; to make observations and experiments themselves, and to point out such observations and experiments as appear best calculated to further their designs, and most deserving those premiums which the society can bestow. But though the improvement of naval architecture in all its branches be certainly the principal object of this institution, yet the society do not by any means intend to confine themselves merely to the form and structure of vessels. Every subordinate and collateral pursuit will claim a share of the attention of the society, in proportion to its merits; and whatever may have any tendency to render navigation more safe, salutary, and even pleasant, will not be neglected.

This institution owes its existence to the patriotic disposition and extraordinary attention of Mr. Sewell, a private citizen of London, who (though engaged in a line of business totally opposite to all concerns of this kind) has been led, by mere accident, to take such ocular notice of, and make such observations on, the actual state of naval architecture in this country, as naturally occurred to a man of plain understanding, zealous for the honour and interest of his country, and willing to bestow a portion of that time for the public good, which men of a different description would rather have devoted to their own private advantage. His attention was the more seriously excited, by finding that it was the opinion of some private ship-builders, who, in a debate on the failure of one of our naval engagements, pronounced, that such "would ever be the case while that business (the construction of our ships of war) was not studied as a science, but carried on merely by precedent; that there had not been one improvement in our navy that did not originate with the French, who had naval schools and seminaries for the study of it; and that our ships were not a match for those of that nation, either singly or in a fleet, &c. &c."

In a short time the society were enabled to offer very considerable premiums for particular improvements in the construction of our shipping, &c. &c. and also to encourage our philosophers, mathematicians, and mechanics, to make satisfactory experiments, tending to ascertain the laws of resistance of water to solids of different forms, in all varieties of circumstances. On this head the reward is not less than 100*l.* or a gold medal. Other premiums of 50, 30, and 20 guineas, according to the importance or difficulty of the particular subject or point of investigation, are likewise offered, for different discoveries, inventions, or improvements. The terms of admission into the society are a subscription of two guineas annually, or twenty guineas for life.

SOCIETY of Civil Engineers. This society took its rise from the following circumstances. Before or about the year 1760, a new era in all the arts and sciences commenced in this country. Every thing which contributes to the comfort, the beauty, and the prosperity of a country, moved forward in improvement, so rapidly and so obviously, as to mark that period with particular distinction. It was about this time that manufactures were extended on a new plan, by the enterprise, the capital, and, above all, by the science of the men of deep knowledge and persevering industry engaged in them. It was seen that it would be better for establishments to be placed in new situations, adapted to the obtaining raw materials, and the labour of patient and retired industry, than to endure the vexations that perpetually occur in corporate towns, and the wages of their extravagant workmen. This produced a new demand, not thought of till that period, in this country,—*internal navigation*. To make communications from factory to factory, and from warehouses to harbours, as well as to carry raw materials to and from such establishments, became absolutely necessary. Hence arose those works, not of pompous and useless magnificence, but of real utility, which have been carried on to a degree of extent and magnitude, to which as yet there is no appearance of limitation.

The *ancient harbours* of this island, it may be said, have ever been an example in the history of mankind. The feats were such as nature had formed, and were but little better, notwithstanding some jetties and piers of defence, which had been made and altered, without knowledge or judgment, at municipal expence. This general situation of things gave rise to a new profession and order of men, denominated "civil engineers." In almost all other polished nations of Europe this was a profession encouraged or instituted by the governments of those countries, of itself, and by itself; but in this country, the formation of a body of such men was left to chance; there was no public establishment, except common schools, for rudimental knowledge necessary to all arts, naval, military, mechanical, and others.

Civil engineers, then, are a self-created set of men, whose profession owes its origin, not to power or influence, but to the encouragement of a great and powerful nation:—a nation become so from the persevering industry of its manufacturing workmen, and their superior knowledge in chemistry, mechanics, and natural philosophy. The same period gave rise to an association of a few gentlemen, of whom Mr. Smeaton was one, who proposed that they might form themselves into a society for the advancement of the science of civil engineering, and in March 1771 it was established, and the members met on Friday evenings, at the Queen's Head tavern, Holborn. It did not increase rapidly, for in twenty years the numbers were less than seventy, and of these, there were only about fifteen who were real engineers, employed in public works, or private undertakings of great magnitude. The other members were either amateurs, or ingenious workmen and artificers connected with, and employed in, works of engineering. A register was kept of the names of its members; and a communication of ideas and knowledge, in the particular walks of each member, were, at the same time, the amusement and the business of the meetings. In this manner the society proceeded till 1792, when it ceased to exist, by mutual consent of the principal members. This dissolution was occasioned by the ill-treatment which Mr. Smeaton experienced from one of the members, who was under very particular obligations to him, but whose name is not mentioned in connection with the act of flagrant ingratitude. See **ENGINEERS**.

An attempt was afterwards made to rebuild the society,

and to place it on a better and more respectable foundation; but before the plan could be matured, Mr. Smeaton was no more. In April 1793, the new society was, however, formed under the denomination of "The Society of Civil Engineers." It consisted of three classes: 1. Of ordinary members, to consist of real engineers, actually employed as such in public or in private service. 2. Honorary members, to consist of men of science and gentlemen of rank and fortune, who had applied themselves to subjects of civil engineering; and who might, for knowledge, have been real engineers, had it not been their good fortune to have it in their power to employ others in this profession; and also of those who are employed in other public service, where such and similar kinds of knowledge are necessary. 3. Honorary members, consisting of various artists, whose professions and employments are necessary, or extremely useful, as well as connected with civil engineering. The meetings of this society are, we believe, still held every other Friday during the session of parliament. It may be mentioned, that the society never meet without paying a just and natural tribute of respect to the memory of Mr. Smeaton, of whom we have already given a biographical article, to which may now be added the following anecdotes, communicated to the public by his daughter Mrs. Mary Dixon.

It was a maxim of this excellent man, that "the abilities of the individual are a debt due to the common stock of public happiness or accommodation." This appears to have governed his actions through life: he devoted his time to the cultivation of talents by which he might benefit mankind. The arrangement of his time was governed by a method as invariable as inviolable; for professional studies were never broken in upon by any one; and these, with the exception of stated astronomical observations, wholly engrossed the forenoon. His afternoons were regularly occupied by practical experiments, or some other branch of mechanics: and he had so complete a command over his thoughts, that his mind was not more entirely devoted to his profession in one division of time, than abstracted from it in another. "Himself," says his daughter, "devoted to his family with an affection so lively, a manner at once so cheerful and serene, that it is impossible to say whether the charm of conversation, the simplicity of instruction, or the gentleness with which they were conveyed, most endeared his home. A home, in which from infancy we cannot recollect to have seen a trace of dissatisfaction, or a word of asperity to any. Yet with all this he was absolute! and it is for casuistry in education, or rule, to explain his authority; it was an authority as impossible to dispute as to define."

At one period the princess Askoff, after having in vain used every persuasion to induce Mr. Smeaton to accept a *carte blanche* from the empress of Russia, as a recompence for directing the vast projects which her majesty had in view, said, "Sir, you are a great man, and I honour you! You may have an equal in abilities, perhaps; but in character you stand single. The English minister, sir Robert Walpole, was mistaken, and my sovereign has the misfortune to know, there is one man, at least, who has not his price."

Early in life Mr. Smeaton attracted the notice of the duke and duchess of Queensbury, from a strong resemblance which Smeaton bore to their favourite Gay, the poet. The commencement of this acquaintance was singular, but the continuance of their esteem and partiality lasted through life. Their first meeting was at Ranelagh, where, walking with Mrs. Smeaton, he observed an elderly lady and gentleman fix an evident and marked attention on him. After some turns they stopped him, and the duchess said, "Sir, I do not know you, but so strongly do you resemble my poor

dear Gay, we must be acquainted; you shall go home and sup with us; and if the minds of the two men accord as much as their countenances, you will find two cheerful old folks, who can love you well, and I think you can as well deserve it." The invitation was accepted, and as long as the duke and duchess lived, the friendship was uninterrupted. In the course of this, he effected the abolition of that inconsiderate indiscriminate play among people of superior rank and fortune, which compels every one to join, and at their own risk. Mr. Smeaton detested cards, and his attention never following the game, he played like a child. The game was *pope Joan*, the general run of it was high, and the stake in *pope* had accidentally accumulated to a very ferocious sum. It was Smeaton's turn by deal to double it, when, regardless of his cards, he busily made some minutes on a scrap of paper, and put it on the board. The duchess eagerly asked what it was; and he as coolly replied, "Your grace will recollect the field in which my house stands may be about 5 acres, 3 roods, and 7 perches, which, at 30 years' purchase, will be just my stake; and if your grace will make a duke of me, I presume the winner will not dislike my mortgage." The joke had the proper effect, and they never after played but for the merest trifle. See Smeaton's Reports, vol. i.

SOCIETY of Artists of Great Britain, which consists of directors and fellows, was incorporated by charter in 1765, and empowered to purchase and hold lands, not exceeding 1000*l.* a year. The directors of this society, annually elected, are to consist of twenty-four persons, including the president, vice-president, treasurer, and secretary; and it is required that they be either painters, sculptors, architects, or engravers, by profession.

SOCIETY of Engravers was established in 1802, under the patronage of the prince of Wales, a president, vice-president, treasurer, and honorary secretary, &c.

SOCIETY of Painters in Oil and Water-Colours was established in 1804, under a president, treasurer, secretary, and committee of management.

SOCIETY of Architects was instituted in 1791; and the *Architectural Society* was formed in 1806, under a president, two vice-presidents, a secretary, and treasurer.

SOCIETY for Insurance, &c. See ASSURANCE and INSURANCE.

SOCIETY, Medical. To this class belong several societies, the principal of which in our own country are the following; *viz.* the Medical Society of London, instituted in the year 1752, on the plan recommended by lord Bacon (*De Augm. Scient. lib. iv. cap. 2.*), to revive the Hippocratic method of composing narratives of particular cases, in which the nature of the disease, the manner of treating it, and the consequences, are to be specified; to attempt the cure of those diseases, which, in his opinion, have been too boldly pronounced incurable; and, lastly, to extend their enquiries after the powers of particular medicines in the cure of particular cases. The collections of this society have been already published, under the title of "Medical Observations and Inquiries," in several volumes:—*Society of Physicians in London*, instituted about the year 1764, the members of which, who must be merely licentiates of the College of Physicians, are elected by ballot, and meet once a fortnight on Wednesday evening, for the purpose of conversing on the prevailing diseases, &c. and dine together once in a quarter:—the Medical Society in Crane-court, instituted in 1773, under the direction of a council, consisting of a president, treasurer, librarian, three physicians, three surgeons, three apothecaries, and three secretaries: the members meet once a fortnight, on Tuesday evening, and their council is annually elected in January, when an oration is delivered by

one of the members on some medical subject :—Society for the Improvement of Medical Knowledge in London, established in 1782, for the purpose of collecting useful essays and observations for publication: the meetings of this society are held once a fortnight, on Tuesday evening, and the members dine together once a quarter; on which occasion candidates for admission are balloted for: the society is under the direction of a president, treasurer, two secretaries, and a committee for revising and selecting papers for publication, who are elected annually by ballot:—the Medical Society of Edinburgh, to which the public are indebted for six volumes of curious and useful essays, collected principally by the late Dr. Monro, from June 1731 to June 1736; but this society was afterwards united to another, called the Philosophical Society:—the Medical Society of Edinburgh, incorporated by royal charter in 1778, under this title: this institution appears to have been coeval with the establishment of a regular school of physic in the university, though none of its records of an earlier date than 1737 are now preserved: the ordinary members of this society are elected by ballot, and three dissentients exclude a candidate; an ordinary member may also be elected an honorary member, who enjoys the privileges of the others, and receives a diploma, but is freed the obligation of attendance, delivering papers in rotation, &c. to which the ordinary members are subject; but in this case the votes must be unanimous; the meetings of this society are held every Saturday evening, in their own hall, during the winter season, when papers on medical subjects are delivered by the several members in rotation; and four of these are annually elected to fill the chair in rotation, with the title of annual presidents.

The Royal Medical Society of Paris was instituted in 1776. The members are divided into associates ordinary, limited to thirty, honorary to twelve, extraordinary to sixty, and foreign to sixty, and correspondents. This society has published several volumes of Memoirs in 4to.

The Medical and Chirurgical Society of London, in Verulam Buildings, Gray's-Inn, was established in 1805. Its council consists of a president, and 15 vice-presidents: it has a treasurer, two secretaries, and a foreign secretary.

SOCIETY, *Philosophical*, designated by the style and title of the "Royal Institution," was established in the year 1799, and in its charter of incorporation, states that it is formed with a view "of diffusing the knowledge and facilitating the general introduction of useful mechanical improvements; and for teaching, by courses of philosophical lectures and experiments, the application of science to the common purposes of life." In the execution of this plan, a spacious and commodious house was purchased in Albemarle-street, where convenient rooms have been prepared for the reception and public exhibition of all such new mechanical inventions and improvements as shall be thought worthy of public notice, and proper to be publicly exhibited; and, more especially, of all such contrivances as tend to increase the conveniencies and comforts of life, to promote domestic economy, to improve taste, or to advance useful industry. Working models are provided and exhibited, of such new mechanical inventions as are applicable to the common purposes of life. A lecture room is also fitted up for philosophical lectures and experiments; a complete laboratory and philosophical apparatus, with the necessary instruments for making philosophical and chemical experiments, are provided; and men of the first eminence, in various branches of science, are engaged for carrying into full effect this important and useful part of the plan. A library well furnished with books in various departments of literature and science is also provided. Access to the library and lectures may be had on certain conditions.

Societies of a similar kind, but in a less perfect and splendid state, although in some respects no less useful, are the London, Surrey, and Russel institutions. See the article LONDON.

SOCIETY of London, *Philosophical*, which owed its rise and present flourishing state, in a very great degree, to the active and persevering exertions of the ingenious T. J. Pettigrew, esq. was founded in October 1810. The objects of this society, stated in its address to the public, are to foster genius, to eradicate unphilosophical prejudice, to increase the knowledge of nature and of man, to destroy, as much as possible, the false definition of words, which has been so justly reprobated by Bacon and Locke, as the origin of sophistry and misconception; but, above all, to remove the barrier erected by pedantry against universal knowledge, and to subdue an *esprit de corps*, which has been introduced into philosophy, tending to confine it within the narrow limits of sects, and preventing its natural diffusion among mankind. The means adopted to attain these objects are, first, to promote a literary taste by the erection of a library common to all the members; humbly to diffuse more widely a familiarity with science by lectures in every department of philosophy; and thereby to cultivate a correct mode of reasoning, by subjecting those lectures to a rigorous subsequent investigation, and by introducing discussions which correspond with the general objects of the society. In this society there are three classes of members, *viz.* ordinary, honorary, and corresponding. Every ordinary member pays at his entrance the sum of two guineas, which shall be repeated annually; he shall also subscribe to the regulations of the society; and upon withdrawing himself forfeit all title to the property of the society. No person shall be deemed eligible as an honorary member, unless he be author of some scientific work of celebrity, or professor of some branch of philosophy; and the same qualifications are required in a corresponding member, except in the case of such ordinary members, removed from town, as the council may think proper to admit. A person proposed for admission must be recommended by three members, whose names, together with that of the person nominated, shall be hung up in the society's lecture-room fifteen days previous to his being balloted for by the council. In ballots, three black balls shall be considered as a rejection. Each member shall be allowed to introduce three persons at the ordinary meetings of the society; and he shall also be permitted to borrow books of the society. The society shall meet on every Thursday, at eight o'clock in the evening, and a lecture shall be delivered at every alternate Thursday, and the intermediate meetings shall be occupied in discussing the preceding lecture, or in the discussion of some philosophical question, which may have been submitted to and approved of by the council. The society shall meet every alternate Tuesday evening at the same time, to converse on philosophical subjects, or for the reading of papers previously presented to and approved of by the council. In the discussions and proceedings of the society, theological and political subjects shall not be admitted.

The business of the society is conducted by a president, eight vice-presidents, a treasurer and secretary, two curators, a registrar and assistant, and a council composed of eighteen members; all of these are elected annually. The patrons of the society are the dukes of Kent and Sussex. The number of members already amounts to 200, and the library consists of about 500 volumes. In both these respects the society is receiving numerous accessions.

SOCIETY Islands, in *Geography*, a cluster of six islands in the Pacific ocean, so called by captain Cook in 1769, because they lie contiguous to each other, so that he did not think

think it proper to distinguish them by any other names than those by which they were known to the natives; viz. Ulitea, Otaha, Bolabola, Huaheine, Tubai, and Maurua. See each respectively. They are situated between S. lat. $16^{\circ} 10'$ and $16^{\circ} 55'$, and between W. long. $150^{\circ} 57'$ and 152° . Ulitea and Otaha lie within about two miles of each other, and are both inclosed within one reef of coral rocks, so that there is no passage for shipping between them. This reef forms several excellent harbours; and though the entrances into them are narrow, yet a ship within them is exempt from all injury. The inhabitants, climate, and produce, are similar, in many respects, to those of Otaheite, from which island they are not above 50 leagues distant towards the N.W. Captain Cook says, "while we were employed about these islands, we expended very little of the ship's provisions, and were very plentifully supplied with hogs, fowls, plantains, and yams, which we hoped would be of great use to us in our course to the southward; but the hogs would not eat European grain of any kind, pulse, or bread-dust, so that we could not preserve them alive; and the fowls were very soon seized with a disease that affected the head, so that they continued to hold it down between their legs till they died: much dependence, therefore, must not be placed in live-stock taken on board at these places, at least not till a discovery is made of some food which the hogs will eat, and some remedy for the disease of the poultry."

SOCIETY-Land, a township of America, in the state of New Hampshire and county of Hillsborough; containing 199 inhabitants.

SOCII, ALLIES, among the Romans. See **ALLIANCE** and **SOCIAL War**.

SOCINIANS, in *Ecclesiastical History*, a sect of Antitrinitarians, who are said to have derived this denomination from the illustrious family of the Sozzini, which flourished a long time at Sienna, in Tuscany, and produced several great and eminent men; and, among others, Lælius and Faustus Socinus, who are commonly supposed to have been the founders of this sect. Lælius was the son of Marianus, a famous lawyer, and distinguished by his genius and learning, as well as by the lustre of an unblemished and virtuous conduct. Having conceived a disgust against popery, and disapproving many doctrines of the church, he left his country in 1547; and having passed four years in visiting France, England, Holland, Germany, and Poland, he at last fixed his residence at Zurich, in Switzerland, where he died in 1562, in the thirty-seventh year of his age. Although he adopted the Helvetic confession of faith, and professed himself a member of the church of Switzerland, he entertained doubts with respect to certain doctrines of religion, which he communicated to some learned men, whose judgment he respected, and in whose friendship he could confide. However, his sentiments were propagated in a more public manner, after his death; as Faustus, his nephew and his heir, is supposed to have drawn from the papers he left behind him, that religious system, upon which the sect of the Socinians was founded. This Faustus Socinus was born at Sienna in 1539; and having continued many years in his own country, twelve of which he spent in the court of the grand duke of Tuscany, he determined, in the year 1574, and the thirty-fifth of his age, to withdraw from Italy into Germany. During this period he had laboured under many disadvantages in the pursuit of knowledge, and his studies had been chiefly confined to the rudiments of logic and jurisprudence; but at Basil, where he first resided after his voluntary exile, he devoted himself for three years to the study of theology, under the direction and assistance of the writings of his uncle Lælius; and in 1577 he began to pro-

pagate his religious opinions without reserve or disguise. In 1578 he was invited by Blandrata, a person of eminence in Transylvania, to compose the commotions which were occasioned by a party under the lead of Francis David, in the Antitrinitarian churches of that country. But failing of success, he removed to Poland in 1579, zealously wishing to join himself to the Unitarian churches; but here he suffered many vexations, and much opposition, from a considerable number of persons, who looked upon some of his tenets as highly erroneous. At length, however, he vanquished the animosity of his enemies by his gentleness and firmness, by his address and eloquence, and the favour and protection of the nobility, with which he was honoured, and lived to form the Unitarians into one community, under his own superintendency and direction. Having retired to a village about nine miles from Cracow, he there closed his life, in the year 1604; and the following epitaph was inscribed on his tomb:

"Tota licet Babylon destruxit testâ Lutherus,
Muros Calvinus, sed fundamenta Socinus:"

i. e. Luther destroyed the houses of Babylon, Calvin the walls, but Socinus subverted the foundations. The sentiments of Socinus, with regard to the principal theological subjects controverted among Christians, will appear in the following abstract of them from his own writings; some of which were published during his own life, and some after his death; and the collection of them, in two volumes, folio, forms part of the "Bibliotheca Fratrum Polonorum." With regard to the nature and character of Christ, Socinus maintained, that he was a man, conceived and formed in the womb of the Virgin, without the intervention of a man, by the power of the divine spirit; on this account he was, in a peculiar sense, God's own and only begotten son, as no other person ever was the son of God in the same way, by the immediate origin of his being. Moreover, he was constituted the son of God by his resurrection from the dead, and was then begotten by God, when God raised him from the dead. As to those passages which have been supposed to assert Christ's existence in the heavenly world, previous to his birth and appearance among men, he explains them, by alleging that Christ himself, after he was born, and before he entered on the office assigned him by his Father, was, in consequence of the divine counsel and agency, in heaven, and remained there for some time; that he might hear from God, and being with him, as the Scripture says, might see those things which he was to announce to the world, in the name of God himself; though he explains John, iii. 13, as figurative language. Accordingly, in explaining the first words of St. John's gospel, *In the beginning was the word*, &c. he observes, that the terms, *in the beginning*, do not relate to eternity, but to the order of those things which John was about to write concerning Jesus Christ; imitating Moses, who, in writing his history, opens his introduction with this word *beginning*, in reference to the transactions which he was about to record. And Jesus is called the Word, he supposes, not on account of his nature or substance, but because of the office he discharged when he revealed to us the word of the gospel from the Father. *The word was with God*, *i. e.* Jesus, as the word of God, before he was pointed out by the preaching of the Baptist, was known to God alone. And *the word was God*: the term God, says this commentator, does not denote substance, but authority, power, and beneficence, which were derived from the Father, and which entitled Christ, according to the opinion of this writer, to adoration and worship. His ideas of the efficacy of our Lord's death and mediation are utterly repugnant

repugnant to those that have been generally entertained by persons called Calvinists. Nothing, he says, can be more incompatible with each other, than a free pardon and satisfaction. He adds, no man of judgment and piety ought to entertain the idea of a satisfaction for sin; since it plainly does very much derogate from the power and authority, or goodness and mercy of God; and though a propitiation be not the same thing as a satisfaction, and though God never refrained from the punishment of sin, on account of any real satisfaction given him, yet it is certain, that in remitting the punishment of our sins by Jesus Christ no propitiation intervened; but God hath, from his free will, exhibited himself so propitious to us in Christ, as not to exact the punishment of our sins, though he might justly have done it. However, he allows not only that the death of Christ, and the pouring out of his blood for us, was an offering and sacrifice to God, but that this sacrifice may be said to have been offered up for our sins in order to their being forgiven; yet he apprehended, that this sacrifice, as far as it was expiatory, was offered by Christ, not on the cross, but in heaven itself, after his resurrection. To which purpose he observes, that Christ did not obtain eternal redemption for us before he entered into the holy place, and there assumed the priesthood; and without a priesthood no expiatory offering could be made.

Socinus does also expressly deny the distinct personality of the Holy Ghost, understanding by the Holy Spirit a divine energy or influence.

With respect to the nature and state of man, Socinus thought, that the progenitor of our race was mortal, *i. e.* liable to death, by reason of his frame, and incapable of exemption, without an exertion of the divine favour and influence, which was not granted to him at creation; and, therefore, when the apostle asserts, that by sin death entered into the world, he meant not natural mortality, but the necessity of dying, or eternal death. To this purpose he explains himself: Adam, if he had not sinned, might have been preserved from death by the kindness of God, though naturally mortal; or, if he had died, have been restored to life, and made immortal. By his sin he did, as it were, refuse to give himself and his posterity this blessing; and, therefore, unless the favour of God be renewed to us, we must all die, and remain in the state of the dead. As to the nature of the human soul, it seems to have been the opinion of Socinus, that, after this life, it doth not subsist of itself, without the body, as to be capable of any reward or punishment, or any sensations at all. To the question, whether the first man had any original righteousness before he sinned? Socinus replies, that if by original righteousness be meant such a condition that he could not sin, this certainly was not the state of Adam, as it is clear he did sin. But if original righteousness consisted in this, that his reason had the absolute rule over his appetites and senses, and invariably directed them, then the opinion of those who ascribe it to Adam is supported by no argument: hence it should seem from Adam's fall, that there was no perfect harmony between them; and that his appetites and senses had the dominion over his reason. If it be asked, says Socinus, whether there is original sin? he answers, this is the same as the inquiry, whether men, when they are born, because they derive their origin from Adam, have, on account of his fall, contracted any guilt or punishment, or are obnoxious to either? Therefore, since the consent of the will must constitute guilt, and there can be no punishment without antecedent guilt, it seems not at all possible that either of these should pertain to a man when he is born, as he neither has, nor could have before, any use of his own will. If by ori-

ginal sin be understood certain innate desires, or evil concupiscence in man, and a proneness to sin, this opinion Socinus denies, and labours to refute; concluding upon the whole, that there is no such thing as original sin, *i. e.* a taint or pravity in consequence of the sin of the first man, necessarily produced, or by any means inflicted on the human race; and that no other evil necessarily flows to all his posterity from that first transgression, than by some means or other the necessity of dying; not indeed through the influence of that transgression, but because man, being naturally mortal, was on that account left by God to his own natural mortality, and what was natural became necessary as a punishment on the offender; consequently, they who were born of him must be born in the same circumstances, for he was deprived of nothing he naturally had or could have. From reasoning on this subject, Socinus concludes, that there is a freedom of will in man, and that the powers of man are not so few and feeble, but that he may, with the assistance of God, obey the divine law by the right use and application of his powers. Divine assistance he considers as external and internal; and the latter, he says, is twofold: the one, when God by some means impelleth on the heart what he hath promised to them that obey him; and the other, when he instructs and illuminates the mind rightly to discern his will, in those instances which cannot be expressly contained in his written word: however, this internal assistance belongs only to those who have made good use of the external. The doctrine of predestination Socinus absolutely denies, and he endeavours to account for the presence of the Deity, without admitting that notion of his decrees, which some divines have adopted. On the head of justification, Socinus observes, that God out of his mere mercy justifies us, *i. e.* pronounces us righteous, and grants us forgiveness of sins, and eternal life; but he requireth from us, before this be done, that we believe in Christ, *i. e.* confide in and obey him; and our good works, or the obedience we render to Christ, though not the efficient or meritorious cause, are the *sine qua non*, or indispensable pre-requisite of our justification before God, and eternal salvation. But if any should deviate from this obedience, by falling into sin, and continuing therein, they cease to be justified; nevertheless, by repentance and amendment of life, they may be justified again: but this second repentance, he says, is not in our power, God granting an ability for it to whom he pleaseth.

Socinus denied the perpetuity of baptism, as an ordinance in the church, alleging that it was not prescribed for those who in any other way have publicly given their names to Christ, or from their earliest years have been educated in the Christian discipline; or if it is to be retained in these days, he apprehends it should be retained principally on account of those who have been converted from other religions to the Christian. He farther thought, that, in order to the right administration of baptism, it is previously necessary that the baptized person should be a believer, and he, therefore, reckoned the practice of infant baptism unscriptural and erroneous.

After this compendious abstract of the chief theological sentiments of Socinus, it is proper to observe, that, according to the usual manner of speaking, all are denominated Socinians, whose opinions bear a certain affinity to the system of Socinus: but, in a strict and proper sense, they only are deemed the members of this sect, who embrace wholly, or with few exceptions, the form of theological doctrine, which Socinus either drew up himself, or received from his uncle, and delivered to the Unitarian brethren, or Socinians, in Poland and Transylvania. Their sentiments

are explained at large in their Catechism, printed several times under the title of "Catechesis Ecclesiarum Polonicarum, unum Deum Patrem, illiusque Filium unigenitum, una cum Sancto Spiritu, ex sacra Scriptura consentientium." See *Catechism of Racow*.

The Socinians, like other sects distinguished by one general denomination, are divided into several parties. Some differ from Socinus with regard to the worship of Christ; some deny the eternity of the future punishment of the wicked; and some apprehend it contradictory to maintain God's foreknowledge of future contingencies, &c. See BUDNÆANS, FARNOVIANS, and SEMIJUDAIZERS.

The chief school of the Socinians was at Racow, where they obtained the grant of a settlement, and there all their first books were published. But in the year 1638, in consequence of the intemperate zeal of some students of the Unitarian academy in this city against Popery, a law was enacted at Warsaw, by which it was decreed, that the academy of Racow should be destroyed, its professors banished, the printing-house of the Socinians destroyed, and their churches shut up. This law was immediately executed; and similar edicts were enacted in other parts of Poland. In 1658 another severe act was published by a diet held at Warsaw, requiring all the Socinians to leave the kingdom for ever, and denouncing capital punishment against all who should profess their opinions, or harbour their persons. This terrible edict was renewed in 1661; and in consequence of these measures, the Socinians sought an asylum among their brethren in Transylvania: a considerable number was dispersed through the adjacent provinces of Silesia, Brandenburg, and Prussia, where their posterity still subsist. Others repaired to Holland and England. In Transylvania they still continue numerous; and are much at their ease. In Holland their number is not considerable; and all who profess themselves such are by law excluded from the general toleration which prevails in that kingdom. They are called Collegians.

As to the present state of the Socinians in Poland, a late writer observes, that since their suppression they have had churches, which have assembled in private houses, woods, or fields, as opportunity permitted; and these assemblies have been conducted under the inspection of regular ministers, educated at Leyden and Amsterdam. Since the edict of 1661, they have been included by the Romish party under the general name of Dissidents: however, in those parts of Poland, which by the late partition fell to the lot of Prussia, Russia, or the emperor, they have now their liberty in common with their other dissenting brethren, and their public places of worship. The only society of Socinians in England was that formed by Mr. John Biddle, under the patronage of Mr. Thomas Firmin, and his adherents were called Bidellians; but this name was lost in the more common appellation of Socinians, or, what they preferred, Unitarians. They differed from Socinus, and the foreign Unitarians, in maintaining the personality of the Holy Spirit. This society does not appear to have subsisted after the death of Biddle; nor have the Socinians, though their sentiments have been adopted by several, made any figure as a community in England. The most distinguished Socinian writers, in Poland, were Crellius, Smalcius, Volkelius, Slichtingius, Wolzogenius, Przipcovius, and Stanislaus Lubianicus; to this number some have added Grotius; and in later times we might enumerate Le Clerc, Biddle, Lardner, Lowman, Fleming, Lindsey, Priestley, &c. See on this subject Socini Oper. tom. i. and ii. passim. Mosheim's Eccl. Hist. vol. iv. p. 167, &c. 8vo. Toulmin's Life of Socinus, passim. See UNITARIANS.

SOCK. See SOCCUS.

SOCK and *Scythe-Land*. See HUSBAND-LAND.

SOCK, in *Agriculture*, provincially the share of a plough, or that part that opens the land; but properly the iron part, or fock, which is put upon it. They are of different kinds, as sharp-pointed and feathered on the edge, &c.

The sharp-pointed fock is the most proper and best adapted for all the rough stony sorts of land, being the least in danger of being thrown out of work in them. They are, therefore, the most commonly employed. The feathered fock is the most useful in all such soils as are in a great measure free from stones, though they may be rough on the top. They are, however, occasionally made use of in other circumstances and cases. The feathers of them vary considerably in their nature and forms; some being small and flat, others large and upright, so as to suit different purposes and intentions.

There is also a mixed kind of fock, which has not only a pointed part, but a feathered one likewise. This is found very useful in ploughing, in many cases, where the lands are of the less stony kinds.

All the different kinds of focks should be made in such a manner as to fit the sheath, or fore-part of the head of the plough in the most exact manner, as much in the business of ploughing depends upon this being nicely adjusted. See PLOUGH.

SOCK, *Paring*, that sort of fock which is made use of on any common plough, for the purpose of paring off the surface of sward land. A fock of this kind may be seen at *fig. 9. Plate Paring Ploughs*, which has an upright cutting feather, with an outside cutting wing, and a middle hollow part to be put upon the sheath or head of any common plough. It is very convenient and useful on many occasions, as it is capable of being employed upon any plough which the farmer may chauce to have by him.

SOCKE, the drainage of a farm-yard, or any other yard where dung is laid. See FARM-YARD.

SOCKE-Pit, the receiver or receptacle of the farm-yard drainage or liquors.

SOCKET. Ball and socket. See BALL.

SOCKETS, in a *Ship*, are the holes which the pintles of the murthering pieces go into.

SOCKIA, in *Geography*, a town of Arabia, in the province of Hedsjas; 75 miles S. of Medina.

SOCKNA, a town of Africa, in Fezzan; 150 miles N.N.W. of Mourzouk.

SOCLE, or ZOCLE, in *Architecture*, a flat, square member under the bases of pedestals, of statues, vases, &c. which it serves as a foot, or stand.

The word is French, formed from the Italian *zoccolo*, or the Latin *foccus*, the shoe of the ancient comic actors. Vitruvius calls it *quadra*; we frequently denominate it *plinth*.

SOCLE, *Continued*, is a kind of continued stand, or pedestal, without either base or cornice, ranging round the whole building; called, by Vitruvius, *stereobata*; and, by the French, *soubassement*.

SOCLO, in *Geography*, a river on the coast of the island of Mindoro, which runs into the sea, N. lat. 22° 56'. E. long. 121° 15'.

SOCKMEN, or SOKEMEN, *Socmanni*, such tenants as held their lands and tenements in *focage*; but the tenants in ancient demesne seem most properly to be called *socmans*. See SOC and VILLENAGE.

SOCNA, in our *Old Writers*, a privilege, liberty, or franchise. The word is Saxon.

SOCO, in *Ornithology*, the name of a Brazilian bird of the heron-kind, the *ardea Brasiliensis* of Linnæus, remarkable,

able, beyond all the rest of that genus, for the length of its neck. It is very common in the Brasils; it is smaller than the common heron; its beak is strong, straight, and sharp; its tail short; its head and neck brown, and variegated with black; and its body is of the same colours in different variegations, but its wings have a mixture of whiteness. See HERON.

SOCOA, in *Geography*, a sea-port of France, in the department of the Lower Pyrenées; 8 miles S.S.W. of Bayonne. N. lat. $43^{\circ} 14'$. W. long. $1^{\circ} 36'$.

SOCOCA, a town of Peru, in the diocese of La Paz; 80 miles E.S.E. of Lipas.

SOCOH, Soco, *Soco*, or *Shoco*, in *Ancient Geography*, a city of Judah (Joh. xv. 35; 1 Sam. xvii. 1.), repaired by Heber (1 Chron. iv. 18.), and the place in which his family resided; and afterwards fortified by Rehoboam. (2 Chron. xi. 7.) According to Eusebius, there were two cities named *Socob*, the higher and the lower; 9 miles from Eleutheropolis towards Jerusalem.

SOCOME, in our *Law-Books*, &c. a custom of grinding corn at the lord's mill.

There is a *bond-focome*, where the tenants are bound to it; and *love-focome*, where they do it freely, out of affection to the lord. See MOLTA.

SOCONUSCO, in *Geography*, a province of Mexico, in the audience of Guatemala, bounded on the north by the province of Chiapa, on the east by Vera Paz and Guatemala, on the south by the Pacific ocean, and on the west by the Pacific ocean and Guaxaca. The climate is very hot, the rainy season from April to September, and storms are very frequent; so that the country is far from being either healthy or pleasant; nor does the soil produce much corn, but it affords great quantities of indigo and cocoa-nuts, which are exported by sea to all the other parts of New Spain. The few Spaniards of this country are very opulent.

SOCONUSCO, or *Gueuelan*, a town of Mexico, capital of a province of the same name, situated on a river near the North Pacific ocean; 460 miles S.E. of Mexico. N. lat. $15^{\circ} 28'$. W. long. $94^{\circ} 36'$.

SOCORRO, an island in the North Pacific ocean, about 20 miles in circumference, uninhabited, and barren; about 200 miles W. from the coast of Mexico. N. lat. $18^{\circ} 30'$. W. long. $120^{\circ} 40'$.

SOCOS, a small island in the Atlantic, near the coast of Africa. S. lat. $19^{\circ} 45'$.

SOCOTAI, a town of Upper Siam; 30 miles S.W. of Porfelouc. N. lat. $17^{\circ} 30'$. E. long. 117° .

SOCOTAN, a town of Persia, in the province of Arokhage; 120 miles E. of Arokhage.

SOCOTORA, or SOCOTRA, an island in the Arabian sea, about 25 leagues from Cape Guardafu, in length about 24 leagues, and in breadth 16. Its shore is bold, and affords safe anchorage and good ports: two of its harbours and bays, *viz.* those of Benin and Cora, are particularly distinguished, on account of the security they give to shipping against every wind that blows. Of this island, though much frequented by different trading nations, very various and contradictory accounts have been given by different authors. Some say that it has only one town, called "Talmart," or "Tamary;" whilst others say, that this is the chief of three towns; and others again state, that it has neither town, village, nor house, and that the inhabitants shelter themselves from the heat of the sun in subterraneous dens and caves. It is agreed, however, that the island is populous and fertile, under the government of a prince, or sultan, who was tributary to the sheriffs of Arabia. The inhabitants are mostly Mahometans, who denominate themselves Arabs, and who resemble them in their manners and

language. The whole island abounds in cattle and fruit, with which, besides some other commodities, they trade to Goa, where they are more favourably received than the native Arabs, who are not allowed to enter that town without passports. The produce of the island consists chiefly in aloes, for which it is proverbially famous, frankincense, ambergris, dragon's blood, rice, dates, and coral, which pass from Goa to many parts of the Indies, and to all the kingdoms of Europe. The East India ships formerly stopped here, when disappointed of their passage by the monsoons; but of late the periods of these winds have been so well ascertained, that this port is entirely neglected. N. lat. $12^{\circ} 15'$. E. long. 54° .

SOCRATES, in *Biography*, an ancient moral philosopher, eminently distinguished by his principles and conduct, and proverbially recognized as one of the wisest and best men, whose name and character history has recorded. He was born at Alopecce, a village near Athens, in the fourth year of the 77th Olympiad, B.C. 469. His parentage was obscure; his father, Sophroniscus, being a statuary, and his mother, Phænareta, a midwife; and at an early age he was employed in his father's business, and is said to have executed statues of the habited Graces, which were allowed a place in the citadel of Athens. His patrimony, upon the death of his father, was only the small sum of 80 minæ, or about 300*l.*; and this sum he lost by the dishonesty of a relation, with whom his father had entrusted it. Thus reduced to the necessity of supporting himself by manual labour in the exercise of his profession, as a statuary, he could only command occasional intervals, which he devoted to the study of philosophy. He soon, however, obtained the patronage of Crito, a wealthy Athenian, who engaged him in the office of instructing his children; and in this situation he availed himself of the opportunities, which were thus afforded him, of attending the public lectures of the most eminent philosophers. Ardently devoting himself to his favourite pursuits, he chose, for his first preceptor, Anaxagoras; and when he left Athens, he attached himself to Archelaus. Prodicus, the sophist, was his preceptor in eloquence, Evenus in poetry, Theodorus in geometry, and Damo in music; and he also derived considerable assistance in his education from Aspasia, a woman highly celebrated for her intellectual as well as personal accomplishments, to whose house persons of the most distinguished character resorted. So diligent and so successful was Socrates in the improvement of these advantages, that his endowments, both natural and acquired, attracted attention; and he appeared at Athens, equally distinguished as a true philosopher and a good citizen. The military valour of Socrates was no less conspicuous than the other qualities which were more adapted to a retired life; nor did he decline any service, however hazardous or difficult, which private friendship or the public interest demanded. On one occasion he preserved the life and arms of Alcibiades, when he fell wounded in an engagement, in which they were jointly concerned; and in order to encourage the rising merit of this noble youth, he declined the prize of valour, which was unquestionably due to himself, and gave his vote that it might be bestowed on Alcibiades. On another occasion, he hazarded his own life, in order to rescue Xenophon, who was left wounded on the field of battle, and carried him on his shoulders till he was out of reach of the enemy.

Socrates, declining military expeditions, settled at Athens; and he was upwards of 60 years, before he undertook to serve his country in any civil office. Accordingly he was chosen to represent his own district in the senate of 500; and though he was first treated contemptuously by his colleagues,

SOCRATES.

leagues, on account of his inexperience, he soon convinced them that in wisdom and integrity he was much their superior. No consideration could ever induce him to give a vote, or sanction a measure, that appeared to him to be contrary to justice and the laws; and in opposition to the thirty tyrants, whose proceedings seemed to him to be cruel and oppressive, he exposed even his life to danger in supporting, with undaunted firmness, the rights of his fellow-citizens; and when they issued an order to apprehend a wealthy citizen of Salamis, which he disapproved, he refused to execute it, alleging that he would rather suffer death himself, than be instrumental in inflicting it unjustly upon another. These proofs of public virtue, both in a military and civil capacity, says one of his biographers, are sufficient to entitle the name of Socrates to a distinguished place in the catalogue of good citizens. But his highest honour and praise are those which belong to him as a philosopher and moral preceptor. Observing with regret how the Athenian youth were misled, and even corrupted in their principles and taste, by the mode of teaching that prevailed among speculative philosophers and artful sophists, he determined to institute a new and more useful method of instruction. He justly conceived the true end of philosophy to be, not to make an ostentatious display of superior learning and ability in subtle disputations or ingenious conjectures, but to free mankind from the dominion of pernicious prejudices; to correct their vices; to inspire them with the love of virtue, and thus conduct them in the path of wisdom to true felicity. He, therefore, assumed the character of a moral philosopher; and, looking upon the whole city of Athens as his school, and all who were disposed to lend him their attention as his pupils, he seized every occasion of communicating moral wisdom to his fellow-citizens. He passed his time chiefly in public. It was his custom, in the morning, to visit the places made use of for walking and public exercises; at noon, to appear among the crowds in the markets or courts; and to spend the rest of the day in those parts of the city which were most frequented. Sometimes he collected an audience about him in the Lyceum, (a pleasant meadow on the border of the river Ilyssus,) where he delivered a discourse from the chair, whilst his auditors were seated on benches around him. At other times he conversed, in a less formal way, with any of his fellow-citizens in places of common resort, or with his friends at meals, or in their hours of amusement; thus making every place to which he came a school of virtue. Not only did young men of rank and fortune attend upon his lectures, but he sought for disciples even among mechanics and labourers.

The method of instruction, which Socrates chiefly made use of, was, to propose a series of questions to the person with whom he conversed, in order to lead him to some unforeseen conclusion. He first gained the consent of his respondent to some obvious truths, and then obliged him to admit others, from their relation, or resemblance, to those to which they had already assented. Without making use of any direct argument or persuasion, he chose to lead the person he meant to instruct, to deduce the truths of which he wished to convince him, as a necessary consequence from his own concessions. He commonly conducted these conferences with such address, as to conceal his design, till the respondent had advanced too far to recede. On some occasions, he made use of ironical language, that vain men might be caught in their own replies, and be obliged to confess their ignorance. He never assumed the air of a morose and rigid preceptor, but communicated useful in-

struction with all the ease and pleantry of polite conversation.

The modesty of Socrates was no less distinguished than his wisdom. He professed "to know only this, that he knew nothing;" meaning by this declaration, which he often repeated, that he had no other intention than to convince his hearers of the narrow limits of the human understanding. Far from encouraging universal scepticism, he always spoke confidently and decidedly on moral subjects; but at the same time he wished to expose to contempt the arrogance of those pretenders to science, who would not acknowledge themselves to be ignorant of any thing. He preferred moral to speculative wisdom; and therefore condemned those whose whole attention and time were occupied about abstruse researches into nature, and who took no pains to render themselves useful to mankind. His favourite maxim was, "whatever is above us, doth not concern us." He estimated the value of knowledge by its utility, and recommended the study of geometry, astronomy, and other sciences, only so far as they admit of a practical application to the purposes of human life. His great object, in all his conferences and discourses, was to lead men into an acquaintance with themselves; to convince them of their follies and vices; to inspire them with the love of virtue; and to furnish them with useful moral instructions. Cicero might, therefore, very justly say of Socrates, that he was the first who called down philosophy from heaven to earth, and introduced her into the public walks and domestic retirements of men, that she might instruct them concerning life and manners.

The moral lessons which Socrates taught, he himself diligently practised; whence he excelled other philosophers in personal merit, no less than in his method of instruction. His conduct was uniformly such as became a teacher of moral wisdom. His mind, through the whole of his life, was superior to the attractions of wealth and power. His instructions were gratuitous, and he refused rich presents, that were offered to him by Alcibiades and others, though his wife earnestly importuned him to accept them. He wanted little for his own personal accommodation. In his clothing and food, he consulted only the demands of nature. Although his fare was simple, he was hospitable; and sometimes invited men of superior rank to partake of his meals. On one of these occasions, his wife complained of the incompetency of their provision for their guests; but to these complaints he merely replied, that if his guests were wise men, they would be satisfied with the provisions which his table afforded; if otherwise, they were unworthy of notice. "Whilst others," says he, "live to eat, wise men eat to live." He knew, that temperance was conducive to health, and he found by experience that this was the case; for he escaped infection in the midst of the plague which proved so fatal to his fellow-citizens.

Although he admired a fair external form, as the index of a mind possessed, or at least capable, of moral beauty, and conversed freely with young persons of both sexes, in order to assist their progress in wisdom and virtue; yet his enemies have never been able to fix upon him the charge of incontinence. "Modern calumnies," says our biographer, "which impute to this great man vices, with which he was never charged by his contemporaries, ought to be treated with universal contempt." In his domestic connection he was unfortunate, yet he converted this into an occasion of exercising his virtue. Xantippe, of whom many tales, that are mere fabrications, are related, was without doubt a woman of a high and unmanageable spirit.

Socrates himself, however, allows that he possessed many domestic virtues; and towards the close of his life, and during his imprisonment, he expressed great affection for her husband; and, indeed, after twenty years' experience, it would have been strange, if it had been otherwise. On all occasions, however, at home and abroad, he maintained an unruffled equanimity of temper; always exercising that self-command, which is founded on virtuous principles, and strengthened by reflection and habit. In this respect he was the more praise-worthy, as he himself acknowledges, that he was, in his natural disposition, prone to vice, but that he had subdued his inclinations by the power of reason and philosophy. This divine power of reason was probably the genius, or demon, which, from time to time, gave him instruction. Without admitting every thing which his disciples have said on this subject, it is possible that Socrates might, in some degree, be influenced by superstitious credulity, concerning this demon; for Xenophon expressly attests, that he believed that the gods sometimes communicate to men the knowledge of future events, and that, on this principle, he encouraged the practice of divination.

It was one of the maxims of Socrates, "that a wife man will worship the gods according to the institutions of the state to which he belongs." He taught, however, a doctrine concerning religion much more pure and rational, than that which was delivered to the people by the priests, and he reprobated the popular fables concerning the gods. Convinced of the weakness of the human understanding, and perceiving that the pride of philosophy had led his predecessors into futile speculations on the nature and origin of things, he judged it most consistent with true wisdom to speak with caution and reverence concerning the divine nature. Nevertheless, there can be no doubt that, whilst he did not deny the existence of inferior divinities, he acknowledged the being and providence of one Supreme Deity, and paid homage, with a pious mind, to the sovereign power.

In fine, Socrates, both on account of his abilities as a moral preceptor, and on account of his personal merit, unquestionably deserves to be ranked in the first order of human beings. "The man," says Xenophon, "whose memoirs I have written, was so pious, that he undertook nothing without asking counsel of the gods; so just, that he never did the smallest injury to any one, but rendered essential services to many; so temperate, that he never preferred pleasure to virtue; and so wise, that he was able, even in the most difficult cases, without advice, to judge what was expedient and right. He was eminently qualified to assist others by his counsel; to penetrate into men's characters; to reprehend them for their vices; and to excite them to the practice of virtue. Having found all these excellencies in Socrates, I have ever esteemed him the most virtuous and the happiest of men."

Socrates, notwithstanding the superiority of his talents, the excellence of his character, and the number of his followers, who venerated and esteemed him, had many enemies. They were chiefly interested *Sophists* (see *SOPHIST*), whose influence and whose emoluments were diminished in consequence of the prevalence of his doctrines and precepts. In order to degrade him in the estimation of the Athenian youth, and to restrain his popularity, they engaged Aristophanes, the first buffoon of the age, to write a comedy, in which Socrates should be the principal character. Aristophanes, pleased with so promising an occasion of displaying his low and malignant wit, undertook the task,

and produced the comedy of "The Clouds," still extant in his works. In this piece Socrates is introduced hanging in a basket in the air, and thence pouring forth absurdity and profaneness. The philosopher, though he seldom visited the theatre, except when the tragedies of Euripides were performed, attended the representation of this play, at a time when the house was crowded with strangers, who happened to be at Athens during the celebration of a Bacchanalian festival. When the performer, who represented Socrates, appeared upon the stage, a general whisper passed along the benches on which the strangers sat, to inquire who the person was whom the poet meant to satirize. Socrates, who had taken his station in one of the most public parts of the theatre, observed this circumstance; and immediately, with great coolness, rose up, to gratify the curiosity of the audience, and continued standing during the remainder of the representation. One of the spectators, astonished at the magnanimity which this action discovered, asked him, whether he did not feel himself much chagrined, to be thus held up to public derision. "By no means," replied Socrates, "I am only a host at a public festival, where I provide a large company with entertainment."

These efforts of envy and malice, however, were not of long duration. When Aristophanes attempted, the year following, to renew the piece with alterations and additions, the representation was so much discouraged, that he was obliged to discontinue it. The consequence was, that the Sophists, and other opponents of Socrates, who appear to have made use of the expedient of the theatrical representation, in order to found the inclinations of the public, chose to postpone the farther prosecution of their malignant intention to a more favourable opportunity.

From this time, Socrates continued, for many years, to prosecute his laudable design of instructing and reforming his fellow-citizens. But as he persevered in opposing every kind of political corruption and oppression, both under the democracy and oligarchy, the number of his enemies increased, and a conspiracy, which had been long concerted against his life, was resumed. Clandestine arts were used, after the dissolution of the tyranny, to excite a general prejudice against him. The people were industriously reminded, that Critias, who had been one of the most cruel of the thirty tyrants, and Alcibiades, who had insulted religion by defacing the public statues of Mercury, and performing a mock representation of the Eleusinian mysteries, had, in their youth, been disciples of Socrates. The minds of the people being thus inflamed, a direct accusation was preferred against Socrates before the supreme court of judicature. His accusers were Anytus, a leather-dresser, who had long entertained a personal enmity against Socrates, for reprehending his avarice, in depriving his sons of the benefits of learning, that they might pursue the gains of trade; Melitus, a young rhetorician, who was capable of undertaking any thing for the sake of gain; and Lycon, who was glad of an opportunity of displaying his talents. The accusation, which was delivered to the senate under the name of Melitus, was this: "Melitus, son of Melitus, of the tribe of Pythos, accuseth Socrates, son of Sophroniscus, of the tribe of Alopece. Socrates violates the laws, in not acknowledging the gods which the state acknowledges, and by introducing new divinities. He also violates the laws by corrupting the youth. Be his punishment death."

This charge was delivered upon oath to the senate, and Crito, a friend of Socrates, became surety for his appearance on the day of trial. Anytus, soon afterwards,

SOCRATES.

sent a private message to Socrates, assuring him, that if he would desist from censuring his conduct, he would withdraw his accusation. But Socrates refused to comply with so degrading a condition, and, with his usual spirit, replied, "Whilst I live I will never disguise the truth, nor speak otherwise than my duty requires." The interval between the accusation and the trial he spent in philosophical conversations with his friends, chusing to discourse upon any other subject, rather than his own situation. Hermogenes, one of his friends, was much struck with this circumstance, and asked him, why he did not employ his time in preparing his defence: "Because," replied Socrates, "I have never in my life done any thing unjust." The eminent orator Lyfias composed an apology, in the name of his master, which he requested him to adopt; but Socrates excused himself by saying, that though it was eloquently written, it would not suit his character.

When the day of trial arrived, his accusers appeared in the senate, and attempted to support their charge in three distinct speeches, which strongly marked their respective characters. Plato, who was a young man, and a zealous follower of Socrates, then rose up to address the judges in defence of his master: but whilst he was attempting to apologize for his youth, he was abruptly commanded by the court to sit down. Socrates, however, needed no advocate. Ascending the chair with all the serenity of conscious innocence, and with all the dignity of superior merit, he delivered, in a firm and manly tone, an unpremeditated defence of himself, which silenced his opponents, and ought to have convinced his judges. After tracing the progress of the conspiracy which had been raised against him to its true source, the jealousy and resentment of men whose ignorance he had exposed, and whose vices he had ridiculed and reformed, he distinctly replied to the several charges brought against him by Melitus. To prove that he had not been guilty of impiety towards the gods of his country, he appealed to his frequent practice of attending the public religious festivals. The crime of introducing new divinities, with which he was charged, chiefly, as it seems, on the ground of the admonitions which he professed to have received from an invisible power, he disclaimed, by pleading, that it was no new thing for men to consult the gods, and receive instructions from them. To refute the charge of his having been a corrupter of youth, he urged the example which he had uniformly exhibited of justice, moderation, and temperance, the moral spirit and tendency of his discourses, and the effect which had actually been produced by his doctrine upon the manners of the young. Then, disdainingly to solicit the mercy of his judges, he called upon them for that justice, which their office and their oath obliged them to administer, and professing his faith and confidence in God, resigned himself to their pleasure.

The judges, whose prejudices would not suffer them to pay due attention to this apology, or to examine with impartiality the merits of the cause, immediately declared him guilty of the crimes of which he stood accused. Socrates, in this stage of the trial, had a right to enter his plea against the punishment which the accusers demanded, and instead of the sentence of death, to propose some pecuniary amercement. But he, at first, peremptorily refused to make any proposal of this kind, imagining that it might be construed into an acknowledgment of guilt; and asserted, that his conduct merited, from the state, reward rather than punishment. At length, however, he was prevailed upon by his friends to offer, upon their credit, a fine of thirty *mine*. The judges, notwithstanding, still remained inexorable: they proceeded, without farther delay, to pronounce sentence

upon him; and he was condemned to be put to death by the poison of hemlock. Socrates received the sentence with perfect composure, and by a smile testified his contempt both for his accusers and his judges. Then, turning to his friends, he expressed his entire satisfaction in the recollection of his past life, and declared himself firmly persuaded, that posterity would do so much justice to his memory as to believe, that he had never injured or corrupted any one, but had spent his days in serving his fellow-citizens, by communicating to them, without reward, the precepts of wisdom. Converting in this manner, he was conducted from the court to the prison, which he entered with a serene countenance and a lofty mind, amidst the lamentations of his friends.

On the day of the condemnation, it happened that the ship, which was employed to carry a customary annual offering to the island of Delos, set sail. It was contrary to the law of Athens, that, during this voyage, any capital punishment should be inflicted within the city. This circumstance delayed the execution of the sentence against Socrates for thirty days. So long an interval of painful expectation, however, only served to afford farther scope for the display of his constancy. When his friends were with him, he conversed with his usual cheerfulness. In their absence, he amused himself with writing verses. He composed a hymn in honour of Apollo and Diana, and versified a fable of Æsop. His friends, still anxious to save so valuable a life, urged him to attempt his escape, or at least to permit them to convey him away; and Crito went so far, as to assure him that, by his interest with the gaoler, it might be easily accomplished, and to offer him a retreat in Thessaly; but Socrates rejected the proposal, as a criminal violation of the laws; and asked them, whether there was any place out of Attica which death could not reach.

News being, at length, brought of the return of the ship from Delos, the officers, to whose care he was committed, delivered to Socrates, early in the morning, the final order for his execution, and immediately, according to the law, set him at liberty from his bonds. His friends, who came thus early to the prison that they might have an opportunity of conversing with their master through the day, found his wife sitting by him with a child in her arms. As soon as Xantippe saw them, she burst into tears, and said, "O Socrates, this is the last time your friends will ever speak to you, or you to them." Socrates, that the tranquillity of his last moments might not be disturbed by her unavailing lamentations, requested that she might be conducted home. With the most frantic expressions of grief, she left the prison. An interesting conversation then passed between Socrates and his friends, which chiefly turned upon the immortality of the soul. In the course of this conversation, Socrates expressed his disapprobation of the practice of suicide, and assured his friends, that his chief support in his present situation was an expectation, though not unmixed with doubts, of a happy existence after death. "It would be inexcusable in me," said he, "to despise death, if I were not persuaded that it will conduct me into the presence of the gods, who are the most righteous governors, and into the society of just and good men: but I derive confidence from the hope, that something of man remains after death, and that the condition of good men will then be much better than that of the bad." Crito, afterwards asking him in what manner he wished to be buried, Socrates replied, with a smile, "As you please, provided I do not escape out of your hands." Then, turning to the rest of his friends, he said, "Is it not strange,

after all that I have said to convince you that I am going to the society of the happy, that Crito still thinks this body, which will soon be a lifeless corpse, to be Socrates? Let him dispose of my body as he pleases, but let him not, at its interment, mourn over it, as if it were Socrates."

Towards the close of the day, Socrates retired into an adjoining apartment to bathe; his friends, in the mean time, expressing to one another their grief, at the prospect of losing so excellent a father, and being left to pass the rest of their days in the solitary state of orphans. After a short interval, during which he gave some necessary instructions to his domestics, and took his last leave of his children, the attendant of the prison informed him, that the time for drinking the poison was come. The executioner, though accustomed to such scenes, shed tears, as he presented the fatal cup. Socrates received it without change of countenance, or the least appearance of perturbation: then, offering up a prayer to the gods, that they would grant him a prosperous passage into the invisible world, with perfect composure he swallowed the poisonous draught. His friends around him burst into tears. Socrates alone remained unmoved. He upbraided their pusillanimity, and entreated them to exercise a manly constancy, worthy of the friends of virtue. He continued walking, till the chilling operation of the hemlock obliged him to lie down upon his bed. After remaining, for a short time, silent, he requested Crito (probably in order to refute a calumny which might prove injurious to his friends after his decease), not to neglect the offering of a cock, which he had vowed to Esculapius. Then covering himself with his cloak, he expired. Such was the fate of the virtuous Socrates! a story, says Cicero, which I never read without tears.

The friends and disciples of this illustrious teacher of wisdom were deeply afflicted by his death, and attended his funeral with every expression of grief. Apprehensive, however, for their own safety, they, soon afterwards, privately withdrew from the city, and took up their residence in distant places. Several of them visited the philosopher Euclid, of Megara, by whom they were kindly received.

No sooner was the unjust condemnation of Socrates known through Greece, than a general indignation was kindled in the minds of good men, who universally regretted that so distinguished an advocate for virtue should have fallen a sacrifice to jealousy and envy. The Athenians themselves, so remarkable for their caprice, who never knew the value of their great men till after their death, soon became sensible of the folly, as well as criminality, of putting to death the man who had been the chief ornament of their city, and of the age, and turned their indignation against his accusers. Melitus was condemned to death, and Anytus, to escape a similar fate, went into voluntary exile. To give a farther proof of the sincerity of their regret, the Athenians, for a while, interrupted public business; decreed a general mourning; recalled the exiled friends of Socrates; and erected a statue to his memory in one of the most frequented parts of the city. His death happened in the first year of the ninety-sixth Olympiad, and in the 70th year of his age. Brucker's Hist. Phil. by Enfield, vol. i.

SOCRATES, an ecclesiastical historian, was born and educated at Constantinople; and having studied under the grammarians Helladius and Ammonius, he commenced his career at the bar. But after some time he relinquished the profession of a law-pleader, and engaged in writing his ecclesiastical history, which comprehends, in seven books, the interval of about 133 years, from the year 306, when Con-

stantine was declared emperor, to the seventeenth consulship of Theodosius, A.D. 439, in which year Cave represents him as flourishing. Socrates, Sozomen, and Theodoret, may be considered as continuators of Eusebius of Cæsarea; and these three writers, who lived in the time of Theodosius the younger, whose reign extended from the year 408 to 450, published their respective histories, which are valuable monuments of antiquity, about the same time, near the end of this reign. Socrates seems to have been distinguished by his moderation and candour, which we may infer from the freedom with which he censures the squabbles and contentions that subsisted amongst the Christian clergy in those times, and condemns the persecution that occurred in the reign of Julian. From the candid manner in which he expresses his sentiments concerning the Novatians, some persons have erroneously concluded that he was one of their number.

As an historian, Socrates has the merit of being judicious in his observations upon men and things, and generally accurate in his chronology. He speaks with great respect of the scriptures of the Old and New Testaments; and has expressly quoted the Acts of the Apostles, and the Epistles to the Romans, the Corinthians, the Galatians, the Colossians, and the Hebrews: he likewise takes notice of a various reading in 1 John, iv. 3. The work of Socrates was translated into Latin by those who made versions of the other Greek ecclesiastical historians, and is usually printed with them. The best editions are those of Valerius, fol. Paris, 1668, and of Reading, fol. Cant. 1720. Dupin. Lardner.

SOCRATIC INDUCTION, in *Rhetoric*. See INDUCTION.

SOCRATIC *Philosophy*, the doctrines and opinions, with regard to morality and religion, maintained and taught by Socrates.

As Socrates left nothing in writing, we are indebted to his illustrious pupils, Xenophon and Plato, for what is known both of his opinions and manner of teaching; and more especially to the former, whose memoirs of Socrates contain more accurate information than the dialogues of Plato, because he intermixes his own conceptions and diction with the ideas and language of his master. Accordingly it is related, that when Socrates heard Plato recite his *Lysis*, he said, "How much does this young man make me say, which I never conceived!" The distinguishing character of Socrates was that of a moral philosopher; and to this purpose Xenophon denies that he ever taught natural philosophy, or any mathematical science, and charges with misrepresentation and falsehood those who had ascribed to him dissertations of this kind, probably in this charge referring to Plato, in whose works Socrates is introduced as discoursing on these subjects.

The doctrine of Socrates concerning God and religion is rather practical than speculative. But he did not neglect to build the structure of religious faith upon the firm foundation of an appeal to natural appearances. He taught, that the Supreme Being, though invisible, is clearly seen in his works, which at once demonstrate his existence, and his wise and benevolent providence. This point is established, with great perspicuity and force of reasoning, in his conferences with Aristodemus, and with Euthydemus. "Reflect," says he, "that your own mind directs your body by its volitions, and you must be convinced that the intelligencer of the universe disposes all things according to his pleasure.—Can you imagine, that your eye is capable of discerning distant objects, and that the eye of God cannot, at the same instant, see all things; or that, whilst your mind contemplates the affairs of different countries, the understanding of God cannot

not attend, at once, to all the affairs of the universe? Such is the nature of the Divinity, that he sees all things, hears all things, is every where present, and constantly superintends all events." Again: "He who disposes and directs the universe, who is the source of all that is fair and good, who, amidst successive changes, preserves the course of nature unimpaired, and to whose laws all beings are subject, this Supreme Deity, though himself invisible, is manifestly seen in his magnificent operations. Learn, then, from the things which are produced, to infer the existence of an invisible power, and to reverence the Divinity."

Besides the one Supreme Deity, Socrates admitted the existence of beings who possess a middle station between God and man, to whose immediate agency he ascribed the ordinary phenomena of nature, and whom he supposed to be particularly concerned in the management of human affairs. Hence, speaking of the gods, who take care of men, he says, "Let it suffice you, whilst you observe their works, to revere and honour the gods: and be persuaded, that this is the way in which they make themselves known; for, among all the gods, who bestow blessings upon men, there are none who, in the distribution of their favours, make themselves visible to mortals." Hence, he spoke of thunder, wind, and other agents in nature, as servants of God, and encouraged the practice of divination, under the notion, that the gods sometimes discover future events to good men.

Concerning the human soul, the opinion of Socrates, according to Xenophon, was, that it is allied to the divine being, not by a participation of essence, but by a similarity of nature; that man excels all other animals in the faculty of reason; and that the existence of good men will be continued after death, in a state in which they will receive the reward of their virtue. Although it appears that, on this latter topic, Socrates was not wholly free from uncertainty, the consolation which he professed to derive from this source in the immediate prospect of death, leaves little room to doubt, that he entertained a real belief and expectation of immortality. The doctrine which Cicero ascribes to Socrates, on this head, is, that the human soul is a divine principle, which, when it passes out of the body, returns to heaven; and that this passage is most easy to those who have, in this life, made the greatest progress in virtue.

The system of morality which Socrates made it the business of his life to teach, was raised upon the firm basis of religion. The first principles of virtuous conduct, which are common to all mankind, are, according to this excellent moralist, laws of God: and the conclusive argument by which he supports this opinion is, that no man departs from these principles with impunity. "It is frequently possible," says he, "for men to screen themselves from the penalty of human laws, but no man can be unjust, or ungrateful, without suffering for his crime: hence, I conclude, that these laws must have proceeded from a more excellent legislator than man." Socrates taught, that true felicity is not to be derived from external possessions, but from wisdom, which consists in the knowledge and practice of virtue; that the cultivation of virtuous manners is necessarily attended with pleasure, as well as profit; that the honest man alone is happy; and that it is absurd to attempt to separate things, which are in nature so closely united as virtue and interest.

But it is impossible, says the author whom we are citing, in detached sentences, to give the reader any tolerable idea of the moral doctrines of Socrates. We must therefore refer him, on this head, to that valuable treasure of ancient wisdom, the "Memorabilia" of Socrates; a work in which he will find his original conversations on many interesting topics,

related with that beautiful simplicity, which distinguishes the writings of Xenophon.

The followers of Socrates may be divided into three classes. The first class consists of such as were neither philosophers by profession, nor addicted to the study of philosophy, but attended upon Socrates as a moral preceptor, for the purpose of correcting and improving their manners. Among these were several young men of the first rank in Athens, particularly Alcibiades and Critias. In this class may also be placed the poets Euenes and Euripides, and the orators Lyfias and Isocrates. The second class included all those who, after his death, became founders of particular sects, and, though they differed from each other greatly, were united under the general appellation of Socratic philosophers. These were Arillippus, the founder of the Cyrenaic sect; Phædo, of the Eliac; Euclid, of the Megaric; Plato, of the Academic; and Antisthenes, of the Cynic. The third class comprehends those disciples of Socrates, who, though their names are found in the catalogue of philosophers, did not institute any new sect. The most distinguished disciples of the Socratic school are Xenophon, Æschines, Simon, and Cebes; for an account of whom, see their respective articles. Brucker's Hist. of Phil. by Enfield, vol. 1.

SOCRATIS INSULA, in *Ancient Geography*, an island of the Arabic gulf, on the coast of Arabia Felix. Ptolemy.

SOCUNDA, a town of Hyrcania, according to Ammianus Marcellinus, named Socanaa by Ptolemy, who places it on the coast of the Caspian sea, between the mouths of the rivers Maxera and Oxus.

SOD, in *Agriculture*, a portion of turf or sward, cut or dug up. It also signifies the soil or earth. The square pieces of surface-turf and earth that are cut up in forming embankments and earth-fences are likewise termed fods, and require nice cutting, so as to be exactly joined in performing the works. Sods are useful too in some other operations of the rural kind.

SOD-BURNING, the practice of paring off the sward or mossy surface of the land. It is observed by Mr. Marshall, in the Rural Economy of West Devonshire, that the most noticeable particular of management in the soil process of that district, is that of "burning beat," as it is provincially termed; answering to the paring and burning, or more technically, sod-burning, of other districts; and that this operation in agriculture has been practised, in this western part of the island, from time beyond which memory or tradition reaches. It has, he conceives, probably been imported from the opposite shore of the continent. And in an old tract, which he saw some years ago in the British Museum, this operation is termed *Devonshiring*, and it is to this day called *Denshiring*, in different districts of the kingdom. He also further states, that there are at present three distinct methods of separating the sward or sod, provincially the "spine," from the soil. The one is performed with a "beating-axe," namely, a large adze, some five or six inches wide, and ten or twelve inches long, crooked, and somewhat hollow, or *disbing*. With this, which was probably the original instrument employed in the operation, large chips, shavings, or fods, are struck off. It is still used in rough uneven grounds, especially where furze, or the stubs of brushwood abound. In using it, the workman appears to the eye of a stranger, at some distance, to be *beating* the surface as with a beetle, rather than to be chipping off the sward with an edged tool. This operation is provincially termed "hand-beating." The next instrument in use is, he says, the spade, resembling the paring spade, or breast-plough of other districts; with, however, in some instances at least, a notable addition, namely, a mould-board, fixed in such a manner as

to turn the sod or turf as a plough turns the furrow-slice, thus becoming literally a breast-plough; a name which has probably been given to the implement in this state, and continued to be applied to the spade or share after the mould-board was laid aside.

It is added, that in working this tool, the labourer proceeds without stopping to divide the sods into short lengths; this part being done by women and children, who follow to break the turfs into lengths, and set the pieces on edge to dry. The price for "spading" is about three halfpence a square perch, of eighteen feet, or 16s. or 17s. a statute acre. Formerly, it is probable, this instrument was much used, but at present it appears to be chiefly in the hands of small farmers.

It is stated, that the instrument at present used for separating the spine or grassy turf from the soil, by farmers in general, is the common team-plough, with some little alteration in the size and form of the share, according to the fancy or judgment of the farmer or his ploughman, there being two different ways of performing the operation. The one is termed "velling," the other "skirting," or "skirwinking." In that for *velling*, the share is made wide, with the angle or outer point of the wing or fin turned upward to separate the turf entirely from the soil. But in that for *skirting*, the common one is used, but made perhaps somewhat wider than when it is used in the ordinary operation of ploughing. And that in this mode of using the plough, little more than half the sward is pared off, turning the part raised upon a line of unmoved turf; as in the operation of ribbing, rice-balking, raftering, or half-ploughing. The paring of turf in this case is from one to two inches thick on the coulter margin, decreasing in thickness to a thin feather edge, by which it adheres to the unmoved sward. And after having lain some time in this state to rot, or grow tender, it is pulled to pieces with rough harrows drawn across the lines of turf; and having lain in this rough state until it be sufficiently dry, it is bruised with a roller, and immediately harrowed with light harrows, walking the horses one way, and trotting them another, to shake the earth out more effectually from among the roots of the grass; going over the ground again, and perhaps again, according to the season, and the judgment of the manager, until most of the earth be disengaged. The "beat" of fragments of turfs being sufficiently dry, is gathered into heaps of five or six bushels each; either with the "drudge," first into rows, and then drawing it along the rows into heaps; or is pulled together with long-toothed hand-rakes, adapted to the purpose. The former is more expeditious, and requires fewer hands; the latter gathers the beat cleaner, freer from earth, which is liable to be drawn together by the drudge. The "beat burrows" or heaps being rounded, and shooed up light and hollow, a wisp of rough straw, a large handful, is thrust, double, into the windward side of each heap; and a number of heaps being thus primed, a match or flambeau is formed, with "reed" or straight unthrashed straw, one end of which being lighted, it is applied in succession to the loose ragged ends of the wisp of straw, which readily communicate the fire to the heaps. The centre of the heap being consumed, the outskirts are thrown lightly into the dimples or hollows, and the heaps rounded up, as at first, continuing to right up the burrows, until the whole of the beat be consumed, or *changed*, by the action of the fire. And the produce of the first skirting being burnt and spread over the surface, the operation is sometimes repeated by running the plough across the lines of the first skirting; thus paring off the principal part of the spine; again dragging, rolling, harrowing, collecting, and burning, as in the former operation. This is a process

of very great importance in the system of Devonshire husbandry, and by which vast advantages and improvements have been effected.

The practice is not now, however, had so much recourse to as formerly, probably on account of its having been carried to too great a length in some cases, and improper modes of cropping having been pursued after it in others; but where well understood, it is still an excellent method of preparation in many instances and situations of land. The great advantages of it seem to consist in the reduction and diminution, which it so readily affords to the more stiff, adhesive, tenacious, clayey sorts of soils; and the quick, certain, and effectual manner in which it brings the inert and useless vegetable matters of them, into more proper states for the purpose of supporting plants, in the way of manures, as crops.

It is most likely that this practice will be the most beneficial in all such soils as contain an over-proportion of dead fibrous vegetable matter, or which lose from about one-third to one-half of their weight by burning; and in all such as contain their earthy constituent parts in a finely reduced state of division, such, for instance, as strong clays, marles, and some other similar kinds: but that in light, coarse, sandy, and rich soils of other qualities, which contain proper proportions of earthy matters in their composition; and in every case where the structure and qualities of them are in their present states properly loose, and the organizable matters in them properly and to a sufficient extent soluble, this practice cannot be employed with success, though it is sometimes attempted upon them. The siliceous poor sandy soils must always, it is supposed, be greatly hurt by it, as is evident from the practical results upon such lands.

It is not improbable, but that in numerous cases it may have failed, in consequence of over-burning the turf, or some other mismanagement in the practice, as there may, by such means, be too great a dissipation and waste of some certain substances and matters, which are in their nature and properties not only necessary, but highly conducive to the fertility and improvement of the soil or land. That carbon, or the refuse of burnt vegetable matters, is of this nature, there can now be no doubt, as the decomposition of such substances has fully shewn it. This material may, therefore, be too much carried off and destroyed in burning the turf of lands, either by combining too freely with the oxygen of the surrounding atmosphere, in consequence of too great a heat being kept up in the operation, and be thereby lost in the form of carbonic acid gas; or by combining in too free a manner with certain proportions of hydrogen, supplied by the vegetable matter in consequence of the increased heat, and by this means furnishing a sort of oleaginous fluid, which is dissipated in large quantities with great rapidity, when a considerable extent of surface is exposed to the air of the atmosphere, during the time of burning the turf. It is therefore evident, on these as well as other accounts, that a slow dull smothering fire, and as small an exposure to the open air as possible, are both circumstances particularly necessary to the proper effect and success of this practice in many cases, if not in all; as when these and such like circumstances are not well attended to and properly regulated, the ashes and other matters which are produced, will be, in a great measure, deprived and destitute of those fertilizing and enriching qualities and properties, which are so necessary and essential to substances of this kind. See PARING and BURNING.

Sod-Drain, that sort of drain which is formed and constructed either wholly, or in the greatest part, of the sods dug

dig up from the land about them. These forts or drains were formerly much in use, and thought highly of in some districts and places, most likely on account of their cheapness; but they are now fallen into neglect and disrepute, probably in consequence of their want of security and durability, especially in lands which are under the plough. They are, however, still made use of occasionally on pasture and sward lands in some situations. The methods of making them differ in different cases and circumstances, according to the nature and kinds of land, being in some instances formed with much more solidity than in others, as may be seen under the articles *SURFACE-DRAINS* and *DRAINING*. They can perhaps, on the whole, be seldom had recourse to with propriety, except in cases where other kinds of more solid materials are procured with great difficulty.

SOD-Fence, any sort of fence which is constructed of materials of this nature, either for inclosing land or defending it against the waters of rivers or the sea. See *FENCES*.

These kinds of fences, when made against the sea or large rivers, should have a good degree of slope, as two, three, or four feet, to one in height, according as the case may be. They have in some districts, as in Lancashire, in many instances, a base of about forty feet, and slope upwards in the direction of the sea as well as that of the land. The extent of base is, however, different in different places, as well as that of the slope or slopes. Fences of this nature against the sea in the above county, cost about 3*l.* the rod of eight yards in their construction.

SOD-Kiln, any sort of kiln which is built or constructed with fods, for the purpose of burning lime or any other material of that kind. They are very common in some places. See *KILN*.

A very close sort of smothering heat is produced in this way, which readily converts any calcareous matters into lime of a good quality for use on land.

SOD-Knife, Draining, an implement of the knife kind, which is made use of with great advantage in scoring and cutting out the sward or grassy surface in forming drains. It is a very useful tool, performing the work in a neat manner.

SODA. See *SODIUM*.

SODA, in the *Materia Medica*. *Muriate of Soda*. See *MURIATE of Soda*, *SALT*, and *SALTS*. It is observed, (see Thomson's Chemistry, cited by Mr. A. T. Thomson in the London Dispensatory,) that the common salt of commerce contains small portions of muriate of magnesia, muriate of lime, and sulphate of lime; and for the separation of these, the salt is to be dissolved in four times its weight of pure water, and into the filtered solution must be dropped first muriate of barytes, and then subcarbonate of soda, as long as any precipitate falls. Then filter and evaporate the clear fluid slowly till the salt crystallizes, which is pure muriate of soda. This pure muriate of soda is inodorous; its taste is strictly salt; and, when pure, perfectly devoid of any degree of bitterness. It is in regular cubes, which are not affected by exposure to the atmosphere. When it deliquesces, it contains muriate of magnesia. Its crystals decrepitate when heated; and in a red heat melt, losing about two *per cent.* of their weight; and in a still greater heat the salt is volatilized, undecomposed, in white fumes. Its specific gravity is 2.126. It is equally soluble in cold and in hot water, nearly three parts of either being required to dissolve one of salt. It consists, according to Kirwan, of 38.88 of acid, 53.00 soda, and 8.12 water in 100 parts. It is decomposed by sulphuric acid and nitric acid.

As an article of the *Materia Medica*, this salt is tonic and anthelmintic in moderate doses; purgative in larger;

and externally stimulant. In the ordinary mode of using it, the tonic power of salt operates in assisting the process of digestion; and, consequently, taken more freely, it proves useful in dyspepsia, and in correcting the weakened state of the intestines, which favours the propagation of worms. In large doses it is said to check vomiting of blood, and may be used as a purgative; although it is seldom employed. But the purgative quality of sea-water does not altogether depend on this salt, as it contains a much larger proportion of muriate of magnesia, which is also purgative. As a local stimulant, its solution in tepid water, in the proportion of ℥ss or ℥j to o*j* of water, forms the common domestic enema. It is used also as a fomentation to sprains and bruises; and dissolved in a large proportion of water, forms the best stimulant general bath, whether used cold, or in a tepid, or a hot state.

With a view to the first intentions, the dose of muriate of soda may be from grs. x to ℥j; but to operate by stool from ℥ss to ℥j is necessary, largely diluted.

The official preparations of this salt are as follow; *viz.* "dried muriate of soda," which is prepared, according to the Dub. Ph., by taking any quantity of muriate of soda, and roasting it over the fire in an iron vessel, slightly covered, until it ceases to decrepitate, occasionally agitating. According to Kirwan, 100 parts of crystallized muriate of soda contain 8.12 of water, which are nearly dissipated by the heat, and the salt is thus rendered of a more uniform strength. It is chiefly employed for the distillation of *MURIATIC Acid*, (see that article,) which is obtained colourless from the dried salt.

Muriatic acid of the Lond. Ph. is prepared by first mixing 1½*lb.* of sulphuric acid with half a pint of distilled water in a glass retort, and when the mixture is cold, adding to it 2*lbs.* of muriate of soda dried: then pouring a pint of the water into the receiver, and having fitted to it the retort placed in a sand-bath, distil over the muriatic acid into this water, with a heat gradually raised, until the retort becomes red-hot. The specific gravity of muriatic acid is to that of distilled water as 1.170 to 1.000. If a piece of limestone be immersed in a fluid-ounce of it, diluted with water, the quantity dissolved ought to be half an ounce. The Edinb. Ph. directs the *muriatic acid* to be prepared by first exposing 2*lbs.* of muriate of soda in a pot to a red heat for a short time, and when it is cold, putting it into a retort; then pouring 16 oz. of sulphuric acid, mixed with 1*lb.* of water, and cooled, upon the muriate of soda; and finally distilling from a sand-bath with a moderate fire, as long as any acid comes over. The specific gravity of this acid is to that of distilled water as 1.170 to 1.000. According to the Dubl. Ph. 6*lbs.* of sulphuric acid are diluted with the same quantity of water; and after it is cold, it is added gradually to 6*lbs.* of muriate of soda, dried and put into a glass retort; and then the liquor is distilled until the residuum becomes dry. The specific gravity of this acid is to that of distilled water as 1.170 to 1.000.

This acid, for a farther account of which see *MURIATIC Acid*, is tonic and antiseptic. It has been used with effect in typhus fevers, and in some cutaneous eruptions. It is a common and useful addition to gargles, in the proportion of from ℥ss to ℥ij in ℥vj of any fluid, in ulcerated throats and cancrum oris; and in a very highly diluted state, ℥viij in ℥ziv of water, it has been recommended as an injection in gonorrhœa. It has also been regarded as an antidote in general syphilitic affections; but this opinion has been shewn by Mr. Pearson to be erroneous: nevertheless, by its salutary effect on the stomach and general health, it is capable of ameliorating the appearance of venereal ulcers, and of restraining for a time the progress of the disease, when

when it is desirable to gain time previously to the commencement of a mercurial course. The dose is from ℥x to ℥xx, in a sufficient quantity of water. Morveau, in 1773, discovered the important power of muriatic acid, in the state of gas, for neutralizing putrid miasmata; and thus it is used as an agent for destroying infection in sick rooms and hospitals, disengaged by pouring sulphuric acid on common salt.

The officinal preparations of muriatic acid are as follow; "muriate of barytes" (see SALTS): the "solution of muriate of lime" (see LIME and MURIATE of Lime), which, according to the Edinb. Ph., is prepared by mixing 16 oz. of muriatic acid with 8 oz. of water, and gradually adding 9 oz. of the harder variety of carbonate of lime (*viz.* white marble) broken into small pieces: when the effervescence is finished, digest for an hour; then pour off the fluid, and reduce it by evaporation to dryness: dissolve the residuum in its weight and a half of water, and filter the solution. This "water of muriate of lime" is prepared, according to the Dubl. Ph., by adding gradually 2 oz. of diluted muriatic acid to 1 oz. of chalk reduced to a coarse powder, and when the effervescence is finished, filtering the solution. This solution is colourless, and has a disagreeable, bitter, acrid taste; it is decomposed by the sulphuric, nitric, phosphoric, fluoric, and boracic acids; the neutral salts into which these enter; and the alkalies and alkaline carbonates which precipitate the lime. In the solid state, 100 parts of muriate of lime, after being exposed to a red heat, consist of 42 of acid, 50 of lime, and 8 of water. By mixing four parts of it with an equal quantity of snow, a degree of cold is produced capable of sinking the mercury in the thermometer from 32° to 40° below 0° of Fahrenheit. Muriate of lime is deobstruent and tonic. Fourcroy introduced it into practice, and it has been much recommended as a remedy in scrophulous and glandular diseases. Mr. T. Thomson says, that he has given it with evident advantage in bronchocele, and that he has witnessed greater benefit resulting from the continued use of it in the varied forms of scrophula, than from any other remedy with which he is acquainted. Its operation is similar to that of muriate of barytes: but the danger of an over-dose is less to be dreaded, and its good effects are more uniform and certain. The dose of the solution is from ℥xx to fʒj, in a sufficient quantity of water, repeated twice or thrice a day.

Another preparation of muriate of soda is "muriate of antimony." (See ANTIMONY) For an account of the "precipitated submuriate of mercury," and of the "ammoniated submuriate of mercury," see MERCURY.

The *sub-borate of soda*, (for the chemical properties of which see BORAX,) purified by solution and crystallization, is inodorous, and has a styptic, cool, and alkalescent taste; and as an article of the materia medica, it is refrigerant and detergent. It is not given internally; and its chief application is in aphthous affections of the mouth, and excessive salivation. It is used either in the form of powder mixed with sugar, or dissolved in water, and united with honey as a lotion. See HONEY.

The *carbonate of soda* is prepared, according to the Lond. Ph., by adding 3 oz. of subcarbonate of ammonia to a solution of 1 lb. of subcarbonate of soda, in a pint of distilled water; then exposing the mixture in a sand-bath to a heat of 180° for three hours, or until the ammonia be expelled, and finally setting it apart to crystallize. The residuary liquor may be evaporated in the same manner, and set apart again to crystallize. This salt does not appear to possess any advantages superior to those of the subcarbonate as a remedy, and may therefore be regarded as a redundant preparation.

The *subcarbonate of soda* of the Lond. Ph. is prepared by boiling 1 lb. of impure soda (barilla) powdered, in a gallon of boiling distilled water for half an hour, and filtering the solution; then evaporating it to two pints, and setting it apart for crystallization: the liquor that remains is thrown away. The *carbonate of soda* of the Edinb. Ph., formerly "purified fixed fossile alkali," is prepared by bruising any quantity of impure carbonate of soda (see CARBONATE of Soda), and then boiling it in water until all the saline matter be dissolved; then filtering the solution through paper, and evaporating it in an iron vessel, so that after refrigeration crystals may be formed. The Dubl. Ph. directs 10 lbs. of powdered barilla to be boiled in two gallons of water, in a covered vessel, for two hours, with occasional stirring; filtering the liquor; then bruising the barilla that remains with an equal quantity of water, and again boiling it, which may be repeated a third time. The leys being filtered and mixed, evaporate them to dryness in a wide iron vessel, taking care that the saline mass which will remain be not again liquefied by too great a heat; stir it with an iron spatula till it becomes white; finally dissolve it in boiling water, and, after due evaporation, set it apart, that as it cools, crystals may form. These will be purer if the barilla before each boiling be exposed for some time to the air. The crystallization should be effected when the air is at the freezing temperature, and in a liquor the specific gravity of which is, to that of water, as 1220 to 1000. If the salt be not very pure, repeat the solution and crystallization.

Barilla, besides the subcarbonate of soda, contains sulphate and muriate of soda, charcoal, lime, magnesia, argil, and silix, from which these processes are intended to separate it. One pound of barilla yields from ʒij to ʒv of the crystallized subcarbonate.

A very pure subcarbonate of soda is now manufactured, on a great scale, by the decomposition of sulphate of soda and of muriate of soda, which will probably supersede altogether the processes ordered in the pharmacopœias.

Subcarbonate of soda has a mild alkalescent taste, and changes the vegetable blue and red colours to green. Its crystals are large transparent octohedrons, truncated at the summits of the pyramids, which effloresce when exposed to a dry air, and crumble down into a white opaque powder. It undergoes the watery fusion; is soluble in two parts of water at 60°, and in considerably less than its weight of boiling water, its abundant water of crystallization assisting the solution of the salt at that temperature. Its constituents, according to the late analysis of D'Arcet, are, in 100 parts, 16.04 of acid, 20.85 of alkali, and 63.61 of water: which corresponds with the statement of Bergman.

This salt is antacid and deobstruent. It is less acrid than the subcarbonate of potash; and hence is in more general use in dyspepsia and acidities of the stomach, and in scrophulous affections. Its use has been lately strenuously recommended in hooping-cough, the protraction of which it is said to prevent. It is given, at first, after the stomach and bowels have been duly evacuated, in combination with ipecacuanha and opium, and afterwards, when the violence of the cough has abated, with myrrh. The dose of this salt is from grs. x to ʒss, given twice or thrice a day, in conjunction with bitters or rhubarb.

The officinal preparations are, "dried subcarbonate of soda" of the Lond. and "dried carbonate of soda" of the Dub. Ph.; "carbonate of soda" of the Lond. Ph.; "water of the supercarbonate of soda" of the Ed. Ph.; "phosphate of soda" of the Ed. and Dub. Ph.; "soda tartarizata" of the Lond. Ed. and Dub. Ph.; "carbonate of iron" of the Lond. Ed. and Dub. Ph.; "carbonate of ammonia," and "water of carbonate of ammonia," of

the Dub. Ph.; "precipitated chalk" of the Dub. Ph.; and "benzoic acid" of the Ed. Ph.

The "dried subcarbonate of soda" of the Lond. Ph. is prepared by exposing 1lb. of subcarbonate of soda to a moderate heat in a clean iron vessel, until it becomes perfectly dry, and at the same time stirring it diligently with an iron spatula, and finally rubbing it into a powder. The Dubl. Ph. directs the "dried carbonate of soda" to be prepared by liquefying the crystals of carbonate of soda in a silver crucible over the fire; then, in an augmented heat, stirring the dissolved salt, until by the evaporation of the water it becomes dry; reducing it to a fine powder, and preserving it in stoppered phials. The constituents of 100 parts, in this state, according to the analysis of Kirwan, are 40.14 of acid, and 59.86 of soda. Dr. Beddoes has extolled this salt in form of pills, as a remedy in calculous affections; and, as Thomson says, it certainly affords decided relief from the painful symptoms attending calculus in the kidneys, and other urinary affections. Its effects, however, are only palliative, and depend on its destroying the prevalent acid in the stomach; and hence it cannot, in strict language, be regarded as a lithontriptic. The dose is from grs. x to grs. xv, given three times a day. Beddoes directed it to be combined with soap and aromatics.

The "water of supercarbonate of soda" of the Ed. Ph. is to be prepared from 10lbs. of water, and 2 oz. of subcarbonate of soda, in the same manner as the water of supercarbonate of potash. This preparation is milder and pleasanter than the water prepared with subcarbonate of potash. It is manufactured in large quantities, on a great scale, of a much superior quality to any which the apothecary can prepare: and is in very general use as a cooling beverage. Half a pint of it poured over two table-spoonfuls of lemon-juice, sweetened with a little sugar, forms an excellent and very agreeable effervescing draught.

The "phosphate of soda" is prepared, according to the Ed. Ph., by mixing 10 lbs. of powdered bones, reduced to whiteness, with 6 lbs. of sulphuric acid, in an earthen vessel; then adding 9 lbs. of water, and again mixing; keeping the vessel in a vapour-bath for three days; afterwards diluting the matter with 9 lbs. more of boiling water, and straining through a strong linen cloth, pouring boiling water gradually over it, until the whole of the acid be washed out. Set the strained liquor apart, that the impurities may subside, from which pour it off, and evaporate it to 9 lbs. To this liquor separated from its impurities, and heated in an earthen vessel, add a warm solution of carbonate of soda, until the effervescence ceases: then strain, and set the liquor aside that crystals may form. These being removed, add to the liquor, if necessary, a little carbonate of soda, that the phosphoric acid may be accurately saturated; and dispose it, by evaporation again, to yield crystals, as long as these shall be produced. Finally, let the crystals be preserved in a well-closed vessel.

The Dub. Ph. directs to take of burnt bones, reduced to powder, 5 lbs.; sulphuric acid, 3½ lbs. Mix the powder with the sulphuric acid in an earthen vessel; add, gradually, five pints of water, and agitate the mixture. Digest for three days, adding from time to time more water, lest the materials should become dry, and continue the agitation; then pour over them five pints of boiling water, and strain through a linen rag, pouring on, at intervals, boiling water, until all the acid be washed out. Set the liquor apart, that the impurities may subside, from which decant it, and evaporate it to one half; then add 3 lbs. 10 oz. of carbonate of soda, dissolved in a sufficient quantity of warm water; filter, and obtain crystals by re-

peated evaporation and cooling. The crystals are to be preserved in well-closed vessels:

If the salt be not sufficiently pure, repeat the solution and crystallization.

A cheaper mode of preparing this salt has been given by M. Funcke, a German chemist. He adds to the matter of calcined bones diffused in water, just enough dilute sulphuric acid to saturate the small portion of carbonate of lime it always contains. When the effervescence ceases, the whole is dissolved in nitric acid, and as much sulphate of soda added to the solution as of bone-ashes used. The whole is then distilled, to recover the nitric acid; and the phosphate of soda is separated from the residue, which is a mixture of sulphate of lime and phosphate of soda, by solution and crystallization.

This salt has a purely saline taste, resembling very much that of common salt. Its crystals are large, regular, transparent, rhomboidal prisms, terminated by three-sided prisms, having a specific gravity of 1.333, and efflorescing on exposure to the air. It is soluble in three parts of water at 60°, and in two parts of boiling water; and undergoes the watery fusion when heated. Its constituents, according to Thenard, are, in 100 parts, 19 of soda, 15 of phosphoric acid, and 66 of water. Muriate of barytes, lime, and magnesia, decompose this salt; and by the strong acids it is converted into superphosphate of soda.

Phosphate of soda is a mild cathartic, excellently adapted for children, and others who have a fastidious taste. It may be given dissolved in gruel or broth, made without salt, by which its taste is very effectually covered. The dose is from ʒvj to ʒij. It was introduced into practice by Dr. George Pearson of London.

The "sulphate of soda" is for the most part artificially prepared, and chiefly in the large way, during the manufacture of sal ammoniac from sulphate of ammonia and common salt. The directions given for preparing it, in the Lond. Ph., are as follow: Take of the salt which remains after the distillation of muriatic acid, 2 lbs.; boiling water, 2½ pints. Dissolve the salt in the water; then add gradually as much subcarbonate of soda as will saturate the acid. Boil the solution until a pellicle appears; and after having filtered it, set it apart to crystallize. Pour the water from off the crystals, and dry them on bibulous paper. The "sulphate of soda" of the Edinb. Ph., formerly "Glauber salts," (see GLAUBER Salt,) is formed by dissolving in water the acidulous salt, which remains after the distillation of muriatic acid, and having mixed with it carbonate of lime (chalk) in powder, to remove the superfluous acid, setting it apart until the impurities subside; then, having poured off the liquor, filtering it through paper, and reducing it by evaporation, that it may crystallize. The Dub. Ph. directs to dissolve the salt, which remains after the distillation of muriatic acid, in a sufficient quantity of boiling water; then to evaporate the filtered solution to a proper point, and set it apart, that, as it slowly cools, crystals may be formed. The taste of this salt is at first simply saline, but afterwards very disagreeably bitter. Its crystals are transparent, six-sided, irregular, channelled prisms, with dihedral summits; efflorescent, and falling to a white powder, when exposed to the air. It is soluble in 2.86 parts of water at 60°, and 0.8 of boiling water; undergoes the watery fusion when heated, and in a strong heat is partially decomposed. According to Kirwan, 100 parts contain 23.52 of acid, 18.48 of alkali, and 58.00 of water; and in the dried state, of 56 of acid, and 44 of water. This salt is a very common and useful purgative; but, on account of its nauseous taste, is not very generally pre-

scribed by the physician. The dose is from ʒfs to ʒij; but in the efflorescent state, half of these quantities is sufficient.

The "tartarized soda" (see CARBONAT of Soda and NATRON) is prepared, according to the Lond. Ph., by dissolving 20 oz. of subcarbonate of soda in 10 pints of boiling water, and adding gradually 2 lbs. of supertartrate of potash in powder; filtering the solution through paper; then boiling till a pellicle is formed on the surface, and setting it aside to crystallize; then pouring off the water from the crystals, and drying them on bibulous paper.

The "tartrate of potash and soda," formerly *Sal Rupelemensis* (which see), is prepared, according to the Edinb. Ph., from carbonate of soda and supertartrate of potash, in the same manner as TARTRITE of Potash; which see.

The "tartrate of soda and kali," of the Dub. Ph., is formed by dissolving 20 oz. of carbonate of soda in 10 pints of boiling water, and gradually adding 2 lbs. of crystals of tartar, reduced to a very fine powder; filtering the solution through paper, evaporating it, and setting it aside, that, as it slowly cools, crystals may be formed. Mr. T. Thomson observes, that of the three appellations of this salt, that of the Dublin college is the least exceptionable; the London name conveying an evidently erroneous notion of the preparation, and the Edinburgh college incorrecly denominating it a tartrate.

This salt has a bitter saline taste. Its crystals are large, regular, transparent, hard, rhomboidal, six-sided prisms; very slightly efflorescent, and soluble in five parts of water at 60°. It is decomposed by the strong acids, muriate of barytes, lime, and by a red heat. The constituents of 100 parts of this salt, according to Schulze, are 41.3 of tartaric acid, 14.3 of potash, 13.3 of soda, and 31.1 of water.

Tartrate of potash and soda is a cooling and not very unpalatable cathartic. It was introduced into practice by M. Seignette, an apothecary of Rochelle, and the preparation kept a secret until it was discovered and published by Boulduc and Geoffrey in 1731. It operates moderately, and without exciting much irritation: hence it is well suited to nephritic and puerperal cases. The dose is from ʒj to ʒjfs, dissolved in any convenient vehicle. Woodville. Thomson's Lond. Disp.

SODA, in *Medicine*, a word of Arabic origin, nearly synonymous with *cardialgia*, and *heart-burn*, signifying any sense of burning heat in the stomach, arising from acidity or acrid humours. See CARDIALGIA and INDIGESTION.

The term *soda* has, however, been considered by some writers as also signifying heat and pain of the head.

SODA, in *Geography*, a town of Arabia, in the province of Nedsjed; 180 miles E. of Medina.

SODA, in *Natural History*. See KALI.

SODA *Subethica*, a term used to express a heavy and dull pain in the head.

SODADA, in *Botany*, from its Arabic name *Sodád*. Forsk. *Ægypt-Arab*. 81. Juss. 243.—A genus of the natural order of *Capparides*, which is undoubtedly distinct, and may perhaps be tolerated under the above appellation, though of avowedly barbarous origin, like *Aucuba*, and one or two similar names, of easy pronunciation. We do not, however, wish to sanction any such, but leave them to future opportunities of a thorough and authentic reform. In the present instance, at least, we attempt no amendment, because we have not materials to describe the genus under consideration. Colonel Hardwicke has brought, from the East Indies, either Forskall's identical plant, or another

species of the same genus. Forskall describes his as follows.

S. decidua. Calyx of four unequal leaves. Petals four, unequal. Stamens inclining. Capsule stalked.

A diffuse *shrub*, with distant, alternate, spreading *branches*, about two inches long, with a pair of short awl-shaped *spines* at each bud. *Leaves* sessile, oblong, deciduous, rarely present. *Flower-stalks* between the spines, single-flowered; three together. *Flowers* red. *Calyx* coloured, deciduous; its upper segment very large, gibbous, compressed, often split at the side; the rest equal, linear-lanceolate, fringed. Two upper *petals* ovate, pointed, flat, at first hidden under the upper leaf of the calyx; two lower narrower, alternate with its lower leaves, downy at the under side and edges. *Stamens* eight, unequal, thread-shaped, longer than the petals, brownish-green. *Germen* globose, with four furrows on a stalk as long as the stamens. *Style* awl-shaped. *Stigma* acute. *Fruit* red, bigger than a hazel-nut, eatable when dressed before it is ripe. This shrub is common throughout the country of Yemen.

SODALES AUGUSTALES. See AUGUSTALES.

SODALITE, in *Mineralogy*, a stone which derives its name from the large portion of mineral alkali that enters into its composition. Its colour is a blueish-green. It occurs both crystallized and massive: the crystals are dodecahedrons, with rhomboidal faces. The structure is lamellar, with joints in two directions. The fracture is conchoidal: it has a shining and resinous lustre, but the lustre of the fresh fracture is vitreous; it is translucent, and yields with difficulty to the knife. The specific gravity is 2.37. It is infusible by the blowpipe.

The constituent parts of sodalite, as given by different chemists, vary.

SODALITIUM, among the Anglo-Saxons, was the name of a voluntary association, the object of which was the personal security of those who joined in it, and which the febleness of government at the time rendered necessary. Among other regulations, which are contained in one of these still extant, the following deserves notice: If any associate shall either eat or drink with a person who has killed any member of the sodalitiun, unless in the presence of the king, the bishop, or the count, and unless he can prove that he did not know the person, let him pay a great fine. Hicks Diss. Epist. apud Thef. Ling. Septentr. vol. i. p. 21.

SODBURY, CHIPPING, anciently *Sopeberie*, in *Geography*, a small parish, containing only 90 acres, and market-town, in the lower division of the hundred of Grombald's-Ash, in the county of Gloucester, England, is situated 12 miles N. from Bristol, 30 S. from Gloucester, and 113 W. from London, at the foot of the Great Howby hill, a continuation of that chain which extends from north to south through the county. This, and the two adjoining parishes of the same name, were so called from the *berie*, or camp, which is found on the summit of Old Sodbury. Chipping distinguishes it as a market-town, and was first used when the market was established, in the reign of Henry III. The town consists of one long street, and is the great thoroughfare between Bristol and the eastern part of the county. The church consists of a nave and two aisles, with

with an embattled tower at the west end. A weekly market is held on Thursdays, and two fairs yearly. By a charter of incorporation, granted by king Charles II. in 1681, the government of the borough was vested in a mayor, six aldermen, and twelve burgesses, with a high steward, recorder, and town-clerk; and at the same time was granted the privilege of holding pleas of all manner of personal suits and debts under five pounds, arising within the borough. But in 1688, at the request of the inhabitants, from what cause is not now remembered, the charter was annulled by proclamation; and from that period the ancient government by a bailiff was revived, who is annually chosen by the lord of the manor out of three persons, returned to him at the court-leet. Two estates, called the Stub-Ridings and Meadow-Ridings, were anciently granted by two lords of the manor, in the reigns of Henry II. and John, to the bailiffs and bailiff-burgesses, for the following purposes. The former, consisting of about 100 acres, is granted for summer-pasture under certain regulations for sixty-eight cow-beasts, to as many persons as have been inhabitants of the town for fourteen years. The latter is divided into eighty-one lots, besides two others, called the Bailiff's and Hayward's piece. Each of these, containing rather more than a statute acre, is held by a lessee for his own life, and the life of his widow. Out of these estates the lord of the manor receives an annual payment of 5*l.*, and the vicar of Old Sodbury 1*l.* 13*s.* 4*d.* in lieu of tythes. The bailiff is entitled to fifty shillings yearly, for which, by ancient custom, he provides an ox and two barrels of ale, on St. Stephen's day, for the inhabitants.

A guild was founded in this borough, dedicated to St. Mary, in the reign of Henry VI., of which John Glover was the last incumbent. The lands were granted, in 1558, to the burghers of Sodbury, part for a town-hall, and part for an alms-house. A free-school is supported in this parish, by the profits of lands in different parishes. In the population returns to parliament in the year 1811, the inhabitants of this parish were stated to be 1235, occupying 236 houses. In the sanguinary reign of Mary, John Pigott was burnt here for his adherence to the Protestant religion.

The manor was granted by the Conqueror to Odo, earl of Champagne, whose grandson, William, granted the privilege of pasture-common in the Riding before mentioned, the original of which is still in existence. About the same time, William Green of Sodbury gave Gaunt's Fields to the burgesses; and Jurdan Bishop, who was lord of the manor of Little Sodbury, granted them common of pasture for cattle in Dymershed and Norwood. The manor, which by successive marriages has been possessed by various families, is now held by that of Hartley.

In the high lands, east of the town, are found a great variety of belemnites, nautilites, of the ribbed sort; and west of the town, some veins of sulphate of strontian have been discovered.

Little Sodbury is a parish adjoining Chipping Sodbury, and consists of about 900 acres of land, the greater part of which is appropriated to the dairy system. On the edge of a hill, in this parish, is a large encampment of an oblong form, comprising an area of about 200 yards from east to west, and 300 from north to south. This was probably formed by the Romans; and according to Leland, it was occupied by Edward IV.'s army, previous to the battle of Tewkesbury.

Old Sodbury is another parish adjoining the former, on the north-east, and consists of 3000 acres of land, the greater part of which is pasture.

Dodington, three miles south-east of Sodbury, is the

magnificent feat of Christopher Codrington, esq. who has long been engaged in building a spacious and splendid mansion here, from the designs of the late James Wyatt, esq. architect. Rudge's History of the County of Gloucester, 2 vols. 8vo. 1803.

SODDER, or SODER. See SOLDER.

SODDERING. See SOLDERING.

SODDING of Brick. See BRICK.

SODDOMA, IL, in *Biography*, the cognomen of Giovanni Antonio Razzi, a native of Verecelli, in Piedmont, born about the year 1479. He was instructed in painting by Giacomo dalle Fonte; but his chief object of study was the style of L. da Vinci. He was employed by Julius II. to paint the chambers of the Vatican; but the charms of Raphael's first productions in that palace were the signal for the obliteration of all other works there: among them Il Soddoma's. Other pictures, which he painted for Agostino Ghigi in the Farnesina, were more fortunate, and yet remain. Their subjects are taken from the history of Alexander the Great, and though inferior to the works of Lionardo, yet they exhibit very considerable talent, many beauties of perspective, and much playful imagery.

After he left Rome, he had considerable employment at Sienna, and there his best productions are to be found, in which he has combined the excellent qualities of the best artists of his day. He died in 1554.

SODENKYLA, in *Geography*, a town of Swedish Lapland; 110 miles N.N.E. of Tornea. N. lat. 67° 25'. E. long. 26° 14'.

SODERALA, a town of Sweden, in Helplingland; 3 miles S.W. of Soderhamn.

SODERBY, a town of Sweden, in Jamptland; 60 miles N. of Frosön.—Also, a town of Sweden, in Upland; 40 miles N.N.E. of Stockholm.

SODERHAMN, a sea-port town of Sweden, in the province of Helplingland, situated at the mouth of a river, near the gulf of Bothnia, first built by gunsmiths and copper-smiths, and erected into a town in the year 1620. The houses are mean, but the church handsome. The trade of this place is considerable in arms, linen, butter, timber, flax, &c.; 20 miles N. of Gefle.

SODERKIOPING, a town of Sweden, in the province of East Gothland. This is a staple town, situated on a navigable river, and one of the most ancient cities in Gothland. It had formerly its own municipal laws, and was in a much more flourishing condition than it is at present. Two kings were crowned, and in 1595 a diet was held in this town. It has at present but two churches; 10 miles S.S.E. of Nordkioping. N. lat. 61° 18'. E. long. 16° 54'.

SODERON, a small island near the coast of Sweden, in the Alands Haf. N. lat. 60° 15'. E. long. 8° 14'.

SODERSKARBAK, a small island in the gulf of Finland. N. lat. 60° 5'.

SODERTELGE, or *Soder Telge*, a town of Sweden, in the province of Sudermanland, situated between the sea and the Macler lake. About two miles and a half distant from this town, at a place called "Aegellstowyk," is a good harbour. Sodertelge was formerly a staple town, and in a flourishing condition; and there is still a manufacture of worsted and silk stockings in this town. In the year 1719, Sodertelge was burnt by the Russian army, but has since been rebuilt; 16 miles W.S.W. of Stockholm. N. lat. 59° 8'. E. long. 18° 28'.

SODE-SHOOTS, in *Botany*, a name given by some to the tree, whose inspissated juice is the gum tacamahacca of the shops.

SODFORS, in *Geography*, a town of Sweden, in West Bothnia; 18 miles N.W. of Umea.

SODIA, a town of Arabia, in the province of Hedsjas; 70 miles S.S.E. of Mecca.—Also, a mountain of Arabia, in the province of Hedsjas; 60 miles S. of Mecca.

SODINUS, in *Ancient Geography*, a navigable river of Asia, which runs into the Cophes, according to Pliny.

SODIUM, in *Chemistry*, a simple body and a metal. This was discovered by sir Humphrey Davy in the year 1807. He had a few days before found that potash was a compound of a peculiar metal combined with oxygen, and he now found that soda consisted of a metallic substance combined with oxygen. He first produced it by exposing soda to the action of the Galvanic battery.

It is now obtained by fusing soda or muriate of soda with potassium. The potassium combines with the oxygen in the soda, and with the chlorine in the salt, leaving pure sodium.

This metal is white, resembling silver; and having the same metallic lustre.

Its specific gravity is between 9 and 10, water being 1. In the common temperature it is malleable.

It assumes the liquid form at 200° of Fahrenheit, and is volatile at a red heat.

If exposed to the air it would soon lose its lustre, by combining with oxygen, and in a little time would be converted into soda.

It is preserved in naphtha, like potassium.

When heated in oxygen or chlorine, it burns with great brilliancy.

When thrown upon water, it does not sink but runs along the surface, the motion being occasioned by the rapid escape of hydrogen gas, from its decomposing the water with great rapidity. The floating mass is seen to diminish as it runs along, till it disappears, when, as may be expected, the water is found to contain a solution of soda.

Sodium, like other metals, is a conductor of electricity.

Sodium combines with two doses of oxygen. The one is that which constitutes soda; the other is of an orange colour, first observed by sir Humphrey Davy; but for the particulars of its nature we are indebted to M. M. Gay Lussac and Thenard.

Soda, in its pure state, is a solid of a greyish-white colour, very hard, and breaks with a smooth fracture. In this state it requires a strong heat for its fusion. When exposed a little to the air, it absorbs water, assumes a whiter colour, and becomes much more fusible by heat. Its volatility is also increased at the same time. In this state, as is the case with lime, potash, and many of the metallic oxyds, it is called an hydrate.

The peroxyd of sodium is formed by burning sodium in oxygen gas, an excess of the gas being present.

It is of a deep orange colour, and fuses at a much less heat than soda.

If thrown into water, one atom of oxygen escapes in the form of gas, leaving pure soda, which dissolves in the water. This proves how closely the excess of oxygen is held. This, however, is more conspicuously shewn in its action upon combustible bodies, with which it desagrates.

The atom of sodium has been considered 22; hydrogen being 1, and oxygen 7.5; hence the protoxyd would be 29.5, and the peroxyd 37. But from the experiments of Gay Lussac and Thenard, it appears that the oxygen in the soda is to that in the peroxyd as 1 to 1½, or as 2 to 3; but as the existence of half atoms would be absurd, the atom of sodium must be considered as equal to 44; the protoxyd will then be 51.5; the deutoxyd, which is soda, will

be $44 + 2 \times 7.5 = 59$, and the peroxyd $44 + 3 \times 7.5 = 81.5$.

Soda combines with sulphur, and is called sulphuret of soda. It possesses properties differing but little from the sulphuret of potash. It is formed by fusing sulphate of soda with common saw-dust. Like sulphuret of potash, when thrown into water, it first dissolves, and decomposing that fluid, the remaining sulphuret combines with the hydrogen in its nascent state to form hydrogen with sulphuret of soda. This forms a greenish-coloured fluid, having the smell of sulphuretted hydrogen. The phosphuret of soda is also similar to the phosphuret of potash. See POTASH.

Sodium also combines with sulphur and phosphorus. When sodium and sulphur are heated together in a vessel filled with vapour of naphtha, they unite with all the signs of splendid combustion, the sulphur supplying the place of oxygen. The compound is of a grey colour, producing sulphate of potash by exposure to the air. Their proportions ought to be 44 sodium to 15 sulphur for the first, and 44 to 30 for the second sulphuret.

Sodium has a similar effect upon phosphorus, by which the phosphuret of sodium is produced. It has no known action upon carbon, azote, or hydrogen.

Sodium combines with many of the metals, forming peculiar alloys. With potassium, in a small proportion, it forms an alloy, which, agreeably to other alloys, is more fusible than either of the metals. The alloy is of less specific gravity than either of the metals, a circumstance not common with other metallic alloys. The latter fact goes to prove that there is not a great affinity between the two metals.

One part of sodium renders 40 of mercury solid, at the common temperature. When they combine, heat is disengaged. It also combines with tin, without changing its colour. When these alloys are exposed to the air, the sodium is gradually separated, by combining with the oxygen of the atmosphere.

Salts of Soda, or its Compounds with the Acids.—Under this head we shall comprise the muriate of soda, although, in strict propriety, we might have been expected to have treated this compound under the action of sodium upon chlorine.

Sulphate of Soda.—This salt is found native in most sea-vegetables; it has been called Glauber salt. It may be easily formed by adding sulphuric acid to the crystallized carbonate of soda, till the effervescence ceases, and the solution is neither acid nor alkaline.

On evaporation and cooling, it easily crystallizes into six-sided prisms of a pearly appearance. Their taste is cooling and rather bitter. At the temperature of 60° it dissolves in less than three times its own weight of water, and in much less than its own weight of boiling water. When a solution of this salt is concentrated till it has something less than half its own weight of water, and carefully set by to cool, it will not crystallize; but if a tremulous motion be given to the vessel, or a crystal of the same salt dropped into it, the whole suddenly crystallizes, exhibiting a beautiful appearance. When the crystals are exposed to the air, they lose their water of crystallization, and assume the form of white powder. In this change they lose about 60 per cent. of their weight, as will be seen in their analyses.

According to Kirwan, it is composed of

Sulphuric acid	-	-	23.52
Soda	-	-	18.48
Water	-	-	58.
			<hr/>
			100
			<hr/>

SODIUM.

According to Bergman,

Acid	-	-	27
Soda	-	-	15
Water	-	-	58
			100

Wenzel's analysis of the dry salt is,

Acid	-	-	55.7
Soda	-	-	44.3
			100

Kirwan's analysis of ditto,

Acid	-	-	56
Soda	-	-	44
			100

It appears that this salt consists of two atoms of acid to one of soda, and 20 atoms of water. This, if hydrogen be 1, will be 37.5×2 acid + 59 soda + 170 water = 304. Reduced to the hundred, it will be

Acid	-	-	19.4
Soda	-	-	24.6
Water	-	-	56.
			100

Nitrate of Soda.—This salt has been called *cubic nitre*, from having the general properties of nitrate of potash, but differing in the form of its crystals, which are of a cubical, or rather rhomboidal form.

It may be formed by saturating pure carbonate of soda with nitric acid.

On evaporation and cooling, it forms rhomboidal crystals, the specific gravity of which is 2.0964, water being 1.

These crystals dissolve in three times their weight of water at 60°, and in less than their own weight of boiling water.

With inflammable bodies and heat, it exhibits phenomena similar to those of nitre: but it is inferior to that substance in forming gunpowder with charcoal and sulphur.

Its proportions, according to Bergman, are

Nitric acid	-	-	43
Soda	-	-	32
Water	-	-	25
			100

According to Kirwan, in the dry state,

Nitric acid	-	-	57.55
Soda	-	-	42.34
			99.89

This salt appears to be composed of one atom of acid and one of soda, in the dry state, or 50.5 acid and 44 soda = 94.5. This will give

Nitric acid	-	-	53.5
Soda	-	-	46.5
			100

Muriate of Soda.—This salt, which is the common culinary salt in a state of purity, is a component part of almost all animal matter; nor is there perhaps a vegetable that does not yield some portion of it.

It exists ready formed in the sea, and forms entire mountains in the substance of the globe. It is from the native salt that all the muriatic acid is obtained. It is never formed by art, but the pure salt may be obtained by adding carbonate of soda to the salt in solution; then evaporate it to obtain crystals; these are of a cubic form, and pure muriate of soda.

According to the prevailing view now taken of this salt, it is a compound of sodium and chlorine, or what was called oxymuriatic acid. Hence it is not considered as a salt, those bodies being compounds of an acid and an oxyd. The substance in question is believed to be a compound of sodium, an inflammable body, combined with another body, having more the properties of oxygen than any other body. Muriate of soda is, therefore, considered as being more allied to an oxyd than a compound of two, the chlorine acting the part of oxygen. It is called by Sir Humphrey Davy *sodane*, by Dr. Thomson *chloride of sodium*, and by the French chemists *chlorure of sodium*. The taste of this salt may be called the standard of that sensation we call *salt*. Its specific gravity is 2.12; it is soluble in about three times its weight of water at 60°, and nearly in the same quantity of boiling water.

It is unchanged by exposure to the air. The moist state in which it is frequently found in commerce, arises from the presence of a little muriate of lime, which the purest native salt always contains; but it is more abundant in the salt obtained from sea-water.

It is composed, according to Bergman, of

Muriatic acid	-	-	52
Soda	-	-	42
Water	-	-	6
			100

According to Kirwan, when dried at 80°,

Acid	-	-	38.88
Soda	-	-	53.
Water	-	-	8.12
			100

Sir Humphrey Davy considers it a compound of 2 atoms of chlorine and 1 of sodium, or 2×33 chlorine + 44 sodium = 110. This will be

Chlorine	-	-	60
Sodium	-	-	40
			100

See the article *SALT*.

Phosphate of Soda.—This salt has been longer known than phosphorus. It exists ready formed in urine, from which it was extracted, and called *sal mirabile perlatum*, or wonderful perlated salt. It was so called from its crystals having a pearly appearance. This salt, with excess of acid, was considered by Proust as a peculiar acid, which he called the perlated acid. But it was ultimately found by Klaproth, and afterwards by Schiele, to be a compound of soda with the phosphoric acid.

SODIUM.

Dr. Pearson first prepared it artificially, and introduced it into medicine as a purgative. He dissolved 1400 grains of crystallized carbonate of soda in 2100 grains of water, and added gradually 500 grains of phosphoric acid, of the specific gravity 1.85. This solution he boiled for a few minutes, and filtered it while hot. The solution was set out in a cool place to crystallize.

This salt is often made by saturating soda with the superphosphate of lime obtained from bones by sulphuric acid, and is never sufficiently free from lime.

The acid should be obtained by burning phosphorus, and the soda used in the state of well-formed crystals, when the pure salt is required.

It crystallizes in the form of rhomboidal prisms, terminating with three-sided pyramids.

It effloresces by exposure to the air.

Its taste is very like muriate of soda, but more mild and agreeable.

It is soluble in four parts of cold, and in about three parts of boiling water.

When exposed to heat it first undergoes the watery fusion. When heated to redness, it melts into a white enamel. From this property it has been proposed as a substitute for borax, in the soldering of metals: it also resembles the same substance in forming coloured glasses with metallic oxys.

It is partially decomposed by the sulphuric, nitric, and muriatic acids, leaving it in a state containing double its original quantity of acid. This is called the superphosphate of soda. It was this salt which Proust took for a peculiar acid. It is more soluble in water than the phosphate, and does not easily crystallize.

Phosphate of soda has not been analysed: since, however, the weight of an atom of phosphorus is 13, and phosphoric acid $13 + 2 \times 7.5 = 28$, then phosphate of soda will be $2 \times 28 + 59$, or

Soda	-	-	-	-	51
Acid	-	-	-	-	49
					—
					100
					—

Fluate of Soda.—This salt may be formed by adding fluoric acid to carbonate of soda, till the effervescence ceases.

On evaporation, it forms into cubic crystals. These are sparingly soluble in water, and have an astringent bitter taste.

Borate of Soda.—This is a salt with half the quantity of acid which the borate contains; it is known in commerce and in the arts by the name of borax. The latter substance is extracted from a substance called tincal: the true borate is, therefore, not used, but the sub-borate or borax.

Sub-borate of soda is crystallized in hexagonal prisms, with two sides broader than the rest. It is semitransparent. Its specific gravity is 1.74. It is soluble in twelve parts of cold water, and in six of boiling water. It has a sweetish taste, and rather alkaline. When exposed to the air, it is soon reduced to a white powder, with much loss of weight. This arises from the escape of the water of crystallization. Artists are apt to use it too plentifully in this state, and fancy that its proper virtue is gone; but the white powder is equally valuable with the salt for all purposes. When the same change is brought about by heat, the borax is said to be calcined. If a strong heat be given to it in a crucible, it melts into a transparent glass. It is frequently used in forming choice specimens of sham crystals, by fusion

with flint, lead, and manganese. The composition of borax, according to Bergman, is,

Acid	-	-	-	39
Soda	-	-	-	17
Water	-	-	-	44
				—
				100
				—

The acid is obtained from this salt by dissolving it in hot water, and then adding sulphuric acid. As the liquid cools, small scaly crystals are precipitated, which are the pure boracic acid.

The base of this acid has been discovered since the commencement of this work, and even since this acid has been treated of: we, therefore, feel it our duty to give some account of it here.

When boracic acid, slightly moistened, is exposed between two plates of platina, one being connected with the copper side of a Galvanic battery, and the other with the zinc side, the oxygen of the acid is attracted to the zinc or positive side, and the inflammable base to the copper or negative side. This is a dark coloured substance, which becomes detached from the rest of the mass, and is the base in question. This experiment was first made by sir Humphrey Davy, in March 1808, about the time that he discovered potassium and sodium. In the November following it appears that he, as well as Messrs. Gay Lussac and Thenard, obtained this base by heating boracic acid with potassium. The latter chemist also succeeded in recomposing the acid. This substance has been called *boron* by sir Humphrey Davy, which name it still retains.

Boron is an opaque substance of a dark olive colour.

It is not fusible or volatile at any known temperature. When heated in the open air, it burns by absorbing oxygen, and is converted into dry boracic acid. In pure oxygen gas it undergoes more vivid combustion, giving out bright scintillations. The mass becomes coated with boracic acid, and the remainder of the base is found unchanged in the crust.

It is a non-conductor of electricity, a proof that it is not of a metallic nature.

It is insoluble in water.

The proportion of oxygen in boracic acid is not yet known. The crust of boracic acid, which forms on boron when it is burned, secures the remainder from the oxygen, so as to render the result ambiguous.

Sir Humphrey Davy judges, from the quantity of potassium required for the decomposition of the acid, that it contains two-thirds its weight of oxygen. Gay Lussac and Thenard, from treating boron with nitric acid, make it to contain one-third its weight of oxygen; but this result is not to be relied upon, since boracic acid is volatile both with water and the nitric acid.

Sir Humphrey Davy found that 90 parts of potash were required to neutralize 160 of boracic acid. This will give 80 for the weight of the atom of boracic acid, potash being 45, and hydrogen 1. If, according to sir Humphrey, it contains two-thirds of oxygen, then the atom of boron will be 27.

Dr. Thomson, from the experiments of Berzelius, which are in some measure corroborated by those of sir Humphrey Davy, makes the atom of boron 5.5, hydrogen being 1. This is the weight of the atom of carbon, to which boron seems in other respects allied. If, like carbon, it combines with two atoms of oxygen, then boracic acid will be

$5.5 + 7.5 \times 2 = 20.5$. Sir Humphrey's atom, which is 80, is nearly a multiple of this number.

Carbonate of Soda.—This is the salt known by the name of sal foda. It exists ready formed in barilla and kelp, and is easily obtained by solution and evaporation, allowing it to crystallize slowly. It crystallizes in flat rhomboidal prisms. It is soluble in two parts of cold water, and in less than its own weight of boiling water. Like the sulphate of soda, it effloresces in the air, and assumes the form of white powder.

When heated, it melts in its own water of crystallization. This soon escapes; and if the heat be raised, one half of the carbonic acid probably escapes.

According to Bergman, its composition is,

Soda	-	-	-	20
Acid	-	-	-	16
Water	-	-	-	64
				100

According to Klaproth, it contains,

Soda	-	-	-	22
Acid	-	-	-	16
Water	-	-	-	62
				100

According to Kirwan, in crystals,

Soda	-	-	-	21.58
Acid	-	-	-	14.42
Water	-	-	-	64
				100

In the dry state,

Soda	-	-	-	59.86
Acid	-	-	-	40.14
				100

This salt is composed of 2 atoms of acid, 1 of foda, and 20 of water; or 41 acid, 59 foda, and 170 water. This, in 100, will be,

Soda	-	-	-	21.8
Acid	-	-	-	15.2
Water	-	-	-	63
				100

This salt, although called a carbonate, is evidently a bicarbonate of soda; and the salt, which results from heating this, must be considered a carbonate.

There is another compound, with a still greater proportion of carbonic acid, which is either a tricarbonate or a tetracarbonate of soda.

Arseniate of Soda.—This is a salt little known, but believed to have the general properties of arseniate of potash. See that salt under SALTS.

Acetate of Soda.—This salt may be formed by saturating carbonate of soda with acetic acid. It crystallizes in prisms resembling sulphate of soda. It is soluble in about three parts of water at 60°. It does not crystallize but with excess of alkali.

The other salts of soda are too little known to be important.

SODMERE POINT, in *Geography*, a cape on the S. coast of the Isle of Wight. N. lat. $50^{\circ} 38'$. W. long. $1^{\circ} 16'$.

SODOM, in *Ancient Geography*, the chief city of the Pentapolis, which comprehended the five cities called Sodom, Gomorrah, Zeboim, Admah, and Zoar or Segor. The four former were destroyed on account of their wickedness by fire from heaven, A.M. 2107 or B.C. 1897; but the latter, though sentenced to the same fate, was spared at the intercession of Lot. Sodom had been his dwelling-place, and the plain on which Sodom and the other cities stood was pleasant and fruitful, like an earthly paradise, but after their destruction it was overflowed by the waters of the river Jordan, which thus formed the "Dead sea," or "lake of Sodom," or the "ASPHALTITE Lake," which see. A French geographer, setting aside the miraculous part of this event, ascribes it to a volcanic eruption, and he conceives the lake to have been the crater of the volcano; but it is sufficient to observe that this opinion contradicts the historical narration of this event.

In the time of Josephus the ruins of these cities were still in being. Strabo (Geog. l. xv.) also speaks of the ruins of Sodom, which were 60 furlongs in compass, and were visible on the shore of the Dead sea. The "Notitia" expressly mentions Sodom as an episcopal city: and we find one Severus, a bishop of Sodom, among the bishops of Arabia who subscribed to the first council of Nice. Reland, however, cannot allow that Sodom was ever rebuilt, and he thinks that the word Sodom, among the subscriptions to the council of Nice, to have been an error of the copiers. Calmet is of a different opinion. The record, he says, is very circumstantial: it puts the episcopal city of Sodom between Thamar and En-geddi. Stephanus, the geographer, places En-geddi near Sodom. Hence Calmet concludes, that the city of Sodom was rebuilt, either in or near its former situation; for though it appears probable that it was not covered by the waters of the Dead sea, and that it stood on the shore of this sea, yet, says Calmet, "I would not strenuously oppose the contrary opinion."

SODOMY, the unnatural crime of buggery; thus called from the city of Sodom, which was destroyed by fire for the same. This is usually, and very justly, denominated the "crime against nature," when committed with man or beast:—a crime, which ought to be strictly and impartially proved, and then as strictly and impartially punished. The delicacy of our English law treats it, in its very indictments, as a crime not fit to be named; "peccatum illud horribile, inter Christianos non nominandum." The edict of Constantius and Constantine observes a similar taciturnity; "ubi scelus est id, quod non proficit scire, jubemus infringere leges, armari jura gladio ultore, ut exquisitis poenis subdentur infames, qui sunt, vel qui futuri sunt rei."

The Levitical laws adjudged those guilty of this execrable evil to death, Lev. xviii. 22, 23. xx. 15, 16; and the civil law assigns the same punishment to it. Our ancient law commanded such miscreants to be burnt to death (Brit. c. 9.), though Fleta says (l. i. c. 37.) they should be buried alive; either of which punishments was indifferently used for this crime among the ancient Goths. At present our laws make it felony. (25 Hen. VIII. c. 6. 5 Eliz. c. 17.) And the rule of the law is, that if both are arrived at years of discretion, "agentes et consentientes pari poena plectantur." 3 Infl. 59.

SODRA BARKER, in *Geography*, a town of Sweden, in Dalecarlia; 40 miles S. of Fahlun.

SODRES, in *Ancient Geography*, a people of India, in the number of those who were subdued by Alexander, according to Quintus Curtius, l. viii.

SODUCENA, a country of Asia, in the Greater Armenia, S. of Colthene, according to Ptolemy.

SODUS, GREAT, in *Geography*, a large township of America, in the N.E. corner of Ontario county, in the state of New York, with a post-office called "Troupville," bounded N. by lake Ontario, E. by Seneca county, S. by Lyons, and W. by Williamfon and Palmyra; about 18 miles square, and including a great part of Sodus bay. The surface is undulated with hillocks and vallies, in a N. and S. direction, and the soil is good and well watered. The timber is luxuriant, and consists of the fugar-maple, beech, oak, hickory, elm, ash, linden or bass-wood, cherry, tulip-tree or poplar, butternut, &c. Crops of wheat, rye, maize, hemp, flax, oats, and the common grasses, succeed well, as do also the common fruits of the country. In the N.E. corner of Sodus is Great Sodus bay, reckoned the best harbour on the S. shore of the Ontario; and on an elevated point of land, projecting into the bay, the post-village of Troupville is very eligibly and handsomely situated, 212 miles from Albany, and about 30 N.E. of Canandaigua. Sodus has two grist-mills, five saw-mills, one fulling-mill, and a considerable number of the common mechanical branches of manufacture for the convenience of the inhabitants. Here are two meeting-houses, one for Presbyterians and one for Baptists, and several school-houses. Iron ore has been found here. The first settlements in this town commenced in 1790, by two German families from the Mohawk river; and though the progress of population was slow, it amounted, by the census of 1810, to 1957 persons, and 343 families. N. lat. $43^{\circ} 10'$. W. long. $77^{\circ} 5'$.

Sonus, *Little*, a town of New York, in Albany, on the S. side of lake Ontario; 12 miles E. of Great Sodus.

SOEBORG, a town of Denmark, in the isle of Zealand, seated on an island in a fresh-water lake. Near this town is a triangular pillar, with Latin, Danish, and German inscriptions, erected in the year 1738, in honour of Frederick IV. and Christian VI., for having stopped the progress of flying sand, which overwhelmed one tract of land and village after another, and threatened the best part of Zealand with desolation. In the reigns of these two monarchs this evil was restrained under the inspection of the prefect Frederick Von Gram, by the address of John Ubr. Rohl. This sandy waste is now covered with verdure, and appears like a fine meadow; 9 miles W.N.W. of Helsingoer.

SOELBO, a town of Norway, in the province of Drontheim; 20 miles E. of Drontheim.—Also, a lake, 18 miles S.E. of Drontheim.

SOELENGAT, a town of Norway, in the province of Bergen; 112 miles N. of Bergen.

SOEST, or **ZOEST, GERARD**, in *Biography*, was a native of Westphalia, born about the year 1637. He acquired the art of painting in his own country, but practised principally in this, whither he came rather before the period of the restoration. His portraits have a considerable portion of truth and animation, wrought in a finished manner, and with great warmth and glow of colour; so much so as to class him among the better rivals of sir Peter Lely. He was most successful in his portraits of men, among whom he had a very considerable share of employment; but the more graceful and engaging pencil of sir Peter secured the charms of the softer sex to himself. Soest died at the early age of 44.

SOEST, in *Geography*, a town of Germany, in the county of Mark, formerly one of the Hanse towns, enjoying imperial privileges and the right of coining money. Its extent is large, and contains several churches. It was the place in which several of the successors of Charlemagne resided; 22 miles E. of Dortmund. N. lat. $51^{\circ} 33'$. E.

long. $8^{\circ} 11'$.—Also, a river of East Friesland, formed by the union of the Solte and Vehne, which, after a straight course, runs into the Leer near Stikhufen.

SOETA, in *Ancient Geography*, a town of Scythia, beyond the Imaus. Ptolemy.

SOETERWEER, in *Geography*, a town of Holland; 8 miles E. of the Hague.

SOFA, in the East, a kind of alcove raised half a foot above the floor of a chamber, or other apartment; and used as the place of state, where visitors of distinction are received.

Among the Turks, the whole floor of their state-room is covered with a kind of tapestry, and on the window-side is raised a sofa or fopha, laid with a kind of matras, covered with a carpet much richer than the other. On this carpet the Turks are seated, both men and women, like the taylor in England, cross-legged, leaning against the wall, which is bolstered with velvet, fatten, or other stuff, suitable to the season. Here they eat their meals; only laying a skin over the carpet, to serve as a table-cloth, and a round wooden board over all, covered with plates, &c.

The ambassadors of France stood out a long while, and refused to visit the grand vizir, unless he would receive them on the sofa: at length he granted them the sofa.

SOFALA, ZOFALA, or *Quitere*, in *Geography*, a kingdom of Africa, bounded on the N. and W. by the states of Mocaranga, on the E. by the Mozambique channel, and on the S. by Sabia, about 350 miles from E. to W. and 120 from N. to S., extending about 50 leagues along the coast and about 80 into the interior of the country. This country is said to be subject to a Mahometan prince, tributary to the king of Portugal. Its capital, of the same name, was, at the arrival of the Portuguese, an inconsiderable town, without walls, and fenced only with a thorny hedge; but it has since been fortified, and much improved, as well as the fort, which they constructed for its defence. It was then called "Cuama;" but geographers and pilots retain its ancient name of Sofala. It is conveniently situated on a small island, at the mouth of the river Cuama. On the coast are also two other towns, *viz.* Haulema and Dardema, with several obscure villages. The natives of Sofala are generally black, with short curled hair; in shape taller and more genteel than the negroes of Mozambique, Quiloa, &c. Their common dress is a piece of silk or cotton, wrapped round the middle, covering them to the knees; the rest of the body being naked, except the head, as persons of the superior class wear a kind of turban. All persons adorn their necks, arms, wrists, legs, and ancles, with rings of gold, silver, amber, or coloured beads, according to their condition. The stuffs and trinkets used in their dress are chiefly imported from Bombay by the Portuguese; and those of the better sort affect to wear swords with handles of ivory. The inhabitants of the country and town of Sofala are a mixture of Mahometan Arabs, idolatrous Caffres, and Portuguese Christians. Those who inhabit the coast speak the Arabic tongue, which is their native language; as they are not the original natives but the descendants of the Arabs, who, leaving their native country, settled more or less on this coast. They cultivate rice and millet for bread, and eat the flesh of elephants, large and small cattle, and also fish, with great variety of which the sea and rivers abound. They likewise make beer both of rice and millet, and some other liquors from honey, palm, and other fruits. Honey is abundant, and bees-wax serves them to exchange for painted cotton or silk, and other cloths. Their principal commerce is carried on with the inhabitants of Mozambique, Quiloa, Mombaça, and Meluda,

linda, who come hither in their "zambucks," or small barges, which are freighted with a variety of the fore-mentioned cloths of all colours, exchanging them for gold, ivory, wax, or ambergris, and also with the Portuguese. The Arabians exchange goods from the East Indies and the Red sea, to the amount of 140,000*l.* sterling annually for ivory and gold. Besides the gold which is brought from Mocaranga, Sofala has some very considerable mines of that metal, which, according to the reports of the Portuguese inhabitants, have yielded to the value of above two millions of merigals yearly, each merigal being valued at about fourteen French livres, amounting, according to Mr. Savary's statement, to 1,166,666*l.* sterling. The sands also of the river Sofala contain a very considerable mixture of gold-dust. Some persons have even affirmed that Solomon obtained his gold, which is so highly commended by the sacred historians, from this country, and that Sofala is the celebrated Ophir; the gold being allowed to be the purest and finest in all Africa. (See OPHIR.) The Mahometan religion is said by many writers to be that of the king and court, and of a great part of the people; but others think it more probable, that the original natives are wholly destitute of any religion; and that the Arabians, who have settled on this coast, are the only Mahometans, except some few profelytes, from the Negroes, who became such for the sake of commerce; as they observe, that all the merchants who came hither from Quiloa, Mombaça, and Melinda, are of that religion. S. lat. 19° to 22°. E. long. 33° to 36°.

SOFALA, a town of Africa, in the country of the same name. S. lat. 19° 22'. E. long. 36°. See the preceding article.—Also, a river of Africa, which rises in the country of Mocaranga, and pursuing an easterly course, runs into the sea, S. lat. 19° 22'.

SOFEE. See SOPHI.

SOFFIETTA, in *Ichthyology*, the bellows-fish, a name by which some have called the scolopax, a small sea-fish, common in the markets of Rome and Venice.

SOFFINGERBA, in *Geography*, a town of Italy, in Friuli; 4 miles N.N.W. of Friuli.

SOFFITA, SOFFIT, or *Sofit*, in *Architecture*, any timber ceiling, formed of cross-beams, or flying corniches; the square compartments or pannels of which are enriched with sculpture, painting, or gilding.

The word is Italian, and signifies the same with the Latin *lacunar* and *laquear*; with this difference, that *lacunar* is used for any ceiling with square, hollow pannels, called *lacus*; and *laquear* for compartments interlaced with plat-bands, after the manner of knots or *laquei*.

Such are those we see in the basilics and palaces of Italy, in the apartments of Luxembourg, at Paris, &c.

SOFFITA, or *Soffit*, is also used for the under side or face of an architrave; and more particularly for that of the corona or larmier, which the ancients called *lacunar*, the French *plafond*, and we usually the *drip*.

It is enriched with compartments of roses; and in the Doric order has eighteen drops, disposed in three ranks, six in each, placed to the right of the guttæ, at the bottom of the triglyphs.

SOFI, or SOPHI. See SOPHI.

SOFIA, in *Geography*. See SOPHIA.

SOFIANA, a town of Persia, in Adirbeitzan; 25 miles S.W. of Tabris.

SOFIT, or SOFFIT, the internal superficies of an arch; sometimes it signifies the opening itself.

SOFR, in *Geography*, a town of Arabia, in the province of Hedsjas; 70 miles S.E. of Mecca.

SOFRA, a town of Arabia, in the province of Nedsjed; 50 miles N.E. of Kariatain.

SOFREGAM, a town of the island of Ceylon; 54 miles S. of Candi.

SOFROI, a town of Fez, in the province of Chaus, trading principally in oil; 12 miles E. of Fez.

SOFT CHALK, in *Agriculture*, a sort of fossile marle, which readily moulders down and becomes blended with the mould of the soil, on which account it forms an excellent manure, free from the objection made to that of the hard kind, which mostly requires to be reduced into lime. This sort of substance is often met with at some depth at the bottoms of chalk hills, where search should be constantly made for it, as it may become of great value as manure. All soft mouldering chalks are not only excellent substances for applying on lands that are of the stiffish kinds, but they commonly form good soils, where they are the principal material.

SOFT Grass, a troublesome sort of grass among moist arable lands in some places. See HOLCUS.

SOFT Meadow-Grass, the common name of a common grass in moist meadows, but which is of no great value for the purposes of the farmer. There is also a creeping soft grass often met with, which is said to be useful on dry sandy soils in producing a turf or sward. See HOLCUS.

SOFT Pulse, Roe, and Soap. See the substantives.

SOFTENING, in *Painting*, the mixing and diluting of colours with the brush or pencil.

To soften designs in black and white, made with the pen, &c. signifies to weaken the teint.

To soften a portrait, according to Felibien, is to change some of the strokes, and give a greater degree of sweetness and softness to the air of it, which before had something rough and harsh in it.

SOGANA, in *Ancient Geography*, a town of Judea, in the half tribe of Manasseh, on the other side of Jordan. It was fortified by Josephus, when he was governor of Galilee.

SOGANLIK, in *Geography*, a town of European Turkey, in Bulgaria, on the Black sea; 8 miles E. of Varna.

SOGD, the most celebrated and fertile district of Great Bucharia, being the ancient *Sogdiana*, which see. See BUCHARIA.—Also, a river which pervades this district, and which, at the distance of 100 miles from Samarcand, situated on its southern bank, after washing the walls of Bokhara, passes through a considerable lake, and is supposed to join the Oxus or Amu.

SOGDI, in *Ancient Geography*, a people of India, on this side of the Ganges, according to Quintus Curtius, who places them on the left bank of the river Indus. The same historian informs us that Alexander built a city in the country of these people, and called it Alexandria. He also relates, that when some of these people, who resided not far from the country of Odin's Goths, were condemned to death by Alexander on account of a revolt, they rejoiced greatly, and testified their joy by singing verses and dancing. When the king inquired the reason of their joy, they answered, that "being soon to be restored to their ancestors by so great a conqueror, they could not help celebrating so honourable a death, which was the wish of all brave men, in their own accustomed songs." This correspondence of manners and principles between the Scandinavians and the Sogdians furnishes a striking proof of Odin's migration from the E. to the N.; first, in the spontaneous exercise of the poetical talent; and, secondly, in the opinion, that a glorious or warlike death, which admitted them to the company of their friends

and parents in another world, was to be embraced with the most eager alacrity, and the highest sensations of pleasure. This is the doctrine of the "Edda." Warton's *Hist. of Eng. Poetry*, Diff. 1.

SOGDIANA, a country of Asia, between the rivers Jaxartes and Oxus, towards the N.E. of the territories known to the ancients. See **BOKHARA**, **BUCHARIA**, **MAWARUL-NERE**, and **SOGD**.

SOGDIANA Petra, a fortress of Asia, in Sogdiana, situated on a craggy rock. Alexander besieged and took it, and there found Roxana, the daughter of Oxiartes, according to Arrian.

SOGERVI, in *Geography*, a town of Nubia, on the E. side of the Nile; 20 miles W. of Ibrim.

SOGESTA, a town of Sweden, in East Gothland; 6 miles N.N.W. of Linköping.

SOGENDAAL, a town of Norway; 32 miles S. of Stavanger.

SOGETTO, Ital., *subject*, an initial theme or text, in *Music*, for a composer to work into a movement for voices or instruments, without any limitation of parts in its accompaniment.

A subject is frequently given by a master to a student in counterpoint, in the bass, the tenor, or the treble, for him to write upon, or find accompaniments to in every station, alternately; which, when happily achieved, becomes double counterpoint. Writing upon *canto fermo*, as is constantly done by the students in the conservatorios at Naples, for several years, before they are allowed to set words or exercise their fancy in instrumental compositions, is of this kind. Candidates for organists' places, and other professional appointments and honours, have subjects of fugue frequently given them at elections, to play upon extempore; which, if the judges are profound and severe, is a trial of abilities and courage, in which few are able to acquit themselves to their satisfaction. See **FUGUE**, **CANTO FERMO**, **DOUBLE COUNTERPOINT**, and **ROSEINGRAVE**.

SOGLAH, in *Geography*, a town of Asiatic Turkey, in the province of Caramania; 42 miles S. of Cogni.

SOGLIO di Bari, an island near the coast of Naples, in the gulf of Tarento; 11 miles W. of Alessano.

SOGNE, a town of Norway, in the province of Christiania, near Christiania.

SOGNE Bay, a wide river of Norway, 40 miles long, and about two broad, which runs into the North sea, N. lat. 61° 2'. E. long. 5° 20'.

SOGNO, **SONGO**, or **Sonbo**, a province of Africa, in the kingdom of Congo, on the S. side of the Zaire, along the coast of the Atlantic: its chief articles of trade are slaves and elephants' teeth: the inhabitants generally profess themselves to be Christians.—Also, a town of Africa, the capital of the above-mentioned province. It is a large straggling town, consisting of about 400 houses, situated on a creek or small river, about a mile from the Zaire. The houses are in general thatched, and the sides or walls, (if they may be so called,) composed of palm-branches, interwoven with leaves. The English factory, that formerly subsisted in this place, has been long since abandoned.

SOGOCARA, in *Ancient Geography*, a town of Asia, in the Greater Armenia. Ptolemy.

SOGONI, in *Geography*, a town of Nubia, on the Nile; 115 miles S. of Syene.

SCHACZOW, a town of the duchy of Warfaw; 38 miles E.N.E. of Lancicz.

SOHAGEPOUR, a circar of Hindoostan, in Allahabad, bounded on the N. by Boggileund and Chandail, on the E. by Singrowla and Chohan, on the S. by Gurry

Mundella, and on the W. by Gurrah.—Also, a town of Hindoostan, and capital of the above-named district; 120 miles S. of Allahabad. N. lat. 23° 30'. E. long. 81° 54'.

SOHAIG, a town of Egypt, on the W. side of the Nile; 3 miles N. of Achmim.

SOHAL, a town of Arabia, in the province of Oman; 72 miles S.W. of Mascat.

SOHAM, formerly *Seham*, a town in the hundred of Staplehoe, and county of Cambridge, England, is situated on the borders of that county, adjoining Suffolk, at the distance of 5 miles S.E. of Ely, and 7 N. of Newmarket. Here was formerly a market on Thursdays, but it has been discontinued about a century. Two annual fairs are, however, still held here. During the Anglo-Saxon dynasty, Soham appears to have been a place of some consequence, and according to Leland ("Collectanea," vol. ii. p. 247.) was the seat of the East Anglian bishops. The same author states, that Felix, the first bishop, was buried at this place, and that his body was afterwards removed to Ramsey. The bishop's palace and the church were destroyed by the Danes in 870. Some remains of ancient buildings are now visible. Part of this parish was formerly occupied by a large mere or lake, which covered about 1369 acres, but the water has been drained off, and the land appropriated to tillage. On the division of the commons of Soham, in 1685, Sir Thomas Chicheley, then lord of the manor, and the other landholders, allotted 116 acres of moor or fen-land for the benefit of the poor. A school was then founded, and a schoolmaster now receives 50*l.* a-year for superintending the poor children of the parish. Three alms-houses were founded here in 1502 by Richard Bond; and in 1581, nine others for widows were founded by Thomas Pechey. Lysons's *Magna Britannia*, Cambridgeshire, vol. ii. part i. 4to. 1808.

SOHAR, a town of Arabia, in the province of Oman, formerly a place of great splendour, but now of little or no importance; 44 miles N.W. of Mascat. N. lat. 24° 17'.

SOHAUL, a town of Hindoostan, in the circar of Boggileund; 30 miles W. of Rewah.

SOHAUN, one of the smaller rivers of the Panjab, in Hindoostan, which takes its course between the Behut and Sinda, and runs into the latter about 60 miles S. of Attock.

SOHDA, a town of Bengal; 35 miles S.E. of Doesa.

SOHLEN, a town of Westphalia; 6 miles S.S.W. of Magdeburg.

SOHNER, a town of Norway, in the province of Aggerhuus; 25 miles S. of Christiania.

SOHO. See **BIRMINGHAM**.

SOHR, a town of Bohemia, in the circle of Konigin-gratz; 6 miles S.E. of Arnau.

SOHRAU, or **ZYORX**, a town of Silesia, in the principality of Ratibor; 11 miles W.N.W. of Ples.

SOIATOI, a small island of Russia, in the Caspian sea; 148 miles S.E. of Astrachan. N. lat. 44° 40'. E. long. 50° 14'.

SOIGNIES, a town of France, in the department of the Jemmapes, and chief place of a canton, in the district of Mons, situated on the Senne, near a forest to which it gives name; 6 miles N.N.E. of Mons. The place contains 4247, and the canton 14,563 inhabitants, on a territory of 125 kilometres, in 9 communes.

SOIL, in *Agriculture*, a general name applied to the surface mouldy parts of all sorts of land, and in which the fine powdery materials, which have been gradually formed

SOIL.

by time from the various earthy and other bodies in nature, being ground down, and incorporated with each other in different states and proportions, constitute earthy layers, which are usually denominated soils, and which are destined to promote the growth and support of various vegetable crops: while the more solid and less reduced substances, which have been excluded from the influence of the atmosphere, and other natural causes, form the under stratum, which is commonly known by the title of sub-soil. On this account, it is evident that there must be a great diversity in the soils of different districts. The more compact and hard substances of nature, the reduction of which is effected in a more slow and gradual manner, are generally found more sparingly in the principles of soils, than those of the more soft and easily reducible kinds. But in the natural state of soils, the clayey, loamy, and vegetable materials are generally found to enter in a pretty large proportion, and to constitute very essential differences, according to the quantities in which they are predominant in them. And the earthy vegetable matter is, in many cases, a principal material in soils, constituting a sort of superficial layer or bed, in which the crops grow and are supported; but which differs greatly according to the quantity, and the state of reduction or decay to which it has advanced, as well as many other circumstances. (See *VEGETABLE Earth*.) Also, substances of the calcareous, siliceous, and sandy kinds, are abundantly prevalent in some tracts of country, while in others they are met with only in a very sparing manner, and thus of course afford much variety in the nature and properties of the soils of such situations. Other causes, which our limits will not allow us to mention in this place, contribute to produce very great varieties and diversities in the natures and compositions of soils.

It has been well observed by professor Davy, in an excellent paper on the Analysis of Soils, that the substances which are found in soils, are certain mixtures or combinations of some of the primitive earths, animal and vegetable matter in a decomposing state, certain saline compounds, and the oxyd of iron. These bodies always retain water, and exist in very different proportions in different lands, and the end of analytical experiments is the detection of their quantities and mode of union. But that the earths found in common soils are principally silex, or the earths of flints, alumina, or the pure matter of clay, lime, or calcareous earth and magnesia. That silex, or silica, or the earth of flints, when perfectly pure, appears in the form of a white powder, which is incombustible, infusible, insoluble in water, and not acted upon by common acids; it is the substance which constitutes the principal part of rock crystal; it composes a considerable part of hard gravelly soils, of hard sandy soils, and of hard stony lands.

That alumine, alumina, or pure clay, in its perfect state is white, like silex; it adheres strongly to the tongue, is incombustible, insoluble in water, but soluble in acids, and in fixed alkaline menstrua. It abounds most in clayey soils and clayey loams; but even in the smallest particles of these soils, it is usually united to silex and oxyd of iron.

That lime is the substance, which is well known in its pure state under the name of quicklime. It always exists in soils in combination, and that principally with fixed air or carbonic acid, when it is called carbonate of lime; a substance which, in the most compact form, constitutes marble, and in its looser form, chalk. Lime, when combined with sulphuric acid (oil of vitriol), produces sulphate of lime (gypsum), and with phosphoric acid, phosphate of lime. The carbonate of lime, mixed with other substances, com-

poses chalky soils and marles, and is found in soft sandy soils.

That magnesia, when pure, appears as white, and in a lighter powder than any of the other earths; it is soluble in acid, but not in alkaline menstrua; it is rarely found in soils; when it does exist, it is either in combination with carbonic acid, or with silex and alumine.

That animal decomposing matter exists in very different states, according as the substances from which it is produced are different; it contains much carbonaceous substance, and may be principally resolved by heat into this substance, volatile alkali, inflammable aeriform products, and carbonic acid; it is principally found in lands that have been lately manured.

That vegetable decomposing matter is likewise very various in its kind; it contains usually more carbonaceous substance than animal matter, and differs from it in the results of its decomposition, principally in not producing volatile alkali; it forms a great proportion of all peats; it abounds in rich mould; and is found in larger or smaller quantities in all lands.

That the saline compounds found in soils are very few, and in quantities so small that they are rarely to be discovered. They are principally muriate of soda (common salt), sulphate of magnesia (Epsom salt), and muriate and sulphate of potash, nitrate of lime, and the mild alkalies.

That the oxyd of iron is the same with the rust produced by exposing iron to the action of air and water; it is found in all soils, but is more abundant in yellow and red clays, and in yellow and red siliceous sands.

There is, besides these, sometimes oxyd of manganese, or manganese, found in soils, which is composed of this substance and oxygen. It is known from other matters met with in soils, by the property which it has of decomposing muriatic acid, and converting it into another substance.

The silex, or silica, is for the most part met with in soils in the state of combination with alumine, or alumina, and the oxyd of iron, or with the former, lime, magnesia, and oxyd of iron, constituting sand and gravel of very different degrees of fineness, as well as varying much in colour. The carbonate of lime is commonly found in an impalpable form; but occasionally in the state of calcareous sand. The magnesia, when not combined with the gravel or sand of the soil, is in general united in a fine powdery state to carbonic acid. The fine impalpable parts of soil, which are most commonly denominated clay or loam, consist, as has been seen, of silex or silica, alumine or alumina, lime, and magnesia; and are in reality, for the most part, of the same composition as the hard sand, but more finely divided in their particles. As to the vegetable and animal matters of soils, the former of which is by much the most common, they exist in many very different states of reduction and decomposition, as sometimes in that of a quite fibrous one, and at other times they are wholly broken down, and reduced so as to be intimately blended and incorporated with the earthy parts of the soils or lands.

The matters therefore which constitute soils are for the most part of a compound nature, and operate as such in the formation of them. They have many of them, likewise, some other qualities and properties, but which need not be noticed in this place.

It has also been stated by a late practical writer, that there are probably few, if any, substances in nature, which, after they have been sufficiently acted upon, and reduced by the influence of the atmosphere and other agents, that are not capable of affording support to some kind of vegetable or

SOIL.

other, though there is considerable difference in this respect among different earthy matters, some being liable to sustain a great number of different plants in a vigorous state of growth, almost immediately after they become mixed with the soil, while others require to be applied and united for a length of time before they afford sustenance to any kind of vegetable whatever, and even then only yield a scanty supply of nourishment, and that for the support of a few particular sorts of plants. Where the former sorts of materials are abundant, the soils are generally fertile and productive; but where the latter prevail, they are mostly sterile and unfriendly to vegetation. Also that soils, besides possessing the proper earthy matters, must be embued with other principles, such as the aqueous and carbonaceous, and have such a consistence and texture as will properly support the plants, as well as such proportions of the several materials as will admit of their being retained, and applied in such quantities as are suitable for the purposes of vegetation, according to the differences of climate in respect to moisture, and the varieties of situation in regard to the lands, in order to be rich, fruitful, and productive, in the different kinds of vegetable crops. It has been stated likewise, that the bodies or materials, so far as they are yet known, that have a tendency to lessen the fertility of soils, are the oxyds or calces of particular metals, some coaly and pyritical matters, acids, and certain heathy vegetable substances. But that some of these substances, though unfriendly to the growth of vegetables, when in these circumstances, on being blended and united with other materials that enter into the composition of soils, operate upon them in such a manner as to render them more fertile than they would have been without them. Mixtures and impregnations of this nature are constantly taking place in soils, which cannot be easily comprehended or ascertained, but which produce great and important effects and changes in them. From this cause, soils which are apparently similar in every respect, on being brought into cultivation, frequently turn out to be essentially different. And it is well known to most persons conversant with practical agriculture, that soils in which calcareous matter is predominant, even when they are grown so poor and exhausted as to be almost incapable of producing any of the other crops commonly cultivated on them, will bear large and repeated crops of one sort of vegetable, that of sainfoin; and that other soils which are capable of affording the common crops in an abundant manner, cannot be made to produce this. In the same way, such calcareous soils as have been cultivated for a great length of time, and are consequently much impregnated with manure, afford plentiful crops of barley; while oat-crops, if attempted to be raised upon them in such a situation, are weak, puny, and relatively extremely small. And, on the contrary, some primitive soils, not originally containing any calcareous materials, and which, not having been cultivated, cannot be impregnated with manures on first being broken up, often yield astonishing crops of oats, while barley can scarcely be raised at all upon them. These and many other similar facts, noticed by cultivators of the soil, sufficiently shew the effects which even trifling mixtures of certain matters have in altering their qualities, and rendering them more or less fertile, as well as more or less proper for the growth of particular sorts of crops without there being any external appearance of such alteration. Further, soils are also found to differ greatly from their depths, and the nature of the sub-soils on which they rest. It is stated as a fact well known by practical farmers, and which the experience of every day confirms, that even the soils that are constituted of the most

suitable substances for the purposes of vegetation, when only a few inches in depth, and deposited upon beds of cold wet clay, rock, or chalk, are by no means so fruitful and productive as those which are thicker, though of inferior quality, but resting on a bottom which is more dry and gravelly. The difference of weight and tenacity in the under strata of soils, likewise introduces great variety in regard to their powers and capabilities of raising and rearing vegetable productions in the way of crops upon them.

The variations in the weights of soils are very material, as they shew in some measure the quantities of animal and vegetable matters with which they are impregnated in different cases, the lighter sorts being in most instances the most abundant in such substances. The variations in their powers and properties of dissipating or holding the moisture which they contain are also very material and important, as they denote, in some degree, the nature of their compositions, and their utility for the growth of different sorts of plants as crops.

The nature and variations of soils, in so far as they are more or less capable of imbibing and retaining the principles of heat, or more *cold* and raw, or *warm* in their qualities, which are by no means absurdities or prejudices, as some have supposed, are highly deserving of the attention of the philosophical farmer, as some soils are evidently much more heated by the effects of the sun than others, all other circumstances being the same, while soils brought to the same state of heat cool in different lengths of time, or some much faster than others. This property, which has hitherto been but little attended to, is thought to be probably of considerable importance by the above writer on chemistry. It is conceived, that in general soils that consist principally of a stiff white clay are difficultly heated; and that, being commonly very moist, they retain their heat only for a very short time. Chalky soils are similar in one particular, which is that of their being heated with difficulty; but being drier they retain their heat longer, less being supposed to be consumed in producing the evaporation of their moisture.

It has been found that a black soil, which contained much soft vegetable matter, was most heated by the sun and air; and that the coloured soils, and those containing a large proportion of carbonaceous or ferruginous matter, when exposed under equal circumstances to the sun, acquire a much higher temperature than pale-coloured soils.

In all cases, when soils are perfectly dry, those that are the most readily heated by the power of the sun, cool likewise in the most ready manner; but sir Humphrey Davy has experimentally ascertained, that the darkest coloured dry soil, or that which contains abundance of animal and vegetable matter; substances which most facilitate the diminution of temperature, when heated to the same extent, provided it be within the common limits of the effects of the sun's heat, will cool more slowly than a wet pale soil, wholly composed of earthy matter. He found that a rich black mould, which contained nearly a fourth part of vegetable matter, had its temperature increased in the course of an hour from 65° to 88° , by exposure to the sun-shine; while a chalk soil was heated only to 69° under the same circumstances and length of time. But the mould removed into the shade where the temperature was 62° , lost, in half an hour, 15° ; while the chalk, under the same circumstances, had lost only 4° . Farther, a brown fertile soil and a cold barren clay were each artificially heated to 88° , having been previously dried: they were then exposed in a temperature of 57° ; in half an hour the dark soil was found to have lost 9° of heat; the clay had lost only 6° . An equal portion of the clay containing moisture,

moisture, after being heated to 88° , was exposed in a temperature of 55° ; in less than a quarter of an hour it was found to have gained the temperature of the room. In all these trials the soils were put upon small trays made of tin-plate two inches square and half an inch in depth, the temperature being ascertained by a thermometer of a very delicate kind.

It is upon the whole supposed, that nothing can be more evident, than that the genial heat of the soil, particularly in the spring season, must be of the greatest and most material use and importance to the raising plants as crops. And that when the leaves are fully and completely developed or spread out, the ground or land is considerably shaded; and any injurious influence or consequence, which in the summer season might have been apprehended from too great a heat, wholly prevented: so that the temperature of the surface, when bare and exposed to the effects of the sun, affords at least, it is supposed, one indication of the state of its fertility; and that the thermometer may therefore be, it is believed, sometimes an useful instrument to the purchaser as well as improver of lands.

The moisture present in soils has likewise an effect and influence on their temperatures; and the particular manner or method in which it is distributed through, or combined with, the earthy, or perhaps other materials, is of great consequence and importance, in so far as it relates to the nourishment of the plants which grow upon them. The above chemico-agricultural writer thinks, that where the water is too strongly attracted by the earths, it will not be absorbed by the roots of the plants; and that where it is in too great quantity, or too loosely united to them, it will tend to injure or destroy the fibrous parts of the roots. In his opinion there are two states in which water seems to exist in the earths, and in animal and vegetable substances: in the first state, it is conceived to be united by chemical, in the other by cohesive attraction. The former of these is illustrated by the pouring of pure solutions of ammonia or potassa into those of alum, when the alumine or alumina falls down combined with water; and the dry powder affording, by distillation, more than half its weight of water. Also, by the moisture which wood, muscular fibre, and gum, that have been heated to 212° , afford in the same way at a red heat, which is likewise water held in the same manner.

The latter is shewn, it is supposed, when dried pipe-clay, at the temperature of the atmosphere, is brought into contact with water, as the last is rapidly absorbed. In general too, soils, as well as vegetable and animal substances that have been dried at a heat below that of boiling water, increase in weight by exposure to the air, in consequence of their absorbing water from it, which is in the state of vapour, on account of this sort of attraction.

The water which is *chemically* combined among the principal component parts of soils, unless in the case of the decomposition of animal or vegetable substances, cannot, it is supposed, be absorbed by the roots of plants; but that which *adheres* to the parts of the soil is in constant use in vegetation. Indeed, it is believed that there are few earthy mixtures met with in soils that contain any chemically combined water; water is expelled from the earths by most substances that combine with them. As for instance, when a combination of lime and water is exposed to carbonic acid, that fluid substance takes the place of the water; and compounds of alumina and silica, or others of the earths, do not chemically unite with water; and soils, as has been seen, are formed either by earthy carbonates, or compounds of pure earths and metallic oxyds.

However, when saline substances exist in soils, they may, it is said, be united to water, both chemically and mechanically; but they are always, it is supposed, in too small a proportion to materially influence the relations of the soils to water.

The power or capability of the soil to absorb and receive water, in consequence of this sort of attraction, depends greatly upon the state of division of its parts; as the finer and more minute this is, the greater and more powerful is the capacity for absorption. The different constituent parts of soils seem likewise to operate, even by this kind of attraction, with different degrees of force and energy. In this way vegetable substances seem, it is said, to be more absorbent than animal substances; animal substances more so than compounds of alumina and silica; and compounds of alumina and silica more absorbent than carbonates of lime and magnesia. These differences may, however, it is suggested, possibly depend upon the differences in their states of division, and on the surface which is exposed.

This power or capability of soils to absorb water from the air is, it is supposed, much connected with fertility. The soils which are the most efficient in supplying plants with water, by means of atmospheric absorption, are, it is said, those in which there is a due and proper mixture of sand, finely divided clay, and carbonate of lime, with some animal and vegetable matter; and which are so loose and light as to be freely and readily permeable to the atmosphere. In so far as regards this quality, carbonate of lime, and animal and vegetable matter, are, it is said, of great use in soils. They give absorbent power to them, without at the same time giving tenacity: sand, too, constantly destroys tenacity, but, on the contrary, affords little power of absorption. The above writer has compared the absorbent powers of many soils, in so far as it relates to atmospheric moisture, and has constantly found it to be the greatest in the most fertile of them; so that it is supposed to afford one mode of judging of the productiveness of land.

Thus, the water, and the decomposing animal and vegetable matter existing in the soil, constitute, it is supposed, the true nourishment of plants; and that as the earthy parts of the soil are useful in retaining water, so as to supply it in the proper proportions to the roots of the vegetables, so they are likewise efficacious in producing the proper distribution of the animal or vegetable matter. When equally blended and intermixed with it, they also prevent it from decomposing in too rapid a manner; and by their means the soluble parts are supplied in proper proportions or quantities. But besides this agency, which may be considered as mechanical, the writer conceives that there is another, between soils and organizable matters, which may be regarded as chemical in its nature. The earths, and even the earthy carbonates, have, it is said, a certain degree of chemical attraction for many of the principles of vegetable and animal substances, as is readily exemplified in the case of alumina and oil: for when an acid solution of alumina is mixed with a solution of soap, which consists of oily matter and potassa, the oil and the alumina will unite and form a white powder, which will sink to the bottom of the fluid which holds it. The extract, too, from decomposing vegetable matter, when boiled with pipe-clay or chalk, forms, it is said, a combination by which the vegetable matter is rendered more difficult of decomposition and solution. Pure silica and siliceous sands have, it is remarked, little action of this kind; and the soils which contain the most alumina and carbonate of lime, are those which act with the greatest chemical energy in preserving manures. Such soils are supposed to deserve the appellation which is commonly given to them, of rich soils:

soils; as the vegetable nourishment is long preserved in them, unless when taken up by the organs of plants. Siliceous sands, on the contrary, are thought to merit the term hungry, which is commonly applied to them; as the vegetable and animal matter they contain, not being attracted by the earthy constituent parts of the soil, are more liable to be decomposed by the action of the atmosphere, or carried off or away from them by water in different ways. In most of the black and brown rich vegetable moulds, the earths seem, it is supposed, to be in combination with a peculiar extractive matter, afforded during the decomposition of vegetables. This is slowly taken up, or attracted, it is believed, from the earths by water, and appears to constitute a prime cause of the fertility of the soil. The standard of fertility of soils for different plants must vary, it is supposed, with the climate, and must be particularly influenced by the quantity of rain. The power of soils to absorb moisture ought, it is said, to be much greater in warm or dry countries than in cold and moist ones, and the quantity of clay or vegetable or animal matter they contain greater. Such soils as are on declivities, also, should be more absorbent than those on plains, or in the bottoms of vallies. Their productiveness is likewise influenced by the nature of the sub-soil, or the stratum on which they rest. When soils are immediately situated upon a bed of rock or stone, they are much sooner, it is said, rendered dry by evaporation, than when the sub-soil is of clay or marle; and a principal cause of the great fertility of the land in the moist climate of Ireland is, it is imagined, the proximity of the rocky strata to the soil. A clayey sub-soil will sometimes, it is thought, be of material advantage to a sandy soil; and in this case it will retain moisture, in such a manner as to be capable of supplying that lost by the earth above, in consequence of evaporation, or the consumption of it by plants as crops. A sandy or gravelly sub-soil often corrects the imperfections of too great a degree of absorbent power in the true soil. In calcareous countries, where the surface is a kind of marle, the soil is often found, it is observed, only a few inches above the limestone, yet its fertility continues unimpaired by the proximity of the rock; though in a less absorbent soil, this situation would occasion barrenness: and thus the sandstone and limestone hilly soils, in some western districts, may be readily distinguished at a distance, in the summer season, by the different tints or casts of colour in the vegetation. On the sandstone kind it will commonly appear brown and burnt up; while on the limestone sort, it will be green and flourishing in a considerable degree.

It not unfrequently happens that soils are met with in a quite unaltered state, upon the rocks from which they were produced. The manner in which they were formed may easily be conceived, it is supposed by sir Humphrey Davy, by referring to the case of *soft* or *porcelain granite*, which consists of three ingredients, quartz, felspar, and mica. The quartz he considers as almost pure siliceous earth, in a crystalline form. The felspar and mica are very compounded substances: both contain silica, alumina, and oxyd of iron; in the former there is commonly lime and potassa; in the latter, lime and magnesia. Therefore, when a granite rock of this sort has been long exposed to the influence of air and water, he supposes the lime and potassa, contained in its constituent parts, are acted upon by water or carbonic acid; and the oxyd of iron, which is mostly in the least oxyded state, tends to combine with more oxygen; in consequence of which the felspar decomposes, as well as the mica, but the first in the most rapid manner. The felspar, which is as it were the cement of the stone, forms a fine clay; the

partially decomposed mica blends and intermixes with it as sand; and the undecomposed quartz appears as gravel, or sand of different degrees of fineness. On the smallest layer of earth being formed on the surface of the rock, the seeds of mosses, and other imperfect plants, which are mostly floating in the surrounding atmosphere, and which have made it their resting place, begin, it is said, to vegetate; and their decay, death, and decomposition afterwards, afford a certain quantity of organizable matter, which mixes with the earthy materials of the rock. In this improved soil, more perfect plants are capable of subsisting: these, in their turn, absorb nourishment from the water of the atmosphere; and, after perishing, afford new materials to those already provided. The decomposition of the rock still continues; and at length, by such slow and gradual processes, a soil is formed, in which even forest trees can, it is supposed, fix their roots, and which is fitted to reward the labours of those undertaking its cultivation.

It is likewise noticed, that where successive generations of vegetables have grown upon a soil, unless part of their produce has been carried away by man, or consumed by animals, the vegetable matter increases in such proportion, that the soil approaches to a peat in its nature; and if it be so placed as that it becomes impregnated with water from a higher situation, it gets spongy, and is gradually rendered incapable of supporting better plants. A great number of peat mosses appear, however, it is said, to have been formed by the destruction of forests, by the imprudent use of the hatchet, at some early former period. It is supposed, that when the trees in the outer parts of the woods were cut down, those in the interior were exposed to the influence of the winds; and, having been accustomed to shelter, became unhealthy, and died in their new situations; the leaves and branches of which, gradually decomposing, produced a stratum of vegetable matter. In several of the great peat bogs in the north of this and the neighbouring country, the larger trees met with on the outer parts of them, it is said, bear the marks of having been felled; while in the interior, few entire trees are found: and the cause is, probably, it is supposed, that they fell by gradual decay; and that the fermentation and decomposition of the vegetable matter were most rapid, where it was in the greatest quantity or proportion.

Other less healthy sorts of spurious peat bogs are formed in watery situations, by the accumulation of the remains of aquatic plants. There is here a fermentation of an apparently different kind, and a much greater evolution of gaseous matter.

It is found that the earthy matter of peats is invariably analogous to that of the stratum on which they repose: the plants which have formed them must have derived the earths that they contained from this stratum. Thus, the above writer observes, that in the counties of Wilts and Berks, where the stratum below the peat is chalk, calcareous earth abounds in the ashes, and very little alumina and silica: They likewise contain much oxyd of iron and gypsum, both of which may be derived from the decomposition of pyrites, which is so abundant in chalk. The different specimens of peat that have been burnt by this experimenter, from the granitic and schistose soils of different parts of these islands, have constantly given him ashes principally of a siliceous and aluminous nature; but one from the county of Antrim, in Ireland, yielded ashes, which afforded very nearly the same constituent parts as the great basaltic stratum of the county.

It is suggested that poor and hungry soils, such as are produced from the decomposition of granitic and sandstone rocks,

SOIL.

rocks, remain very often for ages with only a thin covering of vegetation; but that soils from the decomposition of limestone, chalk, and basalt, are not unfrequently clothed by nature with the perennial grasses, and afford, when ploughed up, a rich bed of vegetation for every sort of cultivated plants.

From what has been said on the formation of rocky soils, it must be obvious that they are as various as the rocky matters from which they are produced, and probably much more so, in consequence of the alterations which have taken place in them, from the continued operation of water, and different other causes.

In so far as the cropping of land is concerned, it must be evident that no general principle can be laid down for it, unless the whole of the circumstances connected with the nature, composition, and situation of the soils, as well as subsoils, be fully understood.

In like manner, in the above writer's opinion, the modes of cultivation in different soils must be different; as the same practice that may be excellent in one case may be destructive in others. Thus, for instance, deep ploughing may be very advantageous and profitable in rich thick soils; but in fertile shallow ones, upon cold clay or sandy sub-soils, very injurious and hurtful. Siliceous sandy soils are much more productive in moist wet climates, where the fall of rain is great, such as those in the south-west and north-west of this country, and in some places in Ireland, than in dry districts; and in such situations, wheat and beans will require less coherent and absorbent soils than in those which are drier; and bulbous-rooted plants will, it is said, thrive well in soils that have as many as fourteen parts out of fifteen of sand. The exhausting powers of crops, too, it is asserted, will be influenced by the same circumstances; as where sufficient moisture cannot be absorbed by plants, they must necessarily take up more manure. In the south-western and north-western parts of this island, as well as in Ireland, corn will, it is said, exhaust less than in dry inland districts; and oats are much more deteriorating, especially in dry climates, than in such as are moist. In many other instances, the same is likewise the case.

In regard to the constitution or composition of fertile soils, the first essential requisite, according to Mr. Kirwan, is, that it contain a sufficient quantity of the three or four simple earths above mentioned, and of the soluble carbonaceous principle; and that the other requisites are, that the proportion of each, and the general texture of the soil, be such as to enable it to admit and retain as much water as is necessary to vegetation, and no more. Also, further, that as it has been seen that the retentive powers of moisture are very different in the simple earths, the proportions in which the fertility of a soil requires them to be mixed must be different in climates and countries that differ considerably in moisture; in the *drier*, they must be such as are most retentive; in the *moister*, such as suffer it to pass or evaporate more easily. The same remark also extends to situation. Lands on a plain should be so constituted, as to be less retentive of water than those situated on a declivity; as has been seen, and is very evident: consequently, lands that have a retentive or impermeable sub-soil, should be differently constituted from those that have one less retentive, or more permeable. And the time of the year in which rain most abundantly falls may also be worthy of notice, in adjusting this business.

From a variety of facts and observations, which we cannot minutely detail, it is inferred that in the drier countries, where the fall of rain is but 20 inches, the soil, to be fertile, must be closer, and the quantity of calcareous earth

much increased, and that of the siliceous earth much diminished. Thus, in the climate of Turin, where the fall of rain exceeds 40 inches, the proportion of siliceous earth is from 77 to 80 *per cwt.*, and that of calcareous from 9 to 14, to suffer this excess of rain more easily to evaporate. In the climate of Upsal, where the fall of rain is 24 inches, the proportion of siliceous is only 56 *per cwt.*, but that of calx is 30; and in the climate of Paris, which is still drier, the proportion of siliceous is only from 46 to 51, and that of calx 37.5 *per cwt.* And hence we may perceive the necessity of attending to the average quantity of rain, to judge of the proper constitution of fertile lands upon fixed principles. The quantity of rain differs much, in different parts of the same kingdom; but in general, in Ireland, Mr. Kirwan believes it to be between 24 and 28 inches, on an average. In the two last mixtures, the proportions vary considerably: the first may serve, it is said, as a model for the heavier soils; and the second for the lighter. In the following experiments, the carbonic principle seems to have been extracted from the surrounding garden-mould, with which the pots communicated, by means of their perforation at the bottom.

The author of a late work on "Agricultural Chemistry" states, that as plants have no locomotive powers, they can only grow in places where they are supplied with food; and that the soil is necessary to their existence, both as affording them properly the means of nourishment, and enabling them to fix themselves in such a manner as to obey those mechanical laws, by which their radicles are kept below the surface, and their leaves exposed to the free atmosphere. That as the systems of roots, branches, and leaves, are very different in different vegetables, so they flourish most perfectly in different soils suited to them: the plants that have bulbous roots require a looser and a lighter soil than such as have fibrous roots; and the plants having only short fibrous radicles stand in need of a firmer soil than such as have tap-roots, or extensive roots of the lateral kind.

He found a good turnip soil from Holkham, in the county of Norfolk, to afford eight out of nine parts siliceous sand; and the finely divided matter to consist of

Carbonate of lime	63
Silica	15
Alumina	11
Oxyd of iron	3
Vegetable and saline matter	5
Moisture	3

A soil particularly fitted for raising flourishing oaks, to be constituted nearly as noticed afterwards, below.

An excellent wheat-soil from near West Drayton, in the county of Middlesex, gave three parts in five of siliceous sand; and the finely divided matter consisted of

Carbonate of lime	28
Silica	32
Alumina	29
Animal or vegetable matter and moisture	11

It is noticed, that of these soils, the first was the least coherent in texture, and the last by far the most so. In all cases, the constituent parts of the soil which give tenacity and coherence are, it is said, the finely divided matters; and that they possess the power of giving those qualities in the highest degree, when they contain much alumina. A small quantity of finely divided matter is sufficient, it is said, to fit a soil for the production of turnips and barley; and the writer has seen a tolerable crop of turnips on a soil containing

SOIL.

taining eleven parts out of twelve sand. Any much greater proportion of sand, however, it is stated, always produces absolute sterility. The soil of Bagshot-Heath, which is wholly devoid of vegetable covering, contains, it is said, less than one-twentieth of finely divided matter; 400 parts of it, which had been heated red, afforded the above writer 380 parts of coarse siliceous sand, 9 parts of fine sand of the same kind, and 11 parts of impalpable matter, which was a mixture of ferruginous clay, with carbonate of lime. Vegetable or animal matters, when finely divided, not only give, it is said, coherence, but likewise softness and penetrability; but neither they, nor any other part of the soil, must be in too great proportion; and a soil is unproductive, if it consists entirely of impalpable matter. Pure alumina or silica, pure carbonate of magnesia, are incapable of supporting healthy vegetation. And no soil is fertile, it is stated, that contains so much as nineteen parts out of twenty of any of the constituent materials that have been mentioned above.

In answer to the important question, whether the pure earths in the soil only act in a mere mechanical manner, or as indirect chemical agents, or actually furnish the food of the plants? it is stated, that as their bases have not yet been decomposed, there is no reason to suppose that they are capable of being converted into the elements of organized compounds, as into carbon, hydrogen, and azote. Plants have been made to grow, it is said, in given quantities of earth, but they consume very small portions only; and what is lost may be accounted for, by the quantities found in their ashes, that is to say, it has not been converted into any new products. The carbonic acid united to lime or magnesia, if any stronger acid happens to be formed in the soil during the fermentation of vegetable matter, which will disengage it from the earths, may, it is said, be decomposed; but the earths themselves cannot be supposed convertible into other substances, by any process taking place in the soil or land. In all cases, the ashes of plants, it is observed, contain some of the earths of the soil in which they grow; but these never equal more than one-fiftieth of the weight of the plant which is consumed. On the whole, it is concluded, that if they be considered as necessary to the vegetable, it is as giving hardness and firmness to its organization. Thus wheat, oats, and many of the hollow grasses, have, it is said, an epidermis principally of siliceous earth; the use of which seems to be to strengthen them, and defend them from the attacks of insects and parasitical plants.

It is stated that, for the most part, the soils, the constituent materials of which are the most various and contrary to each other, are those of the alluvial kind, or which have been formed in a gradual manner from the depositions of rivers, or other waters: they are, in many cases, extremely fertile. The writer just mentioned has examined some productive soils of this sort, which have been very different in their composition. A very productive soil from the banks of the river Parrot, in the county of Somerset, afforded eight parts of finely divided earthy matter, and one part of siliceous sand: the analysis of the former gave these results:

- 360 parts of carbonate of lime,
- 25 parts of alumina,
- 20 parts of silica,
- 8 parts of oxyd of iron,
- 19 parts of vegetable, animal, and saline matter.

A rich soil of this nature from near the Avon river, in the valley of Evesham, in the county of Worcester, gave

three-fifths of fine sand, and two-fifths of impalpable matter: the latter consisted of

- 35 Alumina,
- 41 Silica,
- 14 Carbonate of lime,
- 3 Oxyd of iron,
- 7 Vegetable, animal, and saline matter.

From a specimen of good soil of Tiviotdale, five-sixths of fine siliceous sand, and one-sixth of impalpable matter, were afforded: the latter consisted of

- 41 Alumina,
- 42 Silica,
- 4 Carbonate of lime,
- 5 Oxyd of iron,
- 8 Vegetable, animal, and saline matter.

And a soil affording excellent pasture from the valley of the Avon, near the town of Salisbury, gave one-eleventh of coarse siliceous sand; the finely divided matter of which consisted of

- 7 Alumina,
- 14 Silica,
- 63 Carbonate of lime,
- 2 Oxyd of iron,
- 14 Vegetable, animal, and saline matter.

It is stated that, in all these cases, the fertility seemed to depend upon the state of division and mixture of the earthy materials and the vegetable and animal matters; which may be readily explained from what has been already advanced.

And professor Davy, in speaking of the improvement of soils, as connected with the principle of their composition, remarks in the paper noticed above, that when a barren soil is examined with a view to its improvement, it ought, in all cases, if possible, to be compared with an extremely fertile soil in the same neighbourhood, and in a similar situation: the difference given by their analyses would indicate the methods of cultivation; and thus the plan of improvement would be founded upon accurate scientific principles. And that, if the fertile soil contained a large quantity of sand, in proportion to the barren soil, the process of amelioration would depend simply upon a supply of this substance; and the method would be equally simple with regard to soils deficient in clay or calcareous matter. But that in the application of clay, sand, loam, marle, or chalk to lands, there are no particular chemical principles to be observed; but when quicklime is used, great care must be taken that it is not obtained from the magnesian limestone; for in this case, as has been shewn by Mr. Tennant, it is exceedingly injurious to land. The magnesian limestone may be distinguished from the common limestone by its greater hardness, and by the length of time that it requires for its solution in acids, and it may be analysed by the process for carbonate of lime and magnesia. When the analytical comparison indicates an excess of vegetable matter as the cause of sterility, it may be destroyed by much pulverization, and exposure to air, by paring and burning, or the agency of lately made quicklime. And the defect of animal and vegetable matter must be supplied by animal or vegetable manure.

And it is further stated, that sterile soils in different climates and situations must differ in composition. The general indications of fertility and barrenness, as found by chemical experiments, must necessarily differ in different climates, and under different circumstances. The power of soils to absorb moisture, a principle essential to their productiveness,

ductiveness, ought, as has been seen, to be much greater in warm and dry countries, than in cold and moist ones; and the quantity of fine aluminous earth they contain larger. Soils, likewise, as already seen, that are situated on declivities, ought to be more absorbent than those in the same climate, on plains or in vallies. The productiveness of soils must likewise be influenced by the nature of the sub-soil, or the earthy or stony strata on which they rest; and this circumstance ought to be particularly attended to in considering their chemical nature, and the system of improvement. Thus, a sandy soil may sometimes owe its fertility to the power of the sub-soil to retain water; and an absorbent clayey soil may occasionally be prevented from being barren, in a moist climate, by the influence of a sub-stratum of sand or gravel. In regard to the chemical composition of fertile corn-soils in this climate, those soils that are most productive of corn, contain always certain proportions of aluminous and calcareous earth, in a finely divided state, and a certain quantity of vegetable or animal matter. The quantity of calcareous earth is however very various, and in some cases exceedingly small. A very fertile corn-soil from Ormiston, in East Lothian, afforded the writer, in an hundred parts, only eleven parts of mild calcareous earth; it contained twenty-five parts of siliceous sand; the finely divided clay amounted to forty-five parts. It lost nine in decomposed animal and vegetable matter, and four in water; and afforded indications of a small quantity of phosphate of lime. This soil was of a very fine texture, and contained very few stones or vegetable fibres. It is not unlikely that its fertility was in some measure connected with the phosphate; for this substance is found in wheat, oats, and barley, and may be a part of their food. A soil from the low lands of Somersetshire, celebrated for producing excellent crops of wheat and beans without manure, he found to consist of one-ninth of sand, chiefly siliceous, and eight-ninths of calcareous marl tinged with iron, and containing about five parts in the hundred of vegetable matter. He could not detect in it any phosphate or sulphate of lime, so that its fertility must have depended principally upon its power of attracting principles of vegetable nourishment from water and the atmosphere. And Mr. Tillet found that a soil composed of three-eighths of clay, two-eighths of river-sand, and three-eighths of the parings of limestone, was very proper for wheat.

With respect to the composition of soils proper for bulbous roots and for trees, it is observed that, in general, bulbous roots require a soil much more sandy, and less absorbent, than the grasses. A very good potatoe soil, from Varfel, in Cornwall, afforded him seven-eighths of siliceous sand; and its absorbent power was so small, that one hundred parts lost only two by drying at 400° Fahrenheit. Plants and trees, the roots of which are fibrous and hard, and capable of penetrating deep into the earth, will vegetate to advantage in almost all common soils which are moderately dry, and which do not contain a very great excess of vegetable matter. He found the soil taken from a field at Sheffield-Place, in Suffex, remarkable for producing flourishing oats, to consist of six parts of sand, and one part of clay and finely divided matter. And one hundred parts of the entire soil submitted to analysis, produced

And on the advantages of improvements made by changing the composition of the earthy parts of soils, it is observed that, from the great difference of the causes that influence the productiveness of lands, it is obvious that, in the present state of science, no certain system can be devised for their improvement, independent of experiment: but there are few cases in which the labour of analytic trials will not be amply repaid by the certainty with which they denote the best methods of amelioration; and this will particularly happen, when the defect of composition is found in the proportions of the primitive earths. In supplying animal or vegetable manure, a temporary food only is provided for plants, which is in all cases exhausted by means of a certain number of crops; but when a soil is rendered of the best possible constitution and texture, with regard to its earthy parts, its fertility may be considered as permanently established. It becomes capable of attracting a very large proportion of vegetable nourishment from the atmosphere, and of producing its crops with comparatively little labour and expence.

There are different other cases in which improvements may be directed in this way; as where the salts of iron or some acid material is found to prevail in soils, they may be altered and corrected by the use of lime in its most active state. In this manner very sterile soils, not deficient in texture, have been effectually improved. When the quantity of calcareous matter is too great, sand or clay is the obvious remedy. If there be a deficiency of vegetable materials in light sandy or gravelly soils, they may be permanently improved by the use of peat earth upon them. The peat-boggy and marshy sorts of soils, after proper draining, are mostly made productive, by laying upon them sandy, or stiff earthy matters in due proportion, especially when the former are of the black soft peaty quality. In cases where peaty soils are acid, or much impregnated with ferruginous saline matters, the use of calcareous substances is essentially necessary for bringing them into proper order.

It is conceived that the best natural soils are those, the materials of which have been produced from strata of different kinds, which have been the most perfectly divided in their parts by the operation of air and water, and are the most intimately blended and incorporated together. In improving soils artificially, it is in short supposed, that the farmer cannot do better than imitate the processes of nature. The materials suitable for the purpose are, it is said, seldom far distant: coarse sand is often found immediately upon chalk; and beds of sand and gravel are commonly below clay.

The labour of amending and improving the texture and constitution of soils, is repaid, it is said, by many great permanent benefits; a smaller quantity of manure is required, and their fertility rendered secure, &c.

In order to ascertain the properties and qualities of land, the method of chemical analysis has been adopted. In this case the following rules and directions, laid down by professor Davy in the paper before alluded to, may be found useful in guiding the inquirer. All the varieties of soils may be analysed in this way.

1. *Instruments required for the Analysis of Soils.*—The really important instruments required for the analysis of soils are, in his opinion, few, and but little expensive. They are, a balance capable of containing a quarter of a pound of common soil, and capable of turning, when loaded, with a grain; a series or set of weights, from a quarter of a pound troy to a grain; a wire sieve, sufficiently coarse to admit a pepper-corn through its apertures; an Argand lamp and

stand; some glass-bottles; Hessian crucibles; porcelain or queen's ware evaporating basins; a Wedgewood pebble and mortar; some filters made of half a sheet of blotting-paper, folded so as to contain a pint of liquid, and greased at the edges; a bone-knife, and an apparatus for collecting and measuring aeriform fluids. And the chemical substances or re-agents required for separating the constituent parts of the soil are, muriatic acid (spirit of salt), sulphuric acid, pure volatile alkali dissolved in water, solution of prussiat of potash and iron, succinate of ammonia, soap-ley, solutions of carbonate of ammonia, of muriate of ammonia, solution of neutral carbonate of potash, and nitrate of ammonia. An account of the nature of these bodies and their effects may be found in Dr. Thomson's *Sytem of Chemistry*, and Henry's *Epitome*; and the re-agents are sold together with the instruments mentioned above, by Mr. Knight, Folterlane, Cheapside, arranged in an appropriate chest.

2. *Mode of collecting Soils for Analysis.*—In cases where the general nature of the soil of a field is to be ascertained, specimens of it should be taken from different places, two or three inches below the surface, and examined as to the similarity of their properties. It sometimes happens, that upon plains, the whole of the upper stratum of the land is of the same kind, and in this case one analysis will be sufficient; but in vallies, and near the beds of rivers, there are very great differences, and it now and then occurs that one part of a field is calcareous, and another part siliceous; and in this case, and in analogous cases, the portions different from each other should be separately submitted to experiment. Soils, when collected, if they cannot be immediately examined, should be preserved in phials quite filled with them, and closed with ground-glass stoppers. The quantity of soil most convenient for a perfect analysis, is from two to four hundred grains. It should be collected in dry-weather, and exposed to the atmosphere till it becomes dry to the touch. The specific gravity of a soil, or the relation of its weight to that of water, may be ascertained by introducing into a phial, which will contain a known quantity of water, equal volumes of water and of soil, and this may be easily done by pouring in water till it is half full, and then adding the soil till the fluid rises to the mouth; the difference between the weight of the soil and that of the water will give the result. Thus, if the bottle contains 400 grains of water, and gains 200 grains when half filled with water and half with soil, the specific gravity of the soil will be 2; that is, it will be twice as heavy as water; and if it gained 165 grains, its specific gravity would be 1.825, water being 1000. It is of importance that the specific gravity of a soil should be known, as it affords an indication of the quantity of animal and vegetable matter it contains; these substances being always most abundant in the lighter soils. The other physical properties of soils should likewise be examined before the analysis is made, as they denote, to a certain extent, their composition, and serve as guides in directing the experiments. Thus, siliceous soils are generally rough to the touch, and scratch glass when rubbed upon it; ferruginous soils are of a red or yellow colour; aluminous soils adhere strongly to the tongue, and emit a strong earthy smell when breathed on; and calcareous soils are soft, and much less adhesive than aluminous soils.

3. *Mode of ascertaining the Quantity of Water of Absorption in Soils.*—Soils, though as dry as they can be made by continued exposure to air, in all cases still contain a considerable quantity of water, which adheres with great obstinacy to the earths and animal and vegetable matter, and can only be driven off from them by a considerable

degree of heat. The first process of analysis is, to free the given weight of soil from as much of this water as possible, without, in other respects, affecting its composition; and this may be done by heating it for ten or twelve minutes over an Argand's lamp, in a basin of porcelain, to a temperature equal to 300° Fahrenheit. In several experiments, in which this process has been carried on by distillation, he has found the water that came over pure, and no sensible quantity of other volatile matter was produced. And in case a thermometer is not used, the proper degree may be easily ascertained, by keeping a piece of wood in contact with the bottom of the dish; as long as the colour of the wood remains unaltered, the heat is not too high; but when the wood begins to be charred, the process must be stopped. A small quantity of water will perhaps remain in the soil, even after this operation, but it always affords useful comparative results; and if a higher temperature were employed, the vegetable or animal matter would undergo decomposition, and in consequence the experiment be wholly unsatisfactory. The loss of weight in the process should be carefully noted, and when in four hundred grains of soil it reaches as high as fifty, the soil may be considered as in the greatest degree absorbent, and retentive of water, and will generally be found to contain a large proportion of aluminous earth. When the loss is only from twenty to ten, the land may be considered as only slightly absorbent and retentive, and the siliceous earth as probably most abundant.

4. *The Separation of Stones, Gravel, and vegetable Fibres from Soils.*—None of the loose stones, gravel, or large vegetable fibres, should be divided from the pure soil, till after the water is drawn off; for these bodies are themselves often highly absorbent and retentive, and in consequence influence the fertility of the land. The next process, however, after that of heating, should be their separation, which may be easily accomplished by the sieve, after the soil has been gently bruised in a mortar. The weights of the vegetable fibres of wood, and of the gravel and stones, should be separately noted down, and the nature of the last ascertained; if calcareous, they will effervesce with acids; if siliceous, they will be sufficiently hard to scratch glass; and if of the common aluminous class of stones, they will be soft, easily scratched with a knife, and incapable of effervescing with acids.

5. *Separation of the Sand and Clay, or Loam, from each other.*—The greater number of soils, besides gravel and stones, contain larger or smaller proportions of sand of different degrees of fineness; and it is a necessary operation, the next in the process of analysis, to detach them from the parts in a state of more minute division, such as clay, loam, marl, and vegetable and animal matter, and the matter soluble in water. This may be effected in a way sufficiently accurate, by boiling the soil in three or four times its weight of water, and, when broken down and cool, by agitating the parts of the soil in the water, and then letting them rest. In this case, the coarse sand will generally separate in a minute, and the finer in two or three minutes, whilst the minutely divided earthy, animal, or vegetable matter will remain in a state of mechanical suspension for a much longer time; so that by pouring the water from the bottom of the vessel, after one, two, or three minutes, the sand will be principally separated from the other substances, which, with the water containing them, must be poured into a filter, and after the water has passed through, collected, dried, and weighed. The sand must likewise be weighed, and their respective quantities noted down. The water of lixiviation must be preserved, as it will be found

found to contain saline matter, and the soluble animal and vegetable matters, if any exist in the soil.

6. *Examination of the Sand.*—By the process of washing and filtration, the soil is separated into two portions, the most important of which is generally the finely divided matter. A minute analysis of the sand is seldom or never necessary, and its nature may be detected in the same manner as that of the stones or gravel. It is always either siliceous sand, or calcareous sand, or a mixture of both. If it consists wholly of carbonate of lime, it will be rapidly soluble in muriatic acid, with effervescence; but if it consist partly of this substance, and partly of siliceous matter, the respective quantities may be ascertained by weighing the residuum after the action of the acid, which must be applied till the mixture has acquired a sour taste, and has ceased to effervesce. This residuum is the siliceous part: it must be washed, dried, and heated strongly in a crucible; the difference between the weight of it and the weight of the whole, indicates the proportion of calcareous sand.

7. *Examination of the finely divided Matter of Soils, and Mode of detecting mild Lime and Magnesia.*—The finely divided matter of the soil is usually very compound in its nature; it sometimes contains all the four primitive earths of soils, as well as animal and vegetable matter; and to ascertain the proportions of these with tolerable accuracy is the most difficult part of the subject. The first process to be performed, in this part of the analysis, is the exposure of the fine matter of the soil to the action of the muriatic acid. This substance should be poured upon the earthy matter in an evaporating basin, in a quantity equal to twice the weight of the earthy matter; but diluted with double its volume of water. The mixture should be often stirred, and suffered to remain for an hour, or an hour and a half, before it is examined. If any carbonate of lime or magnesia exist in the soil, they will have been dissolved in this time by the acid, which sometimes takes up likewise a little oxyd of iron; but very seldom any alumine.

The fluid should be passed through a filter; the solid matter collected, washed with rain-water, dried at a moderate heat, and weighed. Its loss will denote the quantity of solid matter taken up. The washings must be added to the solution, which, if not sour to the taste, must be made so by the addition of fresh acid, when a little solution of common prussiat of potash and iron must be mixed with the whole. If a blue precipitate occurs, it denotes the presence of oxyd of iron, and the solution of the prussiat must be dropped in till no farther effect is produced. To ascertain the quantity, it must be collected in the same manner as other solid precipitates, and heated red; the result is oxyd of iron, which may be mixed with a little oxyd of manganese. Into the fluid freed from oxyd of iron, a solution of neutralized carbonate of potash must be poured till all the effervescence ceases in it, and till its taste and smell indicate a considerable excess of alkaline salt. The precipitate that falls down is carbonate of lime; it must be collected on the filter, and dried at a heat below that of redness. The remaining fluid must be boiled for a quarter of an hour, when the magnesia, if any exist, will be precipitated from it, combined with carbonic acid, and its quantity is to be ascertained in the same manner as that of the carbonate of lime. If any minute proportion of alumine should, from peculiar circumstances, be dissolved by the acid, it will be found in the precipitate with the carbonate of lime, and it may be separated from it by boiling it for a few minutes with soap-ley, sufficient to cover the solid matter. This substance dissolves alumine, without acting upon carbonate of lime. Should the finely divided soil be

sufficiently calcareous to effervesce very strongly with acids, a very simple method may be adopted for ascertaining the quantity of carbonate of lime, and one sufficiently accurate in all common cases. Carbonate of lime, in all its states, contains a determinate proportion of carbonic acid, *i. e.* about 45 per cent., so that when the quantity of this elastic fluid, given out by any soil during the solution of its calcareous matter in an acid, is known, either in weight or measure, the quantity of carbonate of lime may be easily discovered. When the process by diminution of weight is employed, two parts of the acid and one part of the matter of the soil must be weighed in two separate bottles, and very slowly mixed together, till the effervescence ceases; the difference between their weight, before and after the experiment, denotes the quantity of carbonic acid lost; for every four grains and a half of which, ten grains of carbonate of lime must be estimated. The best method of collecting the carbonic acid, so as to discover its volume, is by the pneumatic apparatus, the construction and application of which are described below. The estimation is, for every ounce measure of carbonic acid, two grains of carbonate of lime. The bulk may be measured by the quantity of water which is displaced.

8. *Mode of ascertaining the Quantity of insoluble finely divided animal and vegetable Matter.*—After the fine calcareous matter of the soil has been acted upon by muriatic acid, the next process is to ascertain the quantity of finely divided insoluble animal and vegetable matter that it contains. This may be done with sufficient precision, by heating it to strong ignition in a crucible over a common fire, till no blackness remains in the mass. It should be often stirred with a metallic wire, so as to expose new surfaces continually to the air: the loss of weight that it undergoes denotes the quantity of the substance that it contains destructible by fire and air. It is not possible, without nice and difficult trials, to ascertain whether this substance is wholly animal or vegetable matter, or a mixture of both. When the smell emitted during the incineration is similar to that of burnt feathers, it is a certain indication of some animal matter, or that which is analogous to it; and a copious blue flame at the time of ignition, almost always denotes a considerable proportion of vegetable matter. In cases when the experiment is needed to be very quickly performed, the destruction of the decomposable substances may be assisted by the agency of nitrate of ammonia, which at the time of ignition may be thrown gradually upon the heated mass in a quantity of twenty grains for every hundred of residual soil. It promotes the dissipation, or affords the principle necessary to the combustion of the animal and vegetable matter, which it causes to be converted into elastic fluids; and it is itself at the same time decomposed and lost.

9. *Mode of separating aluminous and siliceous Matter and Oxyd of Iron.*—The substances remaining after the decomposition and destruction of the vegetable and animal matter, are generally minute particles of earthy matter, containing usually alumine and siliceous matter, with combined oxyd of iron, or of manganese. To separate these from each other, the solid matter should be boiled for two or three hours with sulphuric acid, diluted with four times its weight of water; the quantity of the acid should be regulated by the quantity of solid residuum to be acted upon, allowing for every hundred grains two drachms, or one hundred and twenty grains of acid. The substance remaining after the action of the acid may be considered as siliceous; and it must be separated, and its weight ascertained, after washing and drying in the usual manner.

SOIL.

The alumine and the oxyd of iron and manganese, if they exist, are all dissolved by the sulphuric acid; they may be separated by carbonate of ammonia, which, added to excess, throws down the alumine, and leaves the oxyd of iron in solution, and this substance may be separated from the liquor by boiling, by succinate of ammonia used to excess, which precipitates the oxyd of iron, and by soap-ley, which dissolves the alumina, but not the oxyd of manganese: the weights of the oxyds ascertained after they have been heated to redness, will denote their quantities. Should any magnesia and lime have escaped solution in the muriatic acid, they will be found in the sulphuric acid; this, however, is scarcely ever the case; but the process for detecting them, and ascertaining their quantities, is the same in both instances. The method of analysis by sulphuric acid, is sufficiently precise for all usual experiments; but if very great accuracy be an object, dry carbonate of potash must be employed as the agent, and the residuum of the incineration must be heated red for half an hour, with four times its weight of this substance, in a crucible of silver, or of well-baked porcelain. The mass obtained must be dissolved in muriatic acid, and the solution evaporated till it is nearly solid; distilled water must then be added, by which the oxyd of iron and all the earths, except silex, will be dissolved in combination as muriates. The silex, after the usual process of lixiviation, must be heated red; the other substances may be separated in the same manner as from the muriatic and sulphuric solutions. This process is the one usually employed by chemical philosophers for the analysis of stones.

10. *Mode of discovering soluble, animal, and vegetable Matter, and saline Matter.*—If any saline matter, or soluble, vegetable, or animal matter, is suspected in the soil, it will be found in the water of lixiviation used for separating the sand. This water must be evaporated to dryness in an appropriate dish, at a heat below its boiling point. If the solid matter obtained is of a brown colour, and inflammable, it may be considered as partly vegetable extract. If its smell, when exposed to heat, be strong and fetid, like burnt feathers, it contains animal, mucilaginous, or gelatinous substance; if it be white and transparent, and not destructible by heat, it may be considered as principally saline matter, the nature of which may be known by the proper tests. Nitrate of potash (nitre) or nitrate of lime, is indicated in this saline matter, by its scintillating with burning coal. Sulphate of magnesia may be detected by its bitter taste; and sulphate of potash produces no alteration in solution of carbonate of ammonia, but precipitates solution of muriate of barytes.

11. *Mode of detecting Sulphate of Lime (Gypsum) and Phosphate of Lime in Soils.*—Should sulphate or phosphate of lime be suspected in the entire soil, the detection of them requires a particular process upon it. A given weight of it, 400 grains for instance, must be heated red for half an hour in a crucible, mixed with one-third of powdered charcoal. The mixture must be boiled for a quarter of an hour, in half a pint of water, and the fluid collected through the filter, and exposed for some days to the atmosphere in an open vessel. If any soluble quantity of sulphate of lime (gypsum) existed in the soil, a white precipitate will gradually form in the fluid, and the weight of it will indicate the proportion. Phosphate of lime, if any exist, may be separated from the soil after the process for gypsum. Muriatic acid must be digested upon the soil, in quantity more than sufficient to saturate the soluble earths, the solution must be evaporated, and water poured upon the solid matter. This fluid will dissolve the compounds of earths with the

muriatic acid, and leave the phosphate of lime untouched. It would not, the writer says, fall within his limits to detail any processes for the detection of substances which may be accidentally mixed with the matters of soils. Metallic oxyds and earths of other kinds are, now and then, found in them, but these in too minute quantities to bear any relation to fertility or barrenness, and the search for them would make the analysis much more complicated without rendering it more useful.

12. *Statement of Results and Products.*—When the examination of a soil is completed, the products should be classed, and their quantities added together; and if they nearly equal the original quantity of soil, the analysis may be considered as accurate. It must, however, be noticed, that when phosphate or sulphate of lime are discovered by the independent process just stated, a correction must be made for the general process, by subtracting a sum equal to their weight from the quantity of carbonate of lime obtained by precipitation from the muriatic acid. In arranging the products, the form should be in the order of the experiments by which they were obtained. Thus, 400 grains of a good siliceous sandy soil may be supposed to contain, and have been actually found to contain as follows:

	Grains.
Of water of absorption - - -	18 to 19
Of loose stones and gravel, principally siliceous, -	42 53
Of undecomposed vegetable fibres - - -	10 14
Of fine siliceous sand - - -	200 212
	270 298

Of minutely divided matter separated by filtration, and consisting of

	Grains.
Carbonate of lime - - -	19 to 25
Carbonate of magnesia - - -	3 4
Matter destructible by heat, principally vegetable, -	15 10
Silex - - -	21 40
Alumine - - -	13 32
Oxyd of iron - - -	5 4
Soluble matter, principally sulphate of potash, } common salt, and vegetable extract, - }	3 5
Gypsum - - -	2 3
Phosphate of lime - - -	0 2
	81 125
	298 270

Amount of all the products in the different cases	379 395
Loss - - -	21 5

In one of these instances the loss is supposed small; but in general, in actual experiments, it will be found much greater, as seen in the other, in consequence of the difficulty of collecting the whole quantities of the different precipitates, and the presence of more moisture than is accounted for in the water of absorption, and the loss of it in the different processes. But when it is within thirty or four hundred grains, there is no reason to suspect any want of due precision in the processes.

13. *This general Method of Analysis may in many Cases be much simplified.*—When the experimenter is become acquainted with the use of the different instruments, the properties of the re-agents, and the relation between the external and chemical qualities of soils, he will seldom find it necessary to perform, in any one case, all the processes that have been described. When his soil, for instance, contains no notable propor-

proportion of calcareous matter, the action of the muriatic acid, 7, may be omitted. In examining peat soils, he will principally have to attend to the operation by fire and air, 8; and in the analysis of chalks and loams, he will often be able to admit the experiment by sulphuric acid, 9. In the first trials that are made by persons unacquainted with chemistry, they must not expect much precision of result. Many difficulties will be met with: but in overcoming them, the most useful kind of practical knowledge will be obtained, and nothing is so instructive in experimental science as the detection of mistakes. The correct analyst ought to be well grounded in chemical information; but perhaps there is no better mode of gaining it than that of attempting original investigations. In pursuing his experiments, he will be continually obliged to learn from books the history of the substances he is employing or acting upon; and his theoretical ideas will be more valuable, in being connected with practical operations, and acquired for the purpose of discovery.

Apparatus for the Analysis of Soils.—The necessary apparatus and other conveniences for effecting the above purposes are different: the first consists of a retort in connection with other vessels, so as to form a peculiar pneumatic apparatus, by which the quantity of elastic fluid that is given out during the action of an acid on calcareous soils may be collected and measured, the bulk of it being ascertained by the amount of the water that is displaced. The different parts of the apparatus are these. A bottle or retort for receiving and containing the soil; another containing the acid, furnished with a stop-cock; a tube connected with a flaccid bladder; a bottle for containing the bladder; and a graduated measure. When this contrivance is used, a given quantity of soil is introduced into the first bottle; the second is filled with muriatic acid, diluted with an equal quantity of water, and the stop-cock being closed, is connected with the upper orifice of the first bottle, which is ground to receive it. The tube connected with the flaccid bladder is introduced into the lower orifice of the same bottle, and the bladder, in its flaccid state, placed into the bottle for containing it, which is filled with water. The graduated measure is put under the tube of the bottle for containing the bladder. When the stop-cock of the second bottle is turned, the acid flows into the first, and acts upon the soil; the elastic fluid which is generated passes through the tube connected with the flaccid bladder into the bladder, and displaces a quantity of water in the bottle for containing the bladder equal to it in bulk; and this water flows through the tube of the last bottle into the graduated measure; and gives by its volume the indication of the proportion of carbonic acid disengaged from the soil; for every ounce measure of which two grains of carbonate of lime may be estimated or allowed, as already suggested.

The other things are, an Argand's lamp and stand; funnels for the purpose of filtering; and bottles for containing the different re-agents, as previously noticed.

Another method of deciding in regard to the nature, properties, and qualities of soils, but which is far inferior to that of chemical analysis, though most frequently had recourse to in purchasing of land, is that of attending to the growth and colour of the vegetables which grow upon or cover it; but it requires a sound judgment, much experience, and a correct eye in the execution.

It is customary, also, for farmers to have recourse to other marks in forming their judgments of soils, such as their appearances or colours, and their adhesion, tenacity, or looseness and friability. Thus, the hazel-brown shews a valuable sort of loamy soil, and the reddish sandy mould a good one of the lighter kind. The wetness of lands should like-

wise be well considered, so far as it is connected with the nature of the soil. From the full consideration of all these different circumstances, with a competent experience, a tolerably correct decision may in general be formed in respect to the nature of land. See FARM.

Sir Humphrey Davy, in his "Elements of Agricultural Chemistry," considers it as a vain labour to attempt to class soils with scientific accuracy. He thinks, too, that the distinctions at present adopted by farmers are quite sufficient for the purposes of agriculture; especially if some degree of precision be had recourse to in the application of the terms. The term sandy, he thus conceives, should never be applied to any soil that does not contain at least seven-eighths of sand; sandy soils that effervesce with acids, should be distinguished by the name of calcareous sandy soil, to distinguish them from those that are siliceous. The term clayey soil should not be made use of to any land which contains less than one-sixth of impalpable earthy matter, not considerably effervescing with acids: the word loam should be limited to soils containing at least one-third of impalpable earthy matter, copiously effervescing with acids. A soil to be considered as peaty, should contain at least one-half of vegetable earthy matter. And that, in cases when the earthy part of a soil obviously consists of the decomposed matter of one particular sort of rock, a name derived from the rock may with propriety, it is supposed, be given to it. In this way it is imagined, that if a fine red earth be found immediately above decomposing basalt, it may be denominated basaltic soil. If fragments of quartz and mica be found abundant in the materials of the soil, as is often the case, it may be called granitic soil; and the same thing may be done in a great number of other similar cases.

It is evident, that the greater precision and correctness there are in this business, the greater will be the advantages of the cultivators of the land or soil.

Division of Soils.

Kinds.

1. Clayey,
2. Loamy,
3. Chalky,
4. Gravelly,
5. Sandy,
6. Peaty or mossy,
7. Boggy and heathy, or
8. Moory,

However, these several divisions must evidently be capable of being subdivided under various other heads, according to the differences in the constituent ingredients.

Clayey Soils.—It may be remarked, that as clay is seldom found in any thing near a state of purity in soils, it is plain that there must be much difference in the soils in which it is the chief constituent principle, according to the proportion and nature of the admixture that has taken place. These soils are mostly found to contain an intermixture of different earthy materials, with various animal, vegetable, and mineral substances, and often blended with considerable quantities of siliceous and sandy matters. It has been observed, in a late practical work, on the authority of Dr. Anderson, that it is upon this account that the clayey soils of some districts are so abundantly fruitful and productive, while those of others are insuperably sterile and refractory. Farmers, or those engaged in cultivating land, for the most part being only acquainted or conversant with earth or mould, as it offers itself to their attention in the gross or whole, have not, he thinks, been led to remark the astonishing diversity that takes place in respect to the properties of clays and other

other bodies that are united with them as primitive and constituent parts of soils, in their original and native states; but having found that they all agreed in possessing the property of imbibing and retaining moisture, and thereby of becoming soft and ductile, have, probably too hastily, concluded them to have in some measure a similarity in their other qualities. In this way erroneous notions have frequently, he supposes, been engendered respecting soils in which these substances abound. For it is well ascertained, from the use of clays in slates of greater purity, that there are essential differences in their qualities. There are some sorts, as that which is denominated fuller's-earth, and several of the soft boles that have the cohesive property in but a very slight degree; while others, such as those which are termed *tills*, are so extremely tenacious and viscid, as to be capable of being drawn out into threads: and there are still others, which, from their softness, and property of imbibing water readily, are capable of being cut with great facility by any sharp instrument; while some other sorts are so firm, hard, and compact, as scarcely to admit of being softened by means of water. The clays which are employed for making the finest porcelain, and those used in the composition of the more coarse wares, are only to be met with in particular situations and districts. This fully shews that much diversity must exist in the nature of soils of this description, and which are perhaps far from being yet fully understood or ascertained. But, besides soils of this sort differing in these respects, they have an equal diversity in their appearances or colours, and their textures; being found in the state of nature of very different colours, as red, white, blue, and yellow, and of very different degrees of compactness or density; in some cases readily admitting the intermixture of other matters to improve them; while in others they are highly refractory in this respect, being with very great difficulty made to unite with them. It is plain, therefore, that in the first of these varieties of clayey soils, the proportion of siliceous or sandy material must be considerably larger than in the latter, in relation to that of the clayey part. But notwithstanding the above, all these descriptions of soils are found to possess some degree or other of the stiff or heavy quality, according to which, with proper attention to their other circumstances, their cultivation and improvement must be conducted and carried on.

The chemical analysis of different sorts of clays, executed by the late ingenious Mr. Somerville, and detailed in his valuable Survey of East Lothian, serves to place the nature of such soils in a clear point of view.

The intelligent writer concludes, that the experiments which he has described seem to prove, that the principal constituent parts of fertile clays are alkaline salts, calcareous earth, and oil, together with a very small proportion of iron. In the strongest and most retentive clays, the proportion of oil is greater, and that of alkaline salt and calcareous earth less, than in such as approach nearer to the nature of loam; except in the experiments, when the clay was taken from the top of a lime-rock, in which it was found to contain less oil than any of the others, and more calcareous earth than either loam or any of the other clays: it differs further in containing no iron. And it is supposed that *tills* (*i. e.* a name given in East Lothian to such of the thin clays as are blue, yellow, and red coloured, and, at the same time, barren) contain the same principles as other clays, with the exception of calcareous earth, of which they appear to be entirely destitute; in place of which, they contain a very great proportion of iron, which seems to be the principal cause of their barrenness; and, according as they contain more or less of it, they are more or less sterile.

But in whatever manner these soils may be constituted, they invariably require greater power, labour, and attention, to bring them into a condition proper for the purposes of the farmer, than those of most other sorts. They are, in fact, naturally sterile, from their adhering together in masses; unless where the summer is so divided between rain and sun-shine, that they are kept in a medium between drought and wetness, a circumstance that rarely happens in this uncertain climate. Where the seasons are wet, the plants growing on such soils are inundated; the closeness of the clay not admitting the water to soak into the ground: and in a dry season the ground becomes so solid, that the roots of plants cannot penetrate or spread themselves in it. A tolerably accurate idea of the fertility or barrenness of clayey soils may be obtained, by regarding the appearance of the different plants, as they vegetate: if they appear lively and vigorous, a favourable opinion may be drawn; the reverse, of course, follows, if they appear languid, unhealthy, and stunted in their growth.

However, the clayey soils are thought to contain more of the food of plants than almost any other; as, without much alteration, such lands will produce good crops of grass, provided care be taken not to feed them too closely, nor to admit cattle into them in the spring. In order, however, to bring them into tillage, it is necessary that such soils should be altered by the admixture of such substances as tend to open the soil, and to break the cohesion of its particles, and which supply vegetable matter in many cases. When once these objects are accomplished, the land will become highly valuable, retaining manure excellently, and never returning to its former state of barrenness. These sorts of soils are consequently capable of much improvement, by the judicious application of substances and manures of suitable kinds, and a proper course of tillage husbandry. And in regard to the former, pounded limestone, gravel, sand, and calcareous marl, are the most useful articles in the view of altering the texture; and the best season for laying them on is in the beginning of the year, as it is only during winter, while the surface is frozen, that teams can stir upon them. Where those fossil substances cannot be procured, and the vegetable principle is deficient, a mixture of dung and sand, especially that from the sea-shores, will contribute greatly to fertilize the ground. But the application of lime alone has, in many instances, been attended with great advantage; though some farmers disapprove of it, on account of its being apt to cake, and not mixing intimately with the soil. However, a variety of other substances may likewise be employed, in cases where a deficiency of those fossils exist, such as composts of chalk and dung, tanners' bark, sea-mud, and other materials that promote a strong fermentation: and it has been found by experience, that chalk and these together not only enrich the soil, but also make it produce earlier crops than it did before. The chalk, indeed, thus laid upon the land at length subsides, settles as deep as the plough goes, and is then of no further value in opening the land; but it may be recovered and brought up again to the surface, by ploughing somewhat deeper than ordinary, after which it will produce its former good effects. Gravel from neighbouring soils may also be carted upon clayey soils, to which may be added sea or pit-coal ashes, dust from saw-pits, chips, and rubbish from the back yards of houses, straw, and stubble, rotten wood, burnt clay, peat ashes, and perhaps *gypsum*, or plaster of Paris in some cases. This last substance, as well as those of lime and other calcareous matters, may also be found useful in such soils of this sort as have a sour tendency, by neutralizing and correcting such acidity, by which they may

may be rendered more proper for the growth of crops of both the grain and grafs kind.

And it has been observed in the third volume of the Farmer's Magazine, that the thinner kinds of these lands are almost univerfally poor: the colder and more unkindly bottoms fuch foils are found upon muft naturally render them fo. And that fuch land is badly adapted to bear much fatigue of the plough, either in winter or fummer: that being the cafe, neither autumn nor late fpring ploughing can be depended on by the farmers; the land being fo delicate of itfelf, it cannot refift the alternate froft and rain in winter; and if it happen to be a wet feafon before feed-time, the profpect of a crop muft be very unpromifing; and by the latter, if drought come on, it cannot fail of penetrating to the bottom of the furrow; in which cafe, the grain caft upon it muft remain deftitute of nourifhment: therefore, the moft proper feafon for ploughing fuch land is February, and the beginning of March, when the weather is dry. And further, that the ftronger forts baffle the operation of the plough more than any other it encounters. The only friend that co-operates with it, in fubduing fuch foils, is ftrong liming: without doubt, winter froft is alfo of much benefit; on which account, the farmer is often induced to plough fuch land early. But it ought to be remembered, that although falutary effects may be produced by early ploughing, when there happens to be much froft; yet very pernicious effects muft follow, when the winter turns out to be very wet: for it is generally understood that clayey foils, for the moft part, lie upon a retentive bottom of the fame nature; therefore, all the water that falls upon them muft eafily penetrate to the bottom, through the feams between the furrows: and as the fubfoil, or bottom of the furrow, will be left with a fmall bank on the land-fide of the coulter cut together, with the under arafe of the back part of the furrow refting upon it, the water muft be prevented from running to the drain-furrow, which will prove very pernicious and hurtful to the foil, being too cold at the bottom, in its beft ftate. It may perhaps be faid, that the fame danger will be incurred, at whatever period the ploughing is performed; but there is a material difference between water ftagnating in the bottom of the furrows for four or five months, and when it only does fo for as many weeks: therefore, wherever autumn or early winter ploughing is praftifed on fuch foils, that of fummer fallow will alfo, he thinks, be often neceffary.

It may be noticed, that the moft proper forts of crops, in the firft fort, are peafe and oats; and where compolls can be had, and applied to the fward, fummer fallow will be beneficial; followed by wheat and artificial graffes: and in the latter, cabbages, wheat, beans, peafe, and grafs-feeds for both hay and palture. See *CLAYEY Land*.

Almost every one of the above modes of improving and bettering the qualities of clayey foils are praftifed with much advantage and fuccefs, in one or other of the different places throughout the country where they are met with. In the northern parts, however, where the ufe of lime on thefe forts of foils, efppecially the better cultivated kinds of them, is more had recourfe to than in the fouthern, they not uncommonly apply farm-yard manure the fame feafon in which the land is limed, though not, by any means, in combination with it; as by this praftice the lime is believed to act more powerfully, as well as more effectually, and with far greater expedition, than when it is employed in the manner of compoft, or mixture with earthy matters. It has been fully fhewn that lime, in its active ftate, has great power in promoting the folution and decay of all vegetable matters in foils, and, of courfe, of greatly increafing the

proportion of that fort of material in them. In this way its readinefs in producing this fort of matter in a large quantity, when applied to foils which contain a confiderable portion of vegetable materials, is eafily explained. And the powers of improving different kinds of clayey foils, in thefe methods, may be very much aided and affifted by well directed modes of ftirring and tilling fuch lands; as where the ploughings, harrowings, and other proceffes on them, efppecially in the more ftiff and retentive kinds, are frequent, and made at feafons of the year in which they are neither too dry and cloddy, nor too wet and poachy, fo that they may be well broken down and reduced in their parts, and fully expofed to the influence of the atmosphere. In thefe ways they are enabled to acquire a high degree of pulverization and finenefs in their particles, by which the growth of plants upon them is greatly forwarded, and rendered more perfect. The feed is here to be covered in, for the moft part, in a complete manner; the previous ploughings having been made to fuitable depths, as the circumftances of the lands may direct. On the thinner forts, where fprings are apt to rife, they fhould have lefs depth than in other cafes. The tools and teams employed in working them fhould be ftrong, and fo attached as to do as little injury by poaching as poffible; fuch feafons as are neither too moift nor too dry being, in all cafes, chofen for the purpofe.

Soils of this nature prevail very greatly in many diftricts of the kingdom; and though they are improved, and brought into proper order for cultivation, with great difficulty, labour, and expence, they commonly anfwer very well in the end, by affording a long continued and very abundant produce.

2. *Loamy Soils*.—It is evident that loam, in its natural ftate, is a fort of earthy material, more compact than chalk, but lefs cohesive than clay. In thefe foils there is likewise much variety; fome being ftiff and compact; while others are more open, loofe, and porous: hence we have heavy, ftiff, and light loams. The materials of which thefe foils are chiefly compofed are thofe of the clayey, chalky, fandy, and gravelly kinds; on which account writers on husbandry have denominated them clayey loams, chalky loams, fandy loams, and gravelly loams; and fometimes, where a fmall portion of the oxyd or calx of iron is found mixed with the loamy material, they are termed *tilly* loams. The firft, according to Kirwan, denotes a compound foil, moderately cohesive, in which the argillaceous ingredient predominates. Its cohesion is, then, greater than that of any other loam, but lefs than that of pure clay. The other ingredient is a coarfe fand, with or without a fmall mixture of the calcareous ingredient. It is this which farmers generally call ftrong, ftiff, cold, and heavy loam, in proportion as the clay abounds with it. And the fecond indicates a loam formed of clay, coarfe fand, and chalk; in which, however, the calcareous ingredient or chalk much predominates. It is lefs cohesive than clayey loams.

The third fort denotes a loam in which fand predominates: it is lefs coherent than either of the above-mentioned. Sand, partly coarfe and partly fine, forms from 80 to 90 *per cent.* of this compound. The fourth differs from the above only in containing a larger mixture of coarfe fand, or pebbles. This and the two laft are generally called by farmers light or hungry foils; particularly when they have but little depth. The fifth is generally of a dark brown or reddifh colour, and much harder than any of the preceding: it confifts of clay and the calces of iron, more or lefs intimately mixed. It may be diftinguifhed not only by its colour, but alfo by its fuperior weight; it fometimes effervesces with acids, and fometimes not; when it does,
much

much of the iron part may be separated, by pouring it, when well dried, into spirit of salt; from which the iron may afterwards be separated by alkalis or chalk. And akin to this are certain vitriolic soils, which, when steeped in water, impart to it the power of reddening syrup of violets. These are generally of a blue colour, but redden when heated.

Further, it has been remarked by a late writer, that in proportion as the clayey principle disappears, they recede from soils of that kind, and that of course the nearer the quality of the clayey matter comes to that of the others, the stronger and heavier the loamy soils must be. And that the differences in the lightness and friability of the soils of this class, in a great measure, depend on the relative proportions of the other ingredients. Where the calcareous ingredient greatly exceeds those of the sandy or gravelly kinds, they are neither so light nor so pulverizable as where they are nearly equal, or where the sandy or gravelly matters considerably predominate over it. In the latter case, indeed, such soils are formed as have been denominated by practical farmers light and hungry, especially where the earthy bed or stratum thus produced is but of little depth, and rests on a gravelly or flinty bottom or sub-soil. It is also added, that the variety in the colours of soils of the loamy kind, seems, in some instances, to be produced by the union or mixture of metallic substances in greater or less proportions, and in more close or more lax states of combination with them; in others, by the prevalence of acid impregnations. The colour in the first case is for the most part reddish, approaching to brown; in the latter it is commonly blueish, changing by heat to a slight red. But these are not, he supposes, the only causes that influence the colour of these soils; they are much altered in their appearances, as well as other qualities, by the different proportions of vegetable or animal matter which they contain, and the different states of decomposition and decay to which they have been carried by length of time, cultivation, and other means. In situations, it is said, where this sort of soil has been but little disturbed, and consequently little changed by the artificial additions of either animal or vegetable substances, and those which it naturally contained not having advanced to the stage of perfect solution and decay, it is generally found of a light brown or hazel colour; but where much culture has been employed for a length of time, and large applications of animal and vegetable matters frequently made, the natural and artificial materials of these kinds, having proceeded more nearly to the state of perfect dissolution and destruction, it has an appearance that approaches to that of black. And it is added, that from these various circumstances, the properties of the soils are likewise considerably altered and affected. Such soils of this kind as are met with in extensive tracts on the borders of the sea, and of large rivers communicating with it, are generally rich and fertile, being mostly composed of a fine sort of sand, calcareous matter in a high state of tenuity from the attrition or rubbing down of different kinds of shells and other marine productions, and a rich matter proceeding from the dissolution of various luxuriant sea plants, and innumerable sorts of animal exuviae. These alluvial materials being all gradually deposited and incorporated with the natural loamy earth of the situations in which they are found.

There are soils of this sort, in particular situations near the sea-coasts, which are extremely rich, being a great deal constituted or composed of layers of oyster and cockle-shells, in combination with their earthy matters, and much impregnated with marine salt from the overflowings of the sea, which seems to have been highly beneficial to them, when

acted upon, for some length of time, by the air of the atmosphere, in the production of grain as well as other crops. In these cases, this saline quality would appear to be entangled in a peculiar sort of loamy substance, very different from any which are met with in upland situations. The richest loamy soils in such places are mostly composed, in a great measure, of sand in mixture with a portion of clay, and are, from this quantity of sand, very friable in their nature. But with the soils in these particular cases, it is very different; as whatever degree of friability they may possess, seems to arise from the fermentative power, which is caused by the action of the atmosphere on substances that abound with mucilaginous matters. They fall, it is said, when exposed to the changes of the weather, into dies, and are more like the crystallized forms of mud drying in the sun, than the crumbling looseness of common loams. There is very little appearance of any sand in them; the particles of which they are composed are so very fine, that it would be readily imagined, they would easily become an impalpable powder; but, on the contrary, they are capable of such adhesion, that a clod will often become very hard. Consequently they appear to be composed of clay, very fine sand, a mucilaginous principle which ferments with rain and warmth, and the saline quality which is derived from their origin and peculiarity of situation. When crumbled in the hand, they yield a strong scent, so that the volatile alkali would probably be discovered by chemical trials, it is thought, in them. Soils of this loamy kind are met with in Foulness island, in Essex, and some other similar situations. Their natural fertility is often so very great, that the farmers are but little attentive to manure; nor is it commonly ventured for any sort of grain, as it throws up too much straw, without increasing the quantity of corn. It might, however, probably be applied for beans, or cabbages, where they were the previous crops, with much advantage.

This sort of excellent loam is supposed utterly incapable of being formed or attained by any kind of artificial means: the great elaboratory of nature in this, as in so many other cases, leaves, it is thought, the utmost skill of the chemical farmer at a vast distance.

The chemical analysis of this sort of soil, as given in the work already mentioned, by Mr. Somerville, may shew still more fully the properties which are possessed by this kind of land.

From the experiments of this ingenious writer it would appear, that the principal constituent parts of the different kinds of loam, upon which they were tried, are vegetable and calcareous earths, oil, alkaline salts, and an inconsiderable quantity of iron. The deep black loams seem to contain considerably more oil than any of the other two, but less alkali and calcareous earth; which, in some measure, accounts for the inactive nature of some soils of that description, which, by no means, yield crops equal to what might be expected from their appearance. The hazel-coloured loam contains less oil than the black, but a greater proportion of alkaline salts and calcareous earth; owing to which, all the loams of that description in East Lothian are more active, and produce better crops than the former. The light loams, from the circumstance of their containing less oily and more alkaline and calcareous matter, are the most active, and are commonly termed *barp* lands, by the farmers in that district.

Further, these soils being, in general, less tenacious or more friable and mellow than clays, are capable of being more easily improved with less expence and labour of team, and also at any season of the year. The manure proper for such soils varies according to their relative degree of fertility,

tility, and the greater or less proportion of acidity and of argillaceous and calcareous matter they contain. Those loams which are contiguous to the banks of rivers, or the sea-coast, are generally admitted, as has been seen, to be fertile, as to require little additional aid from manure; but for the more heavy and adhesive kinds, a compost of effete lime and dung, or lime in combination with pulverized or ground bones and blood, or other animal recrements, and such terrene substances as contain large quantities of sand, may be beneficially applied in such quantities as the tenacity or poverty of the land may require. Where the argillaceous principle abounds, lime alone may be spread on the soil, in order to counteract the acidity prevalent in such soils; in the contrary case, or where there is an abundance of sand, gravelly, or chalky particles duly mixed with the loams, well rotted dung, vegetable manures of different kinds, and the mud or deposition procured from stagnant waters, may be spread to the greatest advantage; and in case the loam be too friable or light, a quantity of clayey loam may be carried on the land, sufficient to impart a proper degree of cohesion or tenacity.

In the county of Oxford they find lime useful on the yellow loams which are wet and stand in need of draining. They are rarely soils of much natural fertility; but lime makes them very productive in oats, and prepares them for future wheat crops; when employed in the quantity of from twenty to thirty quarters *per* acre. It answers greatly, likewise, on the red loamy sand lands in the proportion of from fifteen to twenty-five quarters on the acre.

In Suffex, wherever the land or soil tends to a reddish loam, or inclines to be sandy, they have recourse to marle, which is of a soapy nature, with great success. They employ it in the quantity of from ten to twenty waggon-loads on the acre, which is from eight hundred to sixteen hundred bushels; applying it in the autumnal or winter seasons.

Where a soil deficient in calcareous matter contains much *soluble* vegetable manure, as is the case in some soils of this kind, the application of quicklime to them should always, according to the writer of the work on Agricultural Chemistry, be avoided, as it either tends to decompose the soluble matters by uniting to their carbon and oxygen, so as to become mild lime, or it combines with the soluble matters themselves, and forms compounds having less attraction for water than the pure vegetable substance. And the case is the same in regard to most animal manures, when in such soils; but the operation of the lime is different in different cases, and depends upon the nature of the animal matter. With oily matters lime forms a kind of insoluble soap, and then gradually decomposes them by separating from them oxygen and carbon. It combines likewise with the animal acids, and probably, it is said, assists their decomposition by abstracting carbonaceous matter from them combined with oxygen; and consequently it must render them less nutritive. It tends also to diminish the nutritive powers of albumen from the same causes; and always destroys, to a certain extent, the efficacy of animal manures, either by combining with certain of their elements, or by giving them new arrangements. Lime should, of course, never be applied with animal manures to soils, unless they are too rich, or for the purpose of preventing noxious effluvia. It is injurious when applied in mixture with any common dung to soils, and tends to render the extractive matter of the dung insoluble. But lime is constantly efficacious in all those cases in which fermentation is useful to produce nutriment from vegetable substances in soils.

All the soils of this nature are capable of affording almost

all sorts of crops, both those of the grain and root kind, as well as those of the pulse, hemp, and flax sort, as may be seen under these different kinds of crops.

The modes of cropping in some districts follow, in some measure, the qualities of the loams, whether they be strong, fertile, impalpable, sandy, or of any other kinds or descriptions. The medium fertile loams are probably, however, on the whole, the most suited to every sort of farming purpose.

3. *Chalky Soils.*—All these are soils, which are found to occupy very extensive tracts in many of the southern districts of the kingdom, as well as in some of the more northern; and, like those which have been already noticed, differ very materially both from the diversity of the calcareous material which they contain, its proportion, and the other matters that are intermixed and blended with it, as well as the thickness of the earthy bed on which it rests, and the nature of the inferior stratum on which the whole is deposited. It has been stated by an useful practical writer, that matter of the calcareous kind is contained in many different stony substances, besides that of chalk, as marble, limestone, coral, and shells of different kinds; and in states of union with other materials, such as sand, the different simple earthy bodies, in different proportions, and in some instances with iron and magnesia. Its capability or power of imbibing and retaining moisture is considerable, though not so great as that of clay. It burns to lime by proper degrees of heat, and absorbs carbonic acid gas or fixed air in different proportions from the atmosphere, and returns again to the state of chalk or effete calcareous matter. It is found of very different degrees of hardness and friability, as well as of different states of fineness or pulverization, in different soils of the class to which it belongs. It varies also greatly in its effects in respect to vegetation; from the different matters that may happen to be combined with it in its primitive or original state. And it is further stated, that it has long been known to the practical farmer, that some sorts of lime or calcareous matter may be employed in large proportions; while others cannot be used, except in very small quantities, without doing very considerable injury to the soil with which they are incorporated. But that the long unexplored cause of this diversity of effect in different limes, or calcareous matters, seems lately to have been placed in a more clear and satisfactory point of view, by the experimental attempts of an ingenious philosopher, Mr. Tennant, who has found by repeated experiments, that that sort of lime which is the most friendly to vegetation, consists entirely of calcareous earth, and quickly absorbs a large portion of carbonic acid gas or fixed air from the atmosphere; while that which is injurious and unfriendly to the growth of plants, contains only three parts of pure calcareous earth, the other two consisting of magnesia; and that it absorbs comparatively but an extremely small portion of carbonic acid gas or fixed air from the surrounding atmosphere. It was also found, that this kind of mixture of calcareous matter was very slow in acquiring the power of supporting vegetation, even after it had been converted into lime, and remained for a considerable length of time in the state of mortar. And that the limestone in which there is a mixture of magnesia, is much harder, and dissolves considerably more slowly in acids, than that which is purely calcareous. It is likewise supposed, that the crystallized structure commonly observed in the magnesian limestone indicates, that it has not been formed by the accidental conjunction of the two earths, but constituted by their chemical union. The difficulty with which it is dissolved by

means of acids, may also, it is conceived, in some measure, depend on the attraction of its different component particles to each other. It is a sort of limestone, which is found to extend itself over very large districts in the midland parts of the island, as well as in the more northern counties, as is obvious from the practical distinctions of *mild* and *hot* limes, which are in common use, as noticed by doctor Fenwick, in his excellent Essay on Calcareous Manures.

It has indeed been suggested, that these interesting facts not only shew, that whatever sameness there may be in the nature of calcareous matter, when in its pure and unadulterated state, but that, as met with in soils, and different substances of the calcareous kinds, it has considerable diversity, and when in union with magnesia, it is in a high degree prejudicial to the growth of vegetables. Later trials have, however, rendered this last supposition somewhat doubtful; therefore, until further experiments have more completely cleared up the matter, the farmer should proceed with caution in the use of such materials. But though magnesian lime or earth in its caustic state may be injurious to vegetation, such lime, in ordinary circumstances, is not unfrequently made use of in moderate quantities upon soils of the fertile kind, in the counties of Leicester, Derby, and York, with good effect, and is capable of being employed in larger portions on soils containing more full supplies of vegetable matter. Magnesia, when combined with carbonic acid gas, seems not, it is said, to be hurtful to the growth of plants, and in soils rich in manure, it is soon supplied with this principle, from the decomposition of that substance.

In explanation of the above, sir H. Davy has stated, that magnesia has a much weaker attraction for carbonic acid than lime, and will remain in the state of caustic or calcined magnesia for many months, though exposed to the air; and that as long as any caustic lime remains, the magnesia cannot be combined with carbonic acid, for lime instantly attracts carbonic acid from it. When a magnesian limestone is burnt, the magnesia is deprived of carbonic acid much sooner than the lime; and if there be not much vegetable or animal matter in the soil to supply by its decomposition carbonic acid, the magnesia will remain for a long while in the caustic state; and in such, acts as a poison to certain vegetables. And that more magnesian lime may be used upon rich soils, than those of other kinds, seems to be owing to the circumstance, that the decomposition of the manure in them supplies carbonic acid. And magnesia, when mild or fully combined with carbonic acid, seems to be constantly an useful constituent part of soils. Carbonate of magnesia, produced by boiling the solution of magnesia in supercarbonate of potassa, has been thrown over grass, and upon growing wheat and barley, so as to render the surface white, without injuring the vegetation in the smallest degree, by the same experimenter. Some most fertile districts are also said to contain mild magnesian earth, as the Lizard, in Cornwall.

This explanation has been somewhat confirmed by mixing and using four portions of the same sort of soil in this manner: with one-twentieth of its weight of caustic magnesia, with another the same quantity of magnesia and a proportion of fat decomposing peat, one-fourth of the weight of the soil; one portion was left in its natural state, and one mixed with peat without magnesia. They were made towards the end of the year, and sown in the early spring the next, all of them with barley; which grew very well, it is said, in the pure soil; but better in the soil containing the peat and magnesia; and nearly as well in the soil with the

peat alone; but in the soil mixed with magnesia alone, it rose very feebly, and looked yellow and sickly. The repetition of this trial was attended with similar results; and it was found, that the magnesia in the soil mixed with peat became strongly effervescent, while the portion in the unmixed soil gave carbonic acid in much smaller quantities. In the one case, it is supposed, the magnesia had assisted in the formation of manure, and had become mild; in the other case it had acted as a poison on the plants.

It has also been found, that matter of the calcareous kind, whether effete or in the state of carbonate, or in the more active one of causticity, as quicklime, seems ultimately to promote the resolution and destruction of all vegetable and animal substances; but that in the latter state, it acts with much greater violence on these materials, destroying their organization, and dissipating their principles more quickly, as well as robbing them more completely of the carbonic acid gas or fixed air, which is so essential; while in the former it operates with great mildness, and only aids the resolution of those substances, by gently promoting the process of putrefaction or decay.

It must be obvious, that in them the proportions of clayey, loamy, and gravelly ingredients, in combination with the calcareous matters of these soils, are materially different in different districts: where the clayey and loamy are comparatively in large quantities, the heavier kinds of chalky soils are met with; but where the sandy or gravelly are prevalent, the lighter ones. Material differences also arise from the earthy matter with which the calcareous substance is blended in the state of soil, as where the quantity of this is small, and not reduced into any perfect state of mould, the soil is poor and thin; but where the thickness of this superficial bed or layer is considerable, and the animal, vegetable, or other substances of which it is constituted, have proceeded to a more complete stage of decomposition, the soils are more rich and heavy. Where the state of the sub-soil is of a compact nature, and much blended with siliceous or stony matter, or has a mortary hardness, it is less favourable than where it is of a more open, brittle, or mellow powdery nature. From the calcareous material being abundant in these cases, the principal intention is the changing of their textures, and the supplying of vegetable matter to them.

And it is found, that in the thinner or lighter calcareous soils, clay, or clayey marl, and the vegetable recrements deposited and obtained in wet or swampy situations, may be beneficially applied. In those of a contrary or heavier nature, the spreading of sandy or clayey loams, as circumstances may require, on them, will be attended with advantage, as altering their texture; and to these may be added composts of various vegetable and animal substances, farm-yard manure and ashes; besides which great attention is requisite in breaking up these soils at the proper season, as, if this operation be deferred till a dry season, they become so bound or hard, that it will be impossible to work them, until they are softened by rain, without very great expence both of teams and of labour in other ways. Near London, the use of foot and malt-dust has also been found highly beneficial in many cases of these kinds of soils.

Soils of this nature work, and are capable of being improved very differently, according as they are more or less heavy. The light and mouldering chalky lands readily admit of these means of amelioration, while those which are of a more heavy and solid quality, allow of them with considerable difficulty and trouble. Some sorts of crops are in a great measure peculiar to these sorts of soils, as those

of faintfoin, and some others, but they are capable of bearing most kinds in their different qualities and states. See *STONEBRASH Land*.

Soils of this kind, though they have a barren and unpromising appearance, are sometimes very productive.

4. *Gravelly Soils*.—It may be noticed, that in the gravelly materials, which constitute soils of this description, there is much difference in the size of the stony particles, from that of the smallest pea, to that of the egg of a pullet. But when they become of still larger dimensions, they are denominated stony or rocky soils, according as they are in detached or connected masses. But the gravelly beds, of whatever kind, consist in general of siliceous or flinty, or those of the calcareous or chalky kinds, while the rocky and stony substances are of several different qualities. Various other matters are mixed with these, so as to constitute soils of this kind, which have much diversity in different respects. These are principally matters of the loamy or earthy kind, arising from the putrefaction and decay of different animal and vegetable materials. It is also remarked, that the gravelly mixture is sometimes found to approach nearly to the surface, while at others it recedes considerably from it. In Middlesex, Mr. Middleton found, that when the stratum was very near the top, a full crop of yellow blossomed broom covered the ground; if in a state of grass, and when ploughed, an equally full crop of forrel. This was seen in the old inclosures. In some instances springs arise immediately underneath; in others they are at a great depth. The bottom or sub-soil is likewise various; in some cases it is stony and rocky, in others it is clayey, or a rocky gravel, and sometimes sand, &c. And it is added, that the open porous nature of gravelly soils disposes them to admit moisture very readily, as well as to part with it with equal facility; from the latter of which circumstances they are subject to burn, as it is termed, in dry seasons, which is not the case in the heavier or more retentive sort of soils.

It is evident that the differences of these soils must be remedied according to their nature, by the use of different sorts of matters of the marle kind. In cases where the gravel is of the calcareous kind, clay, or clayey loam, may be properly employed; and a mixture of the carbonate of lime, or lime in its effete state, and clay, may be found beneficial; also chalk, as being of the same nature, may be made use of in the same way. For these kinds of gravel, which, from their contiguity to springs, are apt to lie wet in the winter, there is no manure more properly adapted than chalk; which, although it does not abound with vegetable matters in any large proportion, like yard-dung, and some other dressings, is, however, an excellent preparation for them, and will, in some measure, supply the place of such substances. It is found, from its absorbent nature, to have a good effect, not only in counteracting the superabundant moisture of such soils, but in lessening their heat; by which means the disposition to burn in the summer, so inimical to the growth of various crops, and to which all gravels are in some degree liable, is prevented: and in this last view, chalk, though particularly adapted to those of the wet and springy kind, may be applied with success on gravels of almost every denomination, with the prospect of advantage. Where there exists any deficiency in the vegetable and animal earthy materials, it may be properly supplied by dung of the farm-yard kind in its more reduced state, and various other animal excrementitious matters, which may probably be employed with the greatest benefit in the form of composts, with good loamy mould, ashes, the mucilaginous and clayey depositions of rivers and ponds, and other sub-

stances of a similar kind. Several of these materials, and some others of the animal class, are, however, often used separately to the surface of soils of this sort, with the most evident advantage.

Also much benefit may be derived to such lands by a proper alteration of green vegetables, and other crops that are usually grown upon them; as by such means the moisture is more preserved, and the soils more guarded against injury. In the Agricultural Survey of Hertfordshire, Mr. Young speaks of a poor sort of gravelly soil, the characteristics of which are wetness, or spewiness, as the farmer terms it, from many springs; most of which are sulphury, and extremely unfriendly to vegetation, abounding more or less with smooth blue pebbles, which, at various depths, are conglomerated by sulphury clay into plum-pudding stones; in some places so near the surface as to impede the plough, if set but for an inch or two at a greater depth than the old scratchings of bad ploughmen: it is stiff, without a matrix for the roots of plants; and sharp and burning even in the immediate vicinity of springs: it has much sticky clay in the composition, but of a most sterile nature. He hollow-drained many acres; but as he was obliged to employ the pick-axe, the expence was too great; and he found that the ploughing it into high ridges was considerably the best way of draining it. When it has been drained, manures have then a great effect for a time; but such was the voracity of the soil, that the benefit of manuring was soon lost, even when it had been laid down for pasture some years, as a preparation for corn; the best improvement that can, he supposes, be made on it, when cultivated for such a purpose. But it is suggested by Mr. Walker, that this soil is best adapted to wood; for he was surpris'd to see the hedges thriving with great luxuriance on land not worth cultivation.

Lime, in mixture with good mould, has been found useful in Oxfordshire, on hot gravelly land. It does very well alone, but not equal to where it is employed in combination with some sort of earthy material. In the lighter kinds of gravels, the clayey marles are also frequently of very great utility; and in those of the heavier description, the calcareous sort may often be employed with equal benefit. When well mixed up, and blended with different earthy materials, they may both be laid upon gravelly soils with the best effects, in many cases.

By these different means of improving the textures and qualities of these kinds of soils, they have been so much altered and amended in the nature and arrangement of their parts, as to be capable of affording good crops of many different sorts, as well as of enduring the summer heats, without being subject to become too dry or burnt up by them.

5. *Sandy Soils*.—It is stated that these are a description of soils, which seem to have been formed gradually by the reduction of different sorts of hard bodies in nature, particularly those of the calcareous, siliceous, and stony sorts, the particles being brought into different states of fineness, being in some cases extremely minute. They vary equally in their colours in different instances, being sometimes perfectly white, brownish, yellow, and red. The differences in the quantities in which other sorts of matter enter into their compositions, afford considerable variety in their weights, tenacity, and different other properties. In some districts, soils of this sort exist of different kinds, from the lightest species of loam to the naked sand composed entirely of small flints, and in all of them there is a mixture of earth; according to the proportion of which, they are more or less favourable to vegetation.

And it has been remarked by the late Mr. Somerville, that, in East Lothian, the whole of the sandy soil is evidently superinduced, or placed upon the land; the bottom upon which it is laid being uniformly of the same quality with the circumjacent grounds. The origin of this sand, which is accumulated upon several parts of the coast, is owing, it is supposed, to two causes: the first, and that which no doubt has produced the greatest part of it, has been the washing away of many points of land by the sea, by which the coast, formerly very much indented, is now rendered pretty uniform, and brought nearer to a regular figure: the second cause of its formation has arisen from the washing of the soil in the interior, during heavy falls of rain, by which great quantities have been brought from the higher grounds, and either deposited in places where the current has been less rapid, or carried along with the stream to the sea. The last, however, is a rare occurrence, unless in situations where the land declines very rapidly towards the shore. In that county, however, it is evident that the whole of the land upon the coast has arisen from the washing and washing away of different points of land, while that in the interior has been produced by the washing of the rivers. It is remarked by a writer mentioned above, that in cases where the proportions of clayey, loamy, or other earthy substances with which they are mixed, approach nearly to that of the sand, the heavier sorts of sandy soils are formed; but that where these enter only in very small quantities, the light sandy soils are formed; and where they are hardly met with at all, the soil is a loose blowing sand, most commonly of a white or brownish appearance. And it is added, that the portions of vegetable matters, that are intermixed with different soils of the sandy kind, are not less various than those of the clayey and loamy, from which considerable differences of quality are produced. These differences in their textures and compositions also introduce others, which respect their powers of admitting and retaining heat and moisture. The openness and want of adherence in such soils, while they allow of the admission of heat and water more readily, permit them to be carried off with greater ease and expedition: they are, therefore, less permanently benefited by their influence than many of the clover and more adhesive soils.

But as these sorts of soils are chiefly deficient in the calcareous, clayey, loamy, and vegetable materials, the aim of the farmer must be the augmentation of their cohesive property, and the supplying the calcareous and decayed animal and vegetable materials. They cannot, of course, be cultivated with advantage, without the aid of other fossile manures to counteract their poverty, and prevent the continual evaporation of moisture. For this purpose, clay and loam may be beneficially spread on sandy soils, which may likewise be improved by the use of composts of animal and vegetable manure: though, where these cannot be obtained, good mould or earth may be employed with advantage, as also may peaty earth, either alone, or in combination with other matters. It has been observed by Dr. Fordyce, that a less quantity of clay is required in the improvement of light sandy soils, than of sand in the clayey ones; but whether this be a practical rule or not, the thinner and poorer sorts of sandy soils mostly stand in need of a large quantity of clayey matter. And when the calcareous property prevails, clayey marles and clayey loams are most proper; but in cases of its being deficient, calcareous marle and loams may be used with more advantage. This has been sufficiently proved by their application in different districts. A degree of tenacity or firmness may also be imparted to sandy soils, by the treading of sheep, folded upon

them; while they receive much benefit from the dung and urine deposited by those animals.

And it may be noticed, that these different materials are proper for being laid on either alone, or in the state of composts; but marles and clayey substances are mostly applied in the states in which they are found in nature; but the farm-yard dung, and peaty substances, in mixture with other matters.

Further, it has also been stated by the author of "Practical Agriculture," that the light, open, and porous texture of sandy soils renders them much more easily cultivated, and kept in order, than those of the strong and close kinds; and, consequently, the farms where they prevail are generally large: but that, when properly prepared, they are better adapted for the growth of many sorts of crops, such as those of the bulbous and tap-rooted sorts. And they have also another advantage, which is that of pushing forward the crops with more expedition. Whatever inconveniences attend them are mostly such as proceed from the want of a sufficient degree of cohesion among their constituent particles, and solidity of texture. On these accounts, they often counteract the best and most judicious management. The roots of the crops are liable to become naked and exposed, from storms and various other causes; and if grain, to fall down and be lodged so early in the season as to render them of little value.

It has likewise been remarked by the writer of the East Lothian Agricultural Report, that there, within these few years, considerable tracts of this kind of soil, formerly of little value, have been brought under the plough, and made to produce excellent crops of turnips, clover, barley, rye, &c. as may be seen in different parts of the Survey; but the most valuable improvement upon this description of soil has been made by laying it into grass, and treating it with top-dressings of different kinds of soils, which, when liberally applied, have, in not a few instances, changed the appearance, and so much altered its nature, as to render it capable of bearing a succession of valuable crops of grain.

Some think lime the best of all dressings for sandy lands. This is the case, in particular instances, in the county of Oxford. On the fine red sandy soils there, some lay from ten to twenty quarters on the acre; the former quantity very common in mixture with earth and some dung. The benefit thus produced is generally great, lasting many years.

Besides these, vast improvements have been made in a variety of other cases on these soils, by the use of the above methods. Their textures, compositions, and properties, have been so amended and improved, as to make them capable of producing crops of most sorts with advantage.

6. *Peaty or Mossy Soils.*—These kinds of soils are more common in the northern districts and in Ireland, than in the southern parts of the kingdom, though in these latter they occur in a small extent. And they, like other sorts of soils, vary from the nature and proportions of the ingredients of which they are composed. It has been observed, that where the vegetable or peaty material predominates but little over the other substances with which it is mixed and incorporated, the lighter sorts of peaty or mossy soils are formed; but where the other matters bear only a slight proportion to it, the deep and heavy peaty or mossy soils present themselves. In different districts the peaty matter is found of different depths, and of various degrees of density or closeness of texture, probably proceeding from some original differences in the vegetable substances from which it was formed, or the greater advances which it has made to the state of perfect decomposition. The sub-soil
in

in most of the deep mossy districts is of the clayey kind, more or less stiff and heavy, over which the peaty or mossy material is deposited generally in a sort of stratified order; the first layer of which, being commonly not more than ten or twelve inches in thickness, exhibits the appearance of a richish brown earth, arising, in all probability, from the incorporation of the loamy or clayey matters with the peat or vegetable earth lying immediately upon them, and constituting originally, perhaps, the surface of the ground. The layer that succeeds to this is mostly of a dark colour, and of considerable thickness, apparently formed of a great variety of vegetable and other materials in the more perfect stages of resolution or decay, united together by time and other circumstances, with more or less degrees of compactness and solidity. The uppermost stratum, or that which is placed upon this dense peaty matter, is, in general, of a very pale colour, and very light spongy texture, arising possibly from the grasses, leaves, and other vegetable substances of which it is formed, not having attained that state of decay which constitutes the darker sorts of peaty earth. However, in the more superficial peaty soils, little or nothing of this stratified appearance is met with. A coat of peaty earth, differing greatly in thickness, according to the peculiarity of the situations, and other circumstances, is formed by a great length of time from the destruction and decay of successive crops of grasses, leaves, and other substances of different kinds, and deposited upon, and intermixed with, the various harder materials of the soils which happened to be underneath them. It is observed, that by these means much variety is produced in the soils. Where the under strata of earthy matter are tolerably good, and the crops of vegetables large and luxuriant, the better sorts of light peaty soils seem to be predominant; but where the quality of the under strata is indifferent, and the vegetable products scanty, as well as feeble in their growth, the poorer sorts of these soils are formed. And in many districts, this, as well as the sandy soil, being deposited or superinduced, the bottom being uniformly the same as that of the adjoining grounds, in the low flat parts, owes its origin evidently to the stagnation of water; in these places the moss consists of the roots and decayed leaves of aquatic plants, which are found in distinct strata, and of different kinds, according to their depth. But in situations more elevated, and upon the tops of the highest hills, the moss has been formed in some cases merely by the decay of the plants, which, falling down yearly without being entirely rotted, have, in process of time, accumulated and formed the moss there met with; but in the hollows, its formation is owing to the same deposition, with the addition of a great proportion of earth, washed from the sides of the hills during the floods. In some parts of the county of East Lothian, this soil has made considerable progress towards decay, and nearly resembles black rich loam; but in by far the greatest part, the roots and leaves of the different plants concerned in its formation are in a tolerably perfect state, and when freed from moisture, present little else than a collection of these.

Mr. Somerville concludes, from his experiments made upon moss in all the different stages of decay, that the predominant principle in the whole is an acid; and, according as the moss is more or less decayed, the prevalence of this principle is more or less observable. In the experiments upon moss not much decayed, the quantity of acid was greater, and that of the oil and the alkali less, than in any of the other trials; on the contrary, where it was most decayed, it was found to contain the least acid and the greatest proportion of oil and alkaline salts. A knowledge of these circumstances is of considerable importance in agriculture,

for, by observing the progress that moss has made towards decay, a tolerable idea can be formed of the trouble and expence that will be necessary either to bring it into cultivation, or render it useful as a manure.

And it is suggested, that from the same experiments it would appear, that the constituent parts of moss are, 1, an acid; 2, an alkali; 3, oil; 4, vegetable earth; 5, iron. The iron was met with in one instance only, and in that the quantity of acid was greater than in any of the other trials; the nature of the acid was also different, being evidently vitriolic, a thing seldom met with, unless in cases where the moss contains iron, which is certainly the worst of all its principles, and the most difficult to correct. And it is added, that upon comparing the constituent parts of moss with those of the best soils, they are found nearly the same, with the exception of the acid, but in some different proportions. The alkaline principle in some kinds of moss is scarcely equal to what is met with in good loam or clay, while the oil and vegetable earth are much greater; a great proportion of other soils consists of sand, gravel, earth, &c.; but the earthy part of moss consists entirely of a mould formed by the earthy part of decayed vegetables, together with the sediment of water.

From their composition, these soils must of course be extremely retentive of moisture. It has, indeed, been remarked by the earl of Dundonald, that from the rays of the sun and drying winds being exerted during the summer season in carrying off, by means of evaporation, the superabundant moisture in such cases; and heat being known to be abstracted from bodies, and cold generated thereby, effects must be produced highly injurious not only to climate but to vegetation in general, and more particularly to such plants as stand in need of a higher degree of heat, and more nourishment than such soils are capable of supplying. And further, that there can be very little doubt but that these prejudicial effects on the growth of vegetables extend themselves to the more dry lands adjoining such fens or deep mosses. It has also been found, that the surface-stratum of peaty soils, from its being more exposed to the influence and action of the pure air of the atmosphere, is much less soluble than the under strata, consequently in its simple or unmixed state less proper for the purposes of agriculture. From the same cause, too, it becomes less capable of supporting flame, and is therefore improper for the purposes of fuel, in the way of turf or peat.

The different manners in which mossy or peaty soils are formed, have been seen and explained, in some measure, above, and in speaking of the nature and means of cultivating mossy lands. See *Mossy Land*.

Very extensive improvements, in soils of this kind, have lately been made in Lancashire and different counties in the northern parts of the kingdom, as well as in several districts in Ireland. See *TURFY Land*.

It may be remarked, that these sorts of soils stand in need of different methods of management in bringing them to the condition of producing crops. In those of the deeper kinds, the first thing to be done is to draw off, as much as possible, the superabundant moisture, by the cutting of proper drains, and such other means as the nature of the situation, and other circumstances, will admit of. It has been noticed, that in places where water in sufficient quantity can be conveniently made to pass through such mosses, and where the soil underneath is good, much may be effected by floating away the principal part of the mossy substance; but where the mosses are not deep, or the soils under them of a good quality, after the making of proper drains, the best way is, probably, to ridge them in such directions and

modes as are the most effectual in promoting the exit or passage of the stagnant water which they contain. Different materials may then be applied with the intention of improving their textures, and promoting the dissolution of the undecayed parts of the vegetable matters that are contained in them. The first may be accomplished by the application of various gravelly substances, sand and coarse earth; and the latter, especially where there is a large growth of coarse plants, by the use of lime in its caustic state; but where such plants do not so much abound, alkaline substances, chalk, calcareous marl, the shelly kinds of sea-sand, and the carbonate of lime, may be more advantageously made use of. And as shell-marle, chalky substances, rich clays, and limestone gravels, are frequently met with under deep peat mosses, they should be tried for by boring in various parts. Paring and burning is also useful where the quantity of vegetable matters on the surface is considerable, and of the coarse kind; but the method of applying good earthy matter is to be preferred where it can be procured in an easy and cheap manner. And advantages may be gained in promoting the fertility of these soils by cropping with particular sorts of vegetables, as such as have large branching stems, and cover the surface of the ground very much, so as to exclude the action of the air in a great measure upon it.

It is probable, too, that the hot limes, as they are called by farmers, may be laid upon these soils in full proportions with very great advantage in some cases; and that where lands of any kind have been hurt by the too great use and abundance of them, peat will prove a good means of restoring them.

In these different ways very great improvements have been made in peaty and mossy soils, especially where the drains have been formed sufficiently near to each other, and to proper depths for taking away the water in an effectual manner. Great advantage has also been derived by laying the surfaces of such lands over with any sort of heavy earthy matters to the thickness of three or four inches, such, for instance, as the heavy sorts of marle, the scrapings of roads, the heavy mud of rivers and ponds, &c. By these means, where they are intended for grass, a finer kind of herbage is brought up, and where for the purposes of tillage, the surface is well consolidated, and rendered more suitable to the growth of crops of that sort.

7. *Boggy Soils*.—These are also soils that have much of the nature of the preceding, but which differ in some respects from them, being chiefly in low confined situations, and of less depth than the heavier mossy soils, and of more than those of the lighter description of that sort of soil. There are soils of this description frequently met with in Ireland, and occasionally in low meadows and near large ponds or lakes in this country. These soils are gradually formed by the deposition and decay of the different vegetables that grow in such situations as those of the luxuriant aquatic kinds; and the stagnation of much moisture upon them, by which the roots also become destroyed and reduced to the state of earth. They have of course different appearances or colours, according to the state of putrefaction and decay to which the different parts have advanced, and the nature of the other earthy materials with which they are blended; in some cases being of a lightish brown aspect, as where the fibrous and ligneous matters have only undergone a slight change; but where this has been carried to a considerable extent, they are of a dark colour, approaching to black, or of a deep dusky hue. See PEATY and MOSSY Land.

As the great defects in soils of this nature are chiefly those of their being too much charged with moisture, and of too open and porous a texture, the means of bringing them

into a proper condition are obvious. In deep boggy soils, the business of draining should first, when practicable, be resorted to, in order to draw off the excessive moisture. After which, various hard dry earths will be found of great use in improving bogs, such as gravel, chalk, stony matters, sand, shell-marle, &c. as these substances contribute to bind, ameliorate, and warm the soil, while they prevent springs from oozing out and overflowing the surface. Where they are over-run with rushes and similar coarse vegetables, quicklime may be beneficially applied, and paring and burning may be employed, sometimes with advantage. And another useful mode of reclaiming such soils is, by planting on them those vegetables whose spreading roots serve to bind the earth together, and at the same time, in a great measure, exclude the action of the atmosphere upon it. The practice of flooding, also, where a command of water can be obtained, has proved a cheap and efficacious mode of reclaiming them in some instances. Some cases, at least, have occurred where such soils have been brought into a state of cultivation for meadows, with the happiest success, by it, which had failed under contrary methods of management.

In most of these cases, the first means which are necessary, after well ditching and draining the soils or lands, and levelling the imperfections and inequalities on their surfaces, is to apply earthy matters over them. For this purpose, the lumpy earthy parts, or elevations on them, are to be pared off and intimately blended up with lime into composts, which, with other heavy materials of proper earthy kinds, are to be placed and spread out on the lands or soils in an even manner. And afterwards, when the ground or soil becomes firm and solid, with much coarse plants and herbage rising upon it, eating it constantly close down with light neat cattle and sheep, will be very beneficial, especially where such soils or grounds are designed for pastures. When for tillage, there are various other means which may be had recourse to in different circumstances, for rendering them more firm and dry, with great success. See SWAMPY Land.

The management of such soils, in all these different methods, has been productive of great benefit in different instances, and the land, when improved, is commonly of the most valuable kind. See BOG, and SPRING-Draining.

8. *Heathy or Moory Soils*.—These form a class of soils that occupy very extensive tracts in different districts of the kingdom, and which have considerable relation to those of the peaty sort, though they differ in many particulars. In the southern part of the country they are mostly known under the titles of *heathy* or *moory* soils, but in Scotland they have the name of *muir* soils.

It is remarked by Mr. Somerville, in the agricultural Survey just noticed, that these soils, like those of the mossy kinds, owe their origin evidently to the same cause, namely, the decay of the plants that formerly occupied the surface. This muir soil is of two kinds, one of which is black, soft, and porous, and admits moisture in a greater degree than any other soil; it is at the same time covered with stones of a white colour; evidently whinstone bleached with an acid: the parts, when examined, exhibit the appearance commonly met in turning over the ashes formed by the burning of vegetables, where the skeletons of the plants and roots are seen naked, sapless, and destitute of any of the useful properties they once contained. It is difficult to form an opinion of the cause of these appearances, or to conceive how lands that had once been covered with plants so strong and numerous as to form a thick sod, should become so barren as to be totally unfit for vegetation, as the greatest parts of these muirs are. Were a judgment to be formed from appearances,

fire might be supposed to have been the cause; but as the consumption of vegetables by that element, however great the waste may be of a part of their useful principles, is always productive of more or less fertility, the appearances above-mentioned must be owing to causes of which no correct opinion seems to be at present entertained. This description of muir is the most barren, and its improvement the most hopeless, of any soil known there, and no attempts hitherto made have either rewarded the enterprise of the undertakers, or held out inducements to others to follow their example. But there is another species of muir soil, which consists, like that already described, of a stratum of vegetable substances upon the top, not of a black or burnt appearance, but resembling the plants in a dry state intermixed with earth, without having been acted upon by any thing but the weather. These, when examined, are found to contain a considerable proportion of the properties common to all vegetables, and when properly treated, are capable of being converted into a soil friendly to vegetation. The stones upon this kind of muir are of the same colour with those met with upon the best soils. There are considerable tracts of this soil, which, by good management, might be considerably improved: indeed a great part has been much ameliorated of late years, in many districts, and is in a progressive state of improvement.

And in the analysis of the same writer of the turf of these soils in the district noticed above, he discovered nearly the same principles as are found in those of the mossy kind.

No gypsum was obtained from this turf, nor did the trial by the magnet discover any iron. Many other trials were made with different kinds of turf, taken principally from muirish soils, the result of which seems to establish the constituent parts of the turf to be, 1, an acid; 2, an alkali; 3, oil; and 4, vegetable earth, in a considerable quantity. In cases where the turf is pared very thin, it is found to contain less acid and more alkaline salts and vegetable earth than where it is deep cut, and much of the soil taken along with it.

In the improvement of these kinds of soils different methods must be pursued, according as they possess more or less of the vegetable principle, and as they are of the deeper or thinner kinds. Where there is much heath, the great object will however be that of destroying it as quickly as possible, in which view paring and burning may be had recourse to with vast advantage and success. The application of caustic lime has likewise been found highly beneficial in the same intention.

The use of different substances of the animal and vegetable kinds, as dung and the mud of ponds, in the form of earthy compoils, may likewise be found advantageous on soils of this nature, with judicious modes of cropping with plants of the grain and green kind; the latter being fed off as much as possible upon the land by sheep.

Some think the best means of improving all sorts of soil of this nature, is, after the heath has been, in some measure, removed, where it is long, by the application of lime or marl over the surface, allowing it to continue in that state for the space of two or three years, when these soils are to be broken up and sown with proper sorts of crops in alternation with turnips and potatoes, the ground being laid down again to grass when it has been brought into proper condition for it. The turnips, where it is practicable, should always be eaten off upon the ground. Where the heath is of the long strong kind, it may be destroyed either by burning, pulling it up by the roots, or by suffering the grass to rise and choke it up. See *WASTE-LAND*.

All these and some other modes may be practised in

improving heathy soils with much success in different cases.

It therefore appears, from the whole of what has been said upon soils, that great care and attention are always requisite in improving the nature and qualities of them, and that the farmer should constantly be properly on his guard in undertaking such sorts of work.

SOIL, in *Gardening*, the fine surface-mould or earthy materials, in which plants and trees grow and afford their produce. Different sorts or qualities of soils are necessary, in this point of view, for different uses and applications; but for the more general purposes of culinary gardening, those of the more light and dry loamy kinds, which are readily broken down and reduced in their particles, are probably the most extensively useful and beneficial, particularly when they have been well impregnated and enriched with proper sorts of manure, or other similar matters. See *COMPOST* and *MANURE*.

Some, however, think that the best general soil in this intention, is that middling kind of loam, which, in some parts, is capable of being made of very different degrees of lightness and friability, so as to suit and be proper for different sorts of vegetable crops, by the simple addition of sand or sandy matters, in due proportions; and in other parts, of different degrees of stiffness, tenacity, and cohesion, by the suitable addition of clays or clayey materials, in the necessary quantities. There are others who prefer soils of very different natures and qualities, or which are very differently constituted, for the use of raising the many different sorts of garden vegetables, and think it incapable of being accomplished in the best and most perfect manner, where this is not the case. It is therefore probable, that considerably more latitude in respect to the nature of soils is necessary in the garden cultivation of plants, than in that of the field.

In general, the depth of a garden-soil, where the bottom or sub-soil is perfectly open and dry, should be considerable, as not less than three feet, or more, in any case where such a depth is to be procured; but where there is a bottom or sub-soil of rather moist clay, or any other impervious material of that nature, a less depth may sometimes be more suitable and proper, and particularly where such bottom or sub-soil has been well drained and freed from too much wetness: however, in all or most instances where this is incapable of being properly effected, or the trouble and expence of getting and providing a stratum or layer of gravel, or other similar substance, to be placed over it, are too great to be incurred, the depth of the soil should not by any means be less than four feet, as when it is of less thickness, there may be danger of the roots of herbaceous vegetables, and of fruit and other trees, reaching and striking into it, and being thereby greatly injured or destroyed. And for some purposes, as those of growing particular kinds of fruit-trees, such a soil would be quite ruinous and wholly improper, unless some sort of impediment was given to the roots striking downwards, by forming a kind of pavement with stones, bricks, or tiles, about two and a half or three feet under the surface of the ground, just above the clayey bed. The depth of good garden soils should, of course, in common, be from two to three feet, and in particular cases four feet or more. The nature of the particular soils, and the sub-soils or bottoms on which they rest, must, however, in a great measure, regulate their depths.

In cases where the natural soils of gardens are to be removed, and those of new and better kinds formed and provided, much regard is necessary to be had, in the introduction of the different kinds of earthy materials of which they are to be composed. The soils of all the different parts are

modes as are the most effectual in promoting the exit or passage of the stagnant water which they contain. Different materials may then be applied with the intention of improving their textures, and promoting the dissolution of the undecayed parts of the vegetable matters that are contained in them. The first may be accomplished by the application of various gravelly substances, sand and coarse earth; and the latter, especially where there is a large growth of coarse plants, by the use of lime in its caustic state; but where such plants do not so much abound, alkaline substances, chalk, calcareous marle, the shelly kinds of sea-sand, and the carbonate of lime, may be more advantageously made use of. And as shell-marle, chalky substances, rich clays, and limestone gravels, are frequently met with under deep peat mosses, they should be tried for by boring in various parts. Paring and burning is also useful where the quantity of vegetable matters on the surface is considerable, and of the coarse kind; but the method of applying good earthy matter is to be preferred where it can be procured in an easy and cheap manner. And advantages may be gained in promoting the fertility of these soils by cropping with particular sorts of vegetables, as such as have large branching stems, and cover the surface of the ground very much, so as to exclude the action of the air in a great measure upon it.

It is probable, too, that the hot limes, as they are called by farmers, may be laid upon these soils in full proportions with very great advantage in some cases; and that where lands of any kind have been hurt by the too great use and abundance of them, peat will prove a good means of restoring them.

In these different ways very great improvements have been made in peaty and mossy soils, especially where the drains have been formed sufficiently near to each other, and to proper depths for taking away the water in an effectual manner. Great advantage has also been derived by laying the surfaces of such lands over with any sort of heavy earthy matters to the thickness of three or four inches, such, for instance, as the heavy sorts of marle, the scrapings of roads, the heavy mud of rivers and ponds, &c. By these means, where they are intended for grass, a finer kind of herbage is brought up, and where for the purposes of tillage, the surface is well consolidated, and rendered more suitable to the growth of crops of that sort.

7. *Boggy Soils*.—These are also soils that have much of the nature of the preceding, but which differ in some respects from them, being chiefly in low confined situations, and of less depth than the heavier mossy soils, and of more than those of the lighter description of that sort of soil. There are soils of this description frequently met with in Ireland, and occasionally in low meadows and near large ponds or lakes in this country. These soils are gradually formed by the deposition and decay of the different vegetables that grow in such situations as those of the luxuriant aquatic kinds; and the stagnation of much moisture upon them, by which the roots also become destroyed and reduced to the state of earth. They have of course different appearances or colours, according to the state of putrefaction and decay to which the different parts have advanced, and the nature of the other earthy materials with which they are blended; in some cases being of a lightish brown aspect, as where the fibrous and ligneous matters have only undergone a slight change; but where this has been carried to a considerable extent, they are of a dark colour, approaching to black, or of a deep dusky hue. See PEATY and MOSSY Land.

As the great defects in soils of this nature are chiefly those of their being too much charged with moisture, and of too open and porous a texture, the means of bringing them

into a proper condition are obvious. In deep boggy soils, the business of draining should first, when practicable, be resorted to, in order to draw off the excessive moisture. After which, various hard dry earths will be found of great use in improving bogs, such as gravel, chalk, stony matters, sand, shell-marle, &c. as these substances contribute to bind, ameliorate, and warm the soil, while they prevent springs from oozing out and overflowing the surface. Where they are over-run with rushes and similar coarse vegetables, quicklime may be beneficially applied, and paring and burning may be employed, sometimes with advantage. And another useful mode of reclaiming such soils is, by planting on them those vegetables whose spreading roots serve to bind the earth together, and at the same time, in a great measure, exclude the action of the atmosphere upon it. The practice of flooding, also, where a command of water can be obtained, has proved a cheap and efficacious mode of reclaiming them in some instances. Some cases, at least, have occurred where such soils have been brought into a state of cultivation for meadows, with the happiest success, by it, which had failed under contrary methods of management.

In most of these cases, the first means which are necessary, after well ditching and draining the soils or lands, and levelling the imperfections and inequalities on their surfaces, is to apply earthy matters over them. For this purpose, the lumpy earthy parts, or elevations on them, are to be pared off and intimately blended up with lime into composts, which, with other heavy materials of proper earthy kinds, are to be placed and spread out on the lands or soils in an even manner. And afterwards, when the ground or soil becomes firm and solid, with much coarse plants and herbage rising upon it, eating it constantly close down with light neat cattle and sheep, will be very beneficial, especially where such soils or grounds are designed for pastures. When for tillage, there are various other means which may be had recourse to in different circumstances, for rendering them more firm and dry, with great success. See SWAMPY Land.

The management of such soils, in all these different methods, has been productive of great benefit in different instances, and the land, when improved, is commonly of the most valuable kind. See BOG, and SPRING-Draining.

8. *Heathy or Moory Soils*.—These form a class of soils that occupy very extensive tracts in different districts of the kingdom, and which have considerable relation to those of the peaty sort, though they differ in many particulars. In the southern part of the country they are mostly known under the titles of *heathy* or *moory* soils, but in Scotland they have the name of *muir* soils.

It is remarked by Mr. Somerville, in the agricultural Survey just noticed, that these soils, like those of the mossy kinds, owe their origin evidently to the same cause, namely, the decay of the plants that formerly occupied the surface. This muir soil is of two kinds, one of which is black, soft, and porous, and admits moisture in a greater degree than any other soil; it is at the same time covered with stones of a white colour; evidently whinstone bleached with an acid: the parts, when examined, exhibit the appearance commonly met in turning over the ashes formed by the burning of vegetables, where the skeletons of the plants and roots are seen naked, sapless, and destitute of any of the useful properties they once contained. It is difficult to form an opinion of the cause of these appearances, or to conceive how lands that had once been covered with plants so strong and numerous as to form a thick sod, should become so barren as to be totally unfit for vegetation, as the greatest parts of these muirs are. Were a judgment to be formed from appearances, fire

fire might be supposed to have been the cause; but as the consumption of vegetables by that element, however great the waste may be of a part of their useful principles, is always productive of more or less fertility, the appearances above-mentioned must be owing to causes of which no correct opinion seems to be at present entertained. This description of muir is the most barren, and its improvement the most hopeless, of any soil known there, and no attempts hitherto made have either rewarded the enterprize of the undertakers, or held out inducements to others to follow their example. But there is another species of muir soil, which consists, like that already described, of a stratum of vegetable substances upon the top, not of a black or burnt appearance, but resembling the plants in a dry slate intermixed with earth, without having been acted upon by any thing but the weather. These, when examined, are found to contain a considerable proportion of the properties common to all vegetables, and when properly treated, are capable of being converted into a soil friendly to vegetation. The stones upon this kind of muir are of the same colour with those met with upon the best soils. There are considerable tracts of this soil, which, by good management, might be considerably improved: indeed a great part has been much ameliorated of late years, in many districts, and is in a progressive state of improvement.

And in the analysis of the same writer of the turf of these soils in the district noticed above, he discovered nearly the same principles as are found in those of the mossy kind.

No gypsum was obtained from this turf, nor did the trial by the magnet discover any iron. Many other trials were made with different kinds of turf, taken principally from muirish soils, the result of which seems to establish the constituent parts of the turf to be, 1, an acid; 2, an alkali; 3, oil; and 4, vegetable earth, in a considerable quantity. In cases where the turf is pared very thin, it is found to contain less acid and more alkaline salts and vegetable earth than where it is deep cut, and much of the soil taken along with it.

In the improvement of these kinds of soils different methods must be pursued, according as they possess more or less of the vegetable principle, and as they are of the deeper or thinner kinds. Where there is much heath, the great object will however be that of destroying it as quickly as possible, in which view paring and burning may be had recourse to with vast advantage and success. The application of caustic lime has likewise been found highly beneficial in the same intention.

The use of different substances of the animal and vegetable kinds, as dung and the mud of ponds, in the form of earthy composites, may likewise be found advantageous on soils of this nature, with judicious modes of cropping with plants of the grain and green kind; the latter being fed off as much as possible upon the land by sheep.

Some think the best means of improving all sorts of soil of this nature, is, after the heath has been, in some measure, removed, where it is long, by the application of lime or marl over the surface, allowing it to continue in that state for the space of two or three years, when these soils are to be broken up and sown with proper sorts of crops in alternation with turnips and potatoes, the ground being laid down again to grass when it has been brought into proper condition for it. The turnips, where it is practicable, should always be eaten off upon the ground. Where the heath is of the long strong kind, it may be destroyed either by burning, pulling it up by the roots, or by suffering the grass to rise and choke it up. See *WASTE-Land*.

All these and some other modes may be practised in

improving heathy soils with much success in different cases.

It therefore appears, from the whole of what has been said upon soils, that great care and attention are always requisite in improving the nature and qualities of them, and that the farmer should constantly be properly on his guard in undertaking such sorts of work.

SOIL, in *Gardening*, the fine surface-mould or earthy materials, in which plants and trees grow and afford their produce. Different sorts or qualities of soils are necessary, in this point of view, for different uses and applications; but for the more general purposes of culinary gardening, those of the more light and dry loamy kinds, which are readily broken down and reduced in their particles, are probably the most extensively useful and beneficial, particularly when they have been well impregnated and enriched with proper sorts of manure, or other similar matters. See *COMPOST* and *MANURE*.

Some, however, think that the best general soil in this intention, is that middling kind of loam, which, in some parts, is capable of being made of very different degrees of lightness and friability, so as to suit and be proper for different sorts of vegetable crops, by the simple addition of sand or sandy matters, in due proportions; and in other parts, of different degrees of stiffness, tenacity, and cohesion, by the suitable addition of clays or clayey materials, in the necessary quantities. There are others who prefer soils of very different natures and qualities, or which are very differently constituted, for the use of raising the many different sorts of garden vegetables, and think it incapable of being accomplished in the best and most perfect manner, where this is not the case. It is therefore probable, that considerably more latitude in respect to the nature of soils is necessary in the garden cultivation of plants, than in that of the field.

In general, the depth of a garden-soil, where the bottom or sub-soil is perfectly open and dry, should be considerable, as not less than three feet, or more, in any case where such a depth is to be procured; but where there is a bottom or sub-soil of rather moist clay, or any other impervious material of that nature, a less depth may sometimes be more suitable and proper, and particularly where such bottom or sub-soil has been well drained and freed from too much wetness: however, in all or most instances where this is incapable of being properly effected, or the trouble and expence of getting and providing a stratum or layer of gravel, or other similar substance, to be placed over it, are too great to be incurred, the depth of the soil should not by any means be less than four feet, as when it is of less thickness, there may be danger of the roots of herbaceous vegetables, and of fruit and other trees, reaching and striking into it, and being thereby greatly injured or destroyed. And for some purposes, as those of growing particular kinds of fruit-trees, such a soil would be quite ruinous and wholly improper, unless some sort of impediment was given to the roots striking downwards, by forming a kind of pavement with stones, bricks, or tiles, about two and a half or three feet under the surface of the ground, just above the clayey bed. The depth of good garden soils should, of course, in common, be from two to three feet, and in particular cases four feet or more. The nature of the particular soils, and the sub-soils or bottoms on which they rest, must, however, in a great measure, regulate their depths.

In cases where the natural soils of gardens are to be removed, and those of new and better kinds formed and provided, much regard is necessary to be had, in the introduction of the different kinds of earthy materials of which they are to be composed. The soils of all the different parts are

to be formed and prepared with great attention to their several uses and intentions; and where fruit-trees are to be grown, particular care should be taken, that the borders for such purposes be formed and made up to proper depths, with suitable materials, and upon proper kinds of sub-strata. By sufficiently regarding these points, garden soils of proper qualities, and fit for every purpose, may mostly be provided without much difficulty.

The work of forming and composing garden soils is by far the most cheaply, properly, and easily performed at first when the garden is laid out; as, when done at an after period, great injury and destruction are caused in different finished parts, and in various other places, by defacing and cutting them up in the labour, and rendering their appearance disgusting to the eye, though the business is still capable of being accomplished without any very great difficulty or expence. In all cases of this sort, whatever depth of natural soil may be wanting to form the soils to the proper depths or thicknesses, as suggested above, must be supplied, by conveying it into the garden from the neighbouring lands or other situations, where the proper kind is to be met with in sufficient quantity; as it is rarely, or never advisable to raise and mix up any great quantity of the sub-soil, or bottom part, whatever its nature, texture, or properties may be, with it. For, in many cases, the soils of gardens are greatly injured, or nearly ruined, by the improper mixing of the sub-soil with the surface-mould. Level spots are seldom so proper for gardens as others, as the soils of them have rarely a dry bottom, and the draining of them, when necessary, is a great deal more difficult, than where there is some degree of declivity. Where there is from a foot in twelve, to that of a foot in thirty or forty feet, it will commonly succeed pretty well; but when about one foot in twenty-five, it has the most happy effect in freeing the soil and sub-soil from too much wetness.

It is remarked by the "Scotch Forcing and Kitchen Gardener," as a fortunate and desirable circumstance, that in many instances the different sorts of soil are met with in the same acre or portion of ground, and that they should never be wanting in the same garden, but that where they are naturally deficient, in this respect, in such situations, recourse must be had to artificial means, in the manner that has been already suggested, for providing and producing them; for the variety of vegetables which are to be cultivated in gardens require a variety of soils in them for their production. It would, however, be perfectly absurd, if it is supposed, to conceive, that for every particular sort of vegetable there should be a particular kind of soil formed and prepared. The varieties of soil which are absolutely necessary in almost any garden, may, it is thought, be confined with propriety to the following,—strong clayey loam, —light sandy loam, a composition of one-fourth strong, with three-fourths light loam, half strong and half light, and one-fourth light and three-fourths strong; the two first being obviously the grand or principal sorts, and made to form and compose the whole of the others. These, with the proper and suitable applications of manures to them, may, it is believed, be rendered capable of producing any of the known and commonly cultivated garden vegetables, in the highest state of perfection.

This is probably, however, limiting them too much or too narrowly, as though the principal sorts of culinary vegetables may be raised upon them in an easy and perfect manner, there are several kinds of plants grown in such situations that require soils of other qualities to produce them in perfection, and some that cannot be grown at all without those of quite a different nature.

Garden soils, in many cases, may be greatly and cheaply improved by very simple means, as by the properly drawing away and discharging any over-degree of moisture, where the bottom is wet, and the sub-soil of a cankering ochrey quality; and by supplying and intimately incorporating with the soil, where it is of a very stiff obstinate nature, substances of the small gravel, pebbly, and shelly sea-sand, coal-ash, lime-gravel, reduced brick-bat, brick-kiln ash, mouldering-chalk, and different other similar kinds. In cases where the soil is of a poor sandy, gravelly, or other quality of somewhat the same description, the improvement is to be effected by supplying and intermixing clay, strong clayey loam, scourings of ditches found on clayey sub-soils, muddy depositions of similar situations, scrapings of muddy roads, and other matters of the same kind with them, in suitable proportions and an even manner.

Where soils of the pure sandy, sea-sandy, or peat-earthly kinds, are wanted, they are to be formed by the supply of these different sorts of materials in the proper and necessary proportions to some part of the common soil of the garden, as the case may be, without their being blended or united with it. In all other cases the business is to be accomplished in somewhat similar ways.

It is a very common opinion among gardeners, that culinary vegetables may be raised and grown to the best advantage, and in the fullest perfection, on what is denominated *new*, or rather fresh lands or soil, and this is evidently proved to be the case in a great number of instances. The soil or ground, in consequence of its being exhausted, or *worn out*, as it is termed, is found incapable of producing certain kinds of vegetables of the above nature; not because it is of a poor or hungry nature or quality, or that it is wholly unsuitable for the production of them, having probably, at a former period, produced them in an abundant manner, but on account of, or from the surface soil having been so long under such crops without any sufficient or suitable change. This is, however, much less the case, in open field garden grounds, than such as are inclosed for the purpose of producing the finer sorts of fruit and vegetables.

The inconvenience in these cases is supposed to be capable of being wholly removed, or greatly relieved, by trenching the soil in a peculiar manner at proper periods, so as to have constantly a new or fresh soil for the growth of such vegetables and fruits. See *Rotation of CROPS*, and *TRENCHING*.

The soils of gardens in all cases, except where they are too light and friable, are capable of receiving much improvement, by being fully laid up in such a manner as to expose the largest possible surface to the operation of the weather, whenever they are unoccupied by crops, and especially during the frosty periods of winter. On all stiff, heavy, clayey, loamy, and cankering gravelly soils, the improvement by this means is very great, and ought never to be neglected. On very light soils of the sandy sort, it should, however, be very cautiously employed. See *RIDGING up*.

The most suitable kinds of soil for the growth of different sorts of fruit-trees in gardens, are very various according to their nature and habits, but they all require that they should be of a somewhat dry quality, as will be seen under their different proper heads. Where fruit-trees of the apple kind are grown in such situations, which should as rarely as possible be the case, they succeed in the best manner, are the most healthy, and of the greatest durability in soils of the brown loamy kind, which have a middling degree of consistence, and a depth of a foot and a half or more, resting on a dry, sandy, or soft clayey bottom: they will, however, answer tolerably on any of the loamy sorts of soil
which

which lie upon dry substrata. In all soils which have wet retentive bottoms, they are soon destroyed. The pear stands in need of a stronger and more clayey soil than the above, which has much greater depth, but which rests on the same sort of substrata. Similar sorts of soil are also the most adapted to the growth of the cherry and the plum. And the small fruit-trees, in such cases, may be well grown in any soil which is not of the ochrey or wet stiff clayey kind. See *SMALL Fruits*, and *STANDARD Fruit-trees*.

Soils for the purpose of ornamental gardening are not only of great utility in growing and rearing the different plants and trees which are necessary for it, but have been employed in the way of contrast, and for relieving them. Formerly, much advantage was taken in this manner, by the introduction of different coloured earths or soils, but they have since, probably with justice, been reprobated as too trifling and insignificant by lord Bacon: the natural soil throughout is always, Mr. Loudon thinks, preferable; and when tastefully varied by the green of vegetation, will have a very harmonious effect in such cases.

The quality of the soil for the growth of most sorts of ornamental plants and shrubs, should, it is said, be rather poor; for most of those of the wild or botanical kind, various, though principally dry pasture loam of a virgin nature; but for the ericas or heath sorts, and most of the American and Cape plants, as well as some others, mostly or peaty, and rather moist.

The soil, in its different kinds, has much effect in improving, or *breaking*, as it is termed by the florists, some sorts of fine flowering plants, as several of the bulbous-rooted and more tender herbaceous kinds, such as tulips, pinks, carnations, and many others. The common plants of the latter description will, it is believed, grow in almost any sort of soil.

The particular sort of soil in which most of the moss-plants and shrubs commonly grow to the best advantage, is, it is supposed, that of a sandy moss or peat of a moderate degree of moisture. The soils for wild plants are almost, it is remarked, as various as their names, but, in common, such as are mentioned below, will grow most of them when cultivated in a garden:—dry virgin mountain earth or soil; mossy earth or soil in a damp situation; half of each of the above in a moist situation; half of each in a dry position; moist clay and moss or peat well blended; dry gravel and sand incorporated well together; a clear sandy or gravelly bottom soil, where there is a slight trickling of water; a muddy bottom soil, in a low stagnant pond or other water; rock-work, differently constructed, forms a soil for certain plants, as some mosses, ferns, and others of the same sort; living full-grown trees, as well as such as are decayed, provide a soil for the growth of particular mosses and funguses; the soil of the sea-shore is proper for the growth of sea-plants; and the differently formed soils in heated houses and other places, are suited to the growth of most sorts of exotic plants. The two first sorts, with those of the trickling and sea-shore kinds, will, however, it is supposed, nearly serve the purposes of all the others, when properly managed.

For the purpose of raising different sorts of forest-trees, and forming ornamental plantations, great variety of soils is necessary; such as those of the more light sandy and gravelly kinds, which rest upon free, open, porous under soils or bottoms; sandy and gravelly loams on the same sorts of bottoms; the same and perfectly loamy soils, on bottoms which are of a more retentive or wet nature; chalky or calcareous loams, and gravelly mouldering chalks on open bottoms; loamy clays and clayey loams, on similar bottoms; strong soils of both these

sorts on more retentive and moist under soils; thin, peaty, heathy, and moory soils, which lie on gravelly and other sorts of open dry bottoms; and similar soils, resting on more stiff and retentive substrata, or such as are of a moister quality.

Other variations in the nature of garden-soils may likewise be occasionally necessary for particular purposes, as well as in those of grounds which are intended to be laid out and ornamented.

SOIL, Night, in *Agriculture*, the excrementitious matter which is taken from privies or other places in which it is deposited. Sir Humphrey Davy has remarked, that it is a well-known very powerful manure, which is extremely liable to decompose. That it differs in composition, but constantly abounds in substances constituted of carbon, hydrogen, azote, and oxygen. And that from the analysis of Berzelius, it appears that a portion of it is always soluble in water; and in whatever state it is employed, whether recent or fermented, it supplies abundance of food to plants, either as crops, or in other ways.

It is suggested, that its disagreeable smell may be corrected and destroyed by mixing quicklime with it; and that, if exposed to the atmosphere in thin layers, strewed over with quicklime in fine weather, it speedily becomes dry, is easily reduced into powder, and in this state may be made use of in the same way as rape-cake and other similar manures, being delivered into the drill-furrows at the same time with the feed.

The refuse of charcoal warehouses, and the powdery matter of that substance, might also probably be intermixed with the calcareous and excrementitious materials in the above composition with great advantage.

It is stated that the Chinese, who have more practical knowledge of the use and application of manures than any other people existing, mix their soil of this sort with one-third its weight of a fat marle, make it into cakes, and dry it by exposure to the sun. These cakes, as has been said by the French missionaries, have no disagreeable smell, but form a common article of commerce in the empire. It is supposed that the earth, by its absorbent properties, probably prevents, to a certain extent, the action of moisture upon the excrement, and likewise defends it from the effects of the air.

The Japanese, and some other of the eastern nations, are likewise very careful in preparing and preserving this sort of manure; and different methods of collecting, increasing, and securing it in this country have been noticed in speaking of manure. See *MANURE*.

It is supposed by some to have a great superiority over all other sorts of manure, even that of the rotten horse-dung kind, being considered nearly five times as valuable as this last sort. There is consequently believed to be a great saving in the purchase of this manure, by those who have the carting of their dung seven or eight miles, as their teams would bring as much of it in one, as would be equal to what is usually brought of the other by them in five days: that they would have as much as is equivalent in value for one guinea, to what formerly cost them five. And though the price of it may be on the increase, that should not, it is thought, deter them from the purchase of it, as the saving in carriage is, it is said, amply sufficient to repay every advance in the first cost of the material.

Others, however, suppose that this sort of substance in manuring land will not go farther than three times that of common dung, in giving fertility. It is usually sold at 5s. the load. It has lately, in some places, been the practice to mix and work up this sort of soil or excrement with mould or other earthy matters, in a regular manner, to considerable

siderable extent. This is largely done, it is said, in the neighbourhood of the metropolis.

Upon the whole, considering the smallness of the quantity which is necessary, this may be allowed to be the most powerful and effectual manure of any which is now in use for improving land.

In the county of Essex, about Hornchurch, Mr. Newman has found that, for pasture, this sort of manure is, of all others, the most capital; two waggon-loads on the acre, which cost 7*s.* besides carriage, are, it is said, beyond every thing, and secure a carpet of fine herbage. On corn-land, however, it is thought that it forces straw too much. Others have also found this to be the case, but when well mixed with good earthy substances, in sufficiently full proportions, there can be no doubt of its being equally suitable for raising good grain crops.

On account of the increasing scarcity of manure, this sort of material should be every where more attended to and preserved than has hitherto been the case; and it may be largely increased as a manure by the addition of suitable quantities of earthy or other proper matters, according to circumstances, and the purposes for which it is to be employed, as well as be rendered more fit and convenient for carriage and application.

SOIL, Preparation and after-cultivation of, for and in planting, in Agriculture and Gardening, the manner of rendering it suitable and proper for the reception of the trees, and of keeping and preserving it in order afterwards.

The nature, situation, and state of the soil, must unquestionably have much influence in determining and directing the degrees of preparation that may be requisite in the different cases; and though there may be some soils which require very little, this can but seldom be the case, as good soils should never be planted, except for ornamental purposes, and then as little as possible. It consequently appears proper, that some degree of preparation of the soil should constantly take place in almost all cases, however the mistaken notion in regard to the expence attending it may have hitherto prevented the general adoption of the practice.

The expence of the proper preparation of the soil, before the work of planting commences, in many cases, is not by any means great, when properly managed; and in no few instances, may be more than repaid by the kinds of crops that are afterwards grown for two or three years, and sometimes longer: nay, even where such crops cannot be raised and produced, the saving in plants and planting, which would otherwise be required, will often wholly or nearly defray the charges of the preparation. Thus, it is said by Mr. Loudon, that, independently of timber produce, it would seem that the extra charges of preparing the soil may commonly be provided for in the immediately succeeding years to the work's being finished, either positively by the growth of proper crops, or negatively by obviating the incurring of additional expences. And that, when the difference in the returns of timber produce are taken into the account, it may appear astonishing that the cultivators in this way should disregard their own advantage so much as to neglect and omit the proper preparation of the soil. For if it should be supposed that, during the first ten years, trees grow only twice as fast where the soil is properly prepared, as where it is not, then even a plantation worth 100*l.* in fifty years, had the soil been well prepared, would have been worth 200*l.* in the same length of time. But it must be allowed that many kinds of deciduous trees will grow three, four, and even ten times faster in prepared than in unprepared ground, and, of course, the return of profits be in the same proportion.

These statements can surely leave no doubt of the propriety of preparing the soil with a view to these sorts of undertakings.

The preparation of the soil will vary according to its nature, and the circumstances of it; after the stagnant wetness, where present, has been properly removed, and the surface impediments cleared away as much as may be found necessary. In all stiff soils the land must be more wrought and exposed than in the contrary sorts, which often require but little stirring or exposure. In extensive tracts, the ground or soil, when possible, should be prepared by means of the plough, by turning it up and exposing it to the operation of the atmosphere and frosts in the summer, autumnal, and winter months, when of the more rough and obstinate kind, repeating the ploughings, and making harrowings as there may be occasion. In extremely rough moory, and some other coarse sorts of soil, this may be necessary for more than one season. After this, trench-ploughing may be had recourse to wherever it is wanted, and is capable of being practised. By the use of the plough in these ways, the organic matter becomes more decomposed, and the particles of the soil more fully and completely broken down and reduced, than by performing the work with the spade, while the cost is not more than one-third.

In places where the plough cannot be admitted, other methods must be had recourse to, as those of the spade, the broad-mouthed mattock, and the sharp-pointed strong hoe. The spade must be employed in all cases where digging and trenching can be practised, where the plough cannot work, and in forming pits, slits, and other modes of putting in the plants. Where the spade cannot be made to perform the business, the mattock not unfrequently does the work in a ready and effectual manner. And where the mattock cannot be brought into use, the hoe often completes the work without difficulty. The two last methods may be useful in steep banks and spots filled with stones and other obstructions to the spade. The soil in all these cases is to be properly reduced and rendered sufficiently fine for the reception of the tree-plants, by being stirred, incorporated, and mixed together in a suitable manner.

Particular situations may require particular modes of preparing the soil and putting in the plants: thus, where there is danger of loose soil being carried away by winter rains, the land should be prepared in the previous summer season, by making holes or openings, the earth of one of which is thrown into another with the turf or sward-side downwards, which, when opened again for planting, is become rotten, and intermixed with the rest of the soil in putting in the plant. In other situations, where the wind and rain are liable to carry off the soil, the only safe mode of preparing the soil is in pits, holes, and slits, and placing the plants in them. And in still more difficult places, little or no preparation is necessary, only putting in the plants in openings or slits, or sowing the seeds, which will often grow in rocky crevices, where little or no earthy matter is to be seen or met with. The nature of growth in the plants or seeds points out in some cases the modes of preparation of the soil for them; thus, in the very young plants, and in seeds of the oak-kind, where they are only used, the placing them in holes or pits, prepared in a proper manner, is all that is necessary, as they receive the chief of their support from their tap-root, which runs directly downwards.

In regard to the cultivation of the soil, after the work of planting the young trees has been performed, it must obviously be of great use and importance to keep the surface loose, clean, and free from the production of all sorts of improper plants of the weed kind, as the health, growth, and

and success of such tree-plants will very much depend upon it; and, besides, it may be advantageous in other ways. In cases where this is neglected, or improperly managed, there is often much injury sustained by the young tree-plants, as they are not unfrequently liable to be more choked up and inconvenienced in their growth by the rising of coarse grasses and other productions, than if the soil had not been prepared previously to the trees being put into it. The cause of this is thought, by Mr. Loudon, to be extremely plain; as, if the soil, by preparation, be better suited to the growth of trees which are foreign to it, it must be much better adapted to the growth of the plants which it naturally produces in abundance. Consequently, to check and remove these, so that the roots of the young tree-plants may range, and extend themselves in a free manner, so as to require and enjoy the full strength and support of the soil, must be of very material benefit in raising plantations of the tree-kind.

The nature of the cultivation which is to be pursued must be varied so as to suit the particular quality of the soil, the situation, and the kind of plantation for which it is employed; but the great object, in all such cases, should constantly be, to have in view utility, with as much immediate profit as possible, without the risk of injury to the young tree-crops. Consequently, wherever the ground or soil is capable of admitting and producing any sort of proper useful vegetable, and the roots of the trees do not interfere by approaching too nearly to each other from the different rows, some of them should be planted, or the seeds of them sown in a regular manner, all along the centre parts of the intervals between such rows, for some length of time, as a year or two, and more in some instances, after the planting has been performed. The most useful and valuable vegetable crops to be grown in this way, are those of the potatoe, turnip, cabbage, dwarf bean, and some other similar ones of the green kind. The introduction of such crops necessarily supposes that the whole of such planted grounds are to be wrought over, and kept in a clean order by some proper means, during the lengths of time that have been stated; after which they need only be hoed over two or three times in the course of the year, until the surfaces of them be covered and concealed by the trees, which they will mostly be about the fourth or fifth year from the period of planting: All the work of the above kind, where the scale of planting is extensive, may be executed by means of the plough and horse-hoe; except occasionally, perhaps, some little hand-hoeing about the bottom stems of the tree-plants, where there might be danger in letting the other tools work too near them. Where, from different circumstances, it may be impossible to introduce the plough, the spade and hand-hoe must, of course, be had recourse to in working the soil. But wherever the soil is incapable of admitting and producing useful vegetables, or where it may be thought not advisable to grow and cultivate them, the ground or soil may perhaps be the most properly and advantageously preserved in clean order, simply by hoeing over the surface; or sometimes probably by light ploughing or working with the spade, for a year or two at first, and then to depend on hoeing. The chief point in all cases is the promoting the progress of the young trees, and the preventing them from being injured by the stiffness, rawness, and want of cleanness in the soil.

Whenever the surface of the ground or soil is covered by the young trees, there is no longer any necessity for cultivation, it being from that time preserved in a sufficient loose and open state, and the surface properly free from weedy matters, by the closeness and shade of the trees, and the annual falling of the leaves; and particularly where the

planting consists of resinous trees. It is noticed, too, by the above writer, that it is the peculiar property of deciduous plantations, that the surface among them is covered with herbage of the pasture kind, the seeds of which should be sown when the trees are about nine inches or a foot in diameter, they having been well preserved from weeds previously to the period of sowing. See PLANTATION and PLANTING.

It is not improbable, but that when the business of preparing and cultivating the soil for plantations becomes better understood, and its uses and advantages more fully appreciated, more suitable implements, tools, and contrivances may be provided for accomplishing the work in a more easy, ready, cheap, and convenient manner, than has yet been employed.

SOILS, *Cutting Surface of*, the opening and breaking the surfaces of them in different intentions; as for the purpose of rendering them more dry and firm, of producing a more mellow, mouldy, or powdery state in them, and for improving the nature of their swards and grassy herbage in those of the mossy, rough, mowing, and pasture kind. It may likewise be useful to them for some other purposes in husbandry. It is performed in different manners, and by different means, according to the circumstances of the different cases, and the uses which it is designed to serve. See SPIKE Roller, and SWARD Cutter and Dresser.

SOIL, in *Zoology*, is used in some parts of England as the name for the *phoca*, or *sea-calf*.

This creature, in Cornwall, they frequently find sleeping on the shore, and kill him, sometimes by shooting, and sometimes by striking him over the head with long poles. He defends himself, when on shore, by throwing stones backwards with great violence.

SOILING, in *Agriculture*, the practice of supporting animals of different kinds, in the summer season, with green food of various sorts, cut daily, and given to them in racks in the houses, stalls, or yards. A vast number of different plants and grasses may be had recourse to in this intention, as almost all those which have a quick and luxuriant growth; as lucern, tares, clover, saintfoin, chicory, &c. And it has been suggested, that by having recourse to soiling, a greater variety of plants may be consumed, and consequently prevented from running to waste. Also, that if the consumption of plants be an object principally regarded, it is obvious that the benefits thence derived will be very great, as experience has clearly proved that cattle will eat with avidity many plants, if cut and given to them in the house, which they never will touch while growing in the field; such are the dock, cow-parsley, thistles, nettles, and numerous other plants. But to whatever circumstance this may be attributed, the fact is, that the animals will eat them without exhibiting any marks of dislike or reluctance, even when they are not pressed by hunger, and they often greedily devour such plants, as soon as they are brought in from the field, and before they can have possibly had time to become hungry. There are even vegetables, which, in a green state, are poisonous to cattle; but which, when cut and dried into hay or fodder, may not only be given with impunity, but are also eaten with avidity. Such as the water-crowfoot, with which, Dr. Pulteney says, the cottagers in the vicinity of Ringwood, on the banks of the Avon, almost entirely support their cattle; and so eagerly do these animals consume it, that they deem it unsafe to allow them more than a certain quantity. Cows indeed are asserted to be so peculiarly fond of this vegetable (which keeps them in good milking condition), that, exclusive of the scanty pittance which they obtained on an adjacent heath, *see* cow

SOILING.

and one horse did not consume more than half a ton of hay in the course of a year. Thus it is evident, that fewer plants will either be rejected, or suffered to run up to waste. And that it is further well known that many of the best and finest grasses, which, when young, form a most palatable food to cattle, are, if once suffered to get into ear, so much disliked by them, that the beasts will never taste them unless compelled by extreme hunger. And, as in most pastures many of these grasses get into ear from various causes, their produce is of course inevitably lost to the farmer; whereas, if cut down by the scythe in proper time, not one plant will be suffered to get into that nauseating state, and consequently no waste be sustained on this account. Also, that, in addition, those few plants which are totally disregarded by one class of animals, so as to be rejected by them even in the house, will not, on that account, become less acceptable to others, but greatly the reverse. Thus grass, or other food that has been *blown* or *breathed upon* by any animal for a considerable time, becomes unpleasant to other beasts of the same species, but not so to stock of another class or variety, as for them it appears to acquire a higher relish. Even greater defilement by one animal seems to render food more acceptable to others; for straw, which in a clean state has been refused by cattle, if employed as a litter for horses, acquires for the former such a relish, that they seek for it with avidity. Hence it happens, that the sweepings of the stalls from one animal supply a pleasing repast for those of another kind, which can be easily removed from one to the other, if the plants are consumed in the house, but which must otherwise have been lost in the field.

This is a practice which is also recommended by the food being consumed with much less waste, consequently going much further than when fed upon the land; by the great increase of good manure that is produced; and by that of the stock feeding with less interruption and inconvenience, from their being more effectually shaded from the excessive heat of the sun, and better protected from the attacks of flies and other insects. In all these respects it would seem to have a great superiority over that of letting the animals range over the pastures or other grass lands. One great and principal objection that has been opposed to this plan of feeding, is that of the expence of conducting the business being too considerable. But the extensive trials of Mr. Mure and Young, and other cultivators and promoters of the practice, fully shew that it may be executed at an expence that can never form any real objection to it. It has likewise been contended, in opposition to this practice, that such parts of the live-stock as are in milk do not afford it so abundantly as when fed in the pastures, but which is probably a mere supposition, as it has been almost invariably found that most of the green crops that are cut and employed in this manner have greater effect in exciting that secretion than the common pasture-grass. But as particular sorts of vegetables, as well as other substances, act more powerfully on some of the glandular organs than others, it is probable that some kinds of plants may have a greater tendency to promote this kind of secretion than others, and on this account, cows fed on one sort of food in this practice may afford less milk than on others.

Farther, it is a process of feeding that has also been opposed, on the idea that animals do not thrive so well as when grazed in the pastures. It is, however, well remarked, that the more quiet and free from disturbance cattle are kept, the better they thrive and improve in their flesh. It is not probable that green food, when properly consumed in the sheds of a farm-yard, will be less advantageous in promoting the growth and fattening of stock,

than when eaten in the field, when exposed to the great heat and constant attacks of flies, and of course kept in a continual state of restlessness and inquietude. Besides, in experiments to which we might refer, the cattle were found to go on better than stock of the same kind, fed in the pastures in the most favourable seasons for the purpose. And this is further supported by trials carefully made, and detailed in the Annals of Agriculture. This notion does not, therefore, appear well supported by facts, or to have had any foundation in the experience of farmers in general.

But its superiority in respect to the economical consumption of the food cannot be disputed. In numerous experiments made in proof of the great saving in this way, it has been found to go from twice to four or five times as far as when fed on the land; and in some trials, much more. Mr. Close found that with grass, clover, lucern, and tares, three times as many cattle were capable of being supported in better condition than in the pasture mode of feeding; and with other experimenters it has been found equal to five or six times as many. The author of a late work has remarked, that in the field it is obvious that great waste must be committed by the grass being trampled down, dunged upon, and in many other ways, especially where a great number of cattle are pastured together, most of which are avoided in the stall method.

It has been, however, stated, that it is an error to suppose that all the waste is in feeding in the field, and none in the stall: there is, on the contrary, a waste in soiling; as in cases where the tares become podded, from the butt ends of the plants being coarse, and in a state of decay by lying on the ground, and, of course, rejected by the animals. The same thing also occurs with lucern, when in full blossom. Also, in the heating of the food, by its remaining heaped together, loss may likewise be sustained in some instances; but it should mostly be consumed quite fresh in this practice, and no more cut than is necessary for the day.

However, whatever the waste in these different ways may be, various trials detailed in the Annals of Agriculture clearly prove, that a greatly increased stock may be kept upon the same extent of land in the soiling method, over that of the grazing of the cattle in the fields where the plants grow.

But the most interesting circumstance in which this practice excels that of pasture feeding is, however, in the immense quantity of excellent manure that is raised and provided for the production of increased crops of various kinds, and the additional improvement of the lands. It has been well remarked, that this is a method admirably calculated for producing an abundance of manure; as from the great increase in the urinary discharges, in the consumption of green food in this way, and the heat of the season, the littering material, whatever it may be, is speedily converted into manure; by which means, with proper attention, vast stores may consequently be raised, where there would otherwise be none; which is a circumstance of the greatest importance, and which abundantly shews the great utility and superiority of the practice. By these means, the summer produce in manure may probably be made to exceed that of the winter, and at the same time be superior in quality; as there is reason to suppose that the manure produced by any kind of cattle fed in the same way, when not in a state of fattening, is much better in the summer than in the winter season. The proportion of valuable manure that the careful farmer may be capable of providing, by this system of management, is scarcely to be conceived, except by those who have been in the actual practice of it. In this view, it is of much importance to have reservoirs for the reception of the
urine,

SOILING.

urine, in order that it may be occasionally thrown up over the litter, and thereby promote its speedy conversion into manure. The manure afforded by fattening animals, such as hogs and neat cattle, is in all seasons of a rich and valuable quality.

But in order to ensure the fullest benefit and advantage from this system of management, the most strict attention is necessary to different circumstances: such as those of having convenient sheds and yards for the purpose; providing suitable crops in proper succession, to the proportion of stock to be kept; the feeding and managing the animals in a proper manner; and the making a full provision of the materials, for the purpose of littering down the stalls or farm-yards. And further, in this system of management, much depends on the convenience of the yards and sheds, in respect to the economy of labour in feeding the cattle, as well as making of manure: it is, of course, necessary to have them upon such plans as may afford the greatest advantage in these ways. It has been suggested by some, in order to save the labour and expence of cleaning and feeding in this system, to have the cattle left loose in the yards, so as to consume the food from racks or cribs; the bottoms of the yards being prepared by marle, or other similar materials, and a coat of litter applied, so as that the urine may be absorbed, retained, and contribute to the conversion of them into manure. But a superior plan is probably that of having them tied up in stalls, in sheds for the purpose; as, although something may be gained in the former mode in the labour of cleaning, the latter has considerable advantage in the goodness of the manure, and in the animals being kept more quiet, and less exposed to disturbance from insects of different kinds. In the former of these modes, the stock should be sorted, and those of the same age or size fed together.

In the experience of Mr. Clove, it was found advantageous to soil horses in cheap thatched sheds, in which they have room to walk and roll; and with bullocks and cows, in stalls seven feet wide, each stall holding two fastened by the necks to the sides, by which they are prevented from inconveniencing each other while feeding.

In this method of management, it is not unlikely that great benefit might be produced by having low sheds fixed up round the yards, or other places, with suitable contrivances for the cattle receiving the food from, so as to cause the least possible loss; and by having the stock in all cases properly sorted, in regard to size, kind, and strength. Such sheds might, in some instances too, be provided, with very great utility and convenience, near to the grounds whence the food is raised and procured. In this way, a great saving of labour and expence would necessarily be made in different situations.

In all the cases where low sheds are made use of in this intention, there ought to be proper drains formed for conveying the urine and other fluid matters into the littered yards, and other places designed for forming manure, so that they may have a constant operation in the preparation of it.

It may also be necessary and beneficial, in this practice, sometimes to have different sets and sorts of animals, in order that the refuse of the food left by one set may be eaten by another, and no kind of loss sustained.

But in order that this business may be conducted in the most beneficial manner, it is necessary the farmer should carefully attend to the culture of such green crops as have been mentioned above, and which can be best applied in this way, on a scale fully sufficient for this purpose. In the

view of early application, a full proportion of lucern should be raised on the most deep and fertile soils; and on the better sorts of land, that may be in the condition of fallow, clover and tare crops may be grown. These must be sown so as to come into use at different times; the first crop of winter tares succeeding to the early cut lucern; the later put in winter tares following, after which the clover will most probably be ready, to which the third crop of tares and the second cut of lucern may succeed: at a still later period the spring tares may be employed; and in succession to this, the third cutting of lucern will in general be ready. But there are many other plants that may perhaps be made use of in this way, as chicory, which may be had recourse to with advantage in this management; as in soils that are tolerably fertile, it will admit of repeated cutting. With these different crops there will probably be seldom any necessity for the use of common cut grafs; though this may be employed, if there should be occasion. The proper foddering of the animals in this practice is a matter of great consequence. It is observed in the Annals of Agriculture, that one great object is never to suffer them to have too much at once; as when this is the case, from the heat of the season, it quickly takes on a degree of fermentation, and is rejected or only picked among by the cattle, in consequence of which much waste may be committed, which would otherwise be avoided; and in addition, it is not improbable but that the stock may thrive better by having their food more frequently, and of course in a more fresh state. But it should never, on any account, be left packed in the carts for any length of time. The best mode seems to be that of adapting the size of the cart to the exact consumption of the stock; as in this way, the whole may be conveniently distributed in the cribs or racks at once, the moment it is wanted, before it becomes unpalatable by fermentation, and the least possible loss may be incurred. It is constantly necessary to watch the conduct of labourers in this particular, as they are in general much disposed to over-feed. And there is another matter which should not be disregarded, which is that of not suffering the crops that are used in soiling to advance to too great a head; as by attention in this respect, the food may be more cleanly eaten up and consumed.

However, it must be observed, a late writer says, that in this system litter becomes an object of the greatest importance, as the large quantity of urine that is made by cattle, when soiled on these luxuriant sorts of green food, is capable, by its moistening property, of aiding in the hot season, the more quick fermentation of such materials, and of reducing a very large proportion into the state of manure. In this view, the attentive farmer should, therefore, make an abundant provision, in the winter time, of other sorts of materials, where a proper supply of straw cannot be reserved for the purpose. There are various matters that may be made use of in this intention, such as stubble, fern, rushes, and other aquatic plants, which may be cut and raked together in the places in which they are most abundantly produced, in order to be stacked up for future use. Leaves might also, in windy situations, be useful for the same purpose. And in addition to these vegetable matters, there are other substances that are capable of being employed with utility, such as peat or bog earth, fresh vegetable mould, sand, and the scrapings of roads; as during the decomposition of the various vegetable materials made use of in this practice, not only much hydrogen and carbonic gas are set at liberty, but ammonia is formed in large quantities, in the manner that has already been explained, which, from
its

its action upon such earthy materials, is highly useful in bringing them into the state of manure for the improvement of lands. See MANURE.

Some other sorts of matters might likewise, in different situations, be employed in this manner with considerable benefit; such as saw-dust, when to be procured in large quantities; and the refuse materials of different manufactories, as the weld of the callico-printer, the bark of the tanner, &c. Many of these kinds of substances are excellent for the purpose of manure.

And in support of the advantages of this management, various facts have been stated by writers on farming. It is remarked by the Rev. Mr. Duncan, in the fourth volume of Communications, that he always keeps his work-horses on red clover through the summer; and they are as healthy and fit for labour as any of his neighbours', that are turned out into the pasture. Last year he cut the clover three times, and thirty falls or perches yielded as much as one horse was able to consume. He has frequently intended to try a crop of goose-grass for hay, upon some piece of ground which was not to remain in pasture; but he has always met with some avocation, at the time when the feed of this grass could be procured. He is surprised that goose-grass has been so long neglected, nay despised. It is considered as a weed among rye-grass, though he has observed that the horses are not of the same opinion. Its hay is most substantial, and were it allowed to come to maturity, its seed would, he supposes, be little inferior in weight to oats, and would probably be an excellent substitute for them in the food of horses. And it is added, that he who can procure 200 carts of dung, from the same extent of ground where 100 only were formerly produced, certainly possesses a double power of improving it. A great reserve of straw is necessary for litter to horses, when living on red clover. When the straw fails, some bed their horses with dried rushes; but rushes contribute very little to the manufacture of dung. When fern, or, as it is sometimes called, the "braken," can be gotten, he would recommend it as next to straw for littering of horses or black cattle, and as the best of all laud vegetables for the dunghill.

Mr. Rawson in the same work also highly approves of, and has long practised, the feeding of horses and spring cattle in summer upon clover; he has found that an acre of clover, cut and carried to the cattle and horses in their hovels and stalls, will maintain double the quantity of stock to an acre pastured; besides the very great quantity of manure produced by this mode of feeding, which secures almost to a certainty the turnip crop.

Also in a trial made by Mr. Mure in soiling bullocks with winter tares, as stated in the Annals of Agriculture, the advantages of this practice over that of feeding in the pastures is very fully shewn. The same system of soiling has been practised with advantage by many others, as Mr. J. Wright, &c.

The same system has been carried to a far more considerable extent, and with a new and quite different object, at the callico-printing works at Bannister Hall, near Preston, in the same county, under the direction and management of Charles Swainson, esq. Here the soiling with tares and clover is practised with a view of procuring the pure dung of the cattle which is so useful and necessary in this sort of printing business, as well as for the common purposes, and producing a large supply of milk. The system is practised to the extent of twenty-five cows and six horses, by which a prodigious saving of expence in the raising and providing of dung is made, as well as in the procuring of hay; while

the appearance and condition of the cattle are far better than in the usual methods of managing them.

The horses are some of them soiled upon and consume the refuse food from the cows, so that nothing is wasted or lost. The team-horses are kept in the stable, the others in a small enclosure, eating their food out of racks. The litter employed is the weld which has been used in dyeing, but very little of it is used, as the pure dung of the neat cattle is a material object.

The cows are bound up in sheds or cow-houses, and kept properly supplied with these sorts of green food, in consequence of which they give large quantities of excellent milk. They are kept constantly soiled in this way during the summer, except while they are consuming the after-grass of the meadows. And it is only the trouble and attention which are required in raising and providing other kinds of green food for winter use, which is wholly incompatible with large works, that have prevented the same practice in feeding from being followed during the winter season, as the great superiority and advantage of green food over that of dry in the milking system, as well as the raising of pure dung, are well understood.

The cows, though confined to the house during the whole of the day, are let out once or twice in that time for the purpose of exercise and water, but drink little under the soiling practice. There is often much advantage in varying their food, in the quantity of milk which is afforded. Cows, when tired of clover, will greedily devour tares, and these last when podded are found to be most excellent food in the view of producing milk. The same variety may likewise be equally beneficial in the use of other sorts of crops.

It is considered as of material importance in this practice with milch cows, that they are kept cool and in the shade.

Sir Humphrey Davy thinks, that in feeding cattle with green food, there are many advantages in the practice of soiling, or supplying them with food, where their manure is preserved, out of the field; the plants, it is conceived, are less injured when cut, than when torn or jagged by the teeth of the cattle, and no food is wasted by being trodden down. The cattle are likewise obliged to feed without making any selection; and in consequence the whole food is consumed: the attachment or dislike to a particular kind of food exhibited by animals, affords, it is supposed, no proof of its nutritive properties or powers, as cattle at first refuse linseed cake, one of the most nutritive substances upon which they can be fed. See STOCK, *Choice of Food in*.

Many statements, which the nature of our work does not allow our inserting, sufficiently prove the great benefits which may be derived from a more general introduction of this practice in all cases where it can be had recourse to, which are probably much more numerous than are commonly supposed; as in all places where there are lands proper for the purpose of raising the necessary sorts of green crops, it may be resorted to in the most successful manner. The great causes which have retarded and prevented the spreading of the soiling system of management would seem to be the fear of the great expence of labour that attends it, and the taking of farmers out of their usual methods of cattle feeding. The former has, however, been shewn to be a mere nothing when compared with the number of animals; and the latter obviously deserves no attention whatever. It is not improbable but that great benefit might also arise in many instances from soiling other sorts of animals in this way; such as sheep, hogs, deer, &c. as vast quantities of manure would be produced, and at the same time the animals

imals be kept in better order, and afford greater improvement and profit.

This is a method of practice that has been found, by the most exact trials, to answer perfectly both with horses, neat cattle, and swine; and with cows it has been found very beneficial in the trials of Mr. Curwen and several others, as well as in other instances. See SWINE and TEAM.

The writer of the corrected account of the state of agriculture in the county of Middlesex has, however, observed, in opposition to this system of management, that though "it has lately been suggested by several writers, that carrying grafs into the yards, and giving it to cattle there, is more adviseable than permitting them to collect their own food: where the party can manure half his land annually, or the whole every second year, it may, it is supposed, be expected to support such a high degree of exhaustion; but in other cases, the pasture would soon be so much impoverished, as to produce nothing for the owner of it to mow. Meadows which can be flooded by art at any period of summer, would probably, too, it is thought, admit of having their produce continually carried off: in all other cases, such a system would, in the opinion of the writer, in a short time ruin the land."

But surely no rational or consistent practical agriculturalist ever inculcated the necessity or utility of the practice of mowing and carrying the grafs of pasture or hay-lands to be consumed in the farm-yards by cattle. The system of useful soiling, so far as it is known to us, has been usually confined to luxuriant crops of the artificial grafs kind, raised by means of tillage, and provided for by the increased quantity of manure which is produced and preserved in the process or practice.

"The increased labour and expence of such a practice would also, it is said, render it unprofitable; one man employed in that manner, with a horse and cart, could not attend the cattle, and bring in the produce of many acres, though it would cost a grazier in this county, annually, it is supposed, one hundred and thirteen pounds; to which ought to be added, that the manure would be wasted in such a manner, as to lose a large moiety of it; in all which ways one hundred and twenty pounds would be expended, which is a greater sum than this practice is calculated to repay."

It is evident, however, from what has been seen above, that one man can not only attend to the cattle, but convey the produce of many acres to the places where it is to be eaten, besides doing much other work; and as to the horses and carts which are necessary, as those of the small kind are commonly the most suitable, they will be found on almost all farms where such a method of cattle management can be had recourse to with any benefit. Such an imaginary charge, therefore, seems to be founded on no just grounds. And that there would be any great deal more waste of manure in this than in other ways, is probably a mere supposition, as under good management, evaporation in hot seasons would be guarded against, and the accumulation of it in the practice is universally allowed to be extremely great. There is consequently no well-founded reason for concluding that the practice will not amply repay every expence attending it when properly carried on.

"The only advantage which it promises is, it is said, to avoid the damage done by the treading of cattle: it must be admitted, that in wet seasons and deep grafs this is considerable: but a few additional acres would, it is believed, supply a similar quantity of herbage at a less expence; where that cannot be obtained, reducing the number of cattle would, it is said, have the same effect, and might be done

without incurring so great a diminution of profit as the foregoing one hundred and twenty pounds would certainly be.

"It is obvious, (the writer says, after stating other objections,) that this is one of the closet systems of supporting cattle, which cannot be reduced to practice beyond the extent of a very few acres, and only then, when it can be done without any additional men or horses. If the expence of the men and teams is to be brought into the account, it will, it is said, be altogether unprofitable. Such an expence would, in this county, amount, it is supposed, in fifteen weeks, to thirty-four pounds ten shillings; which, divided by the number of acres (ten), proves the charge to be, on each acre, three pounds nine shillings; or divided by the number of oxen (six), it would be, on each, five pounds fifteen shillings: add this extra expence, it is said, to a long list of usual and unavoidable charges, and it will swell the account to such a sum, as would exceed the value of the improvement of any cattle whatever."

The system of soiling animals can clearly be extended to more than a few acres, and even where additional men and horses are required, though there will be seldom any occasion for them in the practice. Nor is the expence of the men or teams employed about it any real objection, when justly and fairly calculated, or even that of the cattle *per* head of any account, so as to make it more than equal to their advancement in condition. Where no sufficient data are given, from actual trials, it is easy to arrive at conclusions; but the practice and experience of farmers in the best cultivated districts, set all such opinions and conclusions at naught.

SOINI, in *Geography*, a town of Sweden, in the government of Wasa; 70 miles E. of Wasa.

SOINIDRO, a town of the island of Cuba; 75 miles E.S.E. of Havanna.

SOJOURNERS, among the *Athenians*, were permitted to dwell in the city, and follow their own business, without disturbance, provided they observed all the laws and customs of the country; but were allowed no share in the government. However, they were not allowed to act any thing, or manage any business in their own names, but were obliged to choose out of the citizens one, to whose care and protection they would commit themselves, whose duty it was to defend them from all violence and oppression. He was called *prostates*.

SOKALLEN, in *Geography*, a town of Russian Lithuania; 9 miles S. of Ragnit.

SOKASPOGE, a town of the state of Georgia; 4 miles N.E. of Oakfuskee.

SOKE, in *Rural Economy*, an ancient term, used to signify the privilege of mills, &c. By it the lord, in certain cases, was enabled to raise a considerable rent.

SOKE-Mill, that kind of mill which belongs to the lord or superior of the manor, and at which all the tenants, and sometimes the whole parish, are bound to grind their grain. Mills of this nature were once very common, and they exist still in a few places.

SOKELY, in *Geography*, a town of Norway, in the province of Bergen; 24 miles S.W. of Romfdal.

SOKEMANS. See *SOCMEN*.

SOKER, in *Geography*, a small island in the Red sea; 3 miles E. of Dsjabbel.

SOKE-REEVE, in our *Old Writers*, the lord's rent-gatherer in the *soke*, or *soken*.

SOKHIO, in the *Materia Medica*, a name used by some authors for a peculiar species, if it may be so called, of the lignum aloes.

It is of a greyish colour, and seems to have been the blea, or outer part of the wood next the bark.

SOKO, in *Geography*, a district of Africa, on the Gold Coast, extending about a league along the sea-coast, on the borders of the river Volta. The land is fertile, but the inhabitants are poor, and employ themselves chiefly in fishing.

SOKOLMA, a town of Poland, in Volhynia; 12 miles N. of Luckow.

SOKOLOW, a town of Poland, in Podolia; 54 miles N.W. of Kaminiac.

SOKOLOWKA, a town of Austrian Poland, in Galicia; 20 miles S. of Lemberg.

SOKOLVOD, or **KNEZDO**, a mountain of Croatia; 32 miles E. of Bihacs.

SOKOR ZOK, a town of Armenia, situated on a small hill, equally distant from Betlis and Diarbekir, governed by a powerful, independent, and hereditary prince, who has under his orders many different tribes of Kurds, Yezedis, and Turkomans, of a martial and barbarous disposition, and who, it is said, can bring an army of 20,000 men into the field. The climate of this place is less severe than that of Betlis; the districts are extensive, and covered with villages, but the population of the town does not exceed 6000 souls. South of Zok is the town of Sahert, or *Serud*; which see.

SOKOTKA, a town of Lithuania; 15 miles S.W. of Grodno.

SOL, a syllable in the first elements of vocal music, which, in major keys, always implies the 5th above the key-note: as, *do re mi fa sol*; or *do—sol*.

SOL, or *Sou*, *Shilling*, in *Commerce*, a French coin, according to the old system, which prevailed before the revolution, of billon, *i. e.* of copper with a little silver mixed, equal to twelve deniers, or French pence, or four liards; and the twentieth part of the livre Tournois, or pound. See *SHILLING*.

The word is formed from the Latin, *solidus*, a shilling. Bodin is mistaken when he derives it à *sole*, by reason of the sun struck on it.

The fol was first struck on the foot of twelve deniers Tournois, whence it was also called *douzain*, a name it afterwards retained, though its ancient value was changed; the fol having been since augmented by three deniers, and struck with a puncheon of a fleur-de-lis, to make it current for fifteen deniers. Soon after the old fols were coined over again, and both old and new were indifferently made current for fifteen deniers. In 1709, the value of the same fols was raised to eighteen deniers. Towards the latter end of the reign of Louis XIV. the fols of eighteen deniers were again lowered to fifteen. The fol of fifteen deniers was called *sol Parisis*. According to the old system, the silver coins in France were the *ecu*, or crown of six livres; the *petit ecu*, or half-crown (also called *ecu*) of three livres: pieces of twenty-four, twelve, and six fous; also pieces of two fous and six liards, or one and a half fou, containing five parts of silver to nineteen of copper; and pieces (entirely copper) of one fou, two liards, and one liard, or twelve, six, and three deniers. The piece of twenty-four fous, compared in fineness with the English standard of 11 oz. 2 dwts., is W. 0 dr. 7 dwt., its weight 3 dr. 20 gr., its content in pure silver is 83.4 gr., and its value in sterling is $11\frac{1}{4}d$. The pieces of twelve and six fous are in proportion. The piece of thirty fous of 1791 is W. 3 oz. 8 dwt., its weight 6 dwt. 12 gr., its contents in pure silver 100.2 gr., and its value in sterling $1s. 2d$. The piece of fifteen fous is in proportion.

In old authors we read of gold fols, which were different at different times. In the time of the Salic law, the gold fol was forty deniers; and thus it continued till the time of king Pepin, when it was reduced to twelve. Some have also imagined, that the French had anciently silver fols.

The Dutch have also two kinds of fols: the one of silver, called *fols de gros*, and likewise *schelling*; the other of copper, called also the *stuyver*. See *COIN*.

The fol, or fou, is also a money of account and copper coin in Switzerland.

SOL, in *Astrology*, &c. signifies the sun. Sol in Aries, &c. See *SUN*.

SOL, *Sun*, in *Chemistry*, is gold; thus called from an opinion that this metal is, in a particular manner, under the influence of that luminary.

What should have been the principal inducement of torturing this metal, with so much violence, to obtain from it some medicinal virtues, Dr. Quincy observes, is not easy to be guessed.

Most, indeed, acknowledge, that gold in substance, or reduced into the smallest particles by the hammer, as in the leaf-gold, is not digestible in the stomach, so as to be transmitted into the blood, and be of any efficacy there. But there are nevertheless many, who are confident of its doing extraordinary matters, if reduced into a powder, by amalgamation with mercury, and by evaporating the mercury afterwards.

Zacutus Lusitanus is one of the smartest pleaders on this side the controversy, against Musa, Picus Mirandola, and Platerus; who, besides many instances of its efficacy, urges the authority of Avicen, Serapion, Geber, and many of the Arabian physicians, with those of other countries, and of later date. Quercetan, Schroder, Zwelfer, and Etmuller, with many other more modern practical physicians, have fallen into the same opinion. But which side soever is right, the present practice rejects all pretensions to medicines from it. See *GOLD*, in *Medicine* and *Chemistry*.

SOL, in the *Hermetical Philosophy*, signifies sulphur.

SOL,

SOL, in *Heraldry*, denotes *or*, the golden colour in the arms of sovereign princes.

SOL GALICZK, in *Geography*, a town of Russia, in the government of Koltrom; 96 miles N.N.E. of Koltrom. N. lat. 59°. E. long. 42° 24'.

SOL VITCHEGODSK, a town of Russia, on the river Vitcheга; 36 miles N. of Utiug. N. lat. 61° 30'. E. long. 46° 14'.

SOLA, a small island in the Caribbean sea; 30 miles E. of Margarita.—Also, a small island among the Philippines, near the S. coast of the island of Luzon. N. lat. 13° 22'. E. long. 12° 46'.

SOLA, LA, Pylstari's Islands, so called by Maurelle. See **PYLSTART**.

SOLÆUS, in *Anatomy*. See **SOLEUS**.

SOLAGNA, in *Geography*, a town of Italy, in the Trevisan; 5 miles S. of Cismè.

SOLAGUR, a town of Bengal; 25 miles W.N.W. of Silhet.

SOLAKI, a town of Dagestan; 60 miles N.N.W. of Derbend.

SOLAN, a town of Africa, in Cashna. N. lat. 16° 30'. E. long. 10°.

SOLANA, in *Ancient Geography*, a town of Asia, in Serica. Ptolemy.

SOLAND, or **SOLAN-Goose**, in *Ornithology*. See **PELECANUS Bassanus**.

SOLANDER'S ISLAND, in *Geography*, an island in the South Pacific ocean, near the S. coast of New Zealand, discovered by captain Cook in March 1770; and so named after Dr. Solander. It is merely a barren rock, about a mile in circuit, remarkably high, and lying full five leagues distant from the main. The shore of the main lies nearest E. by S. and W. by N., and forms a large open bay, in which there is no appearance of any harbour or shelter for shipping against S.W. and southerly winds: the surface of the country is broken into craggy hills of a great height, on the summits of which were several patches of snow; it is not, however, wholly barren, for wood was seen not only in the vallies, but upon the highest ground; but it exhibited no signs of being inhabited. S. lat. 46° 31'. W. long. 192° 49'. Hawkesworth's Voy. vol. iii.—Also, a small island in the Mergui Archipelago. N. lat. 10° 39'.

SOLANDERS, in *Farrery*. See **MALANDERS**.
