
The former is an ingredient in Venice treacle; its chief use is in disorders of the nerves; in which respect, however, it is held inferior to the latter.

The wild valerian, *valeriana officinalis* of Linnæus, or *valeriana sylvestris major montana* of Bauhin, is perennial, and grows wild in dry mountainous places. The root consists of tough strings, with numerous smaller threads, matted together, issuing from one head, of a dusky-brownish colour approaching to olive. Cows eat the leaves, and cats are very fond of the roots. Rats are also said to be equally fond of these roots, and rat-catchers employ them to draw the rats together. Another species, or variety, of wild valerian is met with in moist watery grounds, distinguishable by the leaves being broader, and of a deep glossy-green colour. Both sorts have been used indiscriminately; but the mountain sort is much the most efficacious, and is, therefore, expressly ordered for the official species by the London College.

The mountain valerian, or narrow-leaved variety of this species, not exceeding two feet in height, and affecting dry heaths and high pastures, is chiefly in repute: its root manifests stronger sensible qualities, and possesses more medicinal power: its smell is strong, resembling that of a mixture of aromatics with fetids, and it has an unpleasent, warm, bitterish, subacid taste: the strength of the smell and taste is the only certain test of its genuineness and goodness. It is a medicine of great esteem against obstinate hemicrania, hysterical and the different kinds of nervous disorders, and is commonly considered as one of the principal antispasmodics. Dioscorides and Galen mention it as an aromatic and diuretic. Columna reports, that he was cured by it of an inveterate epilepsy after many other medicines had been used in vain.

M. Marchant, in the Memoirs of the Academy of Sciences, has confirmed this virtue, by many instances within his own knowledge: and what is very remarkable is, that in the two observations he enlarges most upon, the patients, on taking it, voided great quantities of worms. His custom was always to purge before he administered it.

On more extensive trials it has been found, in some epileptic cases, to effect a cure, in several to abate the violence

or frequency of the fits, and in many to prove altogether ineffectual; oftentimes it either purges or operates by sweat or by urine, or brings away worms, before it prevents a fit. The dose of the root in powder is from a scruple to a drachm or two, which may be repeated, if the stomach will bear it, two or three times a day. Dr. Withering says, that in habitual costiveness it is an excellent medicine; and frequently loosens the bowels when other stronger purgatives have been tried in vain. A remarkable instance of its efficacy in a catalepsy is given by Mr. Mudge (on the *vis vite, &c.*); doses of half an ounce of the powder were exhibited twice a day, and a less quantity was found ineffectual.

The advantages said to be derived from this root in epilepsy, caused it to be tried in several other complaints denominated nervous, particularly those produced by increased mobility and irritability of the nervous system, in which it has been found highly serviceable. Bergius states its virtue to be antispasmodic, diaphoretic, emmenagogue, diuretic, and anthelmintic. And under the head of its use, he enumerates epilepsy, convulsions, hysteria, hemicrania, and visus hebitudo. Fordyce commends it in this last disease. Whytt, who joined it with manna, experienced its utility in epilepsy. Joined with guaiacum, Morgan found it useful in resolving glandular or stromous tumours. Dr. Cullen allows, that its antispasmodic powers are well established, and he thinks it should be given in larger doses than those that are commonly used. Accordingly he has found it frequently useful in epileptic, hysterical, and other spasmodic affections. It is said, however, that it has been sometimes given in cases of epilepsy, to the extent of two ounces a day without effect; and Dr. Woodville observes, that his own experience warrants him in saying, that it seldom has been found to answer the expectation of the prescriber.

The powdered root, infused in water, or digested in rectified spirit, impregnates both menstrua strongly with its smell and taste, and tinges the former of a dark brown, and the latter of a brownish-red colour. Water distilled from it smells considerably of the root, but no essential oil separates: the extract obtained by inspissating the watery infusion, which is about one-fourth the weight of the root, has a pretty strong taste, disagreeably sweetish, and somewhat bitterish: the spirituous extract, which is about one-eighth the weight of the root, is less disagreeable, and more perfectly resembles the root itself.

Tinctures of it are prepared in the shops, by digesting four ounces of the powdered valerian in a quart of proof-spirit, in the same quantity of the volatile aromatic spirit, or of the dulcified spirit of sal ammoniac. The root in substance, however, is generally found to be more effectual than any preparation of it: and its flavour may best be covered with mace. Lewis and Woodville.

VALERIANELLA, in *Botany*, the diminutive of VALERIANA, see that article and FEDIA.

VALERIANO BOLZANI, PIERIO, in *Biography*, was born at Belluno, in 1477, in such a low condition, that he had no opportunity of acquiring the first elements of literature till he attained the age of fifteen years. After having been reduced to the necessity of entering into the service of a noble person at Venice for support, he devoted himself to study under eminent teachers; and agreeably to the practice of the age in which he lived, changed his baptismal name of Giampietro for Pierio. In his 23d year he engaged in the study of philosophy at Padua, and passed three years in a retreat at mount Olivet, in the Veronese. Upon his return to his native place, he found it possessed by the imperial army

army in 1509, so that he was obliged to make his escape to Rome. Here he fortunately became known to cardinal Giovanni de Medici, by whom, when pope Leo X., he was honourably provided for in his court. At the termination of this pontificate, he passed some time at Naples; but upon the accession of Clement VII. he returned to Rome, and was promoted to the chair of eloquence, with the title of protonotary and private chamberlain, to which was added a canonry, and some other benefice in Belluno. Having employed himself in Latin poetry, he relinquished the composition of elegies and amatory pieces, by which he had acquired reputation, upon taking holy orders. To him Leo X. committed the instruction of his two nephews, Ippolito and Alessandro de Medici, and he accompanied them to Florence, where he resided in the year 1527, when they were expelled from that city. After sharing their misfortunes, he attended them to Florence in 1530. Upon their death, he withdrew first to Belluno, and then to Padua, where he closed his life in 1558, at the age of eighty-one years.

The work by which he is principally known, is his treatise "De Infelicitate Literatorum," first printed at Venice in 1620, and often reprinted. Another of his publications was intitled "Hieroglyphica, sive de sacris Ægyptiorum aliarumque Gentium literis Commentariorum, Lib. LVIII.," Basil, 1566. Some of his other performances were, "De Fulminum Significationibus," Romæ, 1517; "Pro Sacerdotum Barbis defensio," 1531; "Caltigationes Virgilianæ lectionis," first printed in R. Stephens's edition of Virgil, Paris, 1532, and since annexed to various other editions; and "Antiquitates Bellunenfes." He also published two volumes of his Latin poems. Moreri. Tiraboschi. Gen. Biog.

VALERIUS FLACCUS. See FLACCUS.

VALERIUS MAXIMUS, a writer whose history is little known. The work which has been ascribed to him, and entitled "De Dicitis et Factis Memorabilibus Antiquorum, Lib. IX." appears to have been written in the reign of Tiberius, probably after the death of Sejanus, and dedicated with high eulogy to Tiberius. It is cited by Pliny the elder, Plutarch, and A. Gellius; and it was much read and quoted at the revival of literature in Europe. One of the early editions, which were numerous, is supposed to have been prior to 1460; of the later editions, the most esteemed are the "Variorum," Lugd.-Bat. 1670; the "Delphin," Paris, 1679; "Torrenii," Lugd.-Bat. 1726; and "Kappii," Lipsi. 1782.

VALERIUS POPLICOLA, PUBLIUS, an eminent Roman, and one of the founders of the republican government, distinguished by his simplicity, eloquence, and liberality. In a contention about the consulate, at the expulsion of the Tarquinian family, he was elected to supply the place of Collatinus, who was removed from office, and lived on terms of the utmost harmony with his colleague, the celebrated Junius Brutus. In the subsequent battle with the allies of Tarquin, in which Brutus was slain, Valerius gained a victory, for which he obtained a triumph, B.C. 507. Delaying the election of a new consul, and having built a house on the Palatine hill, that overlooked the forum, he excited the suspicion of the people; but as soon as he understood the ground of their jealousy, he ordered the house to be levelled in the night, and gave orders for supplying the vacancy in the consulate. The father of Lucretia was chosen, but by his death soon after his election, Valerius was again the sole chief magistrate. In the exercise of his office he enacted several laws, abridging the consular authority, and meliorating the condition of the people; and hence obtained the name of *Poplicola*, or the people's friend. As a proof of his inte-

grity and disinterestedness, he removed the public treasury from his own house to the temple of Saturn, thus committing it to the charge of two senators appointed by the people. Upon an election of consul, his popularity occasioned his being chosen a second time. When, in the following year, Porcena, king of Clusium, in Tuscany, attempted the restoration of Tarquin, and by an army which he marched to Rome reduced the city to great difficulties, Poplicola agreed to resign some of their conquests as the price of peace; and his own daughter Valeria was one of the hostages. In a war with the Sabines, Poplicola was nominated for the fourth time a consul; and by his military skill obtained a complete victory over the enemy, and recovered the town of Fidenæ. For this success he obtained a triumph, and soon after died, having established the character of one of the greatest men and most virtuous citizens of Rome. Although he had occupied many lucrative posts, he did not amass money sufficient to defray the expence of his funeral, which was paid by the public; and in honour of his memory, as in the case of Brutus, the matrons of Rome wore mourning for a year. His principles were transmitted to his family from one generation to another, so that the Valerii were assertors of the rights of the people. Livy. Dionysius Hal. Anc. Un. Hist. Gen. Biog.

VALERIUS, LUCAS, an eminent mathematician, acquired great celebrity at Rome as professor of geometry, and was honoured by Galileo with the appellation of the Archimedes of his time. He died in this city in 1618. He prosecuted the discovery of the centres of gravity of solids, and shewed how to determine them in all the conoids and spheroids, and their respective segments formed by planes parallel to the bases. The result of his investigation was published in 1604, in a work entitled "De Centro Gravitatis Solidorum." He also proposed a quadrature of the parabola different from that of Archimedes. His method was published in 1606, and annexed to the fore-mentioned treatise. Montucla.

VALES REALES, or *Royal Bonds*, in *Commerce*, are a kind of paper currency, which was first issued by the Spanish government in the year 1800, for the following sums:

600 dollars =	9035 reals 10 maravedis vellon.
300 ditto =	4517 ditto 22 ditto.
150 ditto =	2258 ditto 28 ditto.

These bonds are transferrable only by indorsement: they bear an interest of 4 per cent. per annum, and were made a legal tender for their full amount, with any interest that might be due upon them; but, from various causes, they have experienced a considerable depreciation. Kelly's Un. Cambist.

VALESINIANS, VALESIANI, in *Ecclesiastical History*, ancient sectaries, so called from one Valesius, a person unknown to Epiphanius, who, however, makes mention of this sect, Hær. 58. though he owns he knew but very little of them; only this, that they admitted none into their society but eunuchs; at last, if any were admitted before castration, they obliged them not to eat any meat till the operation was performed. For then, being no longer subject to the motions of the flesh, they allowed them to eat any kind of meats. Whiston says of them, that they sprung up about the year 240, and that they rejected the law and the prophets.

VALESIIUS, in *Biography*. See VALOIS.

VALESTRA, in *Geography*, a town of Italy, in the department of the Panaro; 12 miles S.W. of Modena.

VALET, or VALECT, a French term, anciently written *varlet*.

In France, valet is a common name for all domestic servants employed in the lower and more servile offices; including what we call *grooms, footmen, coachmen, bailiffs, &c.* But the word is not used among us in this sense, nor any otherwise than in the phrase *valet de chambre*; which is a servant, whose office is to dress and undress his master, to look to his bed-chamber, wait on him at table, &c. the same with what we otherwise call his *gentleman*.

In the History of Lewis XII. by Scifel, we always find *varlet de chambre du roi, varlet de la gard-robe, &c.* But *varlet*, like *knave*, and divers other words, is now degenerated into a term of reproach.

Valet, valec, vadelec, vadlet, and vallet, Camden observes, were anciently used at our court for a gentleman of the privy-chamber.

Selden, in his Titles, relates, that valets anciently signified young gentlemen, and heirs of great estate and quality; especially such as were to be knighted.

In the accounts of the Inner Temple, valet is used for a bench's clerk, or servant. The butlers of the house still call them *varlets*.

VALET, in the *Manege*, a stick armed at one end with a blunted point of iron, to prick and aid a leaping horse.

Formerly, a valet was called *aiguillon, i. e. goad*, and some of them had spur-rowels upon them, only the points beaten down; and when a horse was first begun round a pillar, without a rider, they used to prick his flanks with the valet, to make him know the spur, and obey it, without resisting. At present the valet is not used for that purpose, and the name of goad is suppressed, as being only proper for oxen.

VALETTA, or CITTA NUOVA, in *Geography*, a city of Malta, and capital of the island, which, in the year 1566, was built by the grand-master Frederic John de Valetta, on a hill, in form like a neck of land extending itself into the sea, and was called by his name. Its walls are of large square stones, dug out of the rock, and planted with several batteries. On the point towards the sea stands the castle of St. Elmo, a fortress which defends both the harbours; one of which, called Marfa Mascietto, lies at the entrance from the sea to the right of the town, and incloses a small island, on which stand both a fort and a lazaretto. The other harbour, on the left side, is simply called Marfa, or The Great Harbour, being the largest, safest, and most commodious in this island, and having some bays. Its entrance, besides the castle of St. Elmo, is guarded by Fort Ricafoli, which stands on the Punta del Orfa, to the left. The town of Valetta lies on its right, and on its left the towns Il Borgo, or Vittoriosa, and Senglea. In Valetta is a handsome palace, where the grand-master resides, and before it a spacious area for exercises. Each of the seven nations, or tongues of this order, has its peculiar hall. The principal church is dedicated to St. John the Baptist. The Jesuits had a college here; besides which are several convents and nunneries, a large hospital, and a building where Turkish slaves are kept. The number of the inhabitants is computed to be about 2000. See MALTA.

VALETTE, LA, a town of France, in the department of the Iere; 15 miles S.S.E. of Grenoble.—Also, a town of France, in the department of the Charente; 12 miles S. of Angoulême.—Also, a fort of France, in the department of the Var, near Toulon.

VALETUDINARY, VALETUDINARIUS, a term sometimes used, by the writers on medicine, for a person of a weak, sickly constitution, who is very frequently out of order, &c.

Dr. Cheyne, by all means, directs the weakly, the stu-

dious, the sedentary, and the valetudinary, to a low, spare regimen.

VALEUR *des Notes*, Fr.; *Value of Notes*, in *Music*. Besides the position of the notes on the staff, which fix the tone with respect to gravity and acuteness, they have all some peculiarity of figure, which marks their duration as to time, or comparative value as to length. In the ancient primitive time-table, in which all the notes are black or full, except the semibreve and minim, which are white and open, the shortest notes then in use are the longest now, and all that are open. The breve, indeed, equal to two semibreves, is still to be found in church-music of some antiquity, known by the titles *alla breve*, or *à capella*; but in all secular music, the semibreve is placed at the head of the other characters for time; and that note, divided into its aliquot parts, furnishes all the fractions in the most rapid compositions.

The dual measure, or common time, is governed by even numbers; as 2 minims, 4 crotchets, 8 quavers, 16 semiquavers, 32 demisemiquavers, all which only amount to a semibreve.

Triple time, or ternary measure, is governed by the number 3: as $\frac{3}{2}$, $\frac{3}{4}$, $\frac{3}{8}$, $\frac{3}{16}$. In these numbers, the upper figure tells how many notes there are in each bar, and the under, of what kind in the time-table; as $\frac{3}{2}$ implies 3 minims, $\frac{3}{4}$ three crotchets, $\frac{3}{8}$ three quavers.

One-third is added to the value of a note by a point or dot: as a semibreve equal to two minims, by a point is equal to three; a minim equal to two crotchets, the point makes equal to three, &c. See *Musical CHARACTERS, TIME, and Plate Time-table*.

It was to John de Muris, who flourished about the year 1330, that the characters for time in music were long ascribed; but on examining and collating MSS. in the several great libraries of Europe, it has been clearly proved that it was not John de Muris who invented these characters, as he himself owns in one of his tracts, but Magister Franco of Cologn, author of a treatise "De Musica Mensurabili," written in the eleventh century, long before De Muris was born; in which the form of the notes is given, and their relative value explained.

This very scarce treatise is preserved in the Bodleian library, 842, f. 49. See FRANCO and DE MURIS.

VALEY ISLAND, in *Geography*, a small island in the North sea, separated by a strait called Valey Sound, from the south-west coast of the island of Shetland. N. lat. 60° 15'. W. long. 1° 58'.

VALFROICOUR, a town of France, in the department of the Vosges; 6 miles S. of Mirecour.

VALGI. When the legs were deformed in such a manner that the feet were twisted outwards, the persons thus disfigured were termed *valgi*; while others, who were deformed by an inclination of their toes inwards, received the appellation of *vari*.

VALGOM, in *Geography*, a town of the island of Ceylon; 6 miles N. of Candy.

VALGORGE, a town of France, in the department of the Ardèche; 9 miles N.W. of Largentiere.

VALGRANA, a town of France, in the department of the Stura; 9 miles W. of Coni.

VALHERMOSA, a town of Portugal, in the province of Estramadura; 9 miles N.E. of Leyria.—Also, a town on the north-west of the island of Gomera.—Also, a town of Spain, in New Castile; 12 miles E.S.E. of Guadalajara.

VALI, in the mythological romances of the Hindoos, is a name given to a monkey, begotten by their god Indra,

on a damsel of the semi-celestial tribe, called Upfara. We may just notice, that this warlike monkey was killed by the great RAMA, the hero of the extraordinary poem Ramayana.

VALIAM, in *Geography*, a small Russian island, in lake Ladoga; 92 miles N. of Petersburg.

VALIANO, a town of Etruria; 10 miles S.S.W. of Cortona.

VALID, a term applied to acts, transactions, expeditions, &c. which are clothed in all the formalities requisite to their being put into execution, and to their being admitted to a court of justice.

A contract by a minor is not valid, or is *invalid*: a marriage is not valid, unless performed with the solemnities enjoined.

VALIERO, AGOSTINO, in *Biography*, a celebrated prelate of the church of Rome and a voluminous writer, was born of a noble family at Venice in 1531. Having studied both at Venice and Padua, with a view to the ecclesiastical profession, he graduated both in theology and canon law. In 1558, having previously been employed in several public offices, he became professor of moral philosophy at Venice, which post he occupied till the year 1565, when he was elected successor to his uncle as bishop of Verona, and he presided over that see for forty-one years. In 1583 he was created a cardinal by Gregory XIII. Through the whole of his life, which terminated at Rome in 1606, in the 75th year of his age, he distinguished himself as the patron and promoter of literature, as well as by his zeal, charity, and munificence. The catalogue of his writings includes one hundred and twenty-eight. Of those that were printed, many being in MS., the most important are, "De Acolytorum Disciplina;" "De Rhetorica Ecclesiastica;" "Episcopus, seu de Optimo Episcopi formâ;" "Cardinalis, five de Optima Cardinalis formâ;" "De rectâ philosophandi ratione;" "De Cautione adhibenda in edendis libris." That his sentiments were liberal for the time in which he lived, appears from his treatise designed to prove that comets are not presages of calamities, and from another against the barbarism of the scholastics. He also wrote on the order and connection of the sciences and arts, and a large work on the Venetian history. Moreri. Tiraboschi.

VALIGA, a name given by some medical writers to an infusion or tincture of jalap in spirit of wine, or spirit of citron, with the addition of a little saffron.

VALIMONT, in *Geography*, a town of France, in the department of the Moselle; 8 miles N.W. of Morhange.

VALINCOURT, JOHN-BAPTIST DU TROUSSET DE, in *Biography*, was born of a noble family at St. Quentin, in Picardy, in 1653, educated at the Jesuits' college in Paris, and distinguished himself as a man of letters. In 1685 he was appointed, by the count of Toulouse, admiral of France, his secretary-general, and afterwards secretary of the marine; but through life he cultivated polite literature, and became a member of the French Academy in the room of Racine, an honorary member of that of Sciences, and an associate of the Academy della Crusca. He succeeded Racine as joint-historiographer with Boileau; but his labours on the reign of Louis XIV. were consumed with his library in 1725, a loss which he bore with philosophical composure, observing to one of his condoling friends, "I should little have profited by my books, if I had not learned how to lose them." He was an active promoter of literature and a protector of learned men, who had always free access to his house; and his character was distinguished by probity, sincerity and good sense. He was held in such estimation, that Boileau dedicated to him his satire on True and False Honour. His time was so much occupied, that his writings are few; they

consist of a critique on the celebrated novel of "The Princess of Cleves;" "A Life of Francis Duke of Guise, surnamed Le Balafre;" "Critical Observations on the Œdipus of Sophocles," and a few poems. Such was his regard for religion, that towards the close of life, he held several conferences with ecclesiastics, for the purpose of terminating the divisions of the church with respect to the bull Unigenitus. He died at Paris, generally esteemed, in 1730, aged seventy-seven years. Moreri.

VALINSAY, in *Geography*, a town on the W. coast of the island of Luçon. N. lat. 16° 18'. E. long. 120° 6'.

VALIODA, a town of Hindoostan; 15 miles E.N.E. of Travancore.

VALJOVA, a town of European Turkey, in the province of Servia; 50 miles N. of Jenibasar.

VALIQUERVILLE, a town of France, in the department of the Lower Seine; 6 miles N.N.W. of Caudebec.

VALIZ. See BALIZE.

VALK, a town of Russia, in the government of Riga; 72 miles N.E. of Riga. N. lat. 57° 50'. E. long. 25° 44'.

VALKI, a town of Russia, in the government of Charkov; 16 miles S.W. of Charkov. N. lat. 49° 36'. E. long. 35° 44'.

VALKENBURG. See FAUQUEMONT.

VALKOVAR, or BARKOVAR, or *Valko*, a town of Slavonia, near the right bank of the Drave; 15 miles S.E. of Efzeck.

VALL, or VALE, in *Commerce*, a weight for gold and silver at Bombay and Surat. See TOLA.

VALL, in *Geography*, a town of Sweden, in Warmeland; 28 miles E.S.E. of Carlstadt.

VALLA, GIORGIO, in *Biography*, a native of Placentia, and professor of polite literature in the university of Pavia in 1471 and 1476, from which he removed to the chair of eloquence at Venice in 1486. As he was one morning preparing to go to his school, where he explained Cicero's Tusculan Questions, and held daily disputations on the immortality of the soul, he died suddenly at the close of the 15th century. He was the author of many works, which are for the most part collections and transcripts from ancient writers, and translations from Greek authors, useful in that age, but not distinguished by judgment or accuracy. Bayle.

VALLA, LORENZO, was probably a relation of the preceding Valla, and born at Rome, as it has been said, in the year 1415, but as Tiraboschi says, before the year 1406. He was educated in his native city, and continued there till his twenty-fourth year. Having visited Placentia to take possession of the inheritance bequeathed to him by his relations, he settled at Pavia as professor of eloquence in the university. Here he was chargeable with some instances of misconduct, so that he changed his abode several times, till he became attached to Alphonso, king of Naples, in which city he resided for some time; but in 1453, on the return of pope Eugenius to Rome, he settled in that city. Investigating the pretended donation of Constantine to the holy see, which he discredited, and reflecting on the characters of several popes, he incurred the displeasure of Eugenius, and found it necessary to withdraw first to Ostia, then to Naples, and finally to Barcelona. From hence he addressed an apology to the pope, and a defence of his writings on moral philosophy and dialectics, without any reference to Constantine's donation. He afterwards returned to Naples under the protection of Alphonso, and there opened a school of eloquence, to which many scholars resorted; but notwithstanding his popularity as a teacher, he was accused and brought into danger on account of the freedom with which

which he maintained his peculiar opinions. Of these, we may mention his rejection of the letter of Christ to Abgarus as a fiction, and his reproach of a celebrated preacher for asserting that each article in the apostles' creed was composed by one of them separately. For the latter of these offences he was brought before the Inquisition, and owed his escape to the interposition of Alphonso, after a private flagellation in the cloister of monks. At length he was invited to Rome by pope Nicholas V., who was distinguished by his patronage of literature; and in this metropolis he opened a school of eloquence, A.D. 1450. Here he entered into a dispute with George of Trebifond, secretary to the pope, on the respective merits of Cicero and Quinctilian, to the latter of whom he gave a decided preference. His next contest was with Poggio Braciolini, who attacked him in five invectives, to which Valla opposed as many antidotes, or dialogues, against Poggio. The manner in which this literary contest was prosecuted was disgraceful to both parties, and has been severely censured by Tiraboschi. Although Valla was much occupied with disputes of this kind, he pursued his studies, and by order of Nicholas V. undertook a version of the Greek of Thucydides into Latin, for which he received from the pope a recompence of 500 gold crowns, a canonry of St. John Lateran, and the place of apostolic scribe. For these favours on the part of the pope, Valla is charged with ingratitude. In the latter years of his life he visited king Alphonso at Naples, who exhorted him to translate Herodotus, but his death prevented his finishing the proposed version; however, for the part which he completed he was liberally rewarded. This translation was concluded by another person, and dedicated to Pius II. Valla's death occurred in August, 1457. The character of Valla is thus sketched by one of his biographers. He was "a man confident of his talents and acquirements, intolerant of other men's opinions, and free in his own, arrogant and contentious. His conduct was probably far from correct, though his enemies may have brought false or exaggerated charges against him. His philosophy was professedly Epicurean, placing the highest good in pleasure, which, however, he might explain in the least obnoxious sense. He was never married, but he confessed in one of his answers to Poggio, that he took a young woman to live with him, by whom he had three children, and whose fidelity to himself he extols, adding, that he hoped to procure for her a husband; but concubinage was at that time very common among the scholars attached to the court of Rome. In the capacity of a reviver of letters he has always held a high rank, which he merited by unwearied application, and an enlarged course of study, comprehending history, criticism, dialectics, moral philosophy, and theology. That in the latter his notions were liberal, may be conjectured from some of the circumstances above related, and also from his notes on the New Testament, in which he was one of the first to consider the sense as a critic rather than as a divine, whence he was led to make many corrections in the received translations. He is however said to have been but moderately versed in the Greek language, and Huet speaks very disparagingly of his versions of Thucydides, Herodotus, and Homer's Iliad. Of his numerous writings, his 'Elegantiae Latini Sermonis,' containing the grammar of that tongue, and rules for composing in it, has been the most generally esteemed, and still retains its reputation: his own style, however, was defective in point of purity and elegance. He has had many eulogists among the learned, and has been particularly praised by Erasmus, as one of those who have most contributed to the revival of sound learning." Tiraboschi. Gen. Biog.

VALLABREGUES, in *Geography*, a town of France,
VOL. XXXVI.

in the department of the Mouths of the Rhone; 3 miles N. of Tarascon.

VALLADOLID, a town of Spain, in the province of Leon, on a small river called Esquava, near the Pisuerga; the see of a bishop, and an university, founded in the year 1346. Several of the churches of Valladolid, those especially of the Dominicans and of San Benito, are elegant, agreeably to the Spanish taste, that is handsome, and full of altars richly gilt. Valladolid is not wholly without manufactures; some stuffs and coarse cloths are made there from the wool of the sheep which are kept in the neighbourhood. There are also gold and silver-smiths; and one street is entirely inhabited by jewellers: this is very lively, and full of business, as are all the others, which terminate in the great square. An academy of the belles lettres was established here in the year 1752. Here was a palace, in which Philip II. was born, now reduced to bare walls; 84 miles N.N.W. of Madrid. N. lat. $41^{\circ} 42'$. W. long. $4^{\circ} 47'$.

VALLADOLID, a town of South America, in the audience of Quito; 40 miles S. of Loja.—Also, a town of Mexico, in Yucatan. N. lat. $19^{\circ} 50'$. W. long. $80^{\circ} 30'$.

VALLADOLID, or *Comayagua*, a town of Mexico, in the province of Honduras; the see of a bishop, who takes the title of bishop of Honduras. N. lat. $14^{\circ} 30'$. W. long. $88^{\circ} 19'$.

VALLADOLID. See MENCHACAN.

VALLAGAM, a town of Hindoostan, in Golconda; 21 miles S. of Combamet.

VALLAIS. See VALAIS.

VALLANCE, a town of France, in the department of the Gers; 4 miles S. of Condom.

VALLAR, VALLARIS, formed from *vallum*, a stake with branches, of which they made the palisade of a camp, called *lorica*, in *Antiquity*, an epithet given to a kind of crown, which the Roman generals bestowed on him who, in attacking the enemy's camp, first broke in upon the line of palisades.

The *corona vallaris* was the same with what was otherwise called *corona castrensis*, from *castra*, a camp. Aulus Gellius assures us, that it was of gold, as the mural and naval crowns also were: yet, though they were made of that precious metal, they were not the most valued; for Pliny, lib. xxii. cap. 3. gives the preference to the *corona obsidionalis*, which was yet only of gramen, or grass. See CROWN.

VALLARIOS, in *Geography*, a town of Spain, in Aragon; 15 miles W. of Balbastro.

VALLARIS, in *Botany*, so called by Burmann, apparently from *vallo*, to inclose, because it serves, in Java and Amboyna, to make bowers and fences, whose shade is very grateful in a tropical climate.—Burm. Ind. 51. Brown Tr. of Wern. Soc. v. 1. 63.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Contorta*, Linn. *Apocinea*, Juss. Brown.

Ess. Ch. Corolla salver-shaped; mouth and tube perivious, without scales; limb in five obtuse segments. Stamens prominent; filaments inserted into the throat, very short, with a fleshy tubercle externally, at the top; anthers arrow-shaped, adhering to the stigma. Germs of two cells; style thread-shaped; stigma conic-ovate. Scales at the base of the germs five, combined below, fringed at the points. Follicles

Obs. Mr. Brown remarks, that "this, the *Flos Pergularis* of Rumphius, was considered by Linnæus as the first species of his genus *Pergularia*." It does not, however, belong to the same order with the plant that afforded his generic

neric character, and to which the name has been since generally applied. See PERGULARIA.

1. *V. Pergulanus*. Sweet Bower-vine. Burm. Ind. 51. (*Flos pergulanus*; Rumph. Amboin. v. 6. book 7. 51. t. 29. f. 2. Carack nassi of the Malays. *Pergularia glabra*; Linn. Mant. 53. Willd. Sp. Pl. v. 1. 1247.)—This, the only known species, is a native of Java and Amboyna, used for bowers and treillis-work, as it makes a very thick shade. The Malay women are fond of adorning their hair with its fragrant flowers. The stem is perennial, shrubby and twining. Leaves opposite, stalked, ovate, acute, entire, thick and shining, five inches long, two and a half or three wide, with strong pale veins. When the leaves or twigs are wounded, they discharge a thick, viscid, yellow milk. Flower-stalks from between the footstalks, forked, corymbose. Flowers white, and highly fragrant, compared by Rumphius to those of Jasmine, (probably *Jasminum Sambac*,) but having a shorter tube, with five shining bodies in the middle. He speaks of the scent of these flowers as too strong for Europeans, though highly esteemed by the natives of the country where they grow.

VALLE, PIETRO DELLA, in *Biography*, a Roman patrician, who, in the year 1614, commenced his travels into Egypt, Turkey, Persia, and India. At Bagdat he fell in love with a young female of the Maronite sect of Christians, and married her. She accompanied him in his journey, and on his return towards Italy, she died near the Persian gulf. The loss so much affected him, that he had her remains embalmed, and carried them with him during his subsequent travels, and on his return to Rome, they were magnificently interred in the church of Ara Cœli; and he himself pronounced her funeral eulogy, which was printed. The account of his travels, written by himself in Italian, and contained in fifty-four letters, was published at Rome in 1650. They have been often cited as authority, though not destitute of marks of credulity, and still bear a respectable rank among books of travels. The style is pure and elegant, though the narration is prolix. Doni has spoken of him in terms of high commendation, and represents him as well acquainted with the Oriental languages, and with music. He wrote on other subjects besides his travels, and was a member of the Academy degli Umoristi. His second wife was a Georgian, attached to his first wife, and the companion of his travels. Moreri.

For the opinion of this agreeable writer concerning the music of his own times, we refer to the article OPERA, inserting here his account of the manner in which the first opera, or musical drama, was exhibited at Rome, which is extremely amusing and curious. "Though no more than five voices, or five instruments, were employed, the exact number which an ambulant cart could contain, yet these afforded great variety: as, besides the dialogue of single voices, sometimes two, or three, and, at last, all the five sung together, which had an admirable effect. The music of this piece, as may be seen in the copies of it that were afterwards printed, though dramatic, was not all in simple recitative, which would have been tiresome, but ornamented with beautiful passages, and movements in measure, without deviating however from the true theatrical style; on which account it pleased extremely, as was manifest from the prodigious concourse of people it drew after it, who, so far from being tired, heard it performed five or six several times; there were some even who continued to follow our cart to ten or twelve different places where it stopt, and who never quitted us as long as we remained in the street, which was from four o'clock in the evening till after midnight."

This narration seems to furnish a curious circumstance to

the history of the stage, which is, that the first opera, or musical drama, performed in modern Rome, like the first tragedy in ancient Greece, was exhibited in a cart. It has been imagined by many of the learned, that the recitative in modern operas is a revival of that species of *melos* in which ancient dramas were sung; and here the *moveable stage* on which it was performed, like that used by Theſpis at Athens, furnishes another resemblance.

"————— Plautus vexiffe,
Poemata Theſpis." Hor.

Della Valle, after having proved that the singing of his time was better, and the compositions more varied, more rational, and amical to poetry, than the more ancient, proceeds to speak of instrumental music; and after discriminating the different kinds of playing on an instrument, in a solo, in a full piece, in accompanying a voice, or leading a band; he says, he must agree with his friend, that solo playing, however exquisite and refined, at length tires; and that it had frequently happened to organists of the highest class, when lost and immersed in carrying on a happy subject of voluntary, to be silenced by a bell; which never happened to singers, who, when they leave off, displease the congregation or audience, to whom their performance seems always too short.

After discussing instrumental music, he comes to *singing*, and this he considers in solo songs, and in music of many parts. His friend, among the *soprani*, or treble voices, of his youth, had greatly praised the *falsetti* who used to sing in the pope's chapel, and elsewhere; and Della Valle says he remembered one of them, Gio. Luca Falsetto, who had great execution, and went up to the clouds; and mentions Orazio, a very good singer, either in a falset or tenor; Ottavuccio and Verovio, famous tenors, who all three sung in his cart. "However, these," he adds, "trills, graces, and a good *portamento*, or direction of voice, excepted, were extremely deficient in the other requisites of good singing; such as *piano* and *forte*, swelling and diminishing the voice by minute degrees, expression, assisting the poet in fortifying the sense and passion of the words, rendering the tone of voice cheerful, pathetic, tender, bold, or gentle at pleasure: these, with other embellishments in which singers of the present times excel, were never talked of even at Rome, till Emilio del Cavaliere, in his old age, gave a good specimen of them from the Florentine school, in his oratorio, at the Chiesa Nuova, at which I was myself, when very young, present."

What follows is extremely curious and satisfactory concerning a delicate point of musical history, which is, the first establishment of *evirati* in the pope's chapel, and the use of them in early operas.

It is astonishing how much sooner Della Valle got rid of the pedantry of the then old school, than any of his contemporaries. He manifests as much good taste in his reflections on imitative and dramatic music, as any writer of the last century.

Della Valle's biographers seem to have known nothing of the correspondence with Guidiccioni, or of his skill and good taste in music. This agreeable and intelligent traveller died in 1652, aged 66.

VALLE, in *Geography*, a town of Norway, in the province of Christianland; 16 miles S.W. of Christianland.—Also, a town of Norway, in the province of Christianland; 44 miles N. of Christianland.—Also, a town of Istria, and chief place of a district; 8 miles N. of Pola. N. lat. 45° 9'. E. long. 13° 57'.—Also, a town of Italy, in the department of the Adda and Oglio; 8 miles N.N.E. of

of Breno.—Alfo, a town of Italy, in the department of the Gogna; 5 miles W. of Lumello. N. lat. 45° 8'. E. long. 8° 40'.

VALLE *Calanochica*, a town of South America, in the province of Tucuman; 40 miles N.E. of St. Louis.

VALLE *Ruffica*, a town of the island of Corfica, in the diftrict of La Porta.

VALLE *di Spagna*, a town on the eaft coast of the ifland of Cephalonia.

VALLEA, in *Botany*, owes its name to Mutis, who fent the plant to Linnæus. In the *Supplementum* it is faid to commemorate a perfon named Valle, "praifed by Allioni." No one having vouchsafed to indicate where this praife is beftowed, and De Theis having transferred the honour of the prefent genus, with true French patriotifm, to one of his own countrymen, Robert Valle, of Rouen, who publifhed, in 1500, fome Commentaries upon Pliny, we have thought it neceffary to inquire into the matter; efppecially as the genus is well worth claiming. In a note to *Allioni's Rariorum Pedemontii Stirpium, Specimen primum*, page 23, the mystery is unravelled, by a narrative, of which the following is the fubftance. Dr. Valle, a phyfician of Turin, a botanift of no common merit, after having attentively investigated the plants around that city, and thofe of the neighbouring alps, was led by an ardent love of botany, and other branches of natural hiftory, to procure, in 1747, the appointment of phyfician to the army in Corfica, in order to examine the productions of that country. There he made ample collections of plants, feeds, fhells, infefts, and other things worthy of notice. But being more anxious to acquire knowledge than to take care of himfelf, the heat of the climate threw him into a violent fever, which carried him off in three days. His dried Corfican plants, falling into the barbarous hands of ignorant people, were all deftroyed. Whatever his friend Allioni could meet with, by the affiftance of the family, he purchafed; and thus became poffeffed of numerous fpecimens, gathered by Dr. Valle about Savona, as well as in various parts of the alps, of which he had drawn up a defcription, after Tournefort's fyftem; but this was completed no further than the firft four claffes.—The name of Valle therefore deferves to be embalmed with thofe of Bartfch, Borone, Lippi, and other premature martyrs to botany, who have juftly been thought worthy of fuch an unfading memorial.—Linn. Suppl. 42. Schreb. Gen. 363. Willd. Sp. Pl. v. 2. 1212. Juff. 434. Poiret in Lam. Dict. v. 8. 318.—Clafs and order, *Polyandria Monogynia*. Nat. Ord. *Tiliaceæ*, Juff.?

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in four or five deep, ovate, ftriated, coloured, deciduous fegments. *Cor.* Petals four or five, obovate, three-cleft, rather larger than the calyx. Nectary a flattifh, undulated, fhining, coloured border, under the germen. *Stam.* Filaments numerous, 30—40, awl-shaped, flattifh, coloured, incurved, fhorter than the calyx, inferted into the receptacle, beneath the nectary; anthers linear, erect, with two pores at the fummit. *Pift.* Germen fuperior, ovate; ftyle nearly cylindrical, as long as the calyx; ftigma four or five fender divifions. *Peric.* Capsule with four or five angles and as many valves, each valve appropriated to two cells. *Seeds* feveral.

Eff. Ch. Calyx in four or five deep fegments, inferior. Petals four or five, three-cleft. Stigmas four or five. Capsule with four or five valves, twice as many cells, and feveral feeds.

1. *V. ftipularis*. Linn. Suppl. 266. Willd. n. 1.—Native of the colder parts of New Granada. A tree, twelve feet high, with round, ftriated, leafy, hairy branches. *Leaves* alternate, on hairy ftalks an inch long, fpreading, fimple,

heart-shaped, acute, entire, two or three inches long and half as broad, fingle-ribbed, beautifully reticulated with innumerable veins; fmoother and fhining above; paler, clothed with fhaggy tawny hairs, efppecially about the rib and larger veins, beneath. *Stipulas* rather large, leafy, kidney-shaped, entire, ftalked, in pairs at the bafe of each footftalk, and clafping the ftem above it. *Flowers* blood-red, near an inch in diameter, in forked, cymofe, hairy, axillary, and terminal *panicles*, fhorter than the leaves.—Linnæus cites Mutis, Amer. v. 7. t. 10, by which botanifts have been led to underftand, that Mutis had publifhed an important work on American plants, extending to feven volumes, at leaft. But in fact no fuch work exifts. The reference is, in every point, erroneous, and alludes merely to a collection of thirty-two Indian-ink drawings of Mexican plants, fent by that learned Spaniard, with numerous dried fpecimens, to Linnæus. (See MUTIS.) From his drawing of the *Vallea*, compared with the fpecimen, we have, as our readers may obferve, ventured to correct fome part of the generic characters. By that drawing the *feed-velfel* appears to have four valves, (fometimes, it feems, varying to five,) each of which has inflexed edges, befides a central partition; and thefe, all meeting at a central column, may eafily be conceived to form a *capsule* of eight or ten cells, explaining the ftrange expreffion in the *Supplementum*, of "*loculis bilocularibus*." Several circumftances indicate the affinity we have hinted above, of this genus, to Juffieu's *TILIACÆ*; fee that article.

VALLEFREDA, in *Geography*, a town of Naples, in Lavora; 8 miles N.W. of Sezza.

VALLELONGA, a town of Italy, in Calabria Ultra; 18 miles E.N.E. of Nicotera.

VALLENÇAY, a town of France, in the department of the Indre; 21 miles N. of Châteauroux. N. lat. 47° 10'. E. long. 1° 38'.

VALLENGEN, or VALLANGEN. See VALENGIN.

VALLERAUQUE, a town of France, in the department of the Gard; 6 miles N. of Le Vigan.

VALLERS, a town of France, in the department of the Indre and Loire; 12 miles W.S.W. of Tours.

VALLESIA, in *Botany*, thus named in the *Flora Peruviana*, after Dr. Francis Valles, phyfician to Philip II. of Spain, and author of a work, amongft others, on the plants of the holy fcriptures; free from herefy, no doubt, if not from error.—"Fl. Peruv. v. 2. 26. t. 151. f. B." Poiret in Lamarck Dict. v. 8. 319.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, fmall, of one leaf, in five acute fegments. *Cor.* of one petal, funnel-shaped; tube much longer than the calyx, fwelling upwards; limb flat, in five ovate, equal, fpreading fegments. *Stam.* Filaments five, very fhort, inferted into the upper part of the tube; anthers arrow-shaped, in the mouth of the corolla. *Pift.* Germen fuperior, oval, cloven; ftyle thread-shaped, as long as the tube of the corolla; ftigma obtufe. *Peric.* Drupas two, oval, obtufe, divaricated, of one cell. *Seed.* Nut folitary, oval, woody, fibrous, ftriated, with a folitary kernel.

Eff. Ch. Drupas two. Nuts folitary, fibrous. Corolla funnel-shaped. Anthers fimple, arrow-shaped.

1. *V. dichotoma*. Forked *Vallesia*. Fl. Peruv. as above. Poir. n. 1. ("V. cymbæfolia; Orteg. Dec. 5. 58." *Rauwolfia glabra*; Cavan. Ic. v. 3. 50. t. 297. Willd. Sp. Pl. v. 1. 1218. Lamarck Dict. v. 6. 83. See *RAUWOLFIA*, n. 2.)—Native of Peru and New Spain. A *fkrub* eight or ten feet high, with fmoother, flexible, round, alternate *branches*. *Leaves* alternate, on fhort ftalks, ovato-lanceolate,

lanceolate, acute, entire, smooth, shining, single-ribbed, two or three inches long and one broad. *Panicles* or *cymes* small, forked, opposite to the leaves. *Flowers* small, white. *Fruit* whitish. *Poirer, after the Fl. Peruv.*

VALLET, in *Geography*, a town of France, in the department of the Lower Loire; 12 miles E. of Nantes.

VALLEY, in *Natural History* and *Geology*, is a tract of ground bordered by hills or mountains on two opposite sides, between which it extends in a straight or waving line. If the valley be short, and the length is not much greater than the breadth, it is called an opening, or pass, through a mountain or chain of mountains.

Large valleys have generally a number of small valleys joining them, like branches to a main trunk. - In almost every valley there is either a lake or a river, and the magnitude of the river bears some proportion to the valley. The lower end of a valley, where the river empties itself into a larger river or lake, or into the sea, is generally much broader than its upper or higher end. Some valleys are nearly closed in at each end, forming elliptical hollows in mountainous districts. Such valleys have once been lakes, but the water having worn itself a passage at the lower end, has reduced the lake to a small stream in the middle, or the lakes have been filled up by the debris from the adjoining mountains.

Sauflure divides valleys into two orders, which he calls *longitudinal* valleys and *transversal* valleys. Grand mountain chains are commonly formed of many ranges of mountains running parallel to the highest or central range, each range diminishing in height as its distance from the central range increases. It is between these parallel ranges that longitudinal valleys are situated. Sauflure cites the valley of the Rhone as a striking example of this kind of valley.

Transversal valleys are those openings which communicate between the longitudinal valleys, either at right angles with them, or obliquely. It is observed by Patrin, that the transversal valleys which cut through the central range of mountains, are sometimes nearly horizontal, at least for a short distance; but those which cut the collateral chains have always a more or less rapid descent; and as they are frequently excavations formed by water-courses, they sometimes present corresponding salient and retiring sides, like the valleys in secondary mountains; but it is evident that this effect is accidental.

One of the essential characters of longitudinal valleys is, that their direction is parallel with the *line of bearing*, or range of the beds of which the mountains are composed. Transversal valleys cut through the beds in the direction of their line of dip or inclination. See *Plate II. Geology, fig. 2.* in which the side of the mountain fronting a represents the beds of a mountain in their line of bearing; and a spectator placed at the station *a*, may be supposed to be placed in a longitudinal valley, in which the edges of each bed in the opposite mountain would appear to range horizontally. The same appearance would present itself to the spectator placed at *B*, *fig. 5.* A transversal valley cutting through the beds at right angles to the former, would shew the true dip or inclination of each bed to a spectator placed at *b*, in the former *fig. 2.* The side *E* of the mountain represents the direction of a longitudinal valley, the side *G*, the direction of a transversal valley.

The Alps present many longitudinal valleys. The valleys in the Pyrenees are transversal. This difference has been supposed to arise from the central parts of the Pyrenees ascending more precipitously above the lower beds; hence the waters, falling with great impetuosity, have cut

passages through the lower beds in direct lines, and taken the shortest course to the plains below.

In the Alps, the currents, being less violent, have followed the course of the longitudinal valleys, which had been traced out by nature in the original formation of those mountains.

Some mountain groups are disposed in forms nearly circular, so as to include great tracts of flat country, as is the case with Swabia, Hungary, Transylvania, &c. These circular basins or valleys have formed lakes, when the relative level of the ocean was much higher than at present; and on inspecting the best maps, where the inequalities of the surface are delineated, we may be led to suspect that a considerable part of Europe has once been covered by these lakes, the present mountain chains forming the boundaries.

The Rhone and the Rhine pass through several smaller circular valleys in their course; and the river Don, in Aberdeenshire, has its course through valleys of this kind. At the mouth of the Don, the rocks confine it to a narrow channel, and give to it an aspect which would convey the idea of its flowing through a mountainous and rugged country, where no space was left for forming even a commodious road along its banks; but on ascending it for about one mile, the hills recede on each side so as to form a spacious vale, through which the river flows in a flow majestic course for many miles. Nor is the prospect here uniform, but agreeably diversified, the hills above Iverury approaching again close to the river, through which it seems to have forced its way with difficulty; then all at once it opens into another spacious vale, from which the hills recede on either hand to a great distance; then it closes again; and after another temporary confinement among rocks, hills, and woods, its waters once more open into another plain of great extent. Such is the general character of this river.

The Danube, whose history has been so well illustrated by the count de Marfigli, has its source in the mountains of Swabia, from whence it passes through Swabia, Bavaria, Austria, Hungary, and Walachia, into the Black sea. Swabia is a great circular valley, from which the Danube escapes by a narrow opening into Bavaria: during its progress through Bavaria, it passes through several circular valleys into Lower Austria, which is also a circular valley. It flows through Austria, and at Presburg, where the valley is nearly shut up, it forces its way through rocks and hills into Hungary, which is one of the most extensive circular valleys in Europe. At the lower extremity of Hungary, the river is again forced to seek its way through a narrow rocky channel to Orfova, which is the only opening between Hungary and Walachia. It now continues its course through Walachia, and at length falls into the Black sea. We have a continuation of this chain of valleys, although still filled with water, in the Black sea, the sea of Marmora, and the Mediterranean.

The valley of Cashmere presents one of the most striking examples of a circular basin or valley, containing a small lake, which has probably once filled a considerable part of the great cavity formed by the surrounding mountains. "This happy valley," says Mr. Pennant, "this Hindoostan paradise of the Indian poets, is of an oval form, about eighty miles long, and forty broad, and is supposed to have been once entirely filled with water, which having burst its mound, left the vale nourished to the most distant ages by the fertilizing mud of the river, which fed its expanse. This delicious spot is surrounded by mountains of vast height and rude aspect, covered with snow, and enclafed in glaciers, in which this enchanting jewel is firmly set."

The formation of valleys has been by some philosophers ascribed

ascribed almost exclusively to the action of running water. That many of the present valleys have been so formed, is rendered probable by various existing phenomena, but other causes must also have operated. Among these we may enumerate the original inequalities of the surface; these were indeed necessary to make the waters flow in a particular course. The sudden elevation of parts of the earth's surface, and the subsidence of other parts, are also proved by the fractures and dislocations of the strata which mountainous districts almost every where present. There are likewise evident marks that the ocean has been thrown suddenly, and with great violence, over our present continents, tearing away and transporting to distant countries various parts of the surface, scooping out hollows in the softer strata, breaking down the boundaries of immense lakes, and thus changing the course of rivers, and opening new valleys where none before existed. Great and sudden risings of the sea have been known to take place in our times, by the agency of subterranean fire operating on a small extent of the globe; and we have only to conceive the same agent operating more powerfully, to explain the changes which may have taken place from the ocean suddenly rising and sweeping over a large portion of the globe. See *SYSTEM of Geology*.

The theory of the formation of valleys by the action of rivers has been supported by Dr. Hutton and professor Playfair. "Every river (says the latter) appears to consist of a main trunk, fed by a variety of branches, each running in a valley proportioned to its size, and all of them together forming a system of valleys communicating with one another, and having such a nice adjustment of the declivities, that none of them join the principal valley either in too high or too low a level, a circumstance which would be infinitely improbable, if each of these valleys was not the work of the stream that flows through it. When the usual form of a river is considered, the trunk divided into many branches, and these again subdivided into an infinity of smaller ramifications, it becomes strongly impressed upon the mind, that all these channels have been cut by the waters themselves, and that they have been slowly dug out by the washing and erosion of the land." This is an accurate description of the structure of many valleys, but there are others in which the smaller valleys do not join the larger at the same level, but terminate abruptly, and the rivers which flow through them fall in cascades to the lower valleys. The valley of Wattenlugh, in Cumberland, is a striking instance of this kind. The lower extremity joins the vale of Keswick, in which the lake of that name is situated, but it does not enter it at the same level, but terminates in a precipice between two cliffs, down which the water is thrown, forming the cataract of Lowdere, which empties itself into the lake.

Where the corresponding strata on each side of a valley have nearly the same elevation as is represented in *Plate III. Geology, fig. 4*, it is obvious that the excavation between the opposite hills has been formed by water which has once flowed at a much higher level than at present. Also, where the strata on the opposite sides of a valley have the same angle of inclination with the horizon, (see *Plate II. Geology, fig. 5*.) we may infer that it has been excavated by water: but where the strata on the sides of a valley dip in an opposite direction, or have a much greater dip on one side than on the other, the original formation of the valley may be attributed to the elevation or subsidence of the strata, forming a fissure through which the water has run, and in the course of ages has worn down and enlarged the passage. Some circular valleys and lakes

may have originated in the subsidence of the surface, forming a large cavity, the sides of which are gradually worn down in many parts into gentle slopes. An accurate examination of the true line of dip of the beds, can alone discover to which of these causes the formation of any particular valley can be ascribed; and it is frequently more difficult to ascertain the true angle of inclination than is generally supposed, and still more difficult to determine whether a slight variation in the angle is occasioned by a fracture, or by an original inequality or waving of a stratum.

That lakes are passing to the state of valleys, and that many of the present valleys have been lakes, is obvious to the most common observer who will attend to the appearances which they present. A lake, says professor Playfair, is but a temporary and accidental condition of a river, which is every day approaching its termination; and the truth of this is attested not only by the lakes that have existed, but by those which continue to exist. Where any considerable stream enters a lake, a flat meadow is usually observed increasing from year to year: the soil of this meadow is disposed in horizontal strata; the meadow is terminated by a marsh, which marsh is acquiring solidity, and is soon to be converted into a meadow, as the meadow will be into an arable field. All this while the sediment of the river makes its way slowly into the lake, forming a mound or bank under the surface of the water, with a pretty rapid slope towards the lake. This mound increases by the addition of new earth, mud, and gravel, poured in over the slope, and thus the progress of filling up gradually advances. By an accumulation of vegetable matter in shallow lakes, marshes and peat bogs have been formed at the bottom of valleys where the waters have not flowed with sufficient rapidity to drain away the moisture. These are common in various parts of the Highlands, and in Ireland. The filling up of lakes, and the enlargement of valleys, by the process above described, may be distinctly seen in the vicinity of the lakes of Cumberland and Westmoreland. Larger lakes exemplify the same process. Where the Rhone enters the lake of Geneva, the beach has been observed to receive an annual increase; and the Portus Valaisie, now Prevallais, which is at present half a league from the lake, was formerly close upon its bank. Indeed the sediments of the Rhone appear clearly to have formed the valley through which it runs, to the distance of about three leagues from the place where the river now discharges itself into the lake. The ground there is perfectly horizontal, composed of sand and mud, little raised above the level of the river, and full of marshes. The deposition made by the Rhone, after it enters the lake, is visible to the eye, and may be seen falling down in clouds to the bottom.

Where lakes are situated at a considerable elevation above the sea, or the adjacent country, they may be emptied by the wearing down of the strait which forms the outlet. Many of the North American lakes are connected by small straits or rivers, which have a rapid descent. On some of them are prodigious water-falls, which are constantly enlarging the passage from one to the other, and will ultimately drain the upper lakes. The falls of Niagara are observed to be progressively shortening their distance from the upper lake, since the banks have been inhabited by Europeans; and when it has completed its progress, the upper lake will become an extensive valley, surrounded by rising grounds, and watered by a river or smaller lake, which will occupy the lowest situation.

Valleys constitute the most fertile and habitable parts of almost

almost every country. Their superior fertility is derived from a constant supply of fresh soil, and from natural irrigation, and a more equal temperature; the vegetation being sheltered and protected from the boisterous winds that sweep over extensive plains, and the more elevated parts of the globe. It has been observed, however, that low valleys are not so favourable to the longevity of the human race as dry and mountainous districts.

VALLEY of Heroes, in *Geography*, a name given to the delightful plains of Oujan, which are said to produce the finest pasture in Persia. It is so called by the natives, from having been formerly the favourite hunting park of the kings and heroes of Iran, and particularly of Bahram Gour, who had seven palaces of different colours in the neighbourhood. This prince, passionately devoted to the chase, took his surname of Gour from the gour khur, or wild ass, with which this valley abounds. In one of the roads from Persepolis to Ispahan there is a pass or defile, called Iman Zada Ishmael, two furlongs in length, and commencing at the 38th mile from Persepolis, which leads into the above-mentioned plains.

VALLEYS, in *Building*, denote the gutters over the sleepers in the roof of a building.

VALLI, in *Ancient Geography*, a people of Asia, upon the Gordian mountains, near the Caucasian gates, which were in these mountains, according to Pliny.

VALLI, in *Botany*, Juss. Gen. 267. Rheede Hort. Malab. v. 7. t. 6—11, the name of several East Indian climbing shrubs, which Jussieu considers as belonging to the genus *VITIS*, hereafter to be described in its proper place. *Kareta-Valli* of the same volume, t. 45, is referred by him to the neighbouring genus *Cissus*.

VALLI, in *Geography*, a town of Naples, in Lavora; 12 miles E.S.E. of Capua.

VALLIERE, a town of France, in the department of the Creuse; 6 miles S.W. of Aubusson.

VALLIES, FOUR, *District of*, otherwise called *The District of Pignerol*, a province of Piedmont, bounded on the north by the marquisate of Suza, on the west by France, on the south by the marquisate of Saluzzo, and on the east by Carmagnola. The four vallies are those of Peroufa, Lucerna, St. Martin, and Angrogna. The province is about 24 miles long, and from eight to eleven broad. The principal towns are Pinerolo, Lucerna, Peroufa, St. Martin, and Fenestrelle. These vallies are watered by the Cluson, and several other smaller rivers; they are all surrounded with mountains and sharp rocks, in which are found white hares, foxes, pheasants, partridges, wolves, and bears; and in the most lofty of the neighbouring alps is found the marmotte, a creature something larger than a rabbit, but more of the nature of the badger; the chamois; and the bouquetin, an animal something like a goat or chamois, but more fleet than either. Among the tame animals is the jumart, produced by a bull and a mare, or a bull and a sheaf. The vallies are fertile in pasturage, and the mountains in fruit, particularly chestnuts. These vallies are celebrated for the cruel persecution of the inhabitants, who were called Waldenses, on account of their religion, about the year 1655. But now they enjoy in peace the worship they embraced, though they have a Catholic church in each parish. The number of inhabitants is reckoned at about 8000, of whom 7000 are supposed to be Protestants.

VALLIS, in *Ancient Geography*, a town of Africa Propria, upon the route from Carthage to Cirta, between Sicilibras and Coreva, according to Antonine's Itinerary.

VALLIS Achor, *Valley of Achor*, a valley of Palestine, north of Jericho.

VALLIS Ajalon, *Valley of Ajalon*, a valley of Palestine, in the tribe of Dan, between Thammath and Bethshemesh.

VALLIS Artificum, *Valley of Craftsmen*, a valley of Palestine, in the tribe of Benjamin, near Jordan.

VALLIS Arundinis, *Valley of Reeds*, a valley of Palestine, near the Dead sea.

VALLIS Benedictionis, *Valley of Blessing*, a valley of Palestine, in the tribe of Judah, west of the Dead sea.

VALLIS Cariniana, a place of Pannonia, on the route from Sopiane to Acincum, between Pons Sociorum and Corfium or Gorgium. Anton. Itin.

VALLIS Cadaverum, *Valley of Tophet*, the slaughter-house of Jerusalem. It lay south of the city, in the valley of the children of Hinnom. It is said, that a fire was constantly kept here for burning the carcases, and other filth, that were brought hither from the city. (Isaiah, xxx. 33.) Others think, that the name of Tophet is given to the valley of Hinnom, on account of the sacrifices offered there to the god Moloch, by beat of drum, to drown the cries of the consuming children; a drum in Hebrew being called *toph*.

VALLIS Domitiana, a place of Lower Mœsia, upon the route from Atrabium to Nicomedia.

VALLIS Gibonis, *Valley of Gibon*, a valley of Palestine, west of Jerusalem, so named from the fountain of Gibon, whose spring is in this place, and runs from west to south.

VALLIS Emona, a town of Judea, in the tribe of Benjamin.

VALLIS Jezreel, a valley of Palestine, having the chain of mount Hermon to the north-east.

VALLIS Illustris, the *Illustrious Valley*, a valley of Palestine, near Sichem. This was the vale or plain of Moreh.

VALLIS Montium, the *Valley of Mountains*, a name given by the prophet Zechariah to the valleys round about Jerusalem, where the inhabitants of that city took shelter, when the city was besieged by the Romans.

VALLIS Rephaim, or *Valley of the Giants*, called in Greek the Valley of the Titans, and in the Vulgate, the Valley of the Giants (2 Sam. xxiii. 13.), lay near Jerusalem, and belonged either to the tribe of Judah or that of Benjamin.

VALLIS Salinarum, the *Valley of Salt* or *Salt-pits*, generally placed in the southern part of Idumæa, S. of the Dead sea, but situated, according to Calmet, in the eastern part of Idumæa, between Tadmor and Bozrah.

VALLIS Sylvestris, the *Vale of Woods*, a valley of Palestine, in which were situated the cities of Sodom and Gomorrah, and where the lake Asphaltites, or the Dead sea, was formed. This was called the vale of Siddim.

VALLIS Tabernaculorum, the *Valley of Succoth*, or *Vale of Tents*, lay beyond Jordan, near the city of Succoth. The psalmist puts the valley of Succoth for the whole country beyond Jordan.

VALLIS Terebinthi, called the Valley of Elah (1 Sam. xvii. 2.) or of the Oak, lay S. of Jerusalem, towards Sochoh and Azekah. The valley of the Terebinthus is also a name given to the valley of Mamre, on account of the terebinthus under which Abraham entertained the angels.

VALLISNERI, ANTHONY, in *Biography*, a celebrated Italian naturalist, was born of a good family, May 3d, 1661, at the castle of Tresilico, of which his father was governor for the duke of Modena. He was first instructed in the rudiments of the learned languages by the Jesuits, at Modena, and was afterwards taught rhetoric, and the Aristotelian philosophy, under the same auspices, at Reggio, where he defended his thesis on that subject in 1682. Nevertheless he began, even at this period, to be dissatisfied with the prevailing system, which he called a philosophy of words; and happening to have a more liberal and enlightened preceptor

preceptor than usual, his attention was directed to natural and experimental philosophy, and the then prevalent hypotheses of Des Cartes. His tutor Biagi, a Jesuit, had the good sense and honesty to avow, that the philosophy of Aristotle might suit theologians and monks, but that he himself knew many able and distinguished men, at Bologna, and elsewhere, who, so far from being indebted to that great person, never thought of his doctrines but to refute them. Vallisneri therefore removed to Bologna in 1683, and very soon gave up theories and hypotheses for the observation of nature. Here the great Malpighi, to whose particular favour he was recommended by the princes of the house of Este, directed his anatomical enquiries, and from him he received, at his first introduction, a valuable lesson on the presumption of those physicians, who boast of a specific for every disease. The learned and experienced Malpighi, confined to his bed by illness, declared that he was unable to cure his own disorder. A candid confession, which then astonished his hearer; but of the truth of which Vallisneri declared himself subsequently more and more convinced by his own practice of physic, when he found the most boasted specifics daily deceiving his expectations.

The father of the young Vallisneri, himself a doctor of laws, offered his son a choice between law and physic; but his earliest inclinations and inquiries were too much allied to the latter profession to allow of hesitation. An anatomist of animals from his youth, he devoted himself so assiduously to dissections, in the instructive and flourishing school of Bologna, that his health became a sacrifice to his curiosity, and Malpighi was obliged to check the dangerous ardour of his promising pupil. Vallisneri would doubtless have graduated in this famous university, then in its meridian glory; but at the time when this should have taken place, the duke of Modena put forth an edict, prohibiting his subjects from taking degrees, except at Modena or Reggio. Vallisneri chose the latter, and took his doctor's degree in 1684; but in order to study with advantage the necessary sciences of chemistry and botany, as well as to improve himself in practical surgery and physic in the hospitals, he was obliged to return to Bologna; as our doctors of Cambridge or Oxford find it expedient to accomplish themselves in London and Edinburgh. He spent about three years more under the auspices of Malpighi, who at length dismissed this favourite pupil with the sound advice of studying nature, and communicating matters of fact. "Systems," said he, "are ideal and mutable. Observation and experience are solid and unchangeable."

The years 1687 and 1688 were usefully passed at Padua, Venice and Parma, and at length Vallisneri settled as a physician at Reggio. Here he planted a botanic garden, and employed his leisure hours in excursions among the neighbouring mountains; to collect herbs, minerals and petrifications; to observe the strata of the rocks, and the origin or nature of the various fountains; as well as to take the pleasures of the chase, of which he was very fond. The first particular object of investigation to which this ingenious philosopher devoted his attention, was the anatomy of the Silk-worm, by which he was led to the study of the metamorphoses and generation of other insects. Malpighi and Redi were his guides; but he soon found, in the intricacies to this new and recondite course of enquiry, that he was able to extend their information, and correct some of their remarks. He gave his discoveries to the world in the form of two Dialogues in Italian, supposed to take place between Pliny and Malpighi, on the arrival of the latter in another world. These brought great reputation to their author, both for the value of their contents, and the ele-

gance of their language and composition. They introduced him to the acquaintance and correspondence of several learned men, engaged in similar studies; amongst others to that of our distinguished Dr. Martin Litter. He was soon afterwards invited to Padua, where he rose successively from one medical professorship to another, till he obtained, in 1711, the first chair of the Theory of Medicine. When Vallisneri first took his place among the teachers of physic in this long-established university, he was well aware of the caution necessary in opening the eyes of the blind, and in teaching the lame to walk. He had already exercised his own powers, and was a proficient in the practical, or experimental, philosophy, of medicine, as well as of anatomy and physiology. But those accustomed to lean upon others, do not at once acquire, or even desire, the use of their own faculties. Established bodies naturally cling to established authorities, and it perhaps becomes them to be cautious of embracing, without due deliberation, any unauthorized novelty. To this duty, whatever others they may neglect, they must be allowed to be piously attentive. Nothing therefore could be more judicious than the subject of our new professor's first thesis, when he took the chair on the 14th of December, 1700; that "the Studies of the Moderns do not overturn, but confirm, the Medical knowledge of the Ancients." He pointed out in Hippocrates traces of the greatest discoveries, which the moderns by their superior opportunities had fully explained, such as the circulation of the blood; and thus without invalidating the merits of the latter, he dexterously confirmed the authority of the former, and flattered, instead of alarming, their disciples. He thus stimulated them to enlarge the sphere of their own knowledge, so that by improving the practical sciences of chemistry, anatomy, &c. they might further elucidate what the ancients had not fully understood or explained. In the progress of his lectures, however, Vallisneri was too judicious, and too honest, to sacrifice truth, to any ancient or modern authority. He attacked, without scruple, Avicenna's theory of fevers, and the erroneous practice founded thereon; as well as the doctrines of the putrescence of the humours, the sanguification of the liver, with many mechanical hypotheses of the old school. All this did not indeed pass without animadversion, especially the new doctrine of glandular secretion; but Vallisneri, supported by truth and experience, finally prevailed, and wrought a great change in the theoretic medicine of his day. Improvements in practice followed of course; and whenever the enlightened teacher met with any troublesome opposition, or, as usual, was attacked with misrepresentation and calumny, he found an able protector in Frederick Marcello, procurator of St. Mark, who being charmed with his earliest writings, had first recommended him to his appointments at Padua.

The intervals of his academical duties were often devoted by Vallisneri to rural excursions, for the improvement of his knowledge in natural history, as well as for the restoration of his bodily and mental powers, amid the wild and majestic, or the variously beautiful, scenes of nature, which lay so profusely within his reach. In the summer of 1704 he visited the recesses of the Apennines, and climbed their stupendous precipices. The scenery which inspired the genius of Salvator Rosa, enlarged the mind, and enriched the acquisitions, of our philosopher, and he descended, like a fertilizing river, to benefit the world below. The following year, he undertook a less laborious journey, to visit his literary friends at Lucca, Pisa, Leghorn and Florence, and was invited by prince Ferdinand of Tuscany to Pratolino, where he met with a most flattering reception, the prince's hospitality

hospitality being extended to the personal, as well as literary, accommodation of Vallisneri at Florence itself, where every door and cabinet were opened to him. From Leghorn he proceeded to Genoa, not without the usual adventure of a shipwreck of his wretched *felucca*, by which accident he had the advantage of seeing for the first time a noble Date Palm, in the open ground. He returned from Genoa to Padua by land. These and many similar excursions, in several following seasons, were productive of much information to a man, who could not pursue the most beaten track without picking up something. Indeed his line of study was new at that period. He contributed to open a new world to microscopic observers, and to direct their enquiries to advantage. He had by this time collected an ample museum, and choice library, both of them the more valuable and useful, for being collected by himself with some particular object.

His studies were not impeded nor embittered by domestic cares or chagrin; for though he married in 1692, and his wife brought him eighteen children, she was a woman of prudence and good sense; she directed his family in such a manner as to render his home comfortable and happy. Of the children, four only survived their infancy; a son who bore his father's name, and inherited his activity of disposition, and three daughters, two of whom became nuns at Padua. The third, named Claudia, a woman of rare talents, and the highest moral worth, remained unmarried at home.

In the beginning of 1728, Rinaldo I., duke of Modena, sent Vallisneri an unsolicited patent of knighthood, for himself, his son and their descendants. This honour was the more just, as he had, eight years before, declined an invitation from pope Clement XI. to become physician to his holiness in the place of the famous Lancisi. He had also refused to accept, from king Victor Amadeus, the appointment of first professor of physic, at Turin, with a very large stipend. Nor were academical honours wanting to his fame. He was associated with the Academy *Natura Curiosorum*, the Royal Society of London, and almost every learned body in Italy. Thus in the indefatigable pursuit of knowledge, and well-merited fame, he completed his sixty-eighth year. On the 12th of January, 1730, he was attacked with a sort of epidemic catarrh, accompanied with great debility, which, falling on his lungs, carried him off on the 18th. He was interred in the church of the Eremitani at Padua, where his son erected a monument to his memory with the following just and elegant inscription.

D. O. M.

Antonio Vallisnerio

Artis Medicæ assertori eximio

Naturalis Historiæ ac Philosophiæ

Restitutori celeberrimo

Summis honoribus undequaque aucto

Antonius filius mæ. p.

Obiit XV Kal. Feb. Anno Sal.

MDCCLXXX. Act. LXVIII. Mens. VIII.

The filial piety of the younger Vallisneri accomplished a more lasting memorial for his distinguished parent, in a complete and splendid edition of all his works, making three folio volumes, printed at Venice in 1733, and illustrated with plates, in one of which the fructification of the *Lemna* is exhibited. These writings, being frequently in the form of letters, are diffuse, but the Italian style of the author is esteemed by his countrymen. The whole work might be epitomized with advantage, and would be found rich in originality and acuteness. An ample life of Vallisneri is

prefixed to this publication, from whence we have extracted the above account. He is certainly entitled to rank with Redi, Malpighi, Reaumur, and Swammerdam, as an original observer of the intricate and obscure physiology of insects, and the lower tribes of the animal kingdom. He co-operated with those philosophers in clearing away the theory of equivocal generation, and other rubbish of the schools. In medicine his merit is of a very high order, and his name marks an epocha in the history of that science in Italy. Those who had so long slumbered over the musty folios of ancient lore, were by him turned unawares out of their dormitories and easy chairs, before they had time to awake, much less to defend their posts. He exalted the science from the study of books, to that of nature, and success was the natural result. In practice he had the good sense to promote the use of the Peruvian Bark, which, at that period, had much prejudice to contend with. His prescriptions were generally simple, and all his inquiries were free from credulity and prejudice. We cannot here enumerate the titles of all his various pieces. What relates to the theory of generation is most esteemed; and he had the courage to oppose the then famous vermicular hypothesis of Leeuwenhoek. The memory of Vallisneri has been preserved by his countryman Micheli, in the name of a very curious and interesting genus of plants. See the next article.

VALLISNERIA, in *Botany*, was dedicated by Micheli, to the honour of his distinguished countryman, of whom we have given an account in the preceding article. No genus could have been more fortunately selected, as its history is now, in the writings of Linnæus, identified with that of the generation of plants; of the theory of which, as taught by that illustrious botanist, it affords one of the most conclusive and celebrated proofs. Yet Micheli was ignorant of this striking fact; and has absolutely, as we shall find, described the two sexes as distinct genera. The male plant is his *Vallisneroides*. We can offer no apology for this oversight of so faithful an observer, but his attachment to Tournefort, who shut his eyes against the sexual doctrine, and Micheli durst not take the liberty of opening his own.—Mich. Gen. 12. t. 10. Linn. Gen. 513. Schreb. 673. Willd. Sp. Pl. v. 4. 650. Mart. Mill. Dict. v. 4. Brown Prodr. Nov. Holl. v. 1. 344. Pursh 602. Juss. 67. Lamarek Illustr. t. 799. (Vallisneroides; Mich. Nov. Gen. 13. t. 10.)—Class and order, *Dioclea Diandria*. Nat. Ord. *Palme*, Linn. *Hydrocharideæ*, Juss. Brown.

Gen. Ch. Male, *Cal.* Common Sheath of one leaf, in two deep, oblong, often cloven, reflexed segments, inclosing a conical, compressed Common Spadix, covered all over with sessile flowers forming a spike. *Cor.* of one petal, in three deep, obovate, widely spreading, or reflexed, segments, without a tube. *Stam.* Filaments two, erect, the length of the corolla; anthers roundish, simple.

Female, on a different plant, *Cal.* Sheath of one leaf, single-flowered, cylindrical, elongated, with two erect segments at the extremity. Perianth superior, in three deep, ovate, equal, spreading segments. *Cor.* of one petal, in three deep, linear, abrupt segments, shorter than the calyx. *Pist.* Germen inferior, cylindrical, longer than the sheath; style very short; stigma in three deep, oval, convex segments, downy on the upper side, cloven half way down, rather longer than the calyx, and bearing at the back a small oblong appendage. *Peric.* Capsule cylindrical, of one cell, not bursting. *Seeds* numerous, ovate, inserted in many rows into the sides of the capsule.

Ess. Ch. Male, Sheath in two deep segments. Spadix covered with flowers. Corolla in three deep segments.

Female,

Female, Sheath divided, single-flowered. Perianth in three deep segments, superior. Corolla in three deep linear segments. Stigmas three, cloven. Capsule cylindrical, of one cell, with many seeds.

Obf. Such is the original genus, of which Micheli's figure is more clear than his description. There can be no doubt that the part marked A, B, in the middle of his plate, below, represents the under side of the three stigmas. Linnæus, who never saw a living flower, mistook this point; but has corrected himself in manuscript. We have profited of this, and partly of Mr. Brown's definition. *V. octandra* of Roxburgh, if it be thought the same genus, must lead to some further correction of the generic characters.

1. *V. spiralis*. Spiral Vallisneria. Linn. Sp. Pl. 1441. Willd. n. 1. Brown n. 1. (*V. palustris*, algæ folio, italica, foliis in summitate denticulatis, flore purpurascens; Mich. Gen. 12. t. 10. f. 1, female. Vallisneroides palustre, algæ folio, italicum, foliis in summitate tenuissimè denticulatis, floribus albis, vix conspicuis; Mich. Gen. 13. t. 10. f. 2, male.)—Stalk of the female flower spiral. Leaves floating, linear, obtuse, finely serrated at the summit; tapering at the base.—In ditches in Italy, especially near Pisa. Communicated from near Arles, in Provence, by the late Dr. Broussonet, in 1784. Mr. Brown found, what he is almost certain of being the same species, in New South Wales, about Port Jackson. This plant is perennial, flowering in summer and autumn. The root consists of long fibres, and propagates itself very widely by means of runners, so that the canals, in which the *Vallisneria* grows, are choked up with its foliage, and rendered not navigable for boats. Stem none. Leaves all radical, very long, linear, flaccid, pellucid, ribbed, smooth, entire, except at the end. Stalks of the female flowers very long, thread-shaped, unbranched, naked, single-flowered, curiously spiral, but becoming more or less straight when the flower is ready to open, by which means the latter floats on the surface, and after impregnation, the stalk coils up again, and lodges the fruit at the bottom of the water. This fruit is three or four inches long, and judged by Mr. Brown to be rather of the nature of a berry than a capsule. The male flowers grow on a separate plant, on short, simple, straight, radical stalks. Each minute white flower separates from the common spadix, and rises closed, like a little bubble, to the surface of the water. Bursting there, these flowers float about in immense numbers, covering the water, and impregnating the females above described. Micheli has faithfully described the economy of this interesting plant, though blind to its physiology.

2. *V. americana*. American Vallisneria. Michaux Boreal.-Amer. v. 2. 220. Willd. n. 2. Pursh n. 1.—“Stalk of the female flower nearly straight. Leaves erect, linear.”—At the bottom of muddy and slow rivers in North America, flowering from August to October. Michaux observed it in the Mississippi and St. John's rivers, Florida; Pursh in the Delaware, near Philadelphia, and elsewhere. The latter doubts whether it be a distinct species from *V. spiralis*; for he found the stalks of the female flowers to be, in deep water, really spiral. Michaux remarks, that the leaves are erect, less elongated than in the foregoing, and not tapering at the base. These circumstances may all be owing to the shallowness and stillness of the water.

3. *V. nana*. Dwarf Vallisneria. Brown n. 2.—“Stalk of the female flower spiral, capillary. Leaves under water, linear, acute, entire.”—Observed by Mr. Brown, in the tropical part of New Holland.

4. *V. octandra*. Octandrous Vallisneria. Roxb. Coromand. v. 2. 34. t. 165. Willd. n. 3.—Stalk of the female

flower straight. Leaves linear, taper-pointed. Stamens eight.—Native of shallow, stagnant, sweet water, on the coast of Coromandel. Roxburgh. Roots annual, fibrous. Leaves radical, erect, flat, smooth, entire, gradually tapering to a point, from nine to twelve inches high. Stalks all radical, straight, cylindrical, erect, simple, much shorter than the leaves. Sheath of the male flowers near three inches long, tumid below, tapering upwards, containing many stalked flowers, which, by the elongation of their partial stalks, rise one by one out of the sheath. Each has a three-leaved calyx; three longer linear white petals, or segments of the corolla; eight unequal stamens, with oblong anthers; and an abortive germen, with three linear stigmas. The stalks of the female flowers, on a separate plant, are shorter than those of the males, single-flowered. Sheath as in the male, but the flower is elevated above it and the germen by a partial stalk, or receptacle. Calyx shorter than in the male; petals longer and narrower, white. Stigmas long, thread-shaped, white. Seeds roundish, stalked, ranged numerously along one side of the tapering capsule.

We have already hinted the affinity of this plant to Loureiro's *Physium*; see that article.

VALLISNEROIDES, Micheli's name for the male plant of his *Vallisneria*; see that article.

VALLOIRE, in *Geography*, a town of France, in the department of Mont Blanc; 9 miles S.S.E. of St. Jean de Maurienne.

VALLON, a town of France, in the department of the Sarthe; 10 miles W. of Le Mans.—Also, a town of France, in the department of the Ardèche; 9 miles N.E. of Pont St. Esprit.

VALLONISE, a town of France, in the department of the Higher Alps; 9 miles S.W. of Briançon.

VALLOR, VALLOW, or *Vale*, among country people, a hollow mould, in which a new-made cheese is pressed.

VALLOTTI, PADRE FRANCESCO ANTONIO, in *Biography*, an ecclesiastic, and maestro di capella of the church of St. Antonio at Padua in 1770, was born in Piedmont in 1705. He was esteemed one of the best composers for the church in Italy. Tartini speaks of him in his *Trattato di Musica*, p. 100, in the following manner: “Padre Vallotti was formerly a most excellent performer on the organ, and is now an admirable composer, and master of his art.” This good father was of so amiable a character, that it was impossible to know and not esteem him. He composed an anthem for the public funeral of Tartini, March 31, 1770; and in 1779 published at Padua the first book of a treatise entitled “Della Scienza Teorica e Prattica della moderna Musica.” This first book is purely theoretical. The author promised three other books, the publication of which has not arrived at our knowledge. Book the second was to contain the practical elements of music; the third, the precepts of counterpoint; and the fourth, rules of accompaniment. It is to be feared, that this venerable author did not live to complete his design, as we have been informed that he died in 1780, at the age of 75.

VALLS, in *Geography*, a town of Spain, in the province of Catalonia; 9 miles N. of Tarragona.

VALLUCE, a small island in the English Channel, near the coast of France. N. lat. 47° 26'. W. long. 2° 55'.

VALLUM, in *Roman Antiquity*, denote a kind of parapet with which they fortified their camps. In the vallum, some distinguish two parts; the *agger*, which was no more than the earth cast up to form the vallum; and the *fudes*, which were a fort of wooden stakes to secure and strengthen it.

VALLY CREEK, in *Geography*, a river of Pennsylvania,

which runs into the Schuylykyl, N. lat. $40^{\circ} 7'$. W. long. $75^{\circ} 30'$.

VALLY *Forge*, a place in Pennsylvania, near the union of Vally Creek with the Schuylykyl. Here general Washington lay encamped in the winter of 1777, 1778; 20 miles N.W. of Philadelphia.

VALMAROSSA, a town of Itria; 8 miles E.S.E. of Capo d'Itria.

VALMASEDA, a town of Spain, in the province of Biscay; 13 miles S.W. of Bilbao.

VALMIKI, in *Biography*, the name of a very celebrated Hindoo poet, author of that extraordinary poem in the Sanscrit language, entitled *Ramayana*, under which word we have given some account of its contents. Sir William Jones, in his ninth anniversary discourse to the Asiatic Society of Calcutta, delivered February 1792, gives his opinion that the Cush of Moses and Valmiki were the same personage. (See *RAMAYANA* and *TRIVENI*.) But we are not in possession of any biographical particulars respecting him. His great work, the *Ramayana*, is esteemed the earliest epic poem, and is cited as nearly equal in authority with the most sacred of the Hindoo books, such as the *Purana* and *Veda*, ascribed to Vyasa. See these articles.

VALMONT DE BOMARE, JAMES CHRISTOPHER, was born at Rouen, in September, 1731. He was intended for the bar, but his inclination to natural history induced him to devote himself entirely to that pursuit, and having obtained an order from the duke d'Argenson, the minister at war, to travel for the improvement of science, with sufficient funds for the purpose, he spent several years in visiting the principal cities of Europe, and examining the most famous collections in natural history. Mines and metallurgic establishments engaged his particular attention; having visited Lapland and Iceland, he described its volcanoes; and returned, with many curious objects, to Paris in July 1756. He then began a course of lectures on natural history, which were continued till the year 1788. These lectures contributed to establish his reputation, and he had many advantageous offers from the courts of Russia and Portugal, the acceptance of which he declined. His works are as follow: *viz.* "Catalogue d'un Cabinet d'Histoire Naturelle," 1758, 12mo.; "Extrait Nomenclature du System complet de Mineralogie," 1759, 12mo.; and "Nouvelle Exposition du Regne Mineral," 1761, 1762, 2 vols. 8vo. But his capital work was his "Dictionnaire raisonne Universel d'Histoire Naturelle," in 6 vols. 8vo. This has passed through several editions in 8vo. and 4to., and being the first of its kind, served as the basis of all the dictionaries of natural history that have appeared since that time. One of the latest editions appeared at Lyons in 1800, 15 vols. 8vo. This celebrated naturalist died at Paris, in August, 1807. Gen. Biog.

VALMONT, or *Vallemont*, in *Geography*, a town of France, in the department of the Lower Seine; 6 miles E. of Fécamp.

VALMONTONE, a town of the Popedom, in the Campagna di Roma; 6 miles S. of Palestrina.

VALNDORF, a town of Hungary; 5 miles S.W. of Szeben.

VALOE, an island of Sweden, in the bay of Christiania; 7 miles S.S.E. of Tonsberg.

VALOGNES, a town of France, and principal place of a district, in the department of the Channel. In 1346, it was pillaged by the English; $7\frac{1}{2}$ posts N. of Coutances. N. lat. $49^{\circ} 31'$. E. long. $1^{\circ} 23'$.

VALOIS, HENRY DE, or VALESIIUS, in *Biography*, born at Paris in 1603, and educated in the Jesuits' school, was admitted an advocate of the parliament of Paris, after having

previously studied the civil law at Bourges. Declining the prosecution of the law, he devoted himself to literature, and particularly to the study of Greek and Latin authors. The assiduity of his application impaired his sight, the imperfection of which was in some degree counterbalanced by the retentiveness of his memory. Besides some private pensions which were granted him, he was appointed, in 1660, historiographer of France, with a considerable salary. At the age of sixty-one he married a lady, by whom he had seven children; and died in 1676, at the age of seventy-three years. His temper was harsh and irritable; fond of praise, and sparing in bestowing it on others; impatient and querulous under bodily indisposition, but unfeeling to the sufferings of others. With many infirmities and failings, he was a learned, discriminating, and accurate critic. His principal publications were, an edition of the "Ecclesiastical History of Eusebius," with a Latin version and notes; the "Ecclesiastical Histories of Socrates and Sozomen," as well as of "Theodoret and Evagrius;" a valuable edition of "Ammianus Marcellinus;" "Remarks upon Harpocration;" "Emendationum Lib. V." with other pieces, printed after his death at Amsterdam, in 1740, under the care of Peter Burman. Moreri.

VALOIS, ADRIAN DE, brother of the preceding, was born at Paris in 1607, and studied in the Jesuits' college. Although he acquired a competent knowledge of the Greek and Latin languages, he attached himself principally to the study of French history; and in 1646 appeared the first volume in folio of his "Gesta Francorum," which was followed by two more in 1658. He began with the reign of the emperor Valerian, and traced the history of the Franks to the deposition of Childeric, and his work was generally admired. As a recompence, he was associated with his brother in the office of historiographer, and in the pension annexed to it. In 1675 he published "Notitiæ Gallorum," fol. comprising, in alphabetical order, an account of the geography, towns, monasteries, &c. of France, deduced from its early records and histories. He followed the example of his brother, with whom he lived on terms of intimate union, by marrying a young wife, who brought him two children. He published, besides the works already mentioned, an edition of two poems written in the middle ages, a second edition of his brother's "Ammianus Marcellinus," and some other pieces relating to antiquities. He died in 1692, at the age of eighty-five years. His son, CHARLES DE VALOIS DE LA MARE, was also a man of letters, and became a member of the Academy of Inscriptions and Belles Lettres, and antiquary to the king. He published a collection of critical, historical, and moral reflections, and Latin poems under the title of "Valesianæ," and edited two posthumous works of Vaillant the medallist, and wrote several papers for the Academy, of which he was a member. He died in 1747, aged seventy-six. Moreri.

VAL-OMBROSO gives its name to a congregation of Benedictine monks, founded in the Apennines by Gualbert of Florence, in the 11th century; who, in a short space of time, propagated their discipline in several parts of Italy.

VALON, in *Ancient Geography*, a river of Africa, in Mauritania Tingitana. Ptolemy.

VALONA, in *Geography*, a sea-port town of European Turkey, in Albania, on a gulf of the Adriatic, gained by the Turks from the Christians in the year 1464. In the year 1690, it was taken by the Venetians, but retaken by the Turks the year following; 68 miles S. of Durazzo. N. lat. $40^{\circ} 36'$. E. long. $19^{\circ} 28'$.

VALONGO, a town of Portugal, in the province of Beira; 21 miles S.E. of Lamego.

VALONIA, in *Botany*. See VELANIA.

VALOR BENEFICIORUM, in *Law*. See FIRST-FRUITS.

VALORE MARITAGII, *Value of Marriage*, a writ which anciently lay for the lord, after having proffered suitable marriage to an infant who refused the same: to recover the value of the marriage. See GUARDIAN.

VALORSINE, in *Geography*, a town of France, in the department of the Lemane; 15 miles S.E. of Nôtre Dame d'Abondance.

VALOVEK, a town of European Turkey, in Moldavia; 52 miles N. of Jassy.

VALPARAYSO, a town of Spain, in New Castile; 15 miles S. of Huete.

VALPARAYSO, a sea-port town of Chili, situated on a bay of the South Pacific ocean. This town was at first very mean, consisting only of a few warehouses, built by the inhabitants of St. Jago, for laying up their goods till shipped off for Callao, the harbour of Valparayso being the nearest port of that city, from which it is only 60 miles distant. The only inhabitants at that time were the few servants left by their respective masters for taking care of the warehouses, and managing their mercantile affairs. But in process of time, the merchants themselves, together with several other families, removed from St. Jago, in order to be more conveniently situated for trade; since which it has gradually increased, so that at present it is both large and populous; and would be still larger, were it not for its inconvenient situation, standing so near the foot of a mountain, that a great part of the houses are built on its acclivity, or in its breaches. Valparayso, besides its parish-church, has a convent of Franciscans, and another of Augustines; but very few religious, and the churches belonging to them small and mean. It is inhabited by families of Spaniards, and casts both of Mulattoes and Mestizos. Here is a military governor nominated by the king, who having the command of the garrisons in the several ports, and of the militia of the place and its dependencies, is to take care that they are properly disciplined. The proximity of this port to St. Jago, has drawn hither all the commerce formerly carried on at that city. To this it owes its foundation, increase, and present prosperity. All the Callao ships which carry on the commerce between the two kingdoms come hither. In this port they take in wheat, tallow, cordovan-leather, cordage, and dried fruits, and with these return to Callao; and a ship has been known to make three voyages in one summer between November and June. Valparayso is abundantly supplied with provisions from St. Jago and other places in its neighbourhood. Among the several kinds of game there is here such a plenty of partridges in their season, which begins at March and lasts several succeeding months, that the muleteers knock them down with sticks, without going out of the road, and bring great numbers of them to Valparayso. But few of these or any other birds are seen near the town. It is the same with regard to fish, very little being to be caught either in the harbour or along the coast, in comparison of what may be taken in the other parts. The harbour is every where free from rocks and shoals, except to the north-east of the breach De los Angeles, where, about a cable's length or two from the land, is a rock, which must be more carefully avoided, as it never appears above water, but sometimes has not a depth sufficient for a ship of any burden to pass over it; 225 miles N. of Conception. S. lat. 33° 3'. W. long. 72° 16'.

VALPERGA, a town of France, in the department of the Dora; 11 miles S.S.W. of Ivrea.

VALPERSCHWEIL, a town of Switzerland, in the canton of Berne; 10 miles N.W. of Berne.

VALPO. See WALPO.

VALPUESA, a town of Spain, in Old Castile; 10 miles N.N.E. of Frias.

VALREAS, a town of France, in the department of the Drôme; 18 miles N.N.E. of Orange.

VALS, a town of France, in the department of the Ardèche, celebrated for several medicinal springs in the neighbourhood; 12 miles S.W. of Privas.

VALSA, in *Botany*, Adanson Fam. v. 2. 9. Scop. Carn. v. 2. 397, an unexplained name, used by those authors for what is now the SPHERIA of botanists; see that article.

VALSALVA, ANTON-MARIA, in *Biography*, an eminent anatomist, physician, and surgeon, was born in 1666, at Imola, in Romagna. Having received the first elements of literature in the Jesuits' seminary, he was sent to the university of Bologna, and placed under the immediate tuition of the celebrated Malpighi, and here he pursued his various studies with an assiduity which impaired his health. He graduated at Bologna in 1687, and connecting surgery with physic, acquired high reputation. He simplified and improved surgical instruments, banished from Bologna the cruel practice of cauterizing the arteries after amputation, and in the cure of deafness employed manual operations. In 1697 he was chosen professor of anatomy in the university, and appropriate buildings were erected for his use at the anatomical theatre. The school of Bologna acquired celebrity under his direction, and some of his pupils became eminent in their profession. Of this number was Morgagni. In advanced years Valsalva grew corpulent and lethargic, and was carried off by an apopleptic stroke in February 1723, at the age of fifty-seven years; leaving a widow and three daughters. His anatomical museum was bequeathed to the Institute of Bologna, and his various apparatus of surgical instruments to the hospital for incurables. The principal of his works is a treatise "De Aure Humana," reprinted at Bologna in 1704, 4to. and again with Morgagni's Epistles, at Venice, 1740. After his death, Morgagni published three of his "Dissertations" on anatomical subjects, which had been read before the Institute. This great anatomist's work "De Sedibus et Causis Morborum," contains a number of dissections by Valsalva. Morgagni Vit. Valsalv. Haller. Gen. Biog.

VALSECA, in *Geography*, a town of Spain, in Old Castile; 11 miles N. of Segovia.

VALSTAGNO, a town of Italy, in the Vicentin; 18 miles N. of Vicentin.

VALTANAS, a town of Spain, in the province of Leon; 15 miles E. of Valencia.

VALTELINE, a lordship of Italy, at the foot of the Alps; bounded on the N. by the Grisons, on the E. by the county of Bormio and the Bressan, on the S. by the Bergamasco and the Milanese, and on the W. by the county of Chiavenna and the Milanese. This country, which is called by the Grisons *Vellin*, or *Veltin*, and by the inhabitants *Valle Tellina*, is a valley inclosed between two chains of lofty mountains, about fifty miles in length, and from eight to twenty in breadth. It is exceedingly fruitful, and throughout its whole extent watered by the Adda, which, after receiving all the streams issuing from the forest, discharges itself into the Como lake. In some parts the heat is intense, but in others more moderate, and on the hills and the greatest part of the adjacent valleys the air is mostly cool. Of this variation in its temperature, the necessary consequence is a variation in the products of the earth. The levels in this valley, through which the Adda pursues its course, and the breadth of which in some parts

is not less than a mile, exhibit a delightful variety of corn-fields, meadows, vineyards, and orchards of chefnuts and other fruits. The vineyards on the mountains towards the north produce the best wine in the whole country, and above them are corn-fields, meadows, and pasture-lands. The hills on the south side are covered with fine woods of chefnuts, fields, meadows, and rich pastures, in which graze numerous herds of cattle. This country abounds also in excellent red wine, of a most delicious flavour, and of so good a body that it will keep for a whole century, improving both in taste and wholesomeness, and gradually turning paler, till at length its redness totally disappears. Great quantities of this wine are exported. The apples and pears in most places are not much esteemed; but the peaches, apricots, figs, and melons, are exquisite. Here is likewise plenty of lemons, citrons, almonds, pomegranates, chefnuts, and other delicious fruits. Its soil also would produce all kinds of grain and pulse; but the levels being interspersed with swampy places, which have hitherto remained without culture, and the wine-trade chiefly engrossing the attention of the inhabitants, it does not yield a sufficiency for their consumption without importation. Some parts grow hemp, and in the levels, particularly on the higher grounds and the mountains, are fine pastures. Bees and silk-worms are bred here in vast numbers. The Adda yields plenty of fish, and is noted for its trout, which often weigh from fifty to sixty pounds. The whole of their mine-works here consist in a few iron-founderies.

The chief commerce of the Valteline is carried on with Milan and the Grisons. The principal exports are wine and silk, which turn the balance of trade in its favour; they enable the inhabitants to exist without any manufactures, and help to supply the money which is exacted by the governors.

The wine is sent into the Grisons, Germany, the Venetian states, Bormio, and occasionally to Milan. Upon a rough calculation, 73,000 foma, or horse-loads, are annually exported. The silk is sent to England, Zurich, and Basse. The district of Delebio and Talomara produces the finest silk, the neighbourhood of Sondrio the next in quality, and the district of Tirano supplies an inferior sort. Three thousand pounds of the finest sort, which is esteemed as good as the silk procured from Piedmont, is sent annually to England by way of Ostend. The greater part is wound in the Valteline, for which purpose there are silk-mills in the principal districts.

Besides these commodities, the Valteline exports planks, cheese, butter, and cattle. The inhabitants receive from Milan, corn, rice, salt, filken stuffs; from Germany and Switzerland, cloth and linen; from Genoa, spices, coffee, and sugar.

There are no manufactures in the Valteline, and almost all the menial trades are exercised by foreigners.

The population of the Valteline may be estimated from the following rough sketch:

	Souls.
Upper District - - - contains	20,000
Government of Teglio - - - -	8,000
Middle District - - - -	18,000
Lower District - - - -	16,000
Total - - - -	62,000

The cottages of the peasants, which are built of stone, are large, but gloomy, generally without glass windows; and exhibit an uniform appearance of filth and poverty.

Perhaps no part of Europe is more fruitful than the Valteline, and yet there is no country in which the people are more wretched. Many reasons may be assigned for the misery to which they are reduced. The first and principal cause is the form of government. The governors generally abuse the exorbitant authority entrusted to them by the laws; the peasants are imprisoned upon the slightest information; and as all transgressions are punished by fines, an accused person is seldom acquitted; so that a considerable number are annually ruined in the courts of justice.

Beside the individuals who are supposed to suffer for their own guilt, the parishes are subject to continual assessments, towards defraying the expences for the trial and imprisonment of the poor parishioners: if they are unable to pay the sum required, it is demanded from the parish to which the criminal belongs. In this case it frequently happens, that the assessments, instead of being laid upon the landholders, are imposed upon each hearth, by which means the chief burden falls upon the poor.

Another cause of wretchedness proceeds from the present state of property. Few of the peasants are landholders; as, from the continual oppression under which the people have groaned for above two centuries, the freeholds have gradually fallen into the hands of the nobles and Grisons, the latter of whom are supposed to possess half the estates in the Valteline. The tenants who take farms do not pay their rent in money, but in kind; a strong proof of general poverty. The peasant defrays the costs of cultivation, and delivers nearly half the produce to the landholder; the remaining portion would ill compensate his labour and expence, if he was not in some measure befriended by the fertility of the soil. The ground seldom lies fallow, and the richest parts of the valley produce two crops; the first is wheat, rye, or spelt, half of which is delivered to the proprietor; the second is generally millet, buck-wheat, maize, or Turkey corn, which is the principal nourishment of the common people: the chief part of this crop belongs to the peasant, and enables him in a plentiful year to support his family with some degree of comfort. Those who inhabit the districts which yield wine are the most wretched; for the trouble and charge of rearing vines, of gathering and pressing the grapes, is very considerable; and they are so apt to consume the share of liquor allotted to them, in intoxication, that, were it not for the grain intermixed with the vines, they and their families would be left almost destitute of subsistence.

Besides the business of agriculture, some of the peasants attend to the cultivation of silk; they receive the eggs from the landholder, rear the silk-worms, and are entitled to half the silk. This employment is not unprofitable; for although the rearing of the silk-worms is attended with much trouble, and requires great caution; yet as the occupation is generally entrusted to the women, it does not take the men from their labour. With all the advantages, however, derived from the fertility of the soil, and the variety of its productions, the peasants cannot, without the utmost difficulty, and constant exertion, maintain their families; and are always reduced to the greatest distress, whenever the season is unfavourable to agriculture.

To these causes of penury among the lower classes, may be added the natural indolence of the people, and their tendency to superstition, which takes them from their labour.

This country is without so much as one city, but has some considerable towns, with many thriving villages. Its language is a corrupt kind of Italian. The Roman Catholic is the only religion. Their clergy are under the jurisdiction

diction of the bishop of Como. They are not responsible to the ordinary courts, their immunities being so exorbitant as to render them almost independent of the civil authority; they are only amenable to the court of the bishop of Como. If a priest is guilty of any misdemeanour, his person cannot be secured without the concurrence of the bishop and governor of the district in which the crime was committed. It is therefore extremely difficult to bring an ecclesiastic to justice; as impunity is easily purchased, either by securing the favour of the bishop's vicar or of the magistrate. Nor are these pernicious privileges confined merely to the clergy, but extend to all persons wearing an ecclesiastical dress, with the permission of the bishop of Como.

All civil causes of the clergy, below the value of two hundred livres, are decided by the vicar of the bishop of Como: above that sum, they are brought before the bishop. An appeal from his decision lies to the pope's nuncio at Lucern, from him to the ecclesiastical tribunal at Aquileia, and from thence to Rome.

The whole country is divided into three districts or *terzeros*, called *Sopra*, *Mezzo*, and *Sotto*, or Upper, Middle, and Lower. Tirano is the capital of the first, Sondrio of the second, and Morbegno of the last. It is divided into five governments; *viz.* those of the upper district; of the middle district, called also the government of Sondrio; of Toglio, of Morbegno, and of Traona.

Each of these five governments is subject to a magistrate appointed by the Grisons, who is changed every two years. The magistrate over the middle district is called governor of the Valteline, and possesses in some respect a superior degree of authority to the others, who are styled *podestas*; he is also captain-general of the Valteline.

All public concerns, which do not fall under the jurisdiction of the Grisons, are discussed and determined by a council composed of five representatives, one from each district, which meets as occasion requires at Sondrio.

The Valteline, together with the counties of Chiavenna and Bormio, (which had long been the constant source of hostility between the bishops of Como and Coire,) came, in the year 1336, under the dominions of Azzo Visconti, sovereign of Milan, who quietly transmitted them to his successors. Upon the death of John Visconti, one of Azzo's successors, his territories were divided between his nephews Galeazzo and Barnabas. Upon the demise of Galeazzo, his son, John Galeazzo, secured the person of his uncle Barnabas, and having confined him in the castle of Trevio, until his death, which happened in 1395, annexed his dominions to his own, and became by this union the greatest and most powerful prince in Italy. Mastino, son of Barnabas, took shelter, upon his father's imprisonment, with Hartman, bishop of Coire, and died in exile, without recovering any share of his inheritance. Previous to his death, he formally ceded all his right and title over the Valteline, Chiavenna, and Bormio, to the bishop of Coire, as a mark of gratitude for his protection. To this cession, at that time of no avail, the Grisons owe the possession of these provinces. The claim lay dormant for above half a century, until some discontents arising in the Valteline, in 1487, the Grisons made an irruption into that country, in support of the bishop's rights, but their arms not being at that time attended with success, they purchased a peace by renouncing all pretensions to the Valteline. They renewed, however, their claim in 1512, when Ludovico, called *the Moor*, duke of Milan, was taken prisoner by Louis XII.; and the whole Milanese, comprising the Valteline, occupied by that monarch. Upon this revolution, the Grisons, in

conjunction with the bishop of Coire, entered the Valteline, and having expelled the French troops, took possession of the country: they were received with joy by the inhabitants, who did homage to their new sovereigns, and in return obtained from them the confirmation of all their privileges. A compromise was immediately entered into between the bishop of Coire and the three leagues to share between them the sovereignty of this country. In the following year, Maximilian Sforza, raised to the ducal throne of Milan upon the expulsion of the French, ceded in perpetuity the possession of the Valteline, Chiavenna, and Bormio, to the bishop of Coire, and the Grisons; and this cession was ratified by Francis I. in the treaty of peace which he concluded with the Swiss and their allies, the Grisons, in 1516, when he obtained possession of the Milanese. In 1530, the republic of the Grisons acquired the whole dominion of the Valteline, to the exclusion of the bishop of Coire, under pretence that the latter had not furnished his quota of men and money in the war with James of Medici, in defence of these ceded countries; accordingly they compelled the bishop to sell his share of the sovereignty over the Valteline, Chiavenna, and Bormio, for a yearly income of 575 florins, to be paid to the bishop and his successors out of the customs of Chiavenna. From that period, these provinces were possessed by the Grisons without molestation, until the rival interests of France and Spain, the intrigues of the pope, religious enthusiasm, the zeal of party, and the exactions of the Grison governors, kindled an insurrection, which commenced with a massacre of the Protestants, and raged for a series of years with the most savage and unremitting fury.

During the constant wars, which from the accession of Philip II. the restless ambition of the Spanish court entailed upon Europe, the German and Spanish branches of the House of Austria were inseparably united; and the councils of Vienna were directed by the cabinet of Madrid. Under these circumstances, the Valteline, which, by connecting the Tyrol and the Milanese, afforded the only secure passage for the junction of the Austrian and Spanish troops, became of signal importance.

The same reasons which rendered the Spaniards desirous to secure the Valteline, induced the French to obstruct their designs. The Spaniards, however, pursued their projects upon the Valteline without opposition, when they were freed from their most formidable rival, the count of Fuentes, governor of Milan, by assassination, and availed themselves of the domestic dissensions between the Grisons and the inhabitants. When all the Protestants were either destroyed or driven out of the country, the remaining inhabitants renounced their allegiance to the Grisons, and framing a new form of government, threw themselves under the protection of the king of Spain, who sent an army to their support. The people of Bormio followed the example of the Valteline, with this difference, that they did not massacre, but only expelled the Protestants. Having entered into an offensive and defensive alliance with the inhabitants of the Valteline, they also formed an independent commonwealth.

The Grisons, divided among themselves, were totally unequal to the chastisement of their revolted subjects. The Catholics were desirous of employing the mediation of Spain, for the purpose of recovering the Valteline; the Protestants, inclined to vigorous measures, proposed an application to the Swiss cantons, Venice, and France. After violent dissensions, which were not terminated without bloodshed, the Protestant interest prevailed, and a deputation was sent to those powers.

When

When cardinal Richelieu acquired ascendancy, and effected a revolution in the French politics, he perceived the importance of the Valteline, and adopted measures, which proved successful; so that in two campaigns the Spaniards were driven from the Valteline, Chiavenna, and Bormio. Under the administration of Richelieu, it was agreed, that the Valteline should again be restored to the Grisons, upon the following conditions: no other religion but the Roman Catholic to be tolerated; the inhabitants to elect their own governors and magistrates either from themselves or from the Grisons, but always from persons of the Roman Catholic persuasion; and the governors to be confirmed by the Grisons. In return for these privileges, it was stipulated that the inhabitants should pay an annual tribute, the amount of which was to be settled by mediation. In consequence of this treaty, concluded on the 5th of March 1626, the French resigned the forts of the Valteline into the hands of the pope, and evacuated the country.

When Richelieu had completed the reduction of the Hugonots by the capture of Rochelle, he turned the whole force of France against the House of Austria; and among other enterprises, directed his attention to the Valteline; but the Grisons, encouraged and aided by the Spaniards, drove the French from the country; the treaty of Milan produced a close alliance between the Spaniards and the Grisons; and the Valteline was restored.

This treaty, contracted in the year 1635, secured to the Spaniards the passage of the valley, which was the great object of the war, and restored the Valteline, Chiavenna, and Bormio, to the Grisons, under the following conditions: an act of oblivion; the immunities of the subject countries to be confirmed as they existed before the revolution of 1620; no religion but the Catholic to be tolerated; no person of any other persuasion to be permitted to reside, excepting the governors, during the two years they should continue in office, and the Protestants possessed of lands, who should not be allowed to remain in the country above three months in the year; the privileges of the ecclesiastics to be restored in their full latitude.

Since the pacification of 1637, no material change took place in the state of affairs. The sovereigns of Milan have always cultivated the friendship of the Grisons; and the inhabitants of the Valteline endured a regular course of tyranny under the government of a free state; confirming a fact notorious in the annals of ancient Greece, that no people are more oppressed than the subjects of a democracy.

During the progress of the French revolution, Bonaparte confirmed the union of the revolted provinces with the Cisalpine republic; so that after a period of nearly three centuries, the Valteline, Chiavenna, and Bormio, were again incorporated with the Milanese under a republican government; but the expulsion of the late French emperor has restored the ancient arrangements in Italy, and the Valteline returns to its former possessors. VALUATION of Land, in Agriculture and Rural Economy, the business of ascertaining its real worth. It is an undertaking which requires considerable knowledge of the nature and application of all sorts of landed property, as well as of the various improvements of which they are capable by cultivation and different other means.

It is necessary, before entering upon it, that the nature of the tenure, title, and other matters should be well understood. The writer of the work on "Landed Property," however, supposes, that the value of the fee-simple, or pure freehold tenure, being properly ascertained, that of any inferior sort of holding may readily be found from it, by means of the general rules of calculation: but that the fee-simple value of lands is liable to fluctuation, and become different, by general causes; and is influenced too, in many cases, in a much higher degree, by local circumstances. It is suggested, that lands of the self-same quality are of five-fold value in one situation, comparatively with what they are worth in another: not merely, though principally, on account of the rental value, or the current price they will let for to tenants in different situations; but through other less permanent causes: such as the quantity of land at market, the number and importance of the demands for it in the given district; as well as the spirit which prevails in it at the time, in regard to the temporary possession of landed property at the particular period.

These are circumstances that are constantly worthy of the attention of those whose views in the obtaining of land are not confined to any particular spot or district.

It is stated, that the usual method of coming at the fee-simple value of land, is first to ascertain the fair rental value or price by the year, and to multiply this by the number of years' purchase which the existing demand for land will bear, in the given situation, at the time. But that the number of years' purchase, or the ratio between the rent and the sale value of lands, varies greatly, as from 20 to 40, 25 to 30 being the more ordinary numbers. Consequently, a parcel of land, the fair rental value of which is 100*l.*, is, in common cases, worth from 2500*l.* to 3000*l.* But the real rental value, which is the only sure and firm groundwork to proceed upon, whether in the purchase or the management of landed property, cannot be easily obtained. Speaking generally of the lands of this country, it is, it is thought, what very few men are able to set down. It is true, that, in almost every district, or almost every township, there are persons who tolerably well know the rate at which the lands of their respective neighbourhoods are usually let. But reciprocally interchange them into each other's districts, and their errors would, it is said, be egregious. Nor can a mere provincialist, especially in a district which is unenlightened by modern improvements, be aware of the value even of his own farm, under the best course of management of which it may be capable: nor can he see, through the double veil of ignorance and prejudice, the more permanent improvements that may be made upon it, so evidently as one who has a more general knowledge of rural subjects and concerns, and is in the habit of discovering and prosecuting such improvements. It is consequently necessary to have different persons to accomplish the business in a complete manner in many instances.

The particular circumstances that require to be considered as giving value to land, are chiefly these: 1. The quantity

VALUATION OF LAND.

of the land, which is the ground-work of the calculation; though it has little weight in the scale of valuation. The fee-simple value of an acre of land may be less than twenty shillings, or it may be more than an hundred pounds. Nevertheless, it is on the quantity the rental value is calculated; and it is usual for the person who parts with it to exhibit a "particular" of the estate or property on its disposal; shewing, or which ought to shew, not only the aggregate quantity, but the number of acres that each piece or parcel contains, as well as other matters; and ought, most particularly, to specify the distinct quantities of the lands of different qualities; in order that their several rental values may be ascertained with greater ease and accuracy.

2. The intrinsic quality of the land, which is essential in forming the estimate. But even this, in a general view of the value of lands throughout the kingdom, is often, it is said, of secondary consideration: for, in many cases, their values are given by situation, rather than by soil and substrata. In some cases, as has been seen, the value of the situation may be a great many times more than that of the intrinsic value of land. But this excessive influence of situation is, however, limited in its effects, and is chiefly confined to the environs of large towns, and other extraordinary markets for produce of the farm-kind. A great majority of the lands of this country owe their values less to situation than to intrinsic quality; and to come at this with sufficient accuracy, is the most requisite, and, at the same time, the most difficult part of valuation; as it depends almost wholly on extemporary judgment, exercised on the frequently few data which rise to the eye in passing over the field of estimation. It is, therefore, almost needless to state, that to acquire the degree of judgment which is necessary to the execution of this difficult critical task, it is required to know and be perfectly acquainted with the nature and productiveness of lands of different appearances: a sort of knowledge which scarcely any thing but mature practice in the cultivation and use of lands of different qualities can sufficiently teach; though long habit may do much in ordinary cases towards hitting off the value of lands, without an extensive knowledge of the practice of agriculture.

There are cases, however, it is said, in which both of these qualifications are found insufficient to give any accuracy of judgment, even among provincial valuers of land. And a person who ventures to step forward as an universal valuer, should have either an extraordinary talent for the purpose, or should, after a suitable initiation, have had great experience in rural concerns in different parts of the kingdom.

3. The situation; which, although it has been already stated, that the value of the lands of this country, aggregate considered, depends less on situation than on intrinsic quality, yet in every part it has great influence. Thus, an acre of land, the intrinsic quality of which renders it, in an ordinary situation, in what regards locality merely, worth twenty shillings the acre, would not, it is observed, in some districts or places, be worth more than fifteen shillings, while in others it would bear to be estimated at twenty-five shillings, or even a higher price of rent, to a farmer on a large scale, and away from the immediate environs of a town, or any populous district of manufacture; for reasons that will be seen in examining the different particulars of situation. In the temperature of situation too, whether it be given by elevation, aspect, or exposure, a powerful influence is found, which is capable of altering exceedingly the value of lands. The same sort of soil and subsoil, it is said, which is not unfrequently seen on exposed mountains, and hanging to the north, and which in that

situation is not worth more than five shillings an acre, would, if situated in a sheltered vale tract, and lying well to the sun, be worth twenty shillings, or a greater rent. Even on climature, something considerable in this business, it is thought, depends. In the southern part of the country, the harvest is, in general, a month earlier than in those of the north; though it is not regulated exactly by the climate, or the latitude of the places: this is consequently a circumstance that requires to be attended to by those who estimate the values of estates or lands. For an early harvest is not only advantageous in itself, but gives time to till the ground, or to take an autumnal crop, which are advantages that a late harvest will not so well admit of being had. And another kind of temperature of situation has still, it is supposed, more influence on the value of lands, which is that of the moistness of the atmosphere. A moist situation not only gives an uncertain and often late harvest, but renders it difficult and hazardous; as is too frequently experienced on the western coast-sides of this island. Even in the turn of surface, exercise is found, it is said, for the judgment. Lands lying with too steep or too flat surfaces, particularly when of the arable kind, and retentive, are of less value than those which are greatly shelving, so as to give a sufficient discharge to surface-water, without their being difficult of cultivation. Steep-lying lands are not only troublesome and expensive under the operations of tillage, but in taking out manures, and getting off the produce. Lands lying with an easy descent, or on a gently billowy surface, may be worth more by many pounds an acre in the money they will bring, than others of the same intrinsic quality, hanging on a steep. Another consideration of the same weight in valuing an estate, or other landed property, is a supply of water for domestic purposes, for the uses of live-stock, and for the purpose of irrigation. There are situations, it is said, in which a copious stream of calcareous water would enhance the fee-simple value of a large estate some thousand pounds. Likewise a sufficient supply of manure, whether dung, lime, marl, or other melioration, being at a moderate price, and within a moderate distance of land-carriage, materially adds to the intrinsic value of lands. And the established practice of management of the district or county in which an estate or land lies, is capable of enhancing or depressing the value of it exceedingly. Even the single practical point of ploughing light and loamy lands with two oxen, or two active horses, instead of four heavy ones, is capable of making a difference, on good land which is kept alternately in herbage and corn-crops, of from five to ten shillings a year, on the acre; or ten pounds an acre in the money value which it is worth.

The price of labour is also stated as another regulator of the marketable value of land in a given district. It is always right, however, to compare this with the habits of exertion and industry which prevail among farm workmen, before the neat amount of labour can be safely set down. The price of living too, or expence of house-keeping, prevalent among farmers, has its share of influence on the value of lands. In the more reclusive parts of the north of this country, the farmers, especially of the lower and the more inferior classes, and their servants, are fed, clothed, and accommodated, at nearly half the expence of those of a similar degree in many parts of the more central and southern districts. In a county where frugality prevails too, lands of a given quality will ever, it is said, bear a higher rent than they will where a more profuse manner of living has gained a footing. Hence, likewise, the spirit of improvement, or the prejudice against it, which prevails in a district, is a circumstance of some value, it is supposed, in this intention. For

if the former be in a progressive state, especially if it be still in the more early stages of its advancement, a rapid increase of rent may, with a degree of certainty, be expected: whereas, under the leaden influence of the latter, half a century may, it is thought, pass away before the golden chariot of improvement can be profitably put in motion. And lastly, may be noticed, it is said, the attractive centre to which the labours of the husbandman will ever tend,—markets, in which, more than in any other circumstance, we are to look for the existing value of lands. Their influence is not confined to towns and populous places of manufacture, for in ports, and on quays, whether of inlets, estuaries, rivers, or canals, markets are met half way: even by good roads their distance from the farmstead may be said to be shortened.

In this detail of the particulars of situation in respect to the value of landed property, it is observed, the attention requisite to be employed by a valuer who is called upon to act in a county that is new to him is perceived. A provincial, or even a professional valuer, who acts in a district, the existing value of the lands of which he is sufficiently acquainted with, determines at sight, and according to the best of his judgment, on their respective values: for he knows, or ought to know, their current prices; what such and such lands let for in that neighbourhood; what he and his neighbours give, or would give, for lands of the same quality and state, without advertent to the particular circumstances of the situation, they being considered and given as the established amounts arising out of them; resting his judgment solely on the intrinsic quality and existing state of each field or parcel as it passes under his eye. But let his skill be what it may in a county or district in which he has acquired a habit of valuing lands, he will, in a distant part or district, the current market prices of the lands of which may be ten, twenty, or fifty *per cent.* above or below those which he has been accustomed to put upon lands of the same intrinsic qualities and existing states, find himself at a loss; until he has learnt the current prices of the place or county, or has well weighed and considered the circumstances of situation: to which, in every case, he must necessarily attend, before he can determine their value under an improved practice, or venture to lay down general rules for their improvement.

4. Another class of circumstances which influence the marketable value of lands still remains, it is said, to be enumerated and considered. These relate to their existing state, or the manner in which they lie at the time. Their state in respect to inclosure is a matter of great consideration. Open lands, though wholly appropriated, and lying well together, are of much less value, except for a sheep-walk, or a rabbit-warren, than the same lands would be in a state of suitable inclosure. If they be disjointed and intermixed in a state of common field, or common meadow, their value may be reduced one-third. If the common fields or meadows be what is often termed *Lanmas* land, and become common as soon as the crops are off, the depression of value may be set down at one-half of what they would be worth in well-fenced inclosures, and unincumbered with that ancient custom. The difference too in the value between lands which lie in a detached state, though within well-fenced inclosures, and those of the same quality that lie in a compact form, or, in the familiar phrase, within a ring-fence, is considerable. The disadvantages of a scattered estate are, it is said, similar to those of a scattered farm. Even the single point of a want of convenient access to detached fields and parcels is, on a farm, a serious evil. And it is on the value of farms that the value of an

estate or land is to be calculated. The state of the roads, whether public or private, within an estate, and from it to the neighbouring markets, or places of delivery of produce, is further an object of consideration. And in this view, the state of the water-courses, or sewers and ditches, within and below an estate, likewise requires to be examined into; as the expence of improvement or reparation will be more or less, according to their existing state at the time; or, perhaps, by reason of natural causes, or through the obliquity of a neighbour, and the defectiveness of the present laws of the country in this respect, the requisite improvements cannot be effected at any expence. The state of drainage of lands that lie out of the way of floods, or collected water, requires also to be taken into consideration. For although the art of draining be now pretty well understood, it cannot be practised on a large scale, without much cost. The state of the lands too, as to tillage and manure, is entitled to more regard than is generally bestowed on it, in valuing them. But even to a purchaser, and still more to a tenant for a term, their state in these respects demands a share of attention. Lands that are in a high state of tillage and condition, so as to be able to throw out a succession of full crops, may be worth five pounds of purchase-money an acre, more than those of the same properties, which are exhausted by repeated crops, and lie in a useless state of foulness; from which they cannot be raised, but at a great expence of manure and tillage. Their state, as to grafs or arable, is, it is thought, better understood, and generally more attended to. Lands in a state of profitable herbage, and which have lain long in that state, are not only valuable as bearing a high rent while they remain in that condition, but, after the herbage has begun to decline, will seldom fail to throw out a valuable succession of corn-crops. Hence the length of time which lands, under valuation, have lain in a state of herbage, especially if it has been kept under pasturage, is a matter of inquiry and estimation in the execution of business of this sort. And, lastly, the state of farm buildings and fences is, it is conceived, a thing of serious consideration. Buildings, yards, and inclosures, that are much let down, and gone to decay for want of timely reparation, incur a very great expence to raise them again to their proper state. And when great accuracy of valuation is called for, as where the purchase value of an estate is left to reference, and when the tenants are not bound, or if bound are not able, to put them in the required state, it becomes requisite to estimate the expence which each farm, in that predicament, will require to put it in sufficient repair, so as to bring the whole into a suitable state of occupation. This comes, however, more properly under the head of deductions, encumbrances, and outgoings, which are considered below. The same principle of valuation as the above holds good too in ordinary cases.

In speaking of encumbrances and deductions, it is said, that it appears, by a long lease, that the fee-simple value of an estate may be in effect annihilated. Even a lease for lives, with a mere conventional rent, may reduce it to nearly one-third of its fee-simple value. And every other kind of lease, if the rent payable be not equal to the fair rental value at the time of the disposal, is an encumbrance, even to a purchaser who has no other object in view than that of securing his property on land, and receiving interest in rent for the money laid out. If personal convenience be immediately wanted, or improvements required to be done, a lease, though the tenant pays a full rent, becomes an obstacle to the purchase, and is consequently to be considered in fixing the value. And an error, which is not unfrequently committed in estimating the encumbrance of a lease

VALUATION OF LAND.

For a term of years, is here, it is said, to be noticed. The difference between the lease rent and the full rental value, encumbered with the same outgoings and repairs as the lease rent, being ascertained, it is multiplied by the number of years unexpired, and the product in full deducted from the value of the land, free from such encumbrance. But from the product, thus found, ought to be deducted half the interest thereof, during the said number of years, together with that of one half-year over, if the rent be payable half-yearly, or of one year, if payable annually. For all that a purchaser has a right to expect is to receive the full rent for his land, during the continuance of the lease. The tenant pays him what the lease stipulates; and if the feller were to make up the remainder, at the end of every six or twelve months, whenever the tenant is to pay his part, the purchaser would receive the full rent, the same as if no encumbrance had existed. But if the feller pay down the whole sum in ready money, at the time of the sale, which in effect he does, he is certainly entitled to some discount for prompt payment. Thus, supposing the difference of rent, occasioned by the lease, to be ten pounds a year, and the length of the term to run to be ten years, the product would be one hundred pounds. And supposing, for the ease of calculation, the stipulated payments to be annual, the interest to be deducted would be the half of fifty pounds, (the interest of one hundred pounds for ten years, at 5 per cent.) with the half of five pounds (one year's interest), together amounting to twenty-seven pounds ten shillings; which being deducted from one hundred pounds, the gross product, leaves seventy-two pounds ten shillings, the clear sum to be deducted. And the truth of this rule of calculation may, it is thought, be familiarly proved: for if the feller were only to pay the deficiency of rent, as it should become due, he would, during the first year, hold the whole hundred pounds in his hands, the interest of which, at 5 per cent., is 5*l*.

The first year (as above) he would hold	£ 100	£ 5	0	0
The second ditto - - - -	90	4	10	0
The third ditto - - - -	80	4	0	0
The fourth ditto - - - -	70	3	10	0
The fifth ditto - - - -	60	3	0	0
The sixth ditto - - - -	50	2	10	0
The seventh ditto - - - -	40	2	0	0
The eighth ditto - - - -	30	1	10	0
The ninth ditto - - - -	20	1	0	0
The tenth ditto - - - -	10	0	10	0
		27	10	0

In respect to tithes, where in valuing lands they are considered as tithe-free, the tithe or modus, if any, requires to be deducted, as an encumbrance; and from the great variation in the values of tithes and moduses, according to custom, and plans of occupation, it is the plainest way of proceeding to value all lands as free of tithe, and afterwards to make an allowance for whatever they may be estimated to be worth. In regard to taxes, too, although it may be called the custom of the country for proprietors to pay the land-tax, and the occupier all the other taxes; yet this is not the universal practice; nor is it, in valuing an estate on sale, and to be let at will, a matter to be inquired into. The annual amount of payable taxes, and other outgoings, are the facts to be ascertained: for whosoever discharges them, they come as a burden upon the gross value of the lands, out of which they are payable. For if a tenant pay them, his rent is, or ought to be, estimated and fixed accordingly. But

if an estate on sale is already let under lease, for a term to come, it is highly requisite to ascertain what parts of the annual outgoings and repairs are discharged by the tenants, and what the proprietor will be liable to, during the term to run. The land-tax, where it still exists, is extremely uncertain as to its value; and the poor-tax is equally varying in different situations. The church, highways, and county rates are, taking them on a par of years, less liable to local uncertainty, and are consequently less entitled to inquiry by a valuer of lands. And the fixed payments, or rent charges, such as chief rents, quit-rents, annuities, endowments, schoolmasters' salaries, charitable donations, and others of the same kind, to which an estate is liable; also repairs of public works, buildings, roads, &c. incumbent on the estate, are subjects of inquiry and estimation; as well as the ordinary repairs. Further, too, the hazard or risk under valuation, as that of their being liable to be inundated in summer, or to be torn away by floods at any season, is entitled to mature consideration. For although these evils may generally be remedied by river-breaks and embankments, the erecting of them is mostly attended with great expence; and the estimated value of this becomes, in course, a fair deduction to be considered by the land-valuer. It is noticed that there are two practical methods of valuation, with respect to taxes and other outgoings, as in regard to tithes; namely, either to set down the gross value of the lands, and then to deduct the outgoings; or to view them under their encumbrances, and to estimate in a summary way their neat rental value. The latter is the more general, but the less accurate, manner of performing the business.

This, it is said, is what relates to the purchase value of the lands, but that, appurtenant to an extensive estate, there are generally other valuable considerations; as *minerals* and *fossils*, whether metals, fuels, calcareousities, or groffer earths; *waters*, whether they are valuable for fisheries, decoys, mills, domestic uses, or the irrigation of lands; and *timber*, as of woods and hedge-rows. Buildings, too, that are not let with the farms, but which bear rent, independent of the lands; which, when scattered over an estate, may well be considered as belonging to landed property. To these may be added, the estimated value of evident improvements: and, lastly, the abstract rights which arise out of appropriated lands, or their appurtenances, as the *right of commonage*, which is generally of some value, even when commons lie open, and may be of more, when they shall be inclosed; provided the cost of inclosure do not turn out to be more than the extra value of the appropriated lands, above that which naturally or fortuitously attends the lands of the common right in their open state. The *right of seigniority* to fee-farm rents, or other chief rents, payable to the possessor of lands on sale out of the lands of other proprietors. These rents, though small, are of certain value in themselves; and the idea of superiority, which they convey to the minds of some, may be worth more than the pecuniary value; which indeed, where the sums are very small, as is often the case, is much lowered by the expence of collecting them. The *rights of feudality*, or manorial rights, are at present, if not in their origin, very different from those last mentioned; and the value of which is to be estimated by the quit-rents, fines, heriots, escheats, and americiaments, which long custom and a train of circumstances have attached to the given court. And beside what relates to the appropriated lands of the manor, the lord has a profit arising from the commonable lands, if any lie within it, as lord of the soil; which cannot be broken without his permission: hence the minerals and fossils which it covers belong to him, as well as the timber which grows upon the waste, and the waters

waters that are connected with it. Moreover, in ordinary cases, he is lord of the game which inhabits or strays upon his manor. This being, however, a right of pleasure rather than profit, has no fixed standard of estimation. The *right of tithes*, when attached to an estate, is the most desirable of abstract rights arising out of landed property. For as far as the right extends, whether to a lay rectory or a vicarial impropriatorship, the lands which it covers become in effect title-free; as every judicious proprietor incorporates the rents of the tithe with those of the lands out of which it is payable: thus, if the right, as it generally is, be rectorial, freeing them wholly from the encumbrance of tithes, as a tax on improvements, and as an obstacle to the growth of grain. The *right of advowson*, or the privilege of appointing a pastor to propagate religion and morality upon an estate, properly enough belongs to its possessor; as no other individual is so intimately concerned in the moral conduct of its inhabitants. The *right of representation*, or election, or the appointment, in whole or in part, of a legislator to assist in promoting good order in the nation at large. And what class of the community, it is asked, can produce a fairer claim to this right than the proprietors of the country? The value of these rights is left for others to estimate and determine. See **TIMBER** and **TITHES**.

The chief circumstances to be considered having thus been pointed out, and their importance and influence explained, in concluding the subject it may be observed, that the difference between the particulars that give value to a landed estate, and the encumbrances to which it is liable, is the net value of the property under valuation.

VALUE, VALOR, in *Commerce*, the price or worth of any thing.

VALUE, Intrinsic, denotes the proper, real, and effective worth of any thing; and is used chiefly with regard to money: the popular value of which may be raised and lowered at the pleasure of the prince; but its real or intrinsic value, depending wholly on its weight and fineness, is not at all affected by the stamp or impression thereon.

It is generally on the foot of this intrinsic value, that species are received in foreign countries; though in the places where they are coined, and where the sovereign power makes them current, they sometimes pass for much more.

It is, in good measure, on the difference of those two values, one of which is, as it were, arbitrary, and the other, in some sort, natural, that the difference of exchanges depends; and those still rising and falling, as the rate at which a species is current, comes nearer or farther off the just price of the metal of which it consists.

VALUE, in *Bills of Exchange*, is used to signify the nature of the thing (as ready money, merchandizes, bills, debts, &c.) which is given, as it were, in exchange for the sum specified in the bill.

From four different manners of expressing this value, some distinguished four kinds of bills of exchange. The first bears *value received*, simply and purely, which comprehends all kinds of value; the second, *valued received in money or merchandize*; the third, *value of myself*; and the fourth, *value understood*.

The first is dangerous, and the fourth but little used: accordingly, to have the value well expressed, and to prevent the ill consequences of oversights therein, it is well provided by the French ordonnance of 1673, that bills of exchange should contain the name of the person to whom the contained sum is to be paid; the time of payment: the name of him who has given the value; and whether it was received in money, merchandize, or other effects.

VALUE, Valor, or *Valentia*, in *Law*. West gives us a nice difference between *value* and *price*; the value (says he) of things in which offences are committed, is usually comprised in indictments; which seems necessary in theft, to make a difference from petty larceny; and in trespasses, to aggravate the fault and increase the fine.

But no price of things *feræ nature* may be expressed, as of deers, hares, &c. if they be not in parks or warrens. And where the number of things taken is to be expressed in the indictment, as of young doves in a dove-house, there must be said *pretii*, or *ad valentiam*: but of divers dead things, *ad valentiam*, and not *pretii*: of coin not current, it shall be said *pretii*; but of coin current, neither *pretii* nor *ad valentiam*; the price and value being certain.

VALVE, VALVULA, formed from *valva*, *folding-doors*, in *Hydraulics, Pneumatics*, &c. is a kind of lid, or cover, of a tube or vessel, so contrived as to open one way; but which, the more forcibly it is pressed the other way, the closer it shuts the aperture: so that it either admits the entrance of a fluid into the tube or vessel, and prevents its return; or admits it to escape, and prevents its re-entrance. For water, those valves are the best which intercept the passage least; and none appear to answer this purpose better than the common clack-valve of leather, which is generally within single, or divided into two parts; but it is sometimes composed of four parts, united so as to form a pyramid, nearly resembling the double and triple valves which are formed by nature in the hearts of animals. A board, or a round flat piece of metal, divided unequally by an axis on which it moves, makes also a very simple valve. Where a valve is intended for intercepting the passage of steam, it must be of metal: such a valve is generally a flat plate, with its edge ground somewhat conically, and guided in its motion by a wire or pin. For air, valves are commonly made of oiled silk, supported by a perforated plate or grating.

Valves are of great use in the air-pump and other wind-engines; in which they are ordinarily made of pieces of bladder, or oiled silk.

In hydraulic engines, as the emboli of pumps, they are frequently of leather; the figure round; and they are fitted to shut the apertures of the barrels or pipes.

Sometimes they are made of two round pieces of leather, inclosed between two others of brass; having divers perforations, which are covered with another piece of brass, moveable upwards and downwards, on a kind of axis, which goes through the middle of them all.

Sometimes they are made of brass, covered over with leather, and furnished with a fine spring, which gives way upon a force applied against it: but, upon the ceasing of that, returns the valve over the aperture. (See **PUMP**.) See also for the construction of different sorts of valves for the buckets of pumps, Defaguliers, Exp. Phil. vol. ii. p. 156, &c.; and for the description of a new valve by M. Belidor, *ibid.* p. 180.

VALVE, in *Anatomy*. See **VALVULA**.

Constantine Varolius, a Bolognese, and physician of Gregory XIII., who died in 1570, was the first that observed the valve in the colon. Bart. Eustachio, a native of San Severo, in Italy, discovered about the same time the valve at the orifice of the coronary vein; and that remarkable one at the orifice of the lower trunk of the vena cava, near the right auricle of the heart: though he did not take it for a valve, but merely for a membrane.

Sig. Lancisi, physician to pope Clement XI., who first published Eustachio's works, takes the use of this valve to be, to prevent the blood of the upper vena cava from

striking with too much violence against that of the lower : and Mr. Winslow, who has considered it very diligently in the *Memoirs of the Royal Academy of Sciences*, is much of the same opinion.

But as it gradually dwindles in children, and at length becomes quite lost in adults, still diminishing as the foramen ovale does, it should seem to have some other office, and that chiefly regarding the circulation of the blood in the fœtus.

In effect, by means of it, M. Winslow reconciles the two opposite systems of the circulation of the blood in the fœtus. See *Circulation of the BLOOD*, and *FÆTUS*.

VALVE, in *Gardening*, the divided parts of a seed-vessel, or properly the external division of a dry seed-vessel, such as a capsule or pod ; as in the pea, bean, vetch, and many others, which, when ripe, splits into two or more divisions, in order to throw out the contents, each of which divisions is denominated a valve. The valves of culinary vegetables are of several different kinds, according to the number of divisions, but principally of the univalve and bivalve kinds.

VALVERDE, or VAL VERDE, in *Geography*. See *IÇA*.

VALVERDE, a town of Spain, in New Castile ; 20 miles S. of Cuença.

VALVERDE *del Camino*, a town of Spain, in the province of Seville ; 17 miles N.E. of Moguer.

VALVERDE *de Fresno*, a town of Spain, in the province of Leon, on the borders of Portugal ; 24 miles N.N.W. of Coria.

VALUIKI, a town of Russia, in the government of Voronez ; 103 miles S.S.W. of Voronez. N. lat. 50° 2'. E. long. 37° 44'.

VALUNTOWN, a town of the state of Connecticut ; 10 miles N.N.E. of Norwich.

VALVULA, VALVE, in *Anatomy*, a name given to various parts in the body. See VALVE.

VALVULA *Coli*, or *Ilei*, the valve placed at the communication of the large and small intestines. See *INTESTINE*.

VALVULÆ *Conniventes*, folds of the mucous membrane of the small intestine. See *INTESTINE*.

VALVULA *Eustachii*, *Nobilis*, or *Reticulata*, a small fold at the entrance of the inferior vena cava into the right auricle. See *HEART*.

VALVULA *Magna Cerebri*, or *Vicussenii*, a part of the brain. See *BRAIN*.

VALVULA *Mitralis*, the valve of the left auriculo-ventricular orifice of the heart. See *HEART*.

VALVULA *Semilunares*, or *Sigmoidea*, valves placed at the entrance of the aorta and pulmonary artery. See *HEART*.

VALVULA *Tricuspidales*, or *Triglochina* ; the valve of the right auriculo-ventricular opening of the heart. See *HEART*.

VALVULÆ *Venarum*, folds of the internal membrane of the veins, preventing the reflux of the blood. See *HEART*.

VAMA, in *Ancient Geography*, one of the navigable rivers of India, which discharged itself into the Ganges. Pliny.—Also, a town of Spain, in Bœtica, belonging to the Bœtice-Celtici. Ptolemy.

VAMANA, in *Mythology*, a name or title of the Hindoo deity Vishnu. It means a *dwarf* ; and was applied in consequence of an incarnation of Vishnu in this humble form. See the next article.

VAMANAVATARA, one of the ten grand incarnations of Vishnu ; called, by way of pre-eminence, *dava-vatara*, or the *ten descents*, to distinguish them from others of the same deity of less importance. As noticed under the article *VISHNU*, this manifestation was the fifth of the ten ;

but the first that occurred after the golden or virtuous age of the Hindoos. It was followed by a less virtuous age, in the course of which Mahabeli, a monarch reasonably virtuous, became so elated, that he omitted the essential ceremonies to the gods ; and Vishnu, deeming it expedient to check the influence of such an example, resolved to punish the arrogant raja. He, therefore, condescended to become the son of Kasyapa and Aditi ; and, as the younger brother of Indra, was incarnated in the person of a wretched Brahman dwarf. (See *INDRA* and *KASYAPA*.) Appearing before the king, he asked a boon ; which being promised, he demanded as much as he could pace in three steps. Nor would he desire farther, though urged by Beli to demand something more worthy of the donor.

Mahabeli, it would appear, had resorted to some of these processes ; and the boon asked and yielded, was, as usual with mighty rajahs, the sovereignty of the universe ; which includes the three regions of the earth, heaven, and hell. To avert the effects of the abuse of this power, dangerous even to the gods, and to resume their sovereignty, Vishnu resorted to the artifice we are describing.

On obtaining the king's promise, the dwarf required a ratification of it ; which was done, as is still practised, by pouring water on the hand of the suppliant. This Beli proceeded to do, though warned of the consequences ; scorning not to ratify that for which his royal word stood pledged.

As the water fell into his hand, the dwarf's form expanded till it filled the world ; and Vishnu now manifesting himself, deprived Beli at two steps of heaven and earth ; but he being in some points a virtuous monarch, left Patala, or the lower regions, still in his dominion. (See *PATALA*.) In this character, Vishnu is sometimes called *Trivikrama*, or *Trivikera*, meaning the three-step-taker. Beli, as king of the infernal regions, seems to correspond with *Yama* ; which see. Sir William Jones deemed this king the same with the Belus of western history. See *BELUS*, and *MAHABELI*.

Writers of the sect of Vaishnava maintain, that the ratifying stream poured on the hand of Vishnu, was the origin or source of the river Ganga, or *Ganges* ; which falling from the hand of the miraculous dwarf, descended thence upon his, now Vishnu's, foot ; whence, expanding like its fount, it gushed a mighty river, and was received on the head of Siva. In pictures and casts of the latter deity, the goddess Ganga is frequently seen half concealed in the folds of his hair, and Siva is hence named *Gangadhara*, or *Ganges-bearer* : a name assumed also by a class of itinerants who sell that holy water through the streets of all Indian cities : it being among Hindoos equal, in sin-expelling potentiality, to the holy water of papacy. This mythological source of the blessing and blessed river is a favourite subject with Hindoo poets.

In the Hindoo Pantheon, whence this article is partly taken, are many legends connected with it.

In pictures of this avatara, the dwarf is usually represented receiving the water from the hand of Beli, through a spouted vessel ; sometimes accompanied by the evil counsellor Indra, or *Sakra*, who is represented either with only one eye, or holding his hand before the other. As the regent of the planet Jupiter, named *Vrihaspati*, is the counsellor or preceptor to the gods and Suras ; so *Sakra* is the adviser of the demons or *Asuras* ; and is constantly watchful in counteracting the divine beings, and their endeavours for the good of man ; and the pious endeavours likewise of holy men. To prevent the conserving power in this avatara from accomplishing the projected end, in the punish-

ment of impiety and arrogance, personified in Beli, Sakra apprized him of the deceit under which he was promising the universe away. But as the monarch had too much pride to recant his royal word, the evil counsellor assumed the form of a musquito; and insinuating himself into the spout of the vessel through which the ratifying stream was to pass, arrested its passage; when the dwarf, taking a straw to clear it, thrust out the eye of the gnat, a defect ever after retained by Sakra in all shapes. It is said to indicate the half enlightenment of evil counsellors: still, why the one-eyed admirer of ill should be the thousand-eyed god, has not been explained. Nor will it, perhaps, be deemed worth while to enter into any lengthened explanation of the apparently ridiculous fables mentioned in this article; though we believe they might be explained from a consideration that all Hindoo history, religion, arts, and science, are buried in a mass of mythological legends. We will just mention, that the fabulous source of the Ganges, whether from the head of Siva, or from the foot of Vishnu, the latter being the principle of humidity, the former of heat, is merely a physical dispute between what in Europe would be called Neptunists and Vulcanists, but what in India assumes the form of theological controversy. Whether the Ganges be of volcanic origin, or descends from the eternal snows of Nepaul, is perhaps the point here disputed between the Saivas and Vaishnavas. (See of this under the articles SAIVA and SIVA.) As to the musquito, Indra is the god of showers, regent of the firmament; closely allied to Vishnu, air being a form of humidity; and the musquito partakes, like Vishnu, of both its forms: it is born, or reposes, like the god, in water, and lives in air. But we shall pursue these mythological allegories no farther.

One of the eighteen sacred poems, called Purana, is named after this avatara, (see PURANA,) and details a great mass of poetical incident connected with it. The reader may perhaps smile in hearing that England is the supposed theatre of several of the incarnations of Vishnu, and of this of Vamana among them. On this point, we refer to the second article of the 11th volume of the Asiatic Researches.

VAMBA, in *Geography*, a river of Angola, which runs into the Coanza, near Cabelo.

VAMIGELA, in *Ancient Geography*, a town of Africa, in Mauritania Cæsariensis. Ptol.

VAM-KAPOSE, in *Geography*, a small island in the Chinese archipelago, where the celebrated St. F. Xavier was buried; 62 miles S.W. of Macao.

VAMPYRE, in *Mythology*, a name given to an imaginary demon, which, it is pretended, sucks the blood of persons during the night, and thereby destroys them. These vampyres were supposed to animate the bodies of dead persons, which when dug up were found fresh, florid, and full of blood. Those who were killed by vampyres were said to become vampyres themselves: the way to destroy them was to drive a stake through them, at which time they would give a horrid groan; and to burn the body to ashes. This species of superstition occasioned, some years ago, great disturbances in Hungary and other places.

VAMPYRE, in *Zoology*, the *Vespertilio vampyrus* of Linnæus, called also *ternate*, and by Buffon *la rouffette* and *la rougette*, is a species of bat with large canine teeth, four cutting-teeth above, and the same below; sharp black nose; large naked ears; tongue pointed, and terminated by sharp aculeated papillæ; exterior toe detached from the membrane; the claw strong and hooked; five toes on the hind-feet; talons very crooked, strong, and compressed sideways; no tail; the membrane divided behind quite to the rump; va-

rying in colour, some being entirely of a reddish-brown, and others dusky; and also in size, some having the extent from tip to tip of the wings four feet, others five feet four inches; and others extending farther than a man can reach with his extended arms. This animal inhabits Guinea, Madagascar, and all the islands from thence to the remotest in the Indian ocean. They are also found in New Holland, the Friendly Islands, the New Hebrides, and New Caledonia. They fly in flocks, obscuring the air with their numbers; beginning their flight from one neighbouring island to another, immediately on sun-set, and returning in clouds from the time it is light till sun-rise, and during the day lodging in hollow trees: they live on fruit, and are so fond of the juice of the palm-tree, that they will intoxicate themselves with it till they drop on the ground. In New Caledonia, the natives use their hair in ropes, and in the tassels of their clubs. The Indians eat them, and declare their flesh to be very good. The French who live in the Isle de Bourbon, boil them in their bouillon, to give it a relish. While they are eating, they make a great noise; their smell is rank; and their bite, resistance, and fierceness, very great when taken. The ancients had some knowledge of these animals, and M. de Buffon apprehends, that from the account of them the poets formed their fictions of harpies. Linnæus calls this species vampyre, conjecturing it to be the kind which draws blood from people in their sleep. The bat is so dexterous a bleeder, as to insinuate its aculeated tongue into the vein without being perceived, and then suck the blood till it is satiated; all the while fanning with its wings, or agitating the air so as to cast the sufferer into a still sounder sleep. In certain parts of America they have destroyed all the great cattle introduced there by the missionaries. Pennant's Hist. Quadrupeds, vol. ii. p. 548, &c.

VAMPYRE is also a name given by M. de Buffon to the *vespertilio spectrum* of Linnæus, or bat with a long nose, large teeth, long, broad, and upright ears; with a long, conic, erect membrane at the end of the nose, bending at the end, and flexible; hair on the body cinereous, and pretty long; wings full of ramified fibres; a membrane extending from one hind leg to the other; no tail, but three tendons extending from the rump, and terminating at the edge of the membrane. This animal inhabits South America, lives in the palm-trees, and grows very fat. Buffon supposes it to be the species that sucks human blood. Pennant. See ANDIRA.

VAN, VANT, or *Vaunt*, (of the French *avant*, or *avaunt*, before,) is a term used in composition with several words in our language. As,

VAN-Couriers, are light armed soldiers, sent before armies to beat the road, upon the approach of an enemy.

VAN-Fosse, a ditch dug without the counterescarp, and running all along the glacis; usually full of water.

VAN, *Vant*, or *Vaunt-Corps*. See CORPS.

VAN, or *Van-Guard*. See GUARD.

VAN-Lay. See VAUNT.

VAN, in *Agriculture*, a name sometimes used to signify an implement or contrivance for winnowing, or cleaning corn with. See WINNOWING Machine.

VAN, in *Sea Language*, denotes the foremost division of any naval armament, or that part which usually leads the way to battle, or advances first in the order of sailing. See ENGAGEMENT and FLEET.

VAN, in *Mining*. To make a van, is to take a handful of the ore or tin-stuff, and bruise, wash, and cleanse it on a shovel; then, by a peculiar motion of the shovel, to shake and throw forth upon the point of it almost all the ore that is freed from waste. This operation being repeated, the ore

is collected and reserved, and from thence they form an estimate how many tons of copper-ore, or how many hundred weight of block-tin, may be produced out of one hundred sacks of that stuff, of which the van is made. Pryce's Mineral. Com. p. 330. See TIN and VANNING-SBOVEL.

VAN, (*Artemita*), in *Geography*, a city of Armenia, situated two miles from a lake of the same name. It is surrounded with a good wall and deep ditch, and has four gates. On the N. is a castle, built on a high and perpendicular hill, which rises abruptly from the plain. This fortress can only be approached by one passage, so narrow as to admit only two persons abreast; it is always supplied with corn and military stores, and in the centre of the work stands the palace of the aga of the janizaries. This city is abundantly furnished with water and provisions; the houses are built of stone and tile; the streets are spacious and well paved, and the population is said to amount to 50,000 souls, of which number two-thirds are Turks, and the rest Curds and Armenians. The air is pure, and the environs of the city delightful. It is four days' journey from Bayazid, a city of one of the Turkish pachalics of Armenia, twelve from Erzeroom, another of them, five from Betlis, and about the same distance from Khoi.

The lake (*Arfsa* of Ptolemy) is about 168 miles in circumference; and although the water is more sweet than that of Urumea, it is so brackish as to be unfit for the common purposes of life, according to the common opinion, though some say it is very good. There are four islands in the lake, on one of which are an Armenian monastery, and 300 priests. The traffic of the surrounding country is carried on by about 20 or 30 small boats, N. lat. 58°. E. long. 43° 55'. On the N.W. side of the lake, three days' journey from Van, is Argish (the ancient Arzes), containing 6000 inhabitants. And in a westerly direction from Argish is Moosh, the ancient Moxoene, occupying a small eminence, washed by the Euphrates, over which is a bridge of 15 arches, badly built, and thinly inhabited, but situated in a country equally fertile and populous. The natives of this district, amounting to about 80,000 souls, of which 12,000 are Yezedis, are a base and degenerate race. Tobacco and manna are exported from hence in considerable quantities. M'Kinneir's Mem. of Persia.

VAN, a town of Norway, in the province of Aggerhus; 20 miles N. of Christiania.—Also, a river of South Wales, which runs into the Bristol Channel, about 5 miles below Cowbridge, in Glamorganshire.

VANAHON, a river of America, which runs into lake Michigan, N. lat. 42° 53'. W. long. 87° 10'.

VANAMALI, in *Mythology*, a name of the Hindoo god *Krishna*; which see. This name is said to be derived from a pendent garland of flowers, with which this frolicsome deity is usually decorated. In the following passage he contrasts his appearance, thus decorated, with that of Mahefa, or Siva. "I am not the terrible Mahefa: a garland of water lilies, with subtle threads, decks my shoulders; not serpents with twisted folds: the blue petals of the lotos glitter on my neck; not the azure gleam of poison: powdered sandal-wood is sprinkled on my limbs; not pale ashes." This is addressed to his enchanting mistress *Radha*, under which article a farther extract from the same "Song" will be found. The gleam of poison on his neck alludes to his having drunk the poison produced by the churning of the ocean, as described in our articles *KURMAVATARA* and *SHITAKOONTHA*; and being powdered with ashes, is noticed in the latter part of the article *SECTS of Hindoos*.

VANANCOUPAN, in *Geography*, a town of Hindoostan, in the Carnatic; 15 miles S.W. of Trivady.

VAN-BALEN, in *Biography*. See *BALEN*.

VANBRUGH, Sir JOHN, a dramatic writer and an architect, was a descendant of an ancient family in Cheshire, and was first known to the public as an officer in the army, being considered as a man of wit and a pleasant companion. The first play which he finished was "The Relapse;" and it was acted with great success in 1697. This was followed, in the succeeding year, by "The Provoked Wife;" and in the same year appeared his "Æsop," blending humour with satire and useful morality. In 1702 appeared his "False Friend;" and he was now knighted, and advanced to the post of Clarencieux king-at-arms. When a theatre was erected in the Haymarket, it was placed under the management of Vanbrugh and Congreve by Betterton and the other patentees; and it was opened in October, 1705, with a comedy by Vanbrugh, entitled "The Confederacy," which, though the best written, is the most licentious of this author's dramatic productions, besides three more pieces, imitated from the French; but finding the concern irksome, he disposed of his share. The popular comedy of "The Journey to London" was begun by him, but finished by Cibber. In speaking of Vanbrugh, Pope has blended praise with censure, when he says,

"How Van wants grace, who never wanted wit."

His taste and talents as an architect were first exhibited in the theatre in the Haymarket, for which he obtained subscriptions; and to him was committed the erection of the palace of Blenheim, voted by the nation to the duke of Marlborough. In 1716, king George II. appointed him surveyor of the buildings at Greenwich-hospital, comptroller-general of the royal works, and surveyor of the gardens and waters. On a visit to France, he employed himself in taking views of the fortifications in that kingdom, which caused him to be apprehended and committed to the Bastille; but when he was observed to amuse himself in prison by making sketches of comedies, he was liberated, as a harmless person, without any application from home in his favour. As an architect, he was engaged to build several great houses in England, besides Blenheim; but in this capacity he has unfortunately been transmitted to posterity rather as an object of ridicule than of admiration. Mr. Walpole has passed upon him a severe censure, when he says that "he wanted all ideas of proportion, convenience, and propriety. He undertook vast designs, and composed heaps of little-ness. The style of no age, no country, appears in his works; he broke through all rule, and compensated for it by no imagination. He seems to have hollowed quarries rather than to have built houses; and should his edifices, as they seem formed to do, outlast all record, what architecture will posterity think was that of their ancestors?" The following epigrammatic epitaph was written for Vanbrugh by Dr. Evans, and accords with the above character of his works:

"Lie heavy on him earth, for he
Laid many a heavy load on thee."

Notwithstanding the obloquy above cited, some modern amateurs have vindicated the character of Vanbrugh's architecture, particularly that of Blenheim, admiring its grandeur, and the magnificence of the whole, as well as the picturesque variety displayed in this and in other of his buildings.

In society Vanbrugh bore a respectable character, and had no personal enemies. Swift and Pope have expressed their wish, that they had not indulged their raillery against
one

one "who was a man of wit and of honour." He died of a quinsey, at his house in Whitehall, in the year 1726. Biog. Dram. Walpole's Anecdotes. Burney's Hist. Motic.

VAN-CAMPENS, in *Geography*, a town of the state of New Jersey; 32 miles N.W. of Morristown.

VAN-CHEAU, an island in the East Indian-sea. N. lat. 18° 50'. E. long. 110° 40'.

VANCOUVER'S FORT, a fort of Kentucky, at the union of the two branches of Sandy river.

VANDBANDA, in *Ancient Geography*, a country of Asia, in Sogdiana, between mounts Caucasus and Imaus. Ptolemy.

VANDALE, ANTONY, in *Biography*, was born in Holland in 1638, and though he manifested an inclination for study in his youth, his parents placed him in the department of commerce. At the age of 30, however, he resumed his literary pursuits, and graduated as a physician; and he was also for some time a preacher among the Menonites. His attachment to study prevailed at length over every other occupation, and his literary character was established by many valuable works. Of these the most noted was "Dissertationes duæ de Oraculis Ethnicorum," first printed in 1683, 12mo., and afterwards in 1700, 4to. His opinion was, that the heathen oracles were mere impostures, and that they did not cease at the coming of Christ; which at the time was a bold assertion, as it contradicted the sentiments of some of the fathers. Fontenelle abridged these dissertations in his "Histoire des Oracles." (See the article ORACLE.) In 1696 he published a work, "On the Origin and Progress of Idolatry," which contained "A Dissertation on true and false Prophecy;" "A Dissertation on the Narrative of Aristæus on the Seventy Interpreters;" "The History of Baptisms, Jewish and Christian;" "A Dissertation on Sanclioniatho;" and "Dissertations on some ancient Marbles." Some of these have been published separately. In all his writings, Vandale manifested solid erudition, united with sagacity and a spirit of free inquiry; but he wants method, and his style is obscure. He was allowed, even by those who differed from him in opinion, to be a man of great probity, of an agreeable disposition, and entertaining conversation. His lot was that, which has not been uncommon with persons of literature, namely, indigence; for he sold his books before his death, which happened at Haerlem in 1708. Moreri. Le Clerc.

VANDALS, in *Ancient Geography*, a people of no very high antiquity, who were originally a Gothic nation. (See GOTHS.) Pliny and Procopius concur in this account of their origin; and the latter writer, more especially, affirms in express terms, that the Goths and Vandals, though distinguished by name, were the same people, agreeing in their manners, and speaking the same language. They were called Vandals, from the Gothic word "Vandelen," which signifies to "wander," because they often changed their situation, migrating from one country to another. They are supposed to have come originally out of Scandinavia, with the other Goths, under the command of king Eric, and to have settled in the countries now known by the names of Mecklenburg and Brandenburg. When Berig, king of the Goths, several ages afterwards, brought with him a colony of Goths from Scandinavia, and settled in Pomerania, he subdued the Vandals, who inhabited those countries, and incorporated them with the new settlers. In the reign of Augustus, some of the Vandals, being frightened in their own country for want of room, took up their abode on the banks of the Rhine; but were driven from thence by Tiberius and Drusus, and compelled to return home. Their country being overstocked

with inhabitants, they soon afterwards pursued an eastern route, and driving out the Sclavi, who occupied the territory that lay between the Bosphorus Cimmerius and the Tanais, and taking possession of their country, assumed the appellation of the ancient inhabitants. Some of them, several ages after, in the reign of Mauritius, which began in 586, settled in Dalmatia and Illyricum, to which they gave the name of Sclavonia; and others migrated to the eastern parts of Dacia beyond the Danube, a province which comprehended the countries now denominated Transylvania, Moldavia, Walachia, and the eastern parts of Upper Hungary. From those who remained in Germany, the present Poles and Bohemians are generally said to have derived their origin; but the Vandals, who, under Godegisilus, their king, entered Gaul, and afterwards settled in Spain and Africa, came, as Procopius says, from Dacia and the vicinity of the Palus Mæotis. As the Vandals were a Gothic nation, they retained the customs, manners, religion, and form of government, that subsisted among the Goths. The first of their kings mentioned in history is Godegisilus, under whose command they entered Gaul in 406. He was succeeded by Gunderic, who passed, in 409, from Gaul into Spain, and settled in Galicia. His successor, Genferic, abandoned Spain in 428, and passed with his vassals into Africa, which the Vandals possessed till the year 533, when, under Gelimer, an end was put to their dominion by Belisarius, and Africa was reunited to the empire. Although the Vandals are said to have been inferior in power and courage to all the other barbarous nations, they nevertheless made themselves masters of the most fertile provinces of the empire. They became proselytes to Christianity at the same time with the Goths, embracing the sentiments of Arius, in common with the other Goths, and becoming irreconcilable enemies to the Catholic church. Salvianus extols their continence and chastity.

It was about the year 166 that they began to be troublesome to the Romans, in the reign of M. Aurelius and Lucius Verus; when forming an alliance with other barbarous nations, they invaded the empire, plundered several cities, and, having put to flight the Roman armies, committed every where unparalleled ravages. Having taken possession of Pannonia, they retained it till they were expelled in the year 170, by M. Aurelius. They afterwards entered into an alliance with the Romans; and in 180, it was one of the articles of peace concluded between the emperor Commodus and the Alemans, that they should not make war upon the Vandals. In the second year of Aurelian's reign, A.D. 271, the Vandals passed the Danube, laying waste the neighbouring provinces; but Aurelian compelled them to retire with great precipitation, and having overtaken them in their retreat, obliged them to sue for peace; which was granted, on condition of their delivering, as hostages, the sons of their two kings, and other persons of distinction. Two thousand of their best men were incorporated among Aurelian's own troops. After his death, they entered Gaul; but they were defeated by Probus in several battles, and obliged to withdraw themselves at the approach of the Roman army. Resenting the insults of the Roman soldiers, they made an attempt to recross the Rhine, but sustained a great defeat; and proving unfaithful to their engagements, after having obtained peace, Probus marched against them, put many to the sword, took a great number of prisoners, among whom was their king, and afterwards sent them into Britain, where they are supposed to have settled in the neighbourhood of Cambridge, giving name, as it has been said, to the village of Vandalsburg. Probus allowed several of them to settle in Thrace, which was almost depopulated.

The next mention of the Vandals that occurs is in the eighth year of the reign of Dioclesian, when they engaged in a war with the Goths. About the year 406, or the twelfth of Honorius's reign, they made an irruption into Gaul; but in attempting to cross the Rhine, they were slaughtered by the Franks; and being relieved by the Alans and Suevians, they obliged the Franks to retire, and actually entered Gaul. Having passed through Germania Prima and Gallia Belgica, they took possession of Aquitain, the most fertile and opulent province of Gaul; and advancing as far as the Pyrenæan mountains, they ravaged all the neighbouring provinces. Constantine, however, having been proclaimed emperor by the British legions, passed from Britain into Gaul with a powerful army, and defeated the Vandals and other barbarians in several battles, and at length granted them peace, without stipulating as a condition their leaving the country. The Vandals soon afterwards took up arms, and seized several cities of Gaul, under Maximus, who assumed the honour of being emperor, in opposition to Constantine, the son of Constantine. Finding themselves more vigorously opposed than they expected, they marched towards Spain, which was then in a distracted state, and in the year 409 entered the country; and before the end of the year 410, obliged Constantine to abandon it. After having reduced the provinces of Spain to a deplorable condition, they concurred with the Alans and Suevians in dividing the country between them, and devoted themselves to the operations of agriculture. In this partition, Galicia fell to the share of the Vandals and Suevians, and Bœtica to those Vandals that were called Silingians, who are supposed to have given to their portion the name of Vandalusia, afterwards changed into Andalusia. In the year 416, Vallia, king of the Goths in Gaul, having made peace with the Romans, undertook to drive the barbarians out of Spain; and in 422, Honorius, having heard of the reduced condition of the Vandals in Spain, in consequence of the conduct of Vallia, determined to recover the provinces which they possessed. But his attempts for this purpose were rendered ineffectual by a signal defeat. In consequence of this victory, the Vandals became powerful, established themselves in Andalusia, almost destroyed the city of Carthage, and extended their ravages to the Balearic islands. In the year 428 or 429, Genferic, the king of the Vandals, assembled them together, with their wives, children, and effects, and abandoning Spain, crossed the straits of Gibraltar, and landed in Africa. After their arrival, they gained several victories over the Romans, and so overran the country, that Cirta and Carthage were the only two strong places in Africa possessed by the Romans. At length, *viz.* A.D. 435, a peace was concluded between Valentinian and Genferic; but though the moderation of the Vandal sovereignty was highly extolled, he nevertheless seized Carthage, A.D. 439, whilst the Romans were engaged in a war with the Goths in Gaul; and thus the Vandals remained masters of the proconsular province of Byzacene, Gætulia, and part of Numidia. The capture of Carthage created an alarm in Italy; and preparations were vigorously made for putting Rome in a state of defence, and for inducing all ranks of people to take up arms for the preservation of the country. In the year 455, Genferic took and plundered Rome; and carried over with him into Africa the empress Eudoxia, and her two daughters Placidia and Eudocia, where he detained them till the year 462, marrying Eudocia to Hunneric, his eldest son, who had by her Hilderic, afterwards king of the Vandals in Africa. Upon his return to Africa, Genferic subdued the countries that were still in the hands of the Romans. The emperor Majorianus, being disappointed in his views and plans for the conquest of Africa, concluded a

peace with Genferic, who, after the death of the emperor in 461, sent a powerful fleet to pillage the coasts of Sicily and Italy, and even made himself master of Sardinia. He afterwards took occasion to ravage Peloponnesus and the Greek islands, whence were carried off many captives. Leo repented the affront offered by Genferic to the eastern empire, and prepared for revenge by carrying the war into Africa. In the progress of his powerful armament, Sardinia and Tripoli were recovered from the Vandals; but whilst Genferic solicited of the Roman admiral a truce of five days for settling the terms of his submission to Leo, he contrived to destroy the whole Roman fleet that was armed against him. In the year 475, he concluded a peace with Zeno, the successor of Leo, who, renouncing all claim to the provinces of Africa, yielded them for ever to Genferic and his descendants. Soon after this event, Genferic died, A.D. 477; but the peace was religiously observed by his successor, till the reign of Justinian, who, espousing the cause of Hilderic against his brother Gilimer, who had usurped the crown, drove the Vandals out of Africa, and reunited those provinces to the empire. (See BELISARIUS.) Africa had been their empire, it now became their prison; nor could they entertain a hope, or even a wish, of returning to the banks of the Elbe, where their brethren, of a spirit less adventurous, still wandered in their native forests. In the country between the Elbe and the Oder, several populous villages of Lusatia are inhabited by the Vandals: they still preserve their language, their customs, and the purity of their blood; support, with some impatience, the Saxon or Prussian yoke; and serve with secret and voluntary allegiance the descendant of their ancient kings, who in his garb and present fortune is confounded with the meanest of his vassals. The name and situation of this unhappy people might indicate their descent from one common stock with the conquerors of Africa; but the use of a Sclavonian dialect more clearly represents them as the last remnant of the new colonies, who succeeded to the genuine Vandals, already scattered or destroyed in the age of Procopius. *Anc. Un. Hist.* vol. xvii. *Gibbon's Hist. Rom. Emp.* vol. i. vi. vii.

VANDELEVILLE, in *Geography*, a town of France, in the department of the Meurte; 9 miles N.W. of Mirecourt.

VANDELLIA, in *Botany*, was so called by Linnæus, at the suggestion of Browne, after his correspondent Dr. Dominick Vandelli, who published at Padua, in 1761, a quarto volume in Latin, on the hot-baths of that neighbourhood, with notices of some cryptogamic plants inhabiting therein. Being afterwards appointed superintendent of the royal botanic garden at Lisbon, he published there, in 1771, a small *Fasciculus Plantarum*, dedicated to sir Joseph Banks, describing some supposed new genera, and several new species, with a few figures. Dr. Vandelli is also the author of one or two zoological tracts; and he wrote against Haller's doctrine of the insensibility of the tendons and membranes, to the great displeasure of that illustrious physiologist. This veteran in botanic science visited London, in 1815, at a very advanced age, and, if we mistake not, is since dead.—*Linn. Mant.* 12. *Schreb. Gen.* 419. *Willd. Sp. Pl.* v. 3. 343. *Mart. Mill. Dict.* v. 4. *Juss.* 122. *Lamarck Illustr.* t. 522. (*Matourea*; *Aubl. Guian.* 641. *Juss.* 119.)—Class and order, *Didynamia Angiospermia*. *Nat. Ord.* *Personate*, *Linn. Scrophulariæ*, *Juss.*

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, in four deep, awl-shaped, equal segments, the uppermost sometimes divided, permanent. *Cor.* of six petal, ringent; tube as long as the calyx; limb small; its upper lip ovate, entire;

entire; lower dilated, two-lobed. *Stam.* Filaments four; two from the disk of the lower lip, curved upwards; two from the throat, higher up; anthers ovate, connected in pairs. *Pist.* Germen oblong; style thread-shaped, the length of the stamens; stigmas two, ovate, membranous, reflexed. *Peric.* Capsule oblong, of one cell. *Seeds* numerous.

Eff. Ch. Calyx four-cleft. Corolla ringent. Two exterior filaments from the disk of the lip of the corolla. Anthers connected in pairs. Capsule of one cell, with many seeds.

1. *V. diffusa.* Round-leaved Vandellia. Linn. Mant. 89. Willd. n. 1. "Vahl Eclog. v. 2. 47."—Leaves roundish, nearly sessile, smooth above.—Native of the West Indian islands of Montserrat and Santa Cruz. *Stem* herbaceous, square, cross-branched. *Leaves* roundish-ovate, bluntish, crenate, or bluntly serrated, opposite, on short stalks; smooth above; rather hairy beneath. *Flowers* axillary, opposite, solitary, on short stalks. The habit and size of the leaves resemble *Veronica serpyllifolia*.

2. *V. pratensis.* Oblong-leaved Vandellia. "Vahl Eclog. v. 2. 48." Willd. n. 2. (*Matourea pratensis*; Aubl. Guian. 642. t. 259. Tupeicava, five Scoparia; Pis. Braf. 246.)—Leaves stalked, elliptic-oblong, acute, finely downy on both sides.—Native of moist ground in Cayenne; about the borders of meadows near the town, flowering almost all the year. It is known by the name of Wild Basil (*Basilic sauvage*), and esteemed a good vulnerary. The stems are several, erect, two feet high, leafy, square, forked. *Young branches*, as well as the leaves, soft to the touch, clothed with fine short pubescence. *Flowers* blueish, axillary, mostly solitary. They are delineated in Aublet's figure as having the upper lip in two lobes, the lower in three, which does not agree with the Linnæan generic description, copied above from the *Mantissa*. Yet the other characters, and the habits of the plants, answer so well, that we are persuaded they must, as Schreber suspected, belong to one genus. This opinion is confirmed by Vahl, who mentions this second species as of very frequent occurrence, by the road-sides in South America, from Trinidad to Brazil. The root is annual. The same learned botanist had, no more than ourselves, any opportunity of examining the rare *Vandellia diffusa* alive, nor does it appear whence Linnæus took his description; except possibly from two or three very incomplete dried specimens, which are now scarcely sufficient to assist in forming an opinion on the subject.

VANDERWERF, ADRIAN. This ingenious painter was born at Ambacht, near Rotterdam, in 1659, and received the principal part of his education under Eglon Vander Neer. At the age of 18, he left that master, and becoming acquainted with M. Fluk, who possessed an extensive collection of drawings by Italian masters, to which he had constant access, he, by this aid, and also by drawing after casts from antique figures, formed a style of design much more elevated and pure than that of his countryman and contemporaries.

At about the age of 37, his works attracted the notice of the elector palatine, on his visit into Holland; and he

commissioned him to paint for him a picture of the Judgment of Solomon, and also his own portrait, to be presented to the Florentine gallery of artists; and he invited him to bring the pictures to Dusseldorf. The following year he effected that object, and the elector was desirous of retaining him in his service; but to this Vanderwerf would not consent, but engaged to devote to him six months of the year, for which he received a liberal pension. In consequence, the gallery of Dusseldorf is the theatre of Vanderwerf's glory, and his pictures there are numerous; but they are not very uncommon in this country. The character of them is given by sir Joshua Reynolds, who, in his critical tour into the Netherlands, says, "they (the pictures by Vanderwerf at Dusseldorf) are twenty-four in number in one room, three of them as large as life; a Magdalen, whole length, and two portraits. His pictures, whether great or small, certainly afford but little pleasure; one of the principal causes appears to me, to be his having entertained an opinion that the light of his picture ought to be thrown solely on the figures, and little or none on the ground or sky. This gives great coldness to the effect, and is so contrary to nature, and the practice of those by whose works he was surrounded, that we cannot help wondering how he fell into the mistake. His naked figures appear to be of a substance much harder than flesh, though his outline is far from cutting, or the light not united with the shade, which are the most common causes of hardness; but it appears to me, that, in the present instance, the hardness of manner proceeds from the softness and union being too general; the light being every where equally lost in the ground, or its shadow, and thus producing the appearance of ivory or plaster, or some other hard substance." There is also a want of transparency in his colouring, and he has constantly the defect of Rembrandt, that of making his light only a single spot. However, to do him justice, his figures and his heads are generally well drawn, and his drapery is excellent. He died in 1727, aged 68.

He had a brother, *Peter Vanderwerf*, who copied his pictures, and imitated his manner. Though he occasionally painted history, yet his pictures more frequently represent domestic scenes; which, though not equal to his brother's, are very highly wrought, and have sometimes been mistaken for his. Peter died in 1718, aged 53.

VANDELDELDE, ADRIAN. This excellent painter was born at Amsterdam in 1639. He discovered, whilst he was yet at school, a decided disposition for painting, and covered the walls of his father's house with sketches of all kinds of animals, drawn with an intelligence very unusual at that early period of life, and which induced his father to place him under the tuition of J. Wynants, where he made a very extraordinary degree of progress. Wynants taught him the practice of drawing from nature, and studying in the open air. It was his constant custom to pass his days in the fields, designing every thing essential to his pursuits; and in this mode, infinitely more variety may be obtained than the most inventive genius can supply without it. Besides this useful mode of study, he also applied himself to draw from the human figure, and obtained a considerable degree of excellence. In this respect he very far surpassed his master, who afterwards constantly employed him, as he had previously done Wouermans and Lingelback, to decorate his landscapes with figures and animals; as also did Hackaert, Hobbma, Vander-Heyden, and others, thus giving an additional interest to their admirable performances.

The scenes which Adrian Vandevelde chose for the exercise of his art are in general very confined, and seldom above the ordinary appearance of common nature; but they are

are rendered with so much purity of colour, and fulness and perfection of execution, that they captivate, notwithstanding their simplicity. His animals, which are generally the subjects of his pictures, are designed with correctness, and painted to perfect imitation; particularly his cows, sheep, and goats; perhaps not with so much spirit as those of Paul Potter, but more soft and delicate. His pictures, which are generally small, are universally held in the highest admiration, and are sold at very high prices. Unhappily he died in the very prime of his life, at the age of 33; and yet his pictures are by no means scarce, as his industry was inconceivable, and his facility very great.

Though landscape and animals were his more regular objects of study, yet he felt himself qualified to undertake an historical picture for the Catholic church at Amsterdam; and the ability with which he executed a Descent from the Cross for the altar-piece there, still testifies the power with which he might have distinguished himself in history, had he more regularly pursued it. He died in 1672. There are about twenty etchings by him of cattle and landscapes.

VANDEVELDE, WILLIAM, the *Elder*, was born at Leyden in 1610, and early in life followed the occupation of a mariner. It is not known at what time he turned his thoughts to painting, or by whom he was instructed in the art; but before he was 20, he had acquired considerable reputation for painting marine subjects in black and white. His skill recommended him to the notice of the States General; and Descamp says, that he was furnished by them with accommodations in a small vessel, for the purpose of attending their fleets, and making sketches of their different manœuvres and actions. He was present at various engagements at sea, and frequently exposed himself to danger in the prosecution of his studies. He is said to have been present at the action between the duke of York and the Dutch admiral Opdam, in 1665; and at the more memorable one the following year, between the English and Dutch fleets, commanded by the duke of Albemarle and De Ruyter. King Charles II. invited him to England, where he came some time before 1675; as in that year the king settled a salary upon him of 100*l. per annum*. He continued in the same capacity under king James II., until his death in 1693. He was buried in St. James's church, where is a tomb-stone to his memory.

VANDEVELDE, WILLIAM, the *Younger*, the son of the preceding artist, was born at Amsterdam in 1633. He was initiated in the art of painting by his father, but obtained more knowledge of colouring and effect by studying under De Vlioger, an eminent marine painter; and at length arrived at a degree of perfection in the treatment of those subjects, which still remains unrivalled. After he had practised with great success for some time in Holland, and enriched many cabinets there with his works, his father prevailed upon him to come to England, where he was soon noticed by the king, and complimented with an engagement and a salary such as his father's, and had also apartments provided for him at Greenwich.

During the life of his father, as appears by an order of the privy seal, he was much employed in painting pictures from his sketches, but doubtless rendered more agreeable by his own better taste and feeling. The exercise of his talents, however, was not confined to the service of his majesty; he was constantly employed by various persons, and his pictures are, therefore, to be found in almost every collection which has any pretence to admiration. One of his grandest compositions for chiaro-scuro is in the gallery of the marquis of Stafford, where the majestic forms of the clouds, the motion of the waves and of the vessels, and the

truth and imposing quality of the tone of colour, contend for pre-eminence.

The compositions of the younger Vandevelde are distinguished by a more tasteful arrangement of forms and objects, than is to be found in those of any other marine painter. His vessels are correctly drawn, and the sails, the cordage, and rigging, finished with a delicacy perfectly astonishing, and with unexampled freedom. No one ever surpassed the purity and truth of his tints: whether he represent the serenity of the calm, or the majestic obscurity of the storm, an undeviating correctness and fulness adorn his canvas, and render his works precious in the eyes of all beholders. He died in 1707, at the age of 74.

VANDYCK, Sir ANTHONY, in *Biography*. This most justly admired painter was born at Antwerp in 1599, and, according to Houbraken, was the son of a painter on glass, who first instructed him in the elements of the art of painting, but afterwards trusted him for further tuition to the care of Henry Van-Balen, a painter of considerable reputation. He had made a rapid progress under that master, when the increasing fame of Rubens, and the beauty of his works, inspired him with a desire of becoming a disciple of so able an instructor; and his wishes were soon crowned with success. Rubens soon beheld with pleasure the value of the talents brought by Vandyck into his school, and found in him an able and useful assistant in forwarding his larger works from the sketches he himself had prepared; and it was not long ere an incident established Vandyck's superiority above his fellow pupils, and rendered him at once an object of interest and of envy. Whilst Rubens was employed upon his renowned picture of the Descent from the Cross, his pupils were anxious to see it in its progress, and procured admission to his study during their master's absence. One of them, in the wantonness of youth, pushed Diepenbeck, and he fell against the picture, and effaced an essential part of it, on the face of the Virgin, and the arm of the Mary Magdalen, which Rubens had just been painting. Consternation and alarm seized every one present; and to prevent, if possible, the discovery of the accident, John Van-Hoeck proposed that Vandyck should endeavour to restore the picture to the state in which they found it. He did so; and the next morning, when Rubens came into his room, on regarding the picture, he is said to have remarked, "there is a head and an arm which are by no means the worst of what I did yesterday;" and though

afterwards he might have discovered the mischief, he did not change the painting.

It has been asserted by D'Argenville and others, that this circumstance, and the growing ability of Vandyck, alarmed the jealousy of Rubens, and that, in consequence of it, he advised his pupil to renounce historical painting, and adhere to portraiture. But this calumny must be regarded as refuted, by the mere consideration of Rubens having advised Vandyck to go to Italy, where he himself had reaped so much benefit, and where history would be the more sure to rivet the attention of a student. Had he, however, advised him to adhere to portrait painting, it is but a farther proof of his clear perception of the native turn of mind of Vandyck, and a liberal hint how to employ his talents to most advantage, not originating in the mean passion to which it has been ascribed, but in judgment and good-will. That they did not separate upon unfriendly terms is evident, by Vandyck acting upon his advice, as to going to Italy; and presenting his master, previous to his departure, with two historical pictures, and a portrait of his second wife Helen Forman; and receiving from Rubens in return a present of one of his finest horses.

In 1619, when he was 20 years old, Vandyck left his native city for a residence in Italy, and first visited that emporium of colour, Venice, where he copied and studied with great attention, and imbibed the real spirit, of the works of Titian. At Petworth, the seat of the earl of Egremont, are two portraits of sir James and lady Shirley, (who was a Persian lady,) in Persian costume, which exhibit, in the freedom and fullness of colour with which they are painted, the perfect understanding he had of the style of that great Venetian master. From Venice he went to Genoa, where his power was recognised, and his pencil employed, by the principal nobility in their portraits, as well as by several churches and convents, for which he painted historical pictures; and nothing is more astonishing in the history of the art, than the rapidity and facility with which so great a number of works was produced by this extraordinary artist. He is reported to have hung up in his study, on his return from Italy, forty copies made by himself from pictures by Titian, though he was much engaged in original works during his residence there. After some stay at Genoa, he went to Rome, and was there introduced to that patron of elegant literature, the cardinal Bentivoglio, who had been nuncio from the pope in Flanders, and to whom, of course, his talents must have been already known. From this celebrated character he painted that prince of portraits, which for several years was an ornament of the gallery of the Louvre, but now is returned to its original station, the museum at Florence. Nothing in painting has ever surpassed the life and vigour of the head in this surprising and agreeable picture. He painted some historical subjects for the cardinal, and also several portraits of distinguished persons; but not uniting with his countrymen, then at Rome, in the Bentivoglio society, they rendered his residence there unpleasant to him, and he returned to Genoa, where he was caressed and honoured, and met with constant employment. Whilst there, he was invited to Palermo, to paint the portrait of Philibert, prince of Savoy, the viceroy of Sicily, and was engaged in several commissions for the court; but the plague breaking out, obliged him to leave that place, and he soon after returned to Flanders.

The reputation of his growing talents had led his countrymen to an anxious desire of witnessing his power, and several religious communities advanced to employ his pencil. His first public work was his celebrated picture painted for the church of the Augustines at Antwerp. For a time it

adorned the walls of the Louvre, but is now restored to the church whence it was taken. The subject is St. Augustine in Ecstasy, supported by angels, with other faints; of which there is a print by De Jode. Of this performance, which procured him great reputation, Rubens was one of the most zealous admirers; but sir Joshua Reynolds observes, "that in some measure it disappointed his expectation: that it has no effect from the want of a large mass of light." In justice to both painter and critic, it must be observed, that as it was originally painted by Vandyck, St. Augustine was dressed in white, and with the two angels that support him, formed a principal mass of light; but that the monks insisted upon their patron being dressed in black, and would not pay for the picture till it was so done.

Commissions now came fast upon him, and most of the principal public edifices of Antwerp, Brussels, Ghent, and Mechlin, were embellished with the productions of his pencil. About this time he painted that beautiful series of small portraits of the eminent artists of his time, which, for character, for variety, and exquisite execution, remain unequalled. Several of them he etched himself, and the rest have been engraved by the best engravers of that day. One of his most excellent historical productions was painted for the church of the Recollects at Mechlin, which also paid a visit to the Louvre, but was returned with the rest of the spoil from Flanders. Its subject is the Crucifixion, and sir Joshua says of it, that, "upon the whole, it may be considered as the finest of Vandyck's works, and establishes his fame to the title of an historical painter."

The taste and ability thus displayed by this great artist did not insure him from ill treatment by his contemporaries, by whom he was accused of tameness and insipidity; and in addition to this, he endured a great mortification from the canons of the collegiate church at Courtray, for whom he painted the Elevation of the Cross, bestowing upon it all the power of his art. The picture being completed, it was sent to the place of its destination, when, instead of receiving the due meed of praise for its extraordinary merit, it was pronounced by the chapter to be a detestable performance, and they treated the author of it as a miserable artist; and with difficulty he could procure payment for his picture. It was not till the picture had been seen and commended by several artists and connoisseurs, that they became sensible of their error; and then, to atone for such foolish and infensible conduct, they resolved to commission him to paint two more pictures for their church; but Vandyck, with becoming indignation, refused to waste his talents upon men so unworthy of regard, and so little capable to judge of works of art.

Soon after this, he accepted an invitation from Frederic, prince of Orange, to visit the Hague; and there he painted the portrait of that prince, and those of his family, with many of the principal personages of the court.

The patronage which it was understood was to be found at the English court, where Charles I. then reigned, induced Vandyck to visit England in 1629, when he lodged with his friend Geldorp, the painter; but had not the good fortune to attract the notice of his majesty. Disappointed, he returned to Antwerp, with intent to pass the remainder of his life there, when a portrait of sir Kenelm Digby, which he had painted, was shewn to Charles, and he immediately gave orders for an invitation being sent to the painter to return; and accordingly in 1631 he did so, and was most graciously received by the king.

On this second arrival, he was lodged at Blackfriars, at the king's expence; and his majesty was so much delighted with his performances, that he often went by water to visit

visit him, and see him paint; frequently sitting to him for his portrait, having others of his wife and children; and on the 5th July, 1632, conferred upon him the honour of knighthood, and soon afterwards granted him an annuity of 200*l.* a-year for his life.

Popularity and occupation now flowed in full tide upon him, and the rapidity of even his pencil could scarcely keep pace with the commissions he received, for portraits especially. There are few houses of the old nobility of the country wherein there are not to be found some pictures by Vandyck. In the king's palaces, the portraits of Charles and his queen and family are numerous. One of a very fine quality adorns the Louvre. At lord Digby's in Warwickshire, is a great number of his portraits. At Petworth, besides the two pictures mentioned above, painted at Venice, are eleven portraits by him, all of the Percy family, or their immediate friends. At Warwick Castle is the like number; and in each are works of the first-rate quality. At Wilton, the grandest of his pictures painted here adorns a magnificent apartment: it is of William, earl of Pembroke, and his family. The style in which it is executed is large and grand, and of a much higher quality than his later productions exhibit, which, in comparison, have only delicacy to compete with the boldness and breadth of this. There are here also many others of his hand; but it would be an almost endless and a needless task to enumerate the pictures which he painted during the sixteen years he resided here, the greater part of which comprehended those of a large size. The prices he was paid confined them to the higher class, and for them only he wrought. For a half length he had 40*l.*, and for a whole length 60*l.* This, which at that time was a large sum, and the facility of his execution, together with his pension, enabled him to indulge a natural taste for splendour and luxury. He kept a splendid table, and often detained those who sat to him to dinner, both for society, and the opportunity of studying their countenances, and for retouching their pictures after dinner. He was, however, indefatigable, as appears from the number of his works, which, though he died so young, are scarcely surpassed in number by those of Rubens. His practice was peculiar. Sir Peter Lely told Mrs. Beale, that Lanier the painter assured him, that he had sat seven entire days, morning and evening, to Vandyck, for his portrait; and that he would not let him look at the picture, till he was himself satisfied with it. He was addicted to pleasure, was fond of music, and treated musicians with liberality; was a generous patron of all ingenious men, and painted the portraits of many gratuitously. But he paid dear for his indulgence; his luxurious and sedentary life brought on the gout, and hurt his fortune; and he unwisely could not, like his master, resist the temptation of the time, the pursuit of the philosopher's stone; in which perhaps, as Mr. Walpole says, he might have been encouraged by his friend sir Kenelm Digby. Towards the close of his life, the king bestowed on him the daughter of the unfortunate lord Gowry (Maria Ruthven) for a wife; with whom he acquired only honour and beauty, and by whom he left one daughter, afterwards married to Mr. Stepney, who was an officer of the horse-guards on the re-establishment of the royal family.

Soon after his marriage he revisited his native city, and from thence went to Paris, hoping to be employed in the decoration of the gallery of the Louvre; but was disappointed, in finding the commission given to Poussin, who had been brought from Rome expressly for this purpose. Vandyck then returned to England, and still emulous of his great master's renown, was ambitious of being employed upon some great national work; and proposed to the king; by sir K. Digby,

to paint the walls of the banquetting-house (of which the ceiling had already been adorned by Rubens) with the history and procession of the order of the Garter, for which he asked 8000*l.*; a proposal far more agreeable to the taste than to the purse of the king: and if it had been accepted, two events which soon after occurred, would have totally prevented its completion, *viz.* the double triumph of death over the patron and the artist. The former indeed lived some years after the decease of the latter; but his political demise followed shortly upon that event, which occurred on the 9th December 1641, when he had only attained the age of 42.

Though Vandyck produced many valuable works, as we have seen, in historical painting, yet it by no means appears to have been his forte; as he seldom exhibited much expression, but a tame sweetness of effect reigns in them. It is doubtless in portraiture that he stands most decidedly conspicuous, and he may be placed at least alongside of Titian: for if the palm of superiority be given to the latter for his heads, the former must have equal praise for every other part of his pictures, and particularly for the ordonnance of the whole. His better compositions are conspicuous for their unity and propriety; but his great quality is his perfect understanding of the nature of all the parts, the head, the hands, drapery, skies, &c. and the delightful union of tone and beauty of execution, which he never failed to give. In identity of character he was not often conspicuous: perhaps the cardinal Bentivoglio is the most perfect exemplar; but sir Joshua Reynolds has superadded that invaluable quality to all that he might have acquired from the works of Vandyck or of Titian.

VANDYCK, PHILIP, known by the name of the little Vandyck, was born at Amsterdam in 1680, of a different family to that of sir Anthony, and was a disciple of Boonen, under whose tuition he remained till he had become almost capable of teaching his instructor. He painted small portraits, and from them obtained his cognomen; but was more successfully employed in painting conversation pieces, ladies at their toilettes, gay assemblies, &c. which he composed and painted ingeniously. He died at the Hague in 1752.

VANDYKE'S ISLANDS, in *Geography*, two islands, Great and Little, in the West Indies, situated to the north-west of Tortola.

VANE, Sir HENRY, in *Biography*, a person of peculiar talents and disposition, who exhibited a conspicuous character during the period of the English Commonwealth, was the eldest son of sir Henry Vane, of Hadlow in Kent, and Raby castle in Durham, secretary and treasurer of the household to Charles I. He was born about the year 1612, educated at Westminster school, and at the age of sixteen admitted as a gentleman-commoner at Magdalen college, Oxford. Here he remained for some time without matriculation, of which he disapproved; and having visited France and Geneva, he returned with an avowed disaffection to the liturgy and government of the English church, which no efforts of bishop Laud were sufficient to overcome, although he was employed by the king for this purpose. In the year 1634 he joined a number of persons, who being made uneasy by the measures that were pursued at home, emigrated to New England; and being favourably received in that colony on account of his rank and talents, he was soon appointed governor of the province of Massachusetts. Here he incurred odium by his patronage of Antinomianism; and having taken an active part in disseminating those sentiments with regard to religion that occasioned contentions very injurious to the colony, he was excluded from his high office, and

and in consequence of this degradation, he returned privately to England in the year 1639.

Experience having taught him wisdom, and having produced a change in his principles and temper, he married a lady of good family, and occupied the place of joint-treasurer of the navy with sir William Ruffel. Devoting himself to business, he was chosen representative for Hull in the parliament of April 1640, and the subsequent Long parliament. He was also so much in favour with the royal party, that he was knighted by the king. His public conduct seems at this time to have justified the character given of him by lord Clarendon, who says, "he was a man of extraordinary parts, a pleasant wit, a great understanding, which pierced into and discerned the purposes of other men with wonderful sagacity, whilst he had himself *vultum clausum*, that no man could make a guess of what he intended. He was of a temper not to be moved, and of rare dissimulation, and could comply when it was not reasonable to contradict, without losing ground by the concession." A crisis, however, was approaching, which required his taking a decided part; and accordingly he enlisted with those who were adverse to the court. On occasion of the trial of lord Strafford, he produced from his father's papers evidence against him, which served in no small degree to produce his condemnation. He also carried up to the lords, the articles of archbishop Laud's impeachment. In 1643, he was nominated one of the Assembly of Divines for the settling of church government: and he was appointed in the same year one of the parliamentary commissioners for negotiating a treaty with the Scotch. His persuasion induced the signature at Edinburgh of the Solemn League and Covenant; and in accomplishing this object, he overreached the Presbyterians of that country by an article which established the existing form of religion in Scotland, but left ambiguous the nature of the reform in the two other countries. About this time he became sole treasurer of the navy, but without any view to his own emolument: for he gave up his own patent for life from the king, and for an agent whom he substituted in his own place, he obtained a salary of 2000*l. per annum*, the residue being brought to the public account. Of his religious principles and character at this time, lord Clarendon speaks in the following terms: "Vane was a man not to be described by any character of religion, in which he had swallowed some of the fancies and extravagancies of every sect or faction; and was become (which cannot be expressed by any other language than was peculiar to that time) a *man above ordinances*, unlimited or unrestrained by any rules or bounds prescribed to other men, by reason of his perfection. He was a perfect enthusiast, and without doubt did believe himself inspired, which so far corrupted his reason and understanding, that he did at some time believe he was the person deputed to reign over the saints upon earth for 1000 years." In connection with the party denominated Independents he opposed terms of peace, when he acted as one of the parliament's commissioners at the treaty of Uxbridge in 1645, and when he negotiated in the Isle of Wight in 1648. Although he had from artifice or feeling no concern in the king's death, he was one of the council of state invested with supreme power after that event. He was a steady adherent to the republican government, under which he occupied an important station; and in 1641 he was one of the commissioners sent into Scotland for introducing the English government there, and for effecting an union between the two countries.

On this occasion he is represented by Burnet as having fomented the division prevailing between two parties in the

kirk, and as having discouraged all attempts to unite them, with a view of maintaining over them more easily temporal authority, whilst they disagreed among themselves. To Cromwell, in all his attempts to assume the supreme power, he was a determined adversary; and on account of his efforts for this purpose, he was summoned before the council by Cromwell in 1656, and ordered to give security that he would not disturb the nation, and for his refusal he was for a short time imprisoned at Carisbrook castle; and though attempts were made to intimidate him by disputing his title to the Raby estate, he remained inflexible during the period of the Usurpation. In Richard's parliament of 1659, he was a representative of the borough of Whitechurch in Hampshire, and was active in his endeavours for restoring the republican government, and his spirited speech for this purpose, on record, is said to have had no small effect in subverting the new phantom of single authority. After the revival of the Long parliament, he was nominated one of the committee of safety, and proposed a new model of government, of which it was a fundamental principle, that in the delegation of the supreme power from the people to their trustees, there were some points which could not be assumed by the latter; and of these he specified the admission of any king or single person to the legislative or executive power, and the exercise of compulsion in matters of faith and worship. Baxter asserts, that Vane's model was that of a "fanatic democracy;" and his notions have been as much reproached by Presbyterian writers as by Episcopalians.

Vane maintained his adhesion to the republican cause, and prosecuted his efforts for supporting it, till the contest was terminated by the Restoration. His conduct on this occasion, though he was not one of the regicides, caused his name to be inserted in the list of those who were excluded from the act of indemnity. Apprehending no personal danger, he continued in his house at Hampstead, till he was taken into custody and committed to the Tower, as a person whom it was hazardous to permit to be at large. A petition, however, was presented to the king by the Convention parliament in favour of him and Lambert, that they should be pardoned as to their lives, to which was returned a gracious answer. Nevertheless in July 1661, in the succeeding parliament, an order was issued by the house of commons, that both Vane and Lambert should be proceeded against according to law. Upon this order Vane was brought from his prison in the isle of Scilly, and committed to the Tower for trial. For his conduct after the death of Charles I., comprehending his active efforts in opposition to the present king, as a member of the council of state and a person in office, he was indicted of high-treason. In June 1662 he was put to the bar, and is said to have defended himself with ability and resolution, or, as his enemies say, with arrogance and insolence. Among other pleas, he urged that treason could only be committed against a king *de facto*, and not *de jure*, which was the situation of Charles II. till the Restoration; and that he had in all changes adhered to the commons, as the fountain of all regal authority: a principle for which he had exposed himself to the tyranny of Cromwell, and for which he was now ready to undergo all the rigour of perverted law and justice. Nevertheless he was found guilty, and sentenced to suffer the whole penalty adjudged to high-treason, which, however, was commuted for beheading. It has been not unreasonably suggested, that though the king could not easily be defended for breach of his promise to the former parliament on this occasion, his death was a retaliation for the part he had acted on the impeachment of lord Strafford. On the 14th of June he was brought to the scaffold on Tower-hill, and though considered

dered as a person possessing little natural courage, he behaved with wonderful composure and firmness. In his addresses to the spectators, whilst he justified himself on certain points that were construed to reflect upon the government and judges, he was rudely interrupted by the lieutenant of the Tower, who repeatedly ordered the trumpets to sound that his voice might not be heard. He died about the 50th year of his age, and left one son. His writings, chiefly on religious topics, were confused and obscure. Bishop Burnet says of him, "that though he set up a form of religion of his own, yet it consisted rather in a withdrawing from all other forms, than in any new or particular opinions or forms, from which he and his party were called 'Seekers,' and seemed to wait for some new and clearer manifestations. In these meetings he preached and prayed often himself, but with so peculiar a darkness, that though I have sometimes taken pains to see if I could find out a meaning in his words, yet I could never reach it. His friends told me he leaned to Origen's notion of an universal salvation of all, both of devils and the damned, and to the doctrine of pre-existence."

As to his political conduct, it is observed by one of his biographers, that "though he employed craft and dissimulation as his means, there seems no reason to doubt of his sincerity as to his ends, which appear to have been those of a visionary, but not of a selfish statesman. His enemies fearfully charge him with mercenary views, and his friends represent him as a real, though mistaken, lover of his country." Clarendon. Ludl. Mem. Biog. Brit. Hume. Gen. Biog.

VANE, in a *Ship*, is a thin slip of hunting hung to the mast-head, or some other conspicuous place, to shew the direction of the wind. It is commonly sewed upon a wooden frame, called the stock, which contains two holes, by which to slip over the spindle, upon which it turns about as the wind changes.

VANE, *Dog*, in *Sea Language*, is a small light vane, formed of a piece of packthread of about two feet in length, upon which are fixed five or six thin slices of cork stuck full of light feathers. It is usually fastened to the top of a staff, two yards high, which is placed on the top of the ship's side, on the quarter-deck, in order to shew the direction of the wind to the helmsman, particularly in a dark night, or when the wind is extremely feeble. Falconer.

VANES, or *Mathematical Instruments*, are sights made to move and slide upon cross-staves, fore-staves, quadrants, &c.

VANES, or *Fanes*, of *Feathers*. See FEATHER.

VANES, *Weather*. See WEATHER.

VANES of *Windmills*. See WINDMILL.

VANEERING. See VENEERING.

VAN-EFFEN, JUSTUS, in *Biography*, was born at Utrecht in 1685, and losing his father during the course of his academical studies, he commenced the profession of an author for a subsistence. His first work, published in 1711, was entitled "Le Misanthrope," written after the model of the English Spectator, which he continued till it amounted to two vols. 8vo. To the "Literary Journal," established by a society of young persons at the Hague in 1713, he was a liberal contributor; and the profits were assigned to him. The contributions to this Journal were examined by the whole society, so that every article was sanctioned by the judgment of the whole body. This was continued till the year 1718, when Van-Effen engaged in a new periodical paper, entitled "Bagatelle, ou Discours Ironiques," designed to ridicule the vices and follies of the time. This publication failed of success. The author afterwards engaged in various literary undertakings, and agreed to continue the "Nouvelles Littéraires," when the prince of Hesse

Philipsstahl, in 1719, took him as a companion in a journey to Sweden. Of this tour he published an account in 1726, in a second edition of his "Misanthrope." He afterwards occupied himself in translations, chiefly from the English; and at Leyden, where in 1724 he superintended the education of a young man at the university, he undertook to translate from Dutch to French Gerard Van Loon's "Medallic History of the United Provinces;" but a dispute occurring between him and the bookellers, he finished only two volumes. In 1725 he commenced a new periodical work, under the title of "Nouveau Spectateur François," of which twenty-nine sheets appeared. In 1727 he accompanied the count of Welderen, ambassador from the States to the court of London, as his secretary, when he wrote an ode in French on the coronation of George II. In 1731 he began a work, entitled the "Dutch Spectator," and continued it till the whole amounted to 12 vols. 8vo. Van-Effen died in September, 1731, at Bois-le-Duc, where he had for some years occupied the post of inspector of the magazines. He sustained the character of an ingenious and worthy man. Moreri. Gen. Biog.

VANELLOE, in *Botany*. See VANILLA.

VANELLUS, in *Ornithology*, a name given by many to the lapwing, more commonly known by the name *capella*.

VANETTI, CLEMENTINO, in *Biography*, knight of the holy Roman empire, and lord of Villanova, was born at Roveredo in 1755; and being educated under the care of his uncle, after the death of his father, he became, by incessantly reading Plautus and Terence, so good a Latin scholar, that, in his 16th year, he wrote a Latin comedy, entitled "Lampadaria;" and, in the following year, recited an inaugural oration in the Academy degli Agiati at Roveredo, in the true language of Plautus. Before the age of 22, he was elected secretary of this Academy, and he had improved his taste by a familiar acquaintance with the works of Cicero. In 1776 he defended Tiraboschi against the attack of the Spaniard Serrano, for his censure of some passages in the epigrams of Martial; and the letter he published on this occasion, considered as the production of a young man 23 years of age, was much admired. Upon the death of his intimate friend, the abbé Zorzi of Venice in 1779, he paid an honourable tribute of respect to his memory by publishing his life, and a collection of letters that had passed between them, and also an examination of a question suggested by d'Alembert, whether any one at present should venture to write Latin, which he decided in the affirmative. But Vanetti's most humorous writing, in the Latin language, was a bitter satire on Cagliostro, who deluded the people at Roveredo, in 1788, by his pretended prophecies and miracles. Vanetti, in order to expose this juggler, wrote a small work in the manner of the book of Chronicles, and in the Latin style of the Vulgate, entitled "Liber Memorialis de Cagliostro." Encouraged by Betinelli and others, he became a classical writer in his native language, beginning with a well-written life of the younger Pliny. But his chief fame was derived from his "Observations on the Poems of Horace, with Imitations of that Poet," which, with respect to matter and language, are said to exceed any thing of the kind in Italian. He also published fourteen dialogues in the manner of Lucian; and having tried his talents in various kinds of poetry, his "Sermoni" in the true Horatian spirit are pre-eminent, and hence he obtained the name of the Italian Horace. Besides the reputation which he acquired as a poet, he also excelled in crayon painting. To the noise and bustle of the world he preferred the tranquillity of domestic life on his estate, which he compared to the Sabine farm of Horace, and never travelled farther from home than Verona, Mantua,

Mantua, or Venice; and he died, univerſally lamented, in his native city, of an inflammation of the lungs, in the 40th year of his age. The abbé Lorenzi published at Roveredo, in 1795, "Commentarium de Vita et Scriptis Clementini Vanetti," from which the preceding account of him has been extracted. Gen. Biog.

VAN-EYCK. See EYCK.

VANGAC, in *Geography*, a river of the iſland of Luçon, which runs into the Chineſe ſea, N. lat. 18° 45'.

VANGEN, a town of France, in the department of the Lower Rhine; 9 miles S.E. of Saverne.—Alſo, a town of Switzerland, in the canton of Berne; 4 miles E. of Soleure.

VANGIONES, in *Ancient Geography*, a people of Belgic Gaul, and originally of Germany. According to Cluvier, they were bounded on the north and eaſt by the Rhine, on the ſouth by the Nemetæ, and on the weſt by the Mediomatriciæ.

VANGOLE, in *Geography*, a town of Hindooſtan, in Coimbatore; 5 miles N. of Aravacourchy.

VAN-GOYEN, in *Biography*. See GOYEN.

VANGS, in *Sea Language*, are a ſort of braces to ſupport the mlzen-gaff, and keep it ſteady. They are fixed on the outer end or peek, and reach downwards to the aftmoſt part of the ſhip's ſide, where they are hooked and drawn tight, ſo as to be ſlackened when the wind is fair; and drawn in to windward, when it becomes unfavourable to the ſhip's courſe. Falconer.

VANG-TCHOUANG, in *Geography*, a town of China, in Kiang-nan, on the river Hoang; 15 miles W.N.W. of Fong-yang.

VANGUERIA, in *Botany*, a barbarous and intolerable name, made by Commerſon out of the Madagaſcar appellation of this plant, *Voa-vanguier*. Von Rohr called the ſame genus *Vavanga*; which Vahl has unwillingly adopted, expreſſing at the ſame time a wiſh, that he could have dedicated the genus to profeſſor Wittmann. We ſhould now have taken advantage of this wiſh, had there not already been a *VITMANNIA*, which will appear in its proper place. Thus circumſtanced, and without meaning, on this or any other occaſion, to uphold ſuch names, except for reprobation, we for the preſent here introduce *Vangueria*.—Juſſ. Gen. 206. Willd. Sp. Pl. v. 1. 976. Poir. in Lamarck Dict. v. 8. 331. Lamarck Illuſtr. t. 159. Venten. Tabl. 586. Jacq. Hort. Schoenbr. v. 1. 20. (*Vavanga*; Vahl Tr. of the Nat. Hiſt. Soc. of Copenhagen, v. 2. part 1. 207.)—Clasſ and order, *Pentandria Monogynia*. Nat. Ord. *Rubiacea*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, with five ſpreading, ſomewhat reflexed, permanent teeth. *Cor.* of one petal; tube bell-shaped, twice the length of the calyx, cloſed at the upper part with erect hairs; limb in five deep, ovate, acute, equal, ſpreading, at length reflexed, ſegments, rather ſhorter than the tube. *Stam.* Filaments five, awl-shaped, very ſhort, inſerted between the ſegments of the corolla; anthers heart-shaped, pointed, incumbent. *Piſt.* Germen inferior, turbinate; ſtyle awl-shaped, rather longer than the tube, inclining to one ſide; ſigma thick, obtuſe, furrowed, two-lipped. *Peric.* Berry globoſe, coriaceous, with a ſcar at the top, containing four or five ſeeds, imbedded in pulp. *Seeds* elliptical, compressed, with a lateral ſcar, and a ſmall incomplete tunic, of two membranous, lanceolate, falcate valves, attached to the ſcar.

Eſſ. Ch. Corolla bell-shaped, five-cleft, hairy within. Stigma two-lipped, furrowed. Berry inferior, coriaceous. Seeds four or five, each with a lateral bivalve tunic.

1. *V. edulis*. Madagaſcar Mediæ. Willd. n. 1. Vahl Symb. v. 3. 36. (*V. Commerſonii*; Jacq. Hort. Schoenbr.

v. 1. 20. t. 44. *Vavanga edulis*; Vahl Tr. of Nat. Hiſt. Soc. of Copenh. v. 2. pt. 1. 208. t. 7.)—Gathered in the iſle of Bourbon, by Commerſon, whoſe ſpecimens are before us. Cultivated in Guadaloupe and Santa Cruz, for the ſake of its eatable fruit. Von Rohr, who communicated this plant to profeſſor Vahl, thought it a native of China, but Commerſon was told it came from Madagaſcar, and was there called *Voa-vanguier*, or *Voa-wangi*. Jacquin mentions it as flowering every year in the ſtove at Schoenbrun, but never ripening fruit. The ſtem is ſhrubby, ſix feet, or more, in height, with round, ſmooth, oppoſite branches, ſlightly quadrangular when young. *Leaves* oppoſite, on ſhort ſtalks, deciduous, elliptical, acute, entire, ſmooth, five or ſix inches long, and two or three broad, with one central rib, and many tranſverſe ones connected by reticulated veins; paler beneath. *Stipulas* intrafoliaceous, triangular, pointed, in pairs connected at the baſe, embracing the branch above the footſtalks, and much reſembling thoſe of *Strychnos*. *Panicles* lateral, oppoſite, cymoſe, many-flowered, downy, much ſhorter than the leaves, ſpringing from between the inſertion of laſt-year's footſtalks. *Flowers* greeniſh-yellow, ſmaller than lily of the valley, frequently four-cleft. *Fruit* the ſize of a large gooſeberry, with a leathery, or ſomewhat woody, coat.

VANHALL, JOHN, in *Biography*, an inſtrumental compoſer of great and original genius, was born at Vienna in 1740. We know not what he had published previous to his ſymphonies, which were compoſed in 1767, and ſoon circulated in M.S. all over Europe. The duke of Dorſet, we believe, firſt brought them to England about the year 1771. Several excellent ſymphonies of the Manheim ſchool had been previously published by Bremner, which introduced us very agreeably to the new ſtyle of German ſymphony founded by the elder Stamitz; but till we were acquainted with the ſymphonies of Haydn, the ſpirited, natural, and unaffected ſtyle of Vanhall excited more attention at our concerts than any foreign muſic which we had imported for a long time. They were admirably played at the Pantheon concerts, when led by La Motte, Giardini, and the elder Cramer. He compoſed too much perhaps, and for too great a variety of inſtruments; but his ſymphonies, quartets, and other productions for violins, certainly deſerve a place among the firſt productions, in which unity of melody, pleaſing harmony, and a free and manly ſtyle are preferred.

VAN-HUYSUM. See HUYSUM.

VANI, a name of the Hindoo goddeſs *Saraswati*; which ſee. This name is alſo given to Agni or Pavaka, regent of fire; when, however, it is uſually written *Vahni*.

VANI, *Cape*, in *Geography*, a cape on the N. coaſt of the iſland of Milo. N. lat. 36° 46'. E. long. 24° 20'.

VANIAMBADDY, a town of Hindooſtan, in Myſore; 112 miles E. of Seringapatam. N. lat. 12° 41'. E. long. 78° 45'.

VANJEMSOAR, a town of Hindooſtan, in Golconda; 21 miles S.W. of Damapetta.

VANIERE, JAMES, in *Biography*, a learned Jeſuit, was born in 1664, at Cauſſes, in the dioceſe of Beziers, Languedoc, and having ſtudied at the Jeſuits' college at Beziers, entered into the ſociety in 1680. His poetic talents were exhibited by two pieces, one entitled "Stagna," during his regency at the college of Tournon; and another entitled "Columbæ," at Toulouſe; and his character as a poet was eſtabliſhed by his "Prædium Ruſticum," in fifteen books, on the ſubject of a farm, in imitation of Virgil's *Georgics*. The moſt complete edition of this work is that of Paris, in 1756. Vaniere was ſucceſſively profeſſor and rector in the ſchools of his order at Montpelier, Toulouſe, and

and Auch, and died at Touloufe in 1739. His other works were a volume of "Opufcula," confifting of eulogies on moral topics, epiftles, odes, epigrams, &c.; a "Dictionary of Poetry," in Latin, quarto, a work in high estimation, and abridged for the ufe of ftudents; and a "Dictionary, Latin and French," which he began, but did not live to finifh. For his encouragement in his ftudies, the king allowed him a penfion. Moreri. Nouv. Dict. Hift. Gen. Biog.

VANIERIA, in *Botany*, received its name from Loureiro, in memory of father James Vanière, a French Jefuit, who was born in 1664, and died in 1739; celebrated for a poem on rural life, in which various plants are beautifully defcribed.—Loureir. Cochinch. 564.—Clafs and order, *Monocia Pentandria*. Nat. Ord. *Urtica*, Juff.

Gen. Ch. Male, *Cal.* Perianth in four deep, ovate, flefhy, erect, converging fegments. *Cor.* none. *Stam.* Filaments fcarcely any; anthers five, inferted into the calyx below its middle, of two kidney-shaped, compressed, pellucid lobes.

Female, on the fame common receptacle, *Cal.* as in the male. *Cor.* none. *Pift.* Germen fuperior, roundifh, compressed; fyle capillary, very flender, the length of the calyx; ftigma fimple. *Peric.* none, except the permanent juicy calyx. *Seed* folitary, lenticular, fmoth, tipped with the permanent fyle. *Common Receptacle* ovate, bearing from ten to twenty flowers, crowding each other into an angular fhape, and mofly confluent, forming a roundifh, compound, flefhy berry, tubercular externally, with fmall intermediate fpaces.

Eff. Ch. Male, Common Receptacle many-flowered. Calyx flefhy, in four deep fegments. Corolla none.

Female, on the fame receptacle. Calyx like the male. Style one. Seed one, enveloped in the pulpy calyx.

1. *V. cochinchinensis*. *Cây vang lô* of the Cochinchinefe.—Stem prickly. Leaves alternate.—Native of thickets in Cochinchina; in which country it ferves for the fmall kinds of fences. *Stems* fhrubby, erect, numerous, branched, round, fmoth, three feet high, befet with many long ftraight prickles. *Leaves* ovato-lanceolate, entire, fmoth. *Fruit* roundifh, about eight lines in diameter, very red, fweet, eatable, on fimple axillary twin ftalks.

2. *V. chinensis*. *Hàng bông Xiông* of the Chinefe.—Stem without prickles. Leaves tufted.—Native of bufhy places about Canton. A *fhrub* fifteen inches high, erect, branched. *Leaves* lanceolate, entire, fmoth, collected into tufts. *Flower* a round head, on a long, fimple, folitary, erect, axillary ftalk. *Common Receptacle* fealy. Loureiro never met with any female flowers, and therefore conceived that this fpecies might be dioecious. We have no acquaintance with any thing anfwerable to the above defcriptions. The genus feems very near *Morus*.

VANIESSA, or *Devil's Key*, in *Geography*, a fmall ifland in the Spanifh Main, near the Mofquito fhore. N. lat. 14° 5'. W. long. 82° 35'.

VANILLA, in *Botany*, a name of Spanifh origin, or at leaft very common among the Spaniards in South America, adopted by Plumier as generic. Though barbarous, it may for its found be tolerated; and we have little doubt that writers of the Auguftan age would have adopted fuch, had they, like Cæfar, met with them in defcribing any new country. However this may be, we merely yield unwillingly to the example of writers of the firft botanical authority, who have now eftablished this name, and we fhould greatly have preferred Mr. Salifbury's appellation of *Myrobroma*.—Plum. Gen. 25. t. 28. Juff. 66. Swartz Ind. Occ. 1513. Aët. Nov. Upfal. v. 6. 66. t. 5. f. 1. Schrad. Journ. v. 2. 208. t. 1. f. 1. Schrad. Neues Journ. v. 1. 82.

Willd. Sp. Pl. v. 4. 121. Brown in Ait. Hort. Kew. v. 5. 219.—Clafs and order, *Gynandria Monandria*. Nat. Ord. *Orthideæ*.

Gen. Ch. *Cal.* Perianth fuperior, of three nearly direct, lanceolate, equal, coloured leaves, deciduous. *Cor.* Petals two, lanceolate, of the fize and colour of the calyx. Nectary a lip, proceeding from the lower part of the fyle, convoluted at the bafe, dilated at the margin, without a fpur, falling off with the petals. *Stam.* Anther a hemifpherical, moveable, terminal, deciduous lid, of two cells, attached by its posterior edge to the top of the fyle; mafes of pollen globular, granulated. *Pift.* Germen inferior, elongated, nearly cylindrical; fyle erect, femicylindrical; ftigma convex, towards the top of the fyle, in front. *Peric.* Capfule elongated, flightly triangular, flefhy, of one cell. *Seeds* very numerous, lenticular, deftitute of a tunic, imbedded in pulp.

Eff. Ch. Calyx-leaves direct, flightly fpreading. Lip convoluted at the bafe, without a fpur; fpreading at the border. Anther a terminal deciduous lid. Capfule linear-oblong, flefhy. Seeds imbedded in pulp, without a tunic.

1. *V. aromatica*. Aromatic Vanilla, Vainilla, or Vanelloe. Willd. n. 1. Ait. n. 1. (*V. flore viridi et albo, fructu nigricante*; Plum. Ic. 183. t. 188. *V. maxima*; Merian Surin. t. 25. Epidendrum Vanilla; Linn. Sp. Pl. 1347.)—Leaves ovate-oblong, ribbed. Calyx and petals undulated. Lip acute. Capfule nearly cylindrical, very long.—Native of South America. *Stem* paraftitcal, climbing by means of fimple, flefhy, fibrous, folitary radicles from each joint. *Leaves* a fpan long, fucculent, as thick as thofe of houfeleek. *Flowers* large, variegated with green and white. *Fruit* eight or ten inches long, acquiring, after it is gathered, a peculiar and delicious fragrance, like the flowers of *Orcis nigra*, and fome others of that family; on which account the *Vanilla* is ufed to perfume chocolate, and becomes a valuable article of commerce.

2. *V. angustifolia*. Narrow-leaved Japan Vanilla. Willd. n. 2. (*Epidendrum Vanilla β*; Linn. Sp. Pl. 1348. Angurèk Warnà; Kämpf. Amoen. 867. t. 869. f. 2.)—Leaves linear-lanceolate. Calyx and petals flat. Lip acute.—Native of Japan. By Kämpfer's account this is a paraftitcal climber like the laft, and agrees with that in the colours of its *flower*, except being dotted with purple. Nothing is faid concerning the fruit.

3. *V. claviculata*. Tendril-bearing Vanilla. Swartz Ind. Occ. 1515. Willd. n. 3. (*Cereo affinis scandens planta aphylla, &c.*; Sloane Jam. v. 2. 160. t. 224. f. 3, 4.)—Leaves lanceolate, acute, concave, rigid, recurved. Calyx and petals flat. Capfules fometimes triangular.—Native of woods, on a very dry calcareous foil, in the mountainous inland parts of Jamaica, Hispaniola, &c. flowering in July. It is vulgarly called Green-with, and the negroes ufe a decoction of the whole plant for fyphilitic complaints. The *flem* climbs to the height of twenty or thirty feet, and is fwelled, as if jointed, at the infertion of each leaf, and tendril-like *radicle*. *Leaves* feffile, an inch long. *Flowers* large, white, in axillary clufters. *Fruit* long and large, flefhy, with black fhining *feeds*. Swartz. The figure of the flower in Swartz's plate belongs to this fpecies.

4. *V. planifolia*. Fragrant Vanilla. Ait. n. 2. Andr. Repof. t. 538. (*Myrobroma fragrans*; Salifb. Parad. t. 82.)—Leaves oblong-lanceolate, flat, flightly ftriated. Calyx and petals even. Lip fringed, abrupt.—Native of the Weft Indies, faid to have been introduced into our ftoves by the prefent duke of Marlborough. In fize this rivals the firft fpecies, but the *leaves* are not fo thick; the *calyx* and *petals* are not undulated, nor the *lip* pointed. We have no account

account of the fruit. The flowers are said to be very fragrant, especially at night. Mr. Salibury is erroneously charged, in Andrews's work, with having confounded this and the *V. aromatica*.

The species of this genus are far from being all known or understood.

The plant which produces the fruit called *vanilla* or *banilla* by the Spaniards, or the *epidendrum vanilla* of Linnæus, has a trailing stem, somewhat like the common ivy, but not so woody, which fastens itself to any tree that grows near it by small fibres or roots produced at every joint; these attach themselves to the bark of the tree; and by them the plants are often nourished, when they are cut or broken off, from the root, at a considerable height from the ground, as is the case with the ivy in England. The leaves are as large as those of the common laurel, and are produced alternately at every joint. It rises to the height of eighteen or twenty feet, and the flowers are of a greenish-yellow mixed with white, which, when fallen, are succeeded by the fruit, which is eight or ten inches long.

The sort which is manufactured, grows not only in the bay of Campeachy, but also at Carthagenæ, at the Caraccas, Hoaduras, Darien, and Cayan, at all which places the fruit is gathered and preserved; but it is rarely found in any of the English settlements, though it might be easily propagated in them: for the shoots are so full of juice, that they will continue fresh, out of the ground, for several months.

When these plants are intended for propagation in the warm parts of America, nothing more is required than to make cuttings of three or four joints in length, which should be planted close to the stems of trees in low marshy places, and the ground about them kept clear of weeds.

The method used to preserve the fruit is, when it turns of a yellow colour, and begins to open, to gather it, and lay it in small heaps to ferment two or three days, in the same manner as is practised for the cocoa pods; then they spread them in the sun to dry, and when they are about half dried, they flat them with their hands, and afterwards rub them over with the oil of palma Christi, or of the cocoa; then they expose them to the sun again to dry, and afterwards they rub them over with oil a second time; then they put them in small bundles, covering them with the leaves of the Indian reed to preserve them. These plants produce but one crop of fruit in a year, which is commonly ripe in May, fit for gathering, for they do not let them remain on the plants to be perfectly mature. When they are about half changed yellow, they esteem them better for keeping than when thoroughly ripe; at which time the fruit splits. While the fruit is green it affords no remarkable scent, but as it ripens it diffuses a most grateful aromatic smell; but when it begins to open, the birds attack them, and devour the seeds greedily.

The fruit which is brought to Europe is of a dark-brown colour; wrinkled on the outside, and full of a vast number of black seeds, like grains of sand, of a pleasant smell, like balsam of Peru.

This fruit is only used in England as an ingredient in chocolate, to which it gives an agreeable flavour to some palates, though it is disagreeable to others; but the Spanish physicians use it in medicine, and esteem it grateful to the stomach and brain, good for expelling wind, for provoking urine, resisting poison, and curing the bite of venomous animals. Miller's Gard. Dict.

The *vanillas*, or *vanilloes*, have an unctuous aromatic taste, and a fragrant smell, like that of some of the finer balsams heightened with musk. They are used chiefly in perfumes: scarcely ever among us in any medical intention: though

they should seem to deserve a place among the principal medicines of the nervous class. By distillation, they impregnate water strongly with their fragrance, but give over little or nothing with pure spirit. By digestion, spirit totally extracts their smell and taste; and in great measure covers or suppresses the smell.

VANINI, LUCILIO, in *Biography*, a reputed atheist, was born about the year 1585, at Taurofano, in the district of Otranto, and kingdom of Naples. He studied philosophy and theology at Rome, where he changed his baptismal name for "Julio Cesare," and completed his education at Naples and Padua, comprehending medicine, law, and astronomy. Possessing himself unfortunately of the works of Cardan and Pomponazzi, he imbibed their reveries; which, with the philosophy of Aristotle and Averroës, and the delusions of astrology, contributed to complete what may be called the confusion of his mind. Having entered into orders, and began to preach, his discourses were a medley of singular notions, which neither he nor any one else could understand. With a view of propagating his opinions, he travelled into Germany, the Netherlands, France, and England, in which latter country he was for a short time imprisoned, on account of his theological disputations. At Geneva, where he set up a school of philosophy, he was suspected of unsound and dubious faith, and therefore removed to France, passing some years at Lyons and at Paris. At this time, he was so far from being willing to acknowledge his desertion of the Catholic faith, that he proposed to the apostolic nuncio at Paris to write an apology for the council of Trent. In 1615 he published at Lyons his "*Amphitheatrum æternæ Providentiæ, Divino-magicum, Christiano-physicum, Astrologico-catholicum, adversus veteres Philosophos, Atheos, Epicureos, Peripateticos et Stoicos*," which was not suspected of atheism, and which indeed contains every thing incompatible with atheistical principles. In the following year he published at Paris another work, entitled "*De admirandis Naturæ Reginæ Deæque Mortalium Arcanis*," which was printed with a privilege; but on a closer examination of its tendency, it was publicly burnt by a decree of the Sorbonne. As the author of this work ascribes to his gods, Nature, attributes which belong only to the Supreme Being, he is chargeable with the same kind of atheism, that was maintained by some ancient sects of philosophers. He was likewise accused of stating arguments against religion, to which his replies were so unsatisfactory, as to furnish ground for suspicion that he designed to favour the cause of infidelity. Being under a necessity of quitting Paris, he withdrew in 1617 to Toulouse, where he taught medicine, philosophy, and theology; but there it was discovered, that he availed himself of his opportunities for general instruction to disseminate his impious and atheistical opinions; he was tried, and being found guilty, was condemned to have his tongue cut out, and then to be burnt alive. It is said, that on his examination, when he was asked if he believed in God, he took up a straw, and replied, "this is sufficient to convince me of the existence of a Creator," and that he afterwards made a long discourse on Providence. However, after his condemnation, he is said to have thrown off the mask, and to have uttered horrid impieties. He suffered death in 1619, (in 1629, according to Mosheim,) at the age of 34, and on his memory has been entailed every kind of reproach which could have been suggested by a detestation of his doctrines. But Mosheim says, "that several learned and respectable writers consider this unhappy man rather as a victim to bigotry and envy, than as a martyr to impiety and atheism; and maintain that neither his life nor

his writings were so absurd or blasphemous as to entitle him to the character of a despiser of God and religion." An Apology for Vanini was published in Holland in 1712, by Peter Frederick Arp, a learned lawyer. Moreri. Mosheim, vol. v.

VANISHING FRACTIONS, are fractions in which, by giving a certain value to the variable quantity or quantities entering into them, both numerator and denominator become zero, and consequently the fraction itself is then $\frac{0}{0}$.

The idea of fractions of this kind first originated about the year 1702, in a contest between Varignon and Rolle, two French mathematicians of some eminence, concerning the principles of the differential calculus, of which the latter was a strenuous opposer; and amongst other arguments against the truth of the doctrine which had then been recently introduced, he proposed an example of drawing a tangent to a certain curve, at the point where the two branches intersect each other; and as the fractional expression for the subtangent, according to that method, had both its numerator and denominator equal to zero, or 0, he regarded such a result as absurd, and adduced it as a proof of the fallacy of this mode of solution. But the mystery was soon after explained by John Bernouilli; and upon a renewal of the dispute, still farther by Saurin, who shewed that the fraction in the case here mentioned had a real value. These fractions were also the cause of a violent controversy between Waring and Powell in 1760, when these gentlemen were candidates for the mathematical professorship at Cambridge: Waring maintaining that the fraction

$\frac{x^5 - x}{x - 1}$, when x is 1, is equal to 4; and Powell, or rather

Maferes, who is commonly supposed to have conducted the dispute on the part of the latter, that it was equal to 0, or indeed that it could have no value whatever: and it must be acknowledged that the same difference of opinion relative to this kind of fractions still exists in all its force. Woodhouse, in his "Principles of Analytical Calculation," in treating of these quantities, after assuming the simple case of

$\frac{x^2 - a^2}{x - a}$ to find the value of it, when $x = a$, observes, that

the signification of this expression is, that $x^2 - a^2$, is to be divided by $x - a$, and the result of that division is $x + a$, or putting $x = a$, it becomes $a + a$, or $2a$. This result, however, he remarks, is no direct and natural consequence arising from the principles of calculation, but, on the contrary, it is a result arbitrarily obtained, by extending a rule, and observing a certain order in the process of calculation.

To the question, what does $\frac{x^2 - a^2}{x - a}$ become when $x = a$;

the obvious and logical answer is $\frac{a^2 - a^2}{a - a}$, and the question

is, whether in this form it will admit of any further reduction. It is true, if we operate upon this quantity according to the rules laid down in other apparently similar cases,

we obtain $\frac{a^2 - a^2}{a - a} = a + a = 2a$; but here is evidently an

extension given to a rule beyond what was first intended; for this rule was instituted for operating on real quantities, whereas in this case we have employed it on quantities having no value whatever, being in fact the division of 0 by 0, for which abstractedly no rule can be given. This, however, is not a case peculiar to these fractions. It is to the

same source we must attribute the introduction of the negative symbol, and all the mysteries attendant upon it, as well as to every kind of imaginary quantity.

In vol. i. p. 219, of Bonnycastle's Treatise of Algebra, we have the following rule for finding the value of vanishing fractions.

1. If both the terms of the given fraction be rational, divide each of them by their greatest common measure; then, if the hypothesis which is found to reduce the original expression to the form $\frac{0}{0}$ be applied to the result, it will give the true value of the fraction under consideration.

2. When any part of the fraction is irrational, observe what the unknown quantity is equal to, when the numerator and denominator both vanish, and put it equal to that quantity + and - i ; then if this be substituted for the unknown quantity, and the roots of the surds be extracted to a sufficient number of places, the result, when i is put equal to 0, will give the true value of the fraction. From which rule the author obtains the following results; viz.

$$1. \frac{x^2 - a^2}{x - a} = 2a, \text{ when } x = a.$$

$$2. \frac{x - x^5}{1 - x} = 4, \text{ when } x = 1.$$

$$3. \frac{b(x - \sqrt{ax})}{x - a} = \frac{1}{2}b, \text{ when } x = a.$$

$$4. \frac{x^m - a^m}{x - a} = ma^{m-1}, \text{ when } x = a.$$

See Bonnycastle's Algebra, Woodhouse's Principles of Analytical Calculation, and Barlow's Dictionary.

VANISI, in *Geography*, a town of Turkish Armenia; 21 miles W. of Akalzike.

VAN-LAER, in *Biography*. See BAMBACCIO.

VANLOO, CARLO, was the son of an artist little known, and was born at Nice in 1705. For some time he resided at Rome, and studied under Benedetto Luti. In 1723 he went to Paris, where he gained the first prize for an historical painting, and was employed with his elder brother, John Baptiste Vanloo, in repairing the paintings of Primaticcio, at Fontainebleau. In 1727 he again visited Italy, and afterwards passed some time at the court of Turin, where he painted a series of pictures from Tasso. On his return to his native country in 1734, he was admitted into the academy, the king conferred upon him the order of St. Michael, and appointed him his principal painter; and he repaid these compliments by his assiduity and his ability. He had acquired by his studies in Italy more correctness than his countrymen generally possessed, and he certainly prevented the French school from running farther into the affected style of Coypel and De Troyes, and yet his style can only be called loose and mechanical, with little relish of the higher beauties of art. He died in 1765, at the age of sixty.

VANLOO, Mad., the daughter of Somis, the great violinist of Turin, concert-master to the king of Sardinia, and wife to the celebrated painter Vanloo of Paris, was born in 1710, and in 1726 she was thought the best singer of her time. We have seen a beautiful print of Mad. Somis, from a painting of Vanloo previous to her marriage. After her nuptials, she settled at Paris, and was living there in 1754. The first wife of the elder Cramer, the excellent performer on the violin, and leader of a band, was a daughter by this marriage; which accounts for her good taste and captivating manner of singing to her own accompaniment on the pedal harp. She was a most accomplished

complished and elegant woman, and we never heard any thing more pleasing than her performance.

VAN-MALDER, concert-master and chamber-musician to prince Charles at Brussels, and leader of the band at that theatre; a composer of spirited and pleasing symphonies, which were long in favour at our national theatres. He composed a comic opera, "La Bagarre," 1754, for the Italian theatre at Paris, and died at Brussels in 1771.

VAN-MANDER, a painter and author, was born at Meulebeke, near Courtray, in 1548, of a noble family, and received an education suited to his rank. His talents developed themselves at an early period of his life, and particularly a disposition to painting; and he was placed under the tuition of Lucas de Heere; afterwards he became a disciple of Peter Vlerick, an historical painter of some eminence at Courtray, and finished his education in art by a journey to Italy, where he studied for three years. From thence, after painting several pictures, he went to Vienna, accompanied by Spranger, whose friendship he had cultivated, and there received a pressing invitation to enter the service of the emperor; but love for his native country prevailed, and thither he returned. He then experienced much encouragement, and was in possession of full employment, when the wars in the Low Countries prevented his enjoyment of it. He took refuge in Haerlem, and there with Goltzius founded an academy. Van-Mander united with the talents of a painter that of a poet, and composed tragedies and comedies, several of which were acted with success, with decorations painted by himself; and we are indebted to him for a very useful history of the painters of antiquity and of his own country. He died at Amsterdam, in 1606.

VANNÆUS, Lat., VANNEO, STEFFANO, Ital., the name of an Augustine monk, born at Ricanati, a small town in the March of Ancona and Ecclesiastical State, was music director at Ascoli, who published at Rome in 1553, small folio, a most ample treatise on music, in which he has inserted all that preceding books on the subject contained. There is nothing that was new in this at the time of its publication; but no one book then published contains half its contents. Walther has given a long list of the divisions and subdivisions of this work, which is written in Latin, and which, perhaps, is all that will ever be read by those who may obtain possession of the book, which is now become very scarce.

VANNE, in *Geography*, a river of France, which runs into the Yonne, near Sens.

VANNEN, a small island in the North sea, on the coast of Norway. N. lat. 70° 10'. E. long. 19° 44'.

VANNES, a sea-port town of France, and capital of the department of the Morbihan, at the union of two small rivers, which form a harbour in the lake Morbihan; before the revolution, the see of a bishop. The principal commerce is in corn, bar-iron, and fish. It has two suburbs, one of which is larger than the town itself. In 1800, the royalists, under Georges, were defeated by the republicans, under Brune; 13 posts N.W. of Nantes. N. lat. 47° 39'. W. long. 2° 40'.

VANNES, *La*, a town of France, in the department of the Ardèche; 6 miles S.W. of Joyeuse.

VANNI, FRANCESCO, *Cavaliere*, in *Biography*, was the son of a painter of little celebrity at Vienna, who died whilst he was very young, and was born in 1563. He went to Rome when he was about sixteen, and entered the school of Giovanni de Vecchi, and became an imitator of Baroccio. He also went to Parma to draw from the same fount as Baroccio, *viz.* the works of Corregio and Parme-

giano. He was invited to Rome to assist in adorning St. Peter's, and there he painted his Simon Magus, which yet, though much injured, attests his capacity. For this performance Clement VIII. conferred upon him the order of Christ. He also painted several other pictures for public edifices in that city; but his best performances are at Sienna, as his Marriage of St. Catharine, in the church of Il Refugio; and S. Raimondo walking on the Sea, in the Dominicans; which is considered the finest work in the city. He died at Sienna in 1610, at the age of forty-seven, leaving a son, Raffaele Vanni, then only thirteen, who afterwards became a painter, and imitated the works of Pietro Cortona. He became a member of the academy of St. Luke in 1655.

VANNICUM REGNUM, in *Ancient Geography*, a kingdom of European Sarmatia, according to Pliny. Tacitus reports that it was the kingdom of Vannius, which Drusus assigned as a portion to the Suevans, when he fixed their abode on the Danube, between Marus and Cusus.

VANNING-*Shovel*, among *Miners*, an instrument used for washing the ores of any metal, after being reduced to powder, by which to discover the richness and other qualities of the ore. See SHOAD, TIN, and VAN.

VANNUCCI, in *Biography*. See *Andrea del SARTE*, and PERUGINO.

VAN-OORT. See OORT.

VAN-OOST. See OOST.

VAN-ORLAY. See ORLAY.

VAN-OSTADE. See OSTADE.

VANQUISH, a disease in sheep, which has often the titles of *pinning* and *daising* given to it by shepherds.

It is described as most severe among young sheep by some, and as, in a great measure, confined to some particular districts in the western portion of the north part of the island, where the land is very coarse, hard, dry, and heathery. It is said that it constantly fixes on the best of the flock, and that although they continue to feed most greedily, they daily pine away to a mere skeleton. But that it is fortunately not a disease that is attended with great danger, as on removing them to soft grassy pastures, especially such as have been recently limed, they almost immediately recover, and never fail, in future, to become excellent and remarkably healthy sheep:—that although, in regard to the gradual wasting of the animal, this disease has some resemblance to the rot in its nature and cause, it is directly the reverse:—that it arises from an excess of moisture, is a disease of debility, and is characterized by extreme thinness of the blood; while in this, or the vanquish, on the contrary, the condition of the animal is too high, its blood too thick, and its pasture too arid, dry, and parched.

Others, however, describe it in so different a manner, that it scarcely appears to be the same disease. On peat-moss lands much exposed to the north-east, in cold moist seasons, where sheep-farmers have not the command of drier sounder pastures, on which the sheep can be turned in the autumn and winter months, the young sheep are liable to be attacked by the vanquish, which consumes them entirely away. This malady has its seat, as is supposed by practical shepherds, chiefly in the blood and bones: but it seems, in a little time, to spread over the whole system, which becomes debilitated and emaciated. Cold and moisture are said to assist in bringing it on, and also to aggravate the appearances; but the principal fault must, it is believed, be in the mossy land. The mosses become the earliest common pastures for sheep in these places in the spring season, but some part of the food they supply is dry, wiry, and unpalatable, and the heath less kindly and grateful

grateful to the sheep than that on dry moory land on gravel, being often scanty, woody, and rigid. The excess of moisture, too, in them may probably, it is thought, affect the qualities and healthiness of the heath, as food for sheep. Besides, there is in such mosses a greater proportion of the cross-leaved sort than is found on dry sheep-walks; and it is thought by many that sheep do not relish it so well as the common kind, when the shoots are young.

From these accounts, it would seem that the true nature of the complaint is not yet well understood, but it is probably some defect in the lacteal organs, by which a due supply of nourishment is prevented from being taken up, the consequence of which is a state of atrophy and emaciation in the animal.

The remedies which have been chiefly depended upon in these cases by sheep-farmers, are those of either removing the sheep into fresh grassy lands, or the change of them from the peaty pasture to one that is sweet and dry, during the autumn and winter. The latter, it is said, not only proves a cure of the disease, but wholly prevents it. In some cases, medicines of the mild stimulating balsamic kind might perhaps be used with benefit.

VANRHEEDIA, in *Botany*, Plum. Gen. 45. t. 18. See **RHEEDIA**.

VANS *les Dames*, or *Vanaut*, in *Geography*, a town of France, in the department of the Marne; 12 miles N.E. of Vitry le Français.

VANSIRE, in *Zoology*, a species of weasel with short ears; the hair brown at the roots, barred above with black, and ferruginous; the tail of the same colour; the length from nine to about fourteen inches, and the tail nearly ten. This animal inhabits Madagascar.

VANSOMER, PAUL, in *Biography*, a portrait painter, born at Antwerp in 1576: he for a while resided at Amsterdam, and with his brother Bernard practised his art there with success. About 1605 or 1606, he visited England, and was very much employed here; as many of his portraits are to be found in the houses of our nobility. He had the honour to be employed to paint king James I., and his queen, Anne of Denmark. He died at about the age of 45, and was buried in St. Martin's, as appears by the register, January 5, 1621.

VANSTOWN, in *Geography*, a town of the Cherokees, on the river Alabama.

VAN-SWIETEN, in *Biography*. See **SWIETEN**.

VANT, or **VAUNT**. See **VAN**.

VANTANEA, in *Botany*, Juss. 434, a name of Aublet's, which Schreber, according to correct rule, could not retain. See **LEMNISCIA**.

VANT-CHIN, in *Geography*, a city of China, of the second rank, in Quang-si; 1147 miles S.S.W. of Peking. N. lat. 23° 1'. E. long. 106° 51'.

VAN-TIEN, a city of China, of the second rank, in Yun-nan; 1295 miles S.W. of Peking. N. lat. 24° 29'. E. long. 109° 14'.

VAN-UDEN, LUCAS, in *Biography*, a landscape painter, born at Antwerp in 1595. He was principally his own instructor, and cultivated his talents by an assiduous attention to nature, and studying the landscapes of Rubens, whom he imitated, and who employed him to paint on the back-grounds of his pictures; which he did with so much congeniality of style, that they appear to be the work of the same hand. He lived to the age of 65. He had a brother, Jacques Van-Uden, also a landscape painter, but inferior to him.

VANVEY, in *Geography*, a town of France, in the department of the Côte d'Or; 6 miles E.S.E. of Châtillon-sur-Seine.

VANZE, a town of Naples, in Basilicata; 10 miles S.E. of Venosa.

VAPINCUM, in *Ancient Geography*, *Gap*, a town of Gallia Narbonensis, between Caturigæ and Alabons.

VAPORARIUM, or **VAPOROSUM Balneum**, *Vapour-Bath*, in *Chemistry*, a term applied to a chemist's bath, or heat, in which a body is placed, so as to receive the fumes of boiling water.

The *balneum vaporosum* consists of two vessels, disposed over one another in such manner, as that the vapour raised from the water contained in the lower, heats the matter enclosed in the upper.

The vapour-bath is very commodious for the distilling of odoriferous waters, and the drawing of spirit of wine. On this subject, see **BATH**, in *Chemistry*.

We also use the term *vapour-bath*, when a sick person is made to receive the vapours arising from some liquid matter placed over a fire.

Many contrivances have been proposed for this purpose; and their expediency and utility are best known to those who are conversant in this business. See *Aqueous BATHS*.

VAPORATION, VAPORATIO, in *Chemistry*, a term applied to the action of a fume, or vapour.

VAPORATION is a kind of bathing, or rather of fomentation, by which the warmth, or humidity, of a vapour is made to act on some other body, that is to be warmed or moistened.

VAPOROSUM BALNEUM. See **VAPORARIUM**.

VAPOUR, VAPOR, in *Meteorology*, a thin vesicle of water, or other humid matter, filled or inflated with air; which, being rarefied to a certain degree by the action of heat, ascends to a certain height in the atmosphere, where it is suspended, till it returns in form of rain, snow, or the like. An assemblage of a number of particles, or vesicles of vapour, constitutes what we call a *cloud*.

Some use the term vapour indifferently, for all fumes emitted, either from moist bodies, as fluids of any kind; or from dry bodies, as sulphur, &c. But sir Isaac Newton, and other authors, better distinguished between humid and dry fumes, calling the latter *exhalations*.

For the manner in which vapours are raised, and again precipitated, see **CLOUD, DEW, RAIN, BAROMETER**, and particularly **EVAPORATION** and **METEOROLOGY**.

We shall here add, with respect to the principles of solution adopted to account for evaporation, that Dr. Halley, about the beginning of the last century, seems to have been acquainted with the solvent power of air on water; for, he says, that, supposing the earth to be covered with water, and the sun to move diurnally round it, the air would of itself imbibe a certain quantity of aqueous vapours, and retain them like salts dissolved in water; and that the air, warmed by the sun, would sustain a greater proportion of vapours, as warm water will hold more dissolved salts; which would be discharged in dews, analogous to the precipitation of salts on the cooling of liquors. Phil. Transf. Abr. vol. ii. p. 127.

Mr. Eeles, in 1755, endeavoured to account for the ascent of vapour and exhalation, and their suspension in the atmosphere, by means of the electric fire. The sun, he acknowledges, is the great agent in detaching vapour and exhalations from their masses, whether he acts immediately by himself; or by his rendering the electric fire more active in its vibrations: but their subsequent ascent he attributes entirely to their being rendered specifically lighter than the lower air, by their conjunction with electrical fire: each particle of vapour, with the electrical fluid that surrounds it, occupying a greater space than the same weight

weight of air. Mr. Eeles also endeavours to shew, that the ascent and descent of vapour, attended by this fire, are the cause of all our winds, and that they furnish a satisfactory solution of the general phenomena of the weather and barometer. (Phil. Transf. vol. xlix. p. 124, &c.) Dr. Darwin, in 1757, published remarks on the theory of Mr. Eeles, with a view of confuting it; and attempted to account for the ascent of vapours, by considering the power of expansion which the constituent parts of some bodies acquire by heat, and also that some bodies have a greater affinity to heat, *i. e.* acquire it sooner, and retain it longer than others. On these principles, he thinks, it is very intelligible how water, whose parts appear from the æolipile to be capable of immeasurable expansion, should by heat alone become specifically lighter than the common atmosphere. A small degree of heat is sufficient to detach or raise the vapour of water from the mass to which it belongs; and the rays of the sun communicate heat only to those bodies by which they are refracted, reflected, or obstructed, whence, by their impulse, a motion or vibration is caused in the parts of such bodies. Hence he infers, that the sphericles of vapour will, by refracting the solar rays, acquire a constant heat, though the surrounding atmosphere remain cold. If it be asked, how clouds are supported in the absence of the sun? it must be remembered, that large masses of vapour must for a considerable time retain much of the heat they have acquired in the day; at the same time reflecting, how small a quantity of heat was necessary to raise them, and that doubtless even a less will be sufficient to support them; as from the diminished pressure of the atmosphere at a given height, a less power may be able to continue them in their present state of rarefaction; and lastly, that clouds of particular shapes will be sustained or elevated by the motion they acquire from winds. Phil. Transf. vol. i. p. 246.

For the effect of vapour in the formation of springs, &c. see SPRING and RIVER.

The quantity of vapour raised from the sea by the warmth of the sun, is far greater than one would imagine. Dr. Halley has attempted to estimate it. The result of his estimate is contained in the following articles.

1. That water salted to about the same degree as salt-water, and exposed to a heat equal to that of a summer's day, did, from a circular surface of about eight inches diameter, evaporate at the rate of six ounces in twenty-four hours. Whence, by a calculus, he finds that the thickness of the pellicle or skin of water, evaporated in two hours, was the fifty-third part of an inch; but, for a round number, he supposes it only a sixtieth part; and argues thence, that if water as warm as the air in summer evaporates the thickness of one-sixtieth part of an inch in two hours, from its whole surface; in twelve hours it will evaporate the tenth of an inch; which quantity, he observes, will be found abundantly sufficient to furnish all the rains, springs, dews, &c.

In effect, on this principle, every ten square inches of the surface of the water yield in vapour *per diem* a cubic inch of water; and each square foot half a wine pint; every space of four feet square, a gallon; a mile square, 6914 tons; and a square degree of sixty-nine English miles will evaporate 33 millions of tons a day; and the whole Mediterranean, computed to contain 160 square degrees, at least 5280 millions of tons. Phil. Transf. N^o 189, or Abr. vol. ii. p. 108, &c. See RIVER.

2. A surface of eight square inches, evaporated purely by the natural warmth of the weather, without either wind or sun, in the course of a whole year, 16,292 grains of water,

or sixty-four cubic inches; consequently the depth of water thus evaporated in one year amounts to eight inches. But this being too little to answer the experiments of the French, who found that it rained nineteen inches of water in one year at Paris; or those of Mr. Townley, who found the annual quantity of rain in Lancashire above forty inches; he concludes that the sun and wind contribute more to evaporation than any internal heat or agitation of the water.

It has since been discovered, that there was a source of error in Mr. Townley's experiments, with which the world was not at that time acquainted: his rain-gauge was fixed ten yards above the surface of the earth; but Dr. Heberden has found, that a rain-gauge fixed below the top of a house, received above a fifth part more rain than another of the same size above the top of the same house; and that there fell upon Westminster Abbey not much above one-half of that which fell in the same space below the tops of the houses; and by several experiments made by Dr. Dobson of Liverpool, it appears, that the quantity of rain received in a vessel placed on the ground exceeded that received by another of the same dimensions eighteen yards higher more than one-third, and less than one-half. Phil. Transf. vol. lix. art. 47. and vol. lxxvii. art. 13. p. 256. See RAIN.

With regard to the cause of this difference, it may be observed, that as in chemical precipitations a greater portion of the precipitating substance will be received on the real bottom of a vessel containing the solution than on a supposed false bottom placed any where above it, and that in proportion to its height above the real bottom; so a greater quantity of water, considering rain as a precipitation of water before dissolved in air, ought, on parting with its former solvent, to fall on the surface of the earth than on an imaginary horizontal plane of the same dimensions above it; and though the cases are not exactly parallel, yet the drops of rain in their descent must be somewhat increased either in number or size; partly by successively impinging on the aqueous particles contained in the air through which they pass, and by attracting others in virtue of their being possessed of a different electricity; and partly by the spontaneous separation and precipitation of that moisture, which is known to be contained in considerable quantities in the air at all times, and the appearance of which, dripping down the walls of our houses, &c. is one of the popular signs of approaching rain. (Monthly Review, vol. xlv. p. 322.) Dr. Dobson states the annual evaporation at Liverpool, taking the medium of four years, at 36.78 inches. Dr. Halley fixes the annual evaporation of London at 48 inches. See Phil. Transf. vol. lxxvii. part i. p. 252.

3. The effect of the wind is very considerable, on a double account; for the same observations shew a very odd quality in the vapours of water, *viz.* that of adhering and hanging to the surface that exhaled them, which they clothe, as it were, with a fleece of vaporous air; which once investing the vapour, it thenceforward rises in much less quantity. Whence, the quantity of water lost in twenty-four hours, when the air was very still from wind, was very small, in proportion to what went away when there was a strong gale of wind abroad to dissipate the fleece, and make room for the emission of vapour; and this, even though the experiment was made in a place as close from the wind as could be contrived.

Add, that this fleece of water hanging on the surface of waters in still weather, is the occasion of very strange appearances, by the refraction of the vapour's differing from and exceeding that of common air; whence every thing appears raised,

raised, as houses like steeples, ships as on land above the water, the land raised, and as it were lifted, from the sea, &c.

4. The same experiments shew, that the evaporation in May, June, July, and August, which are nearly equal, are about three times as great as those in the months of November, December, January, and February. Phil. Transf. N° 212. or Abr. vol. ii. p. 110, &c.

Dr. Brownrigg, in his "Art of making Common Salt," p. 189, fixes the evaporation of some parts of England at 73.8 inches during the months of May, June, July, and August; and the evaporation of the whole year at more than 140 inches. The evaporation of the four summer months at Liverpool, on a medium of four years, was found to be only 18.88 inches. Dr. Hales calculates the greatest annual evaporation from the surface of the earth in England at 6.66 inches; and therefore the annual evaporation from a surface of water, is to the annual evaporation from the surface of the earth in Liverpool, as 36 to 6, or as 6 to 1. Phil. Transf. vol. lxvii. ubi supra.

VAPOURS, *Fiery, Halitus Ignei*, a term used by some to express those exhalations from the earth, which either take fire of themselves on their bursting forth into the air, or are readily inflammable on the bringing of a candle to them. See DAMP, GAS, HYDROGEN, METEOR, and VENTILATION.

Many of the supposed burning lakes are owing to these fumes bursting up through the water, and not to any quality of the water itself. Our famous burning-well at Wigan, in Lancashire, is of this kind. The common people affirm, that the water of this spring burns like oil; but there is nothing of truth in this. There bursts up a vapour through the earth in this place, which keeps the water bubbling, as if boiling over in the fire, though it is not warm; and the stream of this breath may be felt issuing up in these places like a strong wind. This breath alone is inflammable, and takes fire at the approach of a candle, burning with considerable violence for some time. There are coal-pits in the neighbourhood, and the air is certainly of the same kind with that inflammable vapour often met with in those places, and which may also be prepared from iron dissolved in a proper menstruum. The water itself, taken from the place, does not burn; and if the bottom be made dry, the vapour which ascends from it will burn as strongly as if the water were there. The flame is not discoloured like that of sulphureous bodies, nor has it any bad scent; and the fumes, as they are felt bursting out of the earth, by the hand held over the place, are hot. Phil. Transf. N° 20.

VAPOUR-Bath. See VAPORARIUM, and BATH.

VAPOURS, in *Medicine*, a disease popularly called the *hypo*, or the hypochondriac disease; and in men particularly the *spleen*. See HYPOCHONDRIASIS.

Vapours supposed to be emitted from the womb, in women, are what we otherwise call *hysteric affections*, or *suffocations*, or *fits of the mother*. See Hysteria.

VAPPA, a word used by the ancients to express dead wine, or wine deprived of all its spirituous part.

The word is also metaphorically applied to a peculiar state of the blood, when it is in a low, dispirited condition, as is the case even in healthy persons, when worn out with excessive labour, and in cachectic and scorbutic persons.

VAR, in *Geography*, one of the twelve departments of the S.E. region of France, formerly Lower Provence, a maritime territory in N. lat. 43° 30', bounded on the N. by the department of the Lower Alps, on the E. by the county of Nice, on the S. and S.E. by the Mediterranean, and on the W. by the department of the Mouths of the Rhone. Its territorial extent in kilometres is 7510, and in square

leagues 378; and its population consists of 269,142 inhabitants. It is divided into 4 circles or districts, 32 cantons, and 210 communes. The circles are, Brignoles, containing 66,034 inhabitants; Draguignan, 71,383; Grasse, 55,240; and Toulon, 76,485. According to Hassenfratz it is 30 French leagues in length, and 20 in breadth; its circles are 9, its cantons 80, and its population consists of 275,472 persons. Its capital is Draguignan. Its contributions in the eleventh year of the French era amounted to 2,258,028 francs; and its charges for administration, judiciary, and for public instruction, were 274,032 francs 28 centimes. The northern districts, covered with mountains, yield little grain; but throughout the department, grapes, fruits of all sorts, medicinal plants, forests and pastures abound. The plains of Brignoles and Toulon are planted with fruit-trees and vines. Here are mines of different metals, and quarries of marble.

VAR, a river which rises in the department of the Lower Alps, about 10 miles S. from Barcelonnette, crosses the county of Nice, and, in part, separates it from France, till it runs into the Mediterranean; 4 miles W. of Nice. It gives name to the department.

VARA, in *Ancient Geography*, an estuary of Britain, which is the firth of Tayne in Sutherland.

VARA, in *Commerce*, a long measure in Spain and Portugal. At Lisbon, the vara is 5 palmos (or spans), and the covado (another long measure) is 3: the palmo is 8 inches of Lisbon, or 8 $\frac{2}{3}$ English inches: the covado is 300 $\frac{1}{2}$ French lines, or 26 $\frac{1}{2}$ English inches. Goods not sold by the piece, are generally sold by the covado, except some sorts of coarse linens, which are sold by the vara. The Lisbon foot is half a covado, or 13 $\frac{1}{3}$ English inches; and 9 feet of Lisbon are = 10 English feet. At Oporto, the vara is always 5 palmos de craveira (see PALMO), or 40 Portuguese inches = 43 $\frac{1}{2}$ English inches; but the covado is 3 palmos de craveira avantejados (or good measure), and is = 24 $\frac{3}{4}$ inches of Portugal, or 26.73 English inches. The vara (as a brass or wooden measure) is sometimes divided on one side into 43 $\frac{1}{2}$ English inches, and on the other side it is marked at 26 $\frac{3}{4}$ English inches. Each of these measures is divided into 3 tercias, 4 quartas, 6 sexas, and 8 oitavas. In Spain, the vara, a measure for cloth, linen, and silk, is 3 feet, or 4 palmos; and is, therefore, 33 $\frac{1}{3}$ English inches; the palmo measuring 9 pulgadas, or 12 dedos, which equal 8 $\frac{1}{2}$ English inches; but the palmo de ribeira, used for measuring masts, &c. is only 3 inches. A braza or toesa is 2 varas, or 6 feet; i. e. 66 $\frac{2}{3}$ English inches: a paso or pace is 5 feet; an estadal, 12 feet, or 4 varas; and a cuerda, 8 $\frac{1}{2}$ varas. The distances in Spain, on roads made since the year 1766, are laid down at the rate of 8000 varas to the league, i. e. 7416 English yards; so that 5 such leagues are = 21 English miles nearly; but the juridical league is 5000 varas, or 4635 English yards; hence 8 of these are = 21 English miles. Kelly's Un. Camb. See *Tables of WEIGHTS and MEASURES*.

VARADA, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Carpetani. Ptolemy.

VARADEH, in *Geography*, a town of Egypt, on the coast of the Mediterranean; 22 miles N.E. of Catieh.

VARADES, a town of France, in the department of the Lower Loire; 6 miles N.E. of Ancenis.

VARAGE, a town of France, in the department of the Var; 4 miles N.W. of Barjols.

VARAGGIO, a town of Genoa; 5 miles N.E. of Savona.

VARAGIANS, VARANGIANS, or *Varingians*, called also *Northmanni*, the name of a people who had a considerable

able share in founding the Russian state, and who were a northern tribe of Gothic descent and of warlike disposition and character. Their original country was probably Scandinavia; and they consisted of a combined multitude of Danes, Swedes, and Norwegians, who, perpetually in quest of adventures, established governments in the western and eastern parts of Europe, and produced revolutions, especially in the south, the consequences of which extended through one quarter of the globe. The first trace of their maritime expeditions is discoverable about the year 516; though it is thought probable that they carried on their piracies at an earlier period, and were generally comprehended under the name of Franks, who already appeared under the emperor Probus as enterprising mariners. In the year 795, they were first perceived in Ireland. About the year 813, they began their incursions by the Elbe into Friesland and Flanders; in process of time they advanced to Aquitain and along the Seine: about the year 840, they ravaged France; and in 857, made the conquest of Luna, and afterwards of Pisa, in Italy. In the year 862, Rurik founded the Russian monarchy, and became the father of a dynasty which reigned above 700 years. Accordingly, in the ninth century the Varangians conquered from the Russians, a kindred north-gothic people, the earliest mention of whose name is in the year 839, before Rurik's reception in Novgorod, the modern districts of Reval, St. Petersburg, and Archangel; and subjected the Slavonians, Krivitsches, Tschudes, Vessenians, and Mærenes, to a tribute. The Russians retired to Finland and Karelia; but the Slavonians, in conjunction with the rest of the forenamed nations, drove out the Varangians, and formed themselves at the lake Ilmen, near Novgorod, into a federative democratical republic. Although the Varangians composed the predominant, and under Rurik the most consequential part of the people, yet Slavonians and Russians were soon blended into one nation. As piracy was the exercise, the trade, the glory, and the virtue of the Scandinavian youth, the Baltic was the first scene of the naval achievements of the northern adventurers; they then visited the eastern shores, the select residence of Finnic and Slavonian tribes; and the primitive Russians of the lake Ladoga paid a tribute, the skins of white squirrels, to these strangers, whom they saluted with the title of Varangians, or corsairs. Their superiority in arms, discipline, and honour, commanded the fear and veneration of the natives. In their wars against the more inland savages, the Varangians condescended to serve as friends and auxiliaries, and gradually, by choice or conquest, obtained the dominion of a people, whom they were qualified to protect. At length Rurik appeared; his influence was extended by his brothers; the example of service and usurpation was imitated by his companions in the southern provinces of Russia; and their establishments, by the usual methods of war and assassination, were cemented into the fabric of a powerful monarchy.

As long as the descendants of Rurik were considered as aliens and conquerors, they ruled by the sword of the Varangians, distributed citates and subjects to their faithful captains, and supplied their numbers with fresh streams of adventurers from the Baltic coast. But when the Scandinavian chiefs had struck a deep and permanent root into the soil, they mingled with the Russians in blood, religion, and language, and the first Waladimir had the merit of delivering his country from these foreign mercenaries. They had seated him on the throne; his riches were insufficient to satisfy their demands; but they listened to his pleasing advice, that they should seek, not a more grateful, but a more wealthy master; that they should embark for

Greece, where, instead of the skins of squirrels, silk and gold would be the recompence of their service. At the same time the Russian prince admonished his Byzantine ally to disperse and employ, to recompense and restrain, these impetuous children of the north. - Contemporary writers have recorded the introduction, name, and character, of the Varangians: each day they rose in confidence and esteem; the whole body was assembled at Constantinople to perform the duty of guards; and their strength was recruited by a numerous band of their countrymen from the island of Thule. On this occasion, the vague appellation of Thule is applied to England; and the new Varangians were a colony of English and Danes who fled from the yoke of the Norman conqueror. The habits of pilgrimage and piracy had approximated the countries of the earth; these exiles were entertained in the Byzantine court; and they preserved, till the last age of the empire, the inheritance of spotless loyalty, and the use of the Danish or English tongue. With their broad and double-edged battle-axes on their shoulders, they attended the Greek emperor to the temple, the senate, and the hippodrome; he slept and feasted under their trusty guard; and the keys of the palace, the treasury, and the capital, were held by the firm and faithful hands of the Varangians.

About the time of Rurik, a Norman of a similar name, Rurich, became famous in the history of Holland. Soon after this, Oskold and Dir founded another sovereignty at Kief. In the tenth century Ragnvald reigned in Polotsk, from whose daughter, Rogned, the Russian annals derive the grand-dukes of Lithuania. About the year 1000, they took Apulia from the Greeks, and Sicily from the Arabians. They gave Normandy its name, after Rollo had wrested that country from the kings of France. Even the conquest of England by the Danes, in some degree formed a part of the history of these northern adventurers. Tooke's *Russ. vol. i.* Gibbon's *Rom. Emp. vol. x.* See **SLAVONIANS.**

VARAHA, in *Hindoo Mythology*, a name of the god Vishnu, meaning a *boar*; he having in one of his ten grand incarnations assumed that form, called *Varahavata*; which see.

VARHAVATARA, is one of the ten grand incarnations of their god Vishnu. In this the god assumed, as is commonly said, the form of a boar, Varaha; but is usually represented in pictures, with the head of that animal on the body of a man, four-armed, holding the attributes of Vishnu. On the elevated tusks of the boar rests a crescent, containing in its concavity an epitome of the earth, which had been submerged in the ocean, as a punishment for its iniquities. So that this avata, or incarnation, the third of Vishnu, seems to be a repetition of the story of the deluge, like the two former, which are named *Matsyavata* and *Kurmavata*, noticed under those articles. The second combines with it a portion of astronomical allegory, and none of the other ten avatars have any apparent reference to the general catastrophe, so pointedly indicated by the three first, which are understood to have occurred in the earliest ages of Hindoo history; if such a chaotic mass as their fabulous records may be dignified by such a title.

There are many fables accounting for the shape assumed on this occasion by Vishnu, which our limits will not allow us to recite.

VARALLO, in *Geography*, a town of Italy, in the department of the Gogna, on the Sefia; 24 miles N.N.W. of Novara. N. lat. 45° 49'. E. long. 8° 14'.

VARAMBON, or **VAREMBON**, a town of France, in the department of the Ain; 2 miles S.W. of Pont d'Ain.

VARAMUS,

VARAMUS, in *Ancient Geography*, a river of Italy, in Venetia, which discharges itself into the Anafus. Pliny.

VARANASI, the classical name for the city of Benares, in the East Indies. (See BENARES.) This name is said to comprise that of two rivers which form a junction near the city.

VARANGI. See ACOLUTHI.

VARANGUEBEC, in *Geography*, a town of France, in the department of the Channel; 10 miles W. of Carenton.

VARANIA, in *Ancient Geography*, a town of Servia, taken possession of in the year 1143 by Perigord, general of Manuel, emperor of Constantinople.

VARANO, in *Geography*, a lake of Naples, in Capitanata, which communicates with the Adriatic; 13 miles N.N.W. of Monte St. Angelo.

VARANO *de Marchesi*, a town of the duchy of Parma; 12 miles W.S.W. of Parma.

VARASDIN, a town of Croatia, on the S. side of the Drave, with a castle and citadel; near it is a warm bath; 186 miles N.W. of Belgrade. N. lat. $46^{\circ} 30'$. E. long. $16^{\circ} 25'$.

VARASELLYGUNGE, a town of Hindoostan, in Bahar; 14 miles S.S.E. of Bahar. N. lat. $25^{\circ} 2'$. E. long. $85^{\circ} 50'$.

VARBRESIE, a town of France, in the department of the Rhône and Loire; 9 miles N.W. of Lyons.

VARCES, a town of France, in the department of the Isère; 7 miles S. of Grenoble.

VARCHI, BENEDETTO, in *Biography*, was born at Florence in the year 1502, and destined to trade; but manifesting an inclination for literature, he was sent to the university of Padua. His progress in the belles lettres induced his father to educate him for the law at Pisa. But Benedetto, after the death of his father, devoted himself entirely to literature; and when the Strozzi, to whom he was attached, were obliged to quit Florence, he followed them, in 1534, first to Venice and then to Bologna. At Bologna, and also in Padua, he spent some years in study, and in cultivating an intercourse with learned men. At Padua he became a member of the Academy degli Infiammati, and read public lectures on morals, and several dissertations on the poems of Petrarch, Bembo, and others. Cosmo I. grand duke of Tuscany, apprized of his reputation, recalled him to Florence, and assigned to him the office of writing a history of the late revolution in that city, with a yearly stipend. Whilst he was thus employed, he was attacked in the night by several persons, who apprehended that his narrative would not be favourable to them, and inflicted on him many wounds. When he recovered, he declined, from motives of prudence or lenity, to inform against the perpetrators, though he knew them. In the Florentine academy, of which he was one year consul, he delivered lectures. Cosmo recompensed his services with the provostship of Monte Varchi, on which occasion he took holy orders; but before he could remove thither, he died of an apoplexy in 1565, at the age of sixty-three; and his eulogy was delivered, at his funeral, by Lionardo Salviati.

Varchi was a man of general literature. He wrote a Florentine history, comprising the period from 1527 to 1538, in which he was chargeable with gross adulation to the house of Medici. He also published several harangues, academical and funeral; poetical pieces, and a comedy in Italian. As a grammarian, he gained reputation by his dialogue "Ercolano," treating particularly of the Tuscan language. His translations of "Seneca on Benefits," and of the "Philosophical Consolation of Boethius," into Italian,

are deemed elegant. His "Lezioni lette nel Accademia Fiorentina" comprehends much various erudition. Upon the whole, Varchi ranked as a man of learning, to whom Italian literature was much indebted. Moreri. Tiraboschi. Gen. Biog.

VARCIA, in *Ancient Geography*, a town of Belgic Gaul, upon the route from Cambrai to Andematunum, between Vefontio and Andematunum, according to Antonine's Itinerary.

VARDANUS, COUBAN, a large river which discharges itself into the Euxine sea, and into the Palus Mæotis.

VARDAR, in *Geography*, a river of European Turkey, which rises near Kolumbatz, in Macedonia, and runs into the gulf of Saloniki; 16 miles W.S.W. of Saloniki.

VARDEGUS, a small island of Russia, in the Frozen ocean; 100 miles N.N.W. of Kola. N. lat. $70^{\circ} 25'$. E. long. $30^{\circ} 34'$.

VARDEN, or WARDAN, or *Quardan*, a town of Egypt, on the W. branch of the Nile, anciently called Latopolis. In modern times it has been famous or rather infamous for the abode of pirates, who robbed the vessels which navigated the Nile. These robbers were routed out, and dispersed by Ali Bey. Here Father Sicard burned heaps of ancient manuscripts, deposited in a dove-house, as books of magic; 18 miles N.N.W. of Cairo.

VARDHUYS. See WARDHUYS.

VARDLE, in *Rural Economy*, a term applied in some cases to the eye or thimble of a gate, which has a spike only. See GATE.

VARDON, in *Geography*, a town of Abascia, on the Black sea; 28 miles W.N.W. of Mamak.

VARDONES, in *Ancient Geography*, a people of Germany, who formed a branch of the Vandals.

VARDULI, a people of Hispania Citerior, upon the coast, between the Pyrenees to the E. and the Caristes to the W. Ptolemy has assigned to them the town of Menosca.

VARECA, in *Botany*, a bad and merely temporary name, taken from *Walwareka*, by which this fruit appears to be known in Ceylon. Gärtner received it, with that appellation, from the collection of feeds at the Leyden garden, and thought it might constitute a new genus. We shall give his description.—Gärtn. v. 1. 290. t. 60.—Class and order, as well as the Nat. Ord., unknown.

Gen. Ch. *Flower* unknown. *Peric.* Berry superior, of one cell, half an inch long, ovate, with six angles, tipped with a short point; supported at the base by a small round disk, having six slight notches. Coat coriaceous, thin. Pulp by age become spongy and membranous, divided into partial cells for the reception of the seeds. *Recept.* three prominent ribs, attached to the inner coat of the berry, into which the external seeds are inserted. *Seeds* numerous, rather large, nearly ovate, rendered variously angular by mutual pressure, their colour a smoky brown, all inclosed in separate partial cells; the outer seeds attached to the coat of the fruit; the inner imbedded in its pulp. *Integument* double; the outer thick, coriaceous; inner membranous, very thin. *Albumen* the shape of the seed, thick, white, of the substance of an almond. *Embryo* nearly the size of the albumen, compressed, pale yellow. *Cotyledons* ovate, or rounded, leafy, flat, very thin. *Radicle* long, nearly cylindrical, centrifugal, or indeterminate.

Ess. Ch. *Flower* . . . Berry superior, of one cell; pulp in many partial cells, appropriated to each seed. Seeds inserted into the coat of the berry.

Gärtner observes, that the structure of this fruit agrees, in many points, with that of the Gourd tribe, *Cucurbitacea*; but it differs from all hitherto known of that tribe, in being superior,

superior, and in having remarkably albuminous seeds, whereas the *Cucurbitaceæ* usually have no albumen. We would remark, with due deference to this justly celebrated carpologist, that the partial cells of the pulp appear to be merely what must occur, in the drying up of any such berry, and probably have no existence in a recent state of the fruit. They are therefore scarcely entitled to be mentioned in the essential character.

VAREILLES SOMMIERES, in *Geography*, a town of France, in the department of the Vienne; 7 miles N.N.E. of Civray.

VAREL, a town of Germany, in the county of Oldenburg; 22 miles N. of Oldenburg.

VARELLE, a small island in the Chinese sea, near the E. coast of Malacca. N. lat. $3^{\circ} 18'$. E. long. 104° .

VAREN, a town of France, in the department of the Aveyron; 18 miles N.N.W. of Alby.

VARENA, a town of Italy, on the lake of Como; 15 miles N.N.E. of Como.

VARENNE, a town of Canada, on the right bank of the St. Laurence. N. lat. $45^{\circ} 41'$. W. long. $73^{\circ} 10'$.—Also, a town of France, in the department of the Allier; 10 miles N. of Cuffet.—Also, a town of South Carolina; 20 miles S.E. of Queenborough.

VARENNE *le Grand*, a town of France, in the department of the Saône and Loire; 6 miles S. of Châlons.

VARENNES, a town of France, and seat of a tribunal, in the department of the Meuse. In this town the king and queen of France, with the dauphin, the princefs royal, and the princefs Elizabeth, were stopped in their journey to Montmedy, when they attempted to escape, in the month of June 1791; 7 miles N. of Clermont en Argonne. N. lat. $49^{\circ} 14'$. E. long. $5^{\circ} 7'$.—Also, a town of France, in the department of the Upper Marne; 6 miles S.W. of Bourbonne.

VARENTANUM, VARENTUM, in *Ancient Geography*, a town of Italy, in Etruria, according to the Itinerary of Antonine.

VARESA, in *Geography*, a town of Genoa; 10 miles N.N.W. of Brugnato.

VARESIANO, a town of Italy, capital of the department of the Verbano; 24 miles N.N.W. of Milan. N. lat. $45^{\circ} 50'$. E. long. $8^{\circ} 49'$.

VARGAS, LUIS DE, in *Biography*, a Spanish painter of celebrity, was born at Seville in 1528. He went to Italy to improve his talents, and passed seven years in Rome, where he principally directed his attention to Raffaele and P. Perugino's works. When he returned to Seville, he found a formidable rival in Pedro Campaña, and he therefore returned to Italy to cultivate his powers still farther; and on returning a second time to his native city, obtained reputation, and employment. He painted for the cathedral two pictures, *viz.* Christ bearing his Cross, and Adam and Eve; the latter of which is regarded as his master-piece. He executed several other works for the churches in Seville, both in oil and fresco; and he was no less distinguished for his skill in portraiture, particularly in his portrait of Donna Juana Cortes, duchess of Alcala. He died at Seville in 1590, aged 62.

VARGAS MEXIA, FRANCESCO DE, a Spanish lawyer, who occupied several posts in the judicature under Charles V., and became advocate-fiscal in the supreme council of Castile, was sent by Charles, in 1548, to Bologna, to protest against the translation of the council of Trent to that city. After the dissolution of this council, he spent seven or eight years in a public capacity at Venice. Being ordered by Philip II. to act as resident deputy to the Spanish am-

bassador at Rome, his known learning and integrity caused him to be much consulted by the cardinals on the subject of episcopal jurisdiction. On his return to Spain, he was nominated a counsellor of state; but at length retired from the world to the monastery of Cislos near Toledo. He was author of several works; particularly "De Episcoporum Jurisdictione, et Pontificis Maximi Autoritate," Venet. 4to. 1563; "Commentaries upon War against the Infidels," &c. &c. In 1700, Le Vassor published in French, at Amsterdam, "Letters and Memoirs of Vargas," relative to the council of Trent, which are said not to be very respectful to that assembly. Moreri.

VARGAS, in *Geography*, a town of Spain, in the province of Biscay; 11 miles S.S.W. of Santander.

VARGEL, or VARGULA, an ancient town of Germany, in the territory of Erfurt; 10 miles N.W. of Erfurt.

VARGO, a town of Spain, in Catalonia; 14 miles N. of Solsona.

VARHELY, a town of Transylvania, built on the ruins of Sarmizagethusa, the ancient capital of Dacia, afterwards named by Trajan, Ulpia Trajana; 60 miles E. of Temesvar.

VARI. Persons were formerly so termed, when their legs were deformed, and their toes turned in an unusual degree inwards.

VARI, in *Medicine*, hard, inflamed tubercles, occurring on the face and neck of young people, of both sexes, after the commencement of the period of puberty.

This eruption, which disfigures the countenance at that period of life when personal appearance is usually of the greatest importance in the estimation of the persons affected, has been therefore the object of medical attention from the earliest ages, though in itself but a trivial complaint. Celsus observes, that the Roman ladies in his time were so solicitous of maintaining their beauty, that he deemed it necessary to mention the remedies for this affection of the skin, which otherwise he considered as too trifling for the notice of the physician. "Pene ineptiæ sunt, curare varos et lentículas et ephelides (freckles and sun-spots); sed eripi tamen fœminis cura cultus sui non potest." (De Medicinâ, lib. vi. cap. 5.) The circumstance of this eruption occurring at the age of puberty has given rise to the appellations given to it by the Greek physicians, namely, *ionthos* and *acne*. The term *ionthos* signifying the *lanugo*, or first down of the beard, during which it begins; and *αχνη*, *quasi αχνη*, implying that it appears at the *acme*, or period of full growth and evolution of the body. (See Julius Pollux, *Onomasticon*, lib. iv. cap. 25. Aëtius, *Tetrabile* ii. ferm. iv. cap. 13, &c.) Under this term *acne*, Dr. Willan arranged the disease in the order of tubercles, and described four varieties of the eruption, with the epithets *simplex*, *punctata*, *indurata*, and *rosacea*. See Dr. Bateman's *Practical Synopsis of Cutaneous Diseases*, according to the Classification of Dr. Willan, p. 275.

The *acne*, then, consists of an eruption of these *vari*, or distinct, hard, inflamed tubercles, which are sometimes permanent for a considerable length of time, and sometimes suppurate very slowly and partially, forming only a little matter at the top. They usually appear on the face, especially on the forehead, temples, and chin, and not unfrequently on the neck, shoulders, and upper part of the breast, to the extent that might be covered by a tippet; but never descending to the lower parts of the trunk, or appearing on the extremities. This, however, does not depend on the parts being uncovered; for the limitation is the same in both sexes. As the progress of each tubercle is slow, and they appear in succession, they are generally seen at the same time in their various stages of growth and decline; and, in

the more violent cases, are intermixed also with the marks or vestiges of those which have subsided.

In different cases, the progress and appearance of the eruption vary considerably, which has given rise to the subdivision into species suggested by Dr. Willan. Thus in the *acne simplex*, the eruption consists of small *vari*, which appear singly, and are not very numerous, nor accompanied by much inflammation, nor by any intermediate affection of the skin. Many of the tubercles do not proceed to suppuration; but gradually rise, become moderately inflamed, and again slowly subside, in the course of eight or ten days, leaving a transient purplish-red mark behind. But others go on to a partial suppuration, the whole process of which occupies from a fortnight to three weeks. The tubercles are first felt in the skin like a small hard seed, about the size of a pin's head, and enlarge for three or four days, when they begin to inflame: about the sixth or seventh day they attain their greatest magnitude, are prominent, red, smooth, and shining, and hard and painful to the touch. After two or three days more, a small speck of yellow matter appears on the *apices* of some of the tubercles; and when these afterwards break, a thinner humour is secreted, which soon dries into a yellowish scab. The inflammation now gradually declines, the size and hardness of the tubercles diminish, and the small scab becomes loosened at the edges, and at length falls off at about the end of the third week. The individual tubercles, which rise and suppurate in succession, pass through a similar course.

In the *acne indurata*, the tubercles are larger, as well as more indurated and permanent, than in the former variety. They rise often in considerable numbers, of a conical, or oblong conoidal form, and are occasionally somewhat acuminated, as if tending to immediate suppuration, being at the same time of a bright roseate hue; yet many of them continue in a hard and elevated state for a great length of time, without any disposition to suppurate. Others, however, pass on very slowly to suppuration, the matter not being completely formed in them for several weeks, and then only a small part of the tubercles are removed by that process. Sometimes two or three coalesce, forming a large irregular tubercle, which occasionally suppurates at the separate apices, and sometimes only at the largest. In whatever mode they proceed, the vivid hue of the tubercles gradually becomes more purple or even livid, especially in those which shew no tendency to suppurate. Slight crusts form upon the suppurating tubercles, which after some time fall off, leaving small scars, surrounded by hard tumours of the same dark red colour; and these sometimes suppurate again at uncertain periods, and sometimes slowly subside and disappear, leaving a purple or livid discoloration, and occasionally a slight depression, which is long in wearing off.

The tubercles, even when they do not suppurate, but especially while they continue highly red, are always sore and tender to the touch; so that washing, shaving, the friction of the clothes, &c. are somewhat painful. In its most severe form, this eruption nearly covers the face, breast, shoulders, and top of the back, but does not descend lower than an ordinary tippet in dress: yet this limitation of the disorder is independent of the exposure of those parts; for it occurs equally in men and women. In a few instances in young men, an extensive eruption of *acne indurata* has been seen affecting these covered parts, while the face remained nearly free from it. By the successive rise and progress of the tumours, the whole surface, within the limits just mentioned, was spotted with the red and livid tubercles, intermixed with the purple discolorations and depressions left by those which had subsided, and variegated with yellow sup-

purating points and small crusts, so that very little of the natural skin appeared. Sometimes the black puncta of the sebaceous ducts were likewise mixed with the vari and their sequelæ.

Cure of Vari.—Vari being generally a local disease, the acne is to be treated chiefly by external applications. Except in females, indeed, this variety of the eruption seldom calls for the attention of medical men. The ancients agree in recommending a number of stimulant applications, with the view of discussing the "thick humours," which were supposed to constitute the vari. Lotions and liniments, containing vinegar and honey, sometimes combined with an emulsion of bitter almonds, and sometimes with turpentine, resin, myrrh, and other gums, or with alum, soap, and Cimolian earth, or the bruised roots of the lily, cyclamen, narcissus, &c. were the substances which they principally employed. They were doubtless correct as to the principle, as a gentle stimulus to the skin is the most safe and effectual remedy. The apprehensions, which have been strongly expressed by the humoral pathologists, of producing internal disorder by the sudden repulsion, as it has been called, of these cutaneous eruptions, are not altogether hypothetical. Head-ache, and affections of the stomach and bowels, have sometimes been thus produced, which have ceased on the reappearance of the eruption; but, on the whole, as far as our observation goes, this alternation of disease is less frequent and obvious in this form of acne, than in the pustular and crustose eruptions of the face and head.

The stimulant applications, which are most easily proportioned to the irritability of the tubercles, are lotions containing alcohol, which may be reduced or strengthened, according to circumstances, by the addition of any distilled water. It is not easy to describe the appearances of the eruption, which indicate any certain degree of strength in the lotion; but a little observation will teach this discrimination. If the tubercles are considerably inflamed, and a great number of them pustular, a dilute mixture will be requisite; containing, for example, equal parts of spiritus tenuior and of rose or elder-flower water. The effect of a very acrid lotion, under such circumstances, is to multiply the pustules, to render many of them confluent, and to produce the formation of a crust of some extent, as well as to excite an inflammatory redness in the adjoining skin. A slight increase of the inflammation, indeed, is sometimes occasioned by the first applications of a weak stimulus; but this is of short duration, and the skin soon bears an augmentation of the stimulant; until at length the pure spirit is borne with advantage, as the inflammatory disposition subsides. Under the latter circumstances, even a considerable additional stimulus is often useful; such as from half a grain to a grain or more of the muriate of mercury, in each ounce of the spirit; or a drachm or more of the liquor potassæ, or of the muriatic acid, in six ounces. Acetous acid, as recommended by the ancients, and the liquor ammoniæ acetatis, afford also an agreeable stimulant, in proper proportions. Sulphur yields a small portion of its substance to boiling water, poured upon it, and allowed to infuse for twelve or fourteen hours; a quart of water being added to about an ounce of broken sulphur. A lotion of this nature has been found advantageous in slight cases of *acne simplex*, and especially in removing the roughness and duskiness of the face connected with it.

Connected with the eruption of *vari*, and often giving rise to them, is that appearance of black points in the skin of the face and neck, surrounded by a raised border of cuticle, to which the appellation of *acne punctata* was given

by Dr. Willan. These are vulgarly considered as the extremities of small worms or grubs, because, when they are pressed out, a sort of worm-like appendage is found attached to them; but they are, in fact, only little plugs of concremented mucus or sebaceous matter, moulded in the small ducts of the cuticular glands into this vermicular form, the extremity of which is blackened by contact with the air. In consequence of this distention of their ducts, the glands themselves sometimes inflame, and form small tubercles, or *vari*, with the little black points upon their surface, which partially suppurate, as in the preceding species; but many of them remain stationary for a long period, without ever passing into the inflammatory state. Not unfrequently they are intermixed with a few *vari*, in which the *puncta* have not appeared.

These concretions may be extracted, by pressing on both sides of the specks with the nails, until the hardened mucus is sufficiently elevated to be taken hold of. A blunt curved forceps may be employed with advantage for this purpose; and such a one has been contrived by a surgeon's instrument-maker in London. When the plugs are removed, the disorder becomes *simple vari*, and requires the treatment above-mentioned. The formation of these concretions, indeed, seems to be in a considerable degree prevented, by increasing the tone of the skin, both by the use of the stimulant lotions before recommended, and by friction, using always a strong rough towel.

The preceding varieties of the eruption of *vari* occur only in young persons, of either sex, from the period of puberty to the age of thirty or thirty-five, and principally in those of the languine temperament, and they are generally accompanied by good health, and are totally unconnected with any disorder, or with habits of intemperance; but there is another variety of this eruption, which does not occur till after the age of forty, which is always, except from strong hereditary taint, sympathetic of some disease of the digestive organs, or viscera connected with them, and which therefore is not so easily cured, and is not even benefited by the same local means which are so efficacious in the former species. This variety of the disease is the *gutta rosea* of medical authors, and the *acne rosacea* of Dr. Willan.

This eruption of *vari*, indeed, differs in its appearance very essentially from the preceding species. In addition to the eruption of small suppurating tubercles, there is also a shining redness, and an irregular granulated appearance of the skin of that part of the face which is affected, which is not the part usually occupied by the former species. The redness commonly appears first at the end of the nose, and afterwards spreads from both sides of the nose to the cheeks; the whole of which, however, it very seldom covers. In the commencement the redness is not uniformly vivid; but is paler in the morning, and readily increased to an intense scarlet after dinner, or at any time if a glass of wine or spirits be taken; or if the patient be heated by exercise, or by sitting near a fire. After some continuance in this state, the texture of the cuticle becomes gradually thickened, and its surface uneven or granulated, and variegated by reticulations of enlarged cutaneous veins, with smaller red lines stretching across the cheeks, and sometimes by the intermixture of small suppurating *vari*, which successively arise on different parts of the face. Where there is a strong hereditary predisposition, or by the constant immoderate use of wine and spirituous liquors, this disease may affect the greater part of the face, even the forehead and skin; but the nose especially, in such cases, becomes tumid, and of a

fiery red colour: and, in advanced life, it sometimes enlarges to an immoderate size, the nostrils being distended and patulous, or the *ala* fissured, as it were, and divided into separate lobes.

Little can be done in way of cure for this species of *vari*, the visceral or constitutional malady being the root of the disease; against which, of course, the remedies, both moral and physical, must be directed.

VARI, in *Zoology*, a name given to the *maucuaço*, or *lemur catta* of Linnæus, with his tail marked with rings of black and white; it is about the size of a cat, and inhabits Madagascar and the neighbouring isles. The *vari* of Buffon is the ruffed *maucuaço* of Pennant, the black *maucuaço* of Edwards, and *lemur caudatus niger, collari barbato*, of Linnæus. It has orange-coloured irides; long hair round the sides of the head, standing out like a ruff; long tail; the colour wholly black, but sometimes white spotted with black; the feet black. It inhabits Madagascar; is very fierce in a wild state; and makes so violent a noise in the woods, that the noise of two may be easily mistaken for that of a hundred: when tamed, gentle and good-natured. Pennant.

VARI, in *Geography*, a town of Hindoostan, in Concan; 25 miles N. of Goa.

VARIA, in *Ancient Geography*, a town of Hispania Citerior, on the Iberus, N.W. of Calagaris.

VARIA, *Vico-Varo*, a town of Italy, in the Sabine territory, but belonging to the Latins; situated on the Valerian way; 8 miles from Tibur, and 27 from Rome. It was also called *Valeria*.

VARIA, in *Zoology*, a name by which some authors have called the leopard, or *pardalis*, from the beautiful variegations with which it is marked.

VARIABLE, in *Geometry* and *Analytics*, is a term applied by mathematicians to such quantities as either increase or diminish, according as some other quantity either increases or diminishes.

Thus, the semiordinates and abscissæ of an ellipsis, &c. are variable quantities; because, if the one increase, the others increase likewise.

They are thus called, in contradistinction to *constant*, or *given*, or *stable* quantities; which are always the same though others change: as the semidiameter of a circle, which remains the same, though the abscissæ and semiordinates increase.

Variable quantities are usually denoted by the last letters of the alphabet, *x, y, z*.

Some authors, instead of *variable* and *constant* quantities, use the terms *fluent* and *stable* quantities.

The infinitely small quantity by which a variable quantity is continually increasing or diminishing, is called the increment or decrement, or *difference*; and the velocity with which it increases or decreases at any given point, is called its *fluxion*; the calculation of which is the subject of the new *methodus differentialis*, or *doctrine of fluxions*.

VARIABLE Wind. See *WIND*.

VARIAM, in *Geography*, a town of Persia, in the province of Irak; 120 miles E. of Hamadan.

VARIANA, in *Ancient Geography*, a town of Lower Mœsia, upon the route from Viminacium to Nicomedia, between Augustæ and Valeriana. Anton. Itin.

VARIANÆ, a town of Pannonia, upon the route from Cœmona to Sirmium, between Siscia and Menneianæ. Anton. Itin.

VARIANCE, *VARIANTIA*, in *Law*, an alteration or change of condition in a person, or thing, after some former concern or transaction therewith.

Thus,

VARIATION.

Thus, if the commonalty of a town make a composition with a lord, and afterwards bailiffs be granted by the king to the same town, there, if the lord commence any suit for breach of the composition, he must *vary* from the word *commonalty*, used in the composition, and use *bailiffs* and *commonalty*.

VARIANCE is also used for an alteration of something formerly laid in a plea: or where the declaration in a cause differs from the writ, or from the deed upon which it is grounded.

VARIATION of Quantities, in Algebra. See CHANGES and COMBINATION.

VARIATION, in Astronomy. The *variation of the moon*, called by Bullialdus the *reflection of her light*, is the third inequality observed in the moon's motion; by which, when out of the quadratures, her true place differs from her place twice equated. See PLACE, EQUATION, &c.

Sir Isaac Newton takes the moon's variation to arise partly from the form of her orbit, which is an ellipsis; and partly from the inequality of the parts of space, which the moon describes in equal times, by a radius drawn to the earth.

To find the greatest variation, observe the moon's longitude in the octants; and, for the time of observation, compute the moon's place twice equated: the difference between the computed and the observed place is the greatest variation.

Tycho makes the greatest variation $40' 30''$; Kepler makes it $51' 49''$; sir Isaac Newton makes the greatest variation, at a mean distance, between the sun and the earth, to be $35' 10''$: at the other distances, the greatest variation is in a ratio compounded of the duplicate ratio of the time of the moon's synodical revolution directly, and the triplicate ratio of the distance of the sun from the earth inversely. And, therefore, in the sun's apogee, the greatest variation is $33' 14''$, and in his perigee, $37' 11''$; provided that the eccentricity of the sun be to the transverse semidiameter of the orbis magnus, as $16\frac{1}{6}$ to 1000. Or, taking the mean motions of the moon from the sun, as they are stated in Dr. Halley's tables, and the greatest variation at the mean distance of the earth from the sun will be $35' 7''$, in the apogee of the sun $33' 27''$, and in his perigee $36' 51''$. Phil. Nat. Princ. Math. prop. 29. lib. iii. apud Horsley's Newtoni Opera, vol. iii. p. 71.

VARIATION, in Geography, Navigation, &c. a term applied to the deviation of the magnetic needle, or compass, from the true north point, towards either east or west; called also the *declination*.

The variation, or declination, of the needle, is properly defined, the angle which a magnetic needle, suspended at liberty, makes with the meridian line on a horizontal plane; or an arc of the horizon, comprehended between the true and the magnetical meridian.

In sea-language, the variation is usually called *north-easting*, or *north-westing*.

All magnetic bodies, we find, range themselves, in some degree, to the meridian; but it is rare that they fall in precisely with it: in one place they decline from the north to the east, and from the south to the west; and in another place, on the contrary, from the north to the west, and from the south to the east; and that too differently at different times.

The variation of the compass could not be long a secret, after the invention of the compass itself: accordingly, Ferdinand, the son of Columbus, in his life written in Spanish, and printed in Italian at Venice in 1571, asserts, that his father observed it on the 14th of September, 1492: though others seem to attribute the discovery of it to Sebastian Cabot, a Venetian, employed in the service of our king

Henry VII. about the year 1500. And as this variation differs in different places, Gonzales d'Oviedi found there was none at the Azores; whence some geographers have thought fit in their maps to make their first meridian pass through one of these islands; it not being then known that the variation altered in time. See Gilbert de Magnete, Lond. 1600, p. 4, 5: or Purchas's Pilgrims, Lond. 1625, book ii. sect. 1. See *Variation of the MAGNET*.

Various are the hypotheses framed to account for this extraordinary phenomenon; of which we shall mention some of the later, and more probable, only premising, that Mr. Robert Norman, the inventor of the *dipping-needle* (which see), disputes against Cortes's notion, that the variation was caused by a point in the heavens, contending that it should be sought for in the earth, and proposes how to discover its place.

The first is that of Gilbert (De Magnete, lib. iv. p. 151, &c.) which is followed by Cabeus, &c.

This notion is, that it is the earth, or land, that draws the needle out of its meridian direction; and hence they argue, that the needle varied more or less, as it was more or less distant from any great continent; consequently, that if it were placed in the middle of an ocean, equally distant from equal tracts of land on each side, eastward and westward, it would not decline either to the one or the other, but point justly north and south. Thus they say, in the Azores islands, which are equally distant from Africa on the east, and America on the west, there is, in effect, found no variation: but as from the Azores you sail towards Africa, the needle begins to decline from the north to the east; and that still more and more, till you reach the shore.

If you still proceed eastward, the declination gradually diminishes again, by reason of the land left behind on the west, which continues to draw the needle.

The same holds till you arrive at a place where there are equal tracts of lands on each side; and there again there is no variation.

The observations of our mariners, in their first East India voyages, seemed to confirm this system; as they proceed towards the Cape of Good Hope the variation is still eastward; at length arriving at the Cape De las Aguillas, *q. d.* of the Needles, the meridian line, then dividing Africa into two equal parts, there is no variation at all; but as they proceed farther, and leave the African coast on the west, the variation becomes westward.

But the misfortune is, the law does not hold universally; in effect, a great number of observations of the variations, in various parts, made and collected by Dr. Halley, overturn the whole theory.

Some, therefore, have recourse to the frame and compasses of the earth, considered as interwoven with rocks and shelves, which being generally found to run towards the poles, the needle has been observed to have a general tendency that way; but which seldom going perfectly in the direction of the meridian, the needle, of consequence, has commonly a variation.

Others hold various parts of the earth to have various degrees of the magnetic virtue, as some are more intermixed with heterogeneous matters, which prevent the free action or effect of it, than others.

Others ascribe all to magnetic rocks and iron mines, which, affording more of the magnetic matter than other parts, draw the needle more.

Lastly, others imagine earthquakes, or high tides, to have disturbed and dislocated several considerable parts of the earth, and so changed the magnetic axis of the globe, which originally was the same with the axis of the globe itself.

VARIATION.

But still, that great phenomenon, the *variation of the variation*, i. e. the continual change of the declination in one and the same place, which the modern observations daily confirm, is not accountable for on any of these foundations, nor even is it consistent with them.

Dr. Hooke communicated to the Royal Society, in 1674, a theory of the variation, the substance of which is, that the magnet has its peculiar pole distant ten degrees from the pole of the earth, about which it moves, so as to make a revolution in 370 years; whence the variation (he adds) hath altered of late about ten or eleven minutes every year, and will probably so continue to do for some time, till it begins to become slower and slower, and will at length be stationary and retrograde, and in all probability may return. Birch's Hist. of the Royal Society, vol. iii. p. 131.

Dr. Halley, in the Philosophical Transactions, N° 148, invented a new theory, founded on a great number of observations, many of which were made expressly for the purpose by order of the government; but as they do not extend to a more recent date than about 1680, and as perpetual changes are going on in the variation of different places, the table of results of this learned philosopher is now of little use; we shall therefore avail ourselves of the history of these changes, as published in a recent work on the variation of the compass by W. Bain, master in the royal navy; which contains much important information on this subject, and is deserving of the particular attention of every one engaged in the management and navigation of vessels.

At London, in 1580, the quantity of variation was found to be $11^{\circ} 15'$ E.; in 1662, 6° E.; in 1634, $4^{\circ} 5'$ E.; and in 1657, the needle coincided with the true poles of the world; so that a period of 87 years elapsed in changing the $11^{\circ} 15'$ of easterly variation in that city to zero, or until the variation began to take a westerly direction. In 1672, the variation was $2^{\circ} 30'$ W.; in 1723, $14^{\circ} 17'$ W.; in 1747, $17^{\circ} 40'$ W.; in 1780, $22^{\circ} 41'$ W.; and in 1793, viz. 136 years after the time when the variation was zero, it was nearly $24\frac{1}{2}^{\circ}$ W.; and it is still nearly the same.

At Paris, in 1550, the variation was 8° E.; and in 1660, the needle pointed to the true poles of the world; in 1681, the variation was $2^{\circ} 2'$ W.; in 1760, $18^{\circ} 20'$ W.; in 1804, $22^{\circ} 20'$ W. Hence it follows, that whilst the variation was undergoing an annual change of $10' 4''$ during a period of 213 years in London, the yearly change at Paris during a term of 254 years was only $7' 10''$.

At Dublin, in 1657, the needle coincided with the true poles of the world; and in 1791, the variation was $27^{\circ} 23'$ W.; exceeding the variation observed at London by 3° or 4° ; and, consequently, the annual change during 134 years, must have been about $12' 10''$.

While the variation was undergoing this change at London, Paris, and Dublin; we find very nearly a corresponding change at Cape Agullas, and at the Cape of Good Hope.

At the former of these places there was no variation in 1600, and in 1692, it amounted to 11° W. And at the Cape of Good Hope, in 1700, the variation was nearly 10° W.; and in 1791, it had increased to $24^{\circ} 31' 52''$ W.; so that during a period of 91 years, the annual change in the variation at the latter place, must have been about $9' 15''$.

At St. Helena, the variation in 1600 was 8° E.; in 1692, 1° W.; in 1776, $13^{\circ} 15'$ W.; and in 1794, it was found to be $16^{\circ} 16'$ W.; consequently, the mean annual change in the variation at this place, during a period of 194 years, has been at the rate of $7' 52''$.

At Cape Comorin, in 1620, the variation was $14^{\circ} 20'$ W.; in 1688, $7^{\circ} 30'$; in 1756, $0^{\circ} 15'$ W.; and in 1816, there

was still no variation at this place; therefore, during a period of 137 years, the mean annual change was $6' 17''$; but this includes a term of 60 years, in which there appears to have been a very small change in the declination, viz. about $15''$ annually.

The phenomena presented by the variation at Cape Horn and its vicinity, are extremely different from those observed at the Cape of Good Hope, Paris, and London.

In 1683, in S. lat. $57^{\circ} 27'$. W. long. $57^{\circ} 28'$, the variation was found to be $23^{\circ} 10'$ E.: in 1775, in S. lat. $56^{\circ} 27'$. W. long. 54° , the variation was $24^{\circ} 23'$ E.: in 1786, in S. lat. 53° . W. long. $70\frac{1}{2}^{\circ}$, the variation was $22^{\circ} 47'$ E.: and in 1795, in S. lat. 57° . W. long. 67° , the variation was exactly 23° E. Hence it follows, that during a period of 112 years, the variation near Cape Horn has neither increased nor diminished in a perceptible manner.

At Cambridge, in Massachusetts, in 1708, the variation was found to be 9° W.; and since that period, it has been diminishing at the rate of $1\frac{3}{4}'$ annually; whilst at Jamaica, Barbadoes, and Lima, the variation has undergone no change during a period of 140 years. In the northern hemisphere, in the parallel of Spitzbergen, Davis's Straits, Hudson's Bay, &c. the same quantity of variation appears to have existed during the space of 150 years. The quantity or variation from Cape Comorin eastward, towards Nicobar islands, Java, Ceram, Amboyna, Timor, &c. is so very small, as seldom to induce navigators to advert to it in their calculations; and is subject to little or no change. It may, however, be worthy of remark, that 60 miles east from the coast of Coromandel, about the meridian of Madras, the variation changes from east to west; and the same local changes probably take place on the coasts of Chili, Peru, and Mexico. In 1704, from Valparayso to Acapulco, a distance of 50° of latitude, the variation was very inconsiderable; for from the former of these places to Lima, it never exceeds 3° E.; and from Lima to the latter place, never more than 4° W.

The greatest variation that the author, from whom the preceding abstract has been made, is acquainted with, is that which has been observed between Cape Farewell and Labrador, in Hudson's Straits and Baffin's Bay. In N. lat. 52° . W. long. 52° , it was found by the author above alluded to, to be $40^{\circ} 10' 53''$ W.; and as high as N. lat. 60° , in about the same longitude, it was found to be 50° or 52° ; but he expresses some doubt whether this great excess of variation might not have been partially produced by the effects of local attraction.

In 1616, in N. lat. 78° . W. long. 80° (Baffin's Bay), the variation was found to be 57° W.; and in 1757, N. lat. 62° . W. long. 65° , the variation was 41° W.; and in the same year, in N. lat. 63° . W. long. 79° , the variation was 43° W.: and in all these high latitudes, the variation still continues nearly the same.

On the west side of America, in the same parallel of latitude as Davis's Straits, Cape Farewell, &c. we perceive the variation assuming another character, and seldom exceeding half the quantity found at the above-mentioned places.

In 1786, in N. lat. 53° . W. long. $145^{\circ} 21'$ from Paris, the variation was from 23° to 24° E.; in the same year, in N. lat. $58\frac{1}{2}^{\circ}$. W. long. 138° , it was 25° E.; and in Port des François, in N. lat. $58^{\circ} 37'$. W. long. $137^{\circ} 30'$, the variation, as ascertained by the meridian line, amounted to 27° E. In 1793, in N. lat. 53° . W. long. 129° , the variation was only $20^{\circ} 41'$ E.; and in 1794, in N. lat. $61^{\circ} 17'$. W. long. $149^{\circ} 7'$, $29^{\circ} 30'$ easterly variation was found the greatest quantity observed by Vancouver while on that coast.

VARIATION.

But of all the places on the globe with which we are acquainted, none exhibit such wonderful phenomena in the variation as the coasts of China, Corea, Tartary, Japan, and Kamtschatka northward.

In 1787, from Macao to N. lat. 41° . E. long. 136° from Paris, the quantity of westerly variation never exceeded 2° ; and from this last point to N. lat. $51\frac{1}{2}^{\circ}$. E. long. $142\frac{1}{2}^{\circ}$, where the variation was only $53'$ E., the quantity never exceeded 3° .

In 1804, in N. lat. 52° . E. long. 143° from Paris, there was no variation; 16° farther to the E., and 4° to the S., $5^{\circ} 20'$ of westerly variation was observed; and in 1779, in N. lat. $69^{\circ} 55'$. E. long. $195^{\circ} 14'$ (Bhering's Straits), there was found $35^{\circ} 37'$ E. variation.

From observations made between 1700 and 1775, there appeared three places or points on the globe where the change in the variation was much greater than elsewhere.

These were, *first*, in the middle of the Indian ocean, from 10° to 15° S. lat., and from 64° to 69° E. long., where the change was 11° and $11^{\circ} 45'$; *secondly*, in the Ethiopian sea, from 5° N., to 20° or 25° S. lat., and from 10° to 15° or 20° E. long., the change in the variation was about 10° ; and *thirdly*, at 50° N. lat., and between 17° E. and 10° W. long., the change was nearly 11° . In these different places, the variation has since continued to increase at nearly the same rate.

During the same interval it was also ascertained, that there were four places or points on the globe where the variation has undergone no change.

These were, *first*, from the eastern point of Africa to the farthest of the Bermuda islands; *secondly*, the environs of the isle of Madagascar and part of Zanguebar; *thirdly*, that part of the ocean which is to the S. and S.E. of the Sunda islands, between them and New Holland; and *fourthly*, in the same sea, about 4° S. lat., and 97° E. long., that is, in the middle of the space comprised between the western angle of New Holland and the southern point of Africa. In all these places, the variation did not vary perceptibly during 56 years. And it may be remarked, that observations made since the above period, have not shewn any change worthy of notice in its quantity at the above-mentioned places.

Some intelligent sea-officers are of opinion, that in the western part of the English Channel, the westerly variation has begun to decline, whilst others assert, that the variation is still increasing in the Channel, and as far westward as W. long. 15° , in N. lat. 51° ; at which place they say the variation amounts to 30° W. Neither of these opinions, however, can, according to Mr. Bain, be relied on as correct, though each may have been deduced from observation. If the head of the ship is on the *east* point of the compass at the time of observation, from 20° to 23° of variation will be observed; but on the other hand, if the ship's head is at the *west* at the time, the observed variation will amount to 30° or 33° .

The circumstance above alluded to, of the apparent variation being so much influenced by the local attraction of the ship, is certainly of the highest importance; and the means which Mr. Bain has adopted of making it generally known are highly laudable: at the same time, we cannot but feel considerable doubt, after this fact is once pointed out, of the

accuracy of many of the observations stated in the preceding pages, as several of these were made by persons wholly unconscious of such an influence, which seems to have been entirely unknown till Mr. Wales, the astronomer, who sailed with Capt. Cook, first noticed the phenomenon; and his observations have been since confirmed by Capt. Flinders; and Mr. Bain, in the work we have above alluded to, has added many additional facts to those before known, and to which we shall have again occasion to refer; but in the first place, it will be proper to insert a general table of variations in different latitudes, as given in the Philosophical Transactions for 1757, with additional observations of the above author.

It may not be amiss to add here, as belonging to the history of this subject, that we owe the first variation chart to Dr. Halley. Previously to this period he had collected, and made, a multitude of observations on the variation of the needle in many parts of the world, and was enabled to draw on a Mercator's chart, lines shewing the variation of the compass in the places through which they passed. But as the deviation of the magnetic meridian from the true one was then, as now, subject to continual alteration, this chart was soon found useless.

However, in 1744, Mountain and Dobson published a new variation chart, adapted to that year; which being well received, they published a second, adapted to 1756; and a third in the following year: the last we know of.

Nicholson strongly recommends the employment of the variation as a means of finding the longitude at sea; but navigators are long since convinced of its inadequacy. Vancouver, speaking of this subject, says, "This very able seaman, Nicholson, still wedded to formerly-adopted opinions, strongly recommends the variation of the compass as a means for ascertaining the longitude at sea; yet, had we been no better provided, we might have searched for the Cape of Good Hope, agreeable to his propositions, to little effect; for when we were in lat. $35^{\circ} 7'$ S., with $20^{\circ} 16'$ W. variation, we had only reached the long. of $6^{\circ} 30'$ W.; and again, when in lat. $35^{\circ} 22'$ S., with $22^{\circ} 7'$ W. variation, we had only advanced to the long. of $11^{\circ} 25'$, instead of being, according to Mr. Nicholson's hypothesis, in the first instance, nearly under the meridian of the Cape of Good Hope, and in the second, under that of Cape Aguillas; and it was not until we had nearly 26° W. variation, that we approached the meridian of the Cape of Good Hope. The observations for the variation were made with the greatest care and attention; and though generally considered as correct, they differed from one to three, and sometimes to four degrees; not only when made by different compasses, placed in different situations on board, and the ships on different tacks, but by the same compass in the same situation, and at moderate intervals of time; the difference in the results of such observations, at the same time, not preserving the least degree of uniformity. Hence the assertion amounts nearly to an absurdity, which states, 'that with 20° to $20^{\circ} 10'$, or $20^{\circ} 30'$ westerly variation, you will be certain of such and such longitudes;' and it is greatly to be feared, that navigators who rely on such means for ascertaining their situation in the ocean, will render themselves liable to errors that may be attended with the most fatal consequences."

VARIATION.

A TABLE exhibiting the Changes of Variation from the Year 1700, in the most frequented Seas.

Lat.	Long.	Year.	Variation.	Year.	Variation.	Year.	Variation.	Lat.	Long.	Year.	Variation.	Year.	Variation.	Year.	Variation.
Deg.	Deg.		Deg.		Deg.		Deg.	Deg.	Deg.		Deg.		Deg.		Deg.
50 N.	5 W.	1700	7 $\frac{1}{4}$ W.	1756	19 $\frac{1}{4}$ W.	1814	27 $\frac{1}{2}$ W.	20 N.	60 E.	1700	12 $\frac{1}{2}$ W.	1757	6 W.

VARIATION.

Of the Curves of no Variation.—In the preceding part of this article, we have principally alluded to the variation east or west, at different times and in different places; but it is no less interesting to trace the curve in which no variation is observed. We have seen, that there are certain points in the northern and southern hemispheres where the needle points to the true poles of the world; these points, however, are not all situated on the same meridian, but form an irregular curve, inflected different ways, and in perpetual motion.

In the northern hemisphere, a curve of no variation moved from west to east during two centuries prior to 1662. This curve first passed the Azores, then the meridian of London, and, after a certain number of years, the meridian of Paris. But in the southern hemisphere, there was another curve of no variation moving from east to west. This curve first passed Cape Aguillas, and then the Cape of Good Hope; the westerly variation following the easterly, the same as in the northern hemisphere, but in a contrary direction. And from the observations that have since been made, it appears that the curve of no variation in the northern hemisphere, after passing the meridian of London and Paris, has discontinued its eastern progress; while the curve of no variation in the southern hemisphere, still continues its course north-westward.

The variation on the east side of the curve of no variation, which passed the meridian of Aguillas in 1600, and extended north and south to a high degree of latitude in both hemispheres, being westerly; and the curve which passed the meridian of London in 1662 being easterly; it follows, that the curve which passed London could not reach beyond the 18th degree of east longitude, as the denomination of the variation was the same eastward of that meridian in 1600 that it now is, namely, westerly. The exact point where the southern curve of no variation passed the northern curve cannot be satisfactorily ascertained; but it is known, that while the northern curve passed London eastward, the southern curve passed westward in nearly the same longitude.

Dampier, in his voyage to the East Indies in 1669, found, that from 6° south latitude and 25° west longitude, to the point where the 37th degree of south latitude was intersected by the meridian of Greenwich, the variation was easterly, but never exceeding 13°; at which latter point the easterly variation was 0, and thence became westerly, and continued to increase to 47° E. long., and 25° S. lat., where it appears to have attained its maximum; *i. e.* 25° or 26° W.; and from this point the variation gradually diminished, till it again assumed another denomination in S. lat. 10°, and E. long. 125°: and from this last point, as far north of the equator as 10°, the variation appears to have then been, as it still is, influenced by local attractions; the quantity being always small, sometimes east, and at others west. Captain Cook, in 1772, in S. lat. 6°, and W. long. 16°, found 9° 30' westerly variation; and in S. lat. 24°, and W. long. 23° 51', found only 39' west variation. From this point the westerly variation gradually increased, as the southern latitude and eastern longitude augmented to 96° of east longitude, and 60° 49' south latitude, where it attained its maximum; *i. e.* 43° 45' west. From this last point it rapidly decreased, and became east in S. lat. 58° 53', and E. long. 143° 40'. But as the tract of D'Entrecasteaux, in 1791, nearly coincides with Dampier's in 1669, the change in the position of the curve of no variation, will be best illustrated by a comparison of their respective observations.

D'Entrecasteaux found the variation in S. lat. 6°, and W. long. 25°, to be 7° 15' west; and in S. lat. 25°, and W. long. 25°, only 1° 56' west; from which last point it again

increased as the west longitude diminished, till the meridian of Greenwich intersected the 33d degree of south latitude, where the variation was 15° west; and it attained its maximum of 30° 48' 9" in S. lat. 34° 52', and E. long. 38° 14' 18" from Paris; and from hence, to S. lat. 44°, and W. long. 133°, the variation continued westerly, but it there changed and became east.

The space between the two curves observed by Dampier in 1669, reached from the meridian of Greenwich to 130° E. long.; and the distance between them, according to D'Entrecasteaux, in 1791, must be 155°, Dampier having cut the curve in 80° E. long., and the other in 25° W. The curve of no variation must therefore have advanced from the westward annually about 16', in the parallel of 34° south latitude, to have shifted its place 25° in ninety-two years, and at a yearly rate of 14' 8" from the time it passed Cape Aguillas in 1600 to 1791. This curve is now known to extend across the magnetic and terrestrial equators, to a point in N. lat. 37° 27', and W. long. 70° 44'.

From a comparison of the above results, and others drawn from the observations of captain Flinders, and the Russian navigator Krusenstern, it appears, that a curve of no variation bending westward, extends from the highest degree of southern latitude, in about 144° E. long. to 52° N. lat. in the same parallel, intersecting the equator in 130° E. long. Now from the observations of La Perouse and Krusenstern, the westerly variation ceased, and the curve of no variation terminated in about 52° N. lat., and 153° E. long.; for the variation north-east of this point assumes another character; and 18° farther north, and 52° to the east, captain Cook found near 36° of easterly variation.

It appears also, from a comparison of observations made in Persia and the frontiers of China by Schubert, with those of Perouse, Krusenstern, and others, made on board his majesty's ship *Sybill* by Mr. Bain, that a curve of no variation again takes its rise in about 52° N. lat., and 143° E. long., and terminates a little east from Spitzbergen, extending in a direction nearly east by south, and west by north, through 6780 miles of longitude.

Biot, in speaking of this subject, says, "that a curve of no variation seems to take its rise in the great Southern ocean, passing through the western part of New Holland, traverses the Indian ocean, enters the continent of Asia at Cape Comorin, and thence passes through Persia and West Siberia, and proceeds towards Lapland. But what is more remarkable, that line divides itself into two in the great Asian archipelago, and gives rise to another branch, which, pointing directly from the south to the north, passes that archipelago, traverses China, and is again found in Eastern Siberia. The existence of this branch, and its separation from the former, are clearly indicated by the observations made in the Chinese seas; but I am able to offer a still farther confirmation of it, by the observations made in Russia and the frontiers of China, by the celebrated astronomer Schubert, who has been kind enough to communicate them to me;" which latter are the observations spoken of above.

We have seen that a curve of no variation, extending from 60° of south latitude to 52° of north latitude, in about 143° east longitude, but taking a small bend to the westward, is intersected by the meridian of Amboyna: and by comparing with each other different observations made by Mr. Wales, in his voyage with captain Cook, and those of Vancouver in 1791, and others made by sir Home Popham, and by Humboldt, it appears, that from the westerly part of the curve of no variation, found in about 130° east of the meridian of Greenwich, where the westerly changes to an easterly variation, to the meridian where the easterly varia-

tion was found to terminate by captain Cook, S. lat. $58^{\circ} 27'$. W. long. $13^{\circ} 10'$, the distance east and west will be $216^{\circ} 50'$.

To the meridian of Peroufe, S. lat. $20^{\circ} 39'$. W. long. $28^{\circ} 38'$, the distance is $201^{\circ} 22'$.

To the meridian of Vancouver, S. lat. 35° . W. long. $28'$, the distance is 202° .

To the meridian of fir H. Popham, S. lat. 30° . W. long. 26° , the distance is 204° .

To the meridian of Humboldt, N. lat. 13° . W. long. 59° , the distance (taking the mean) is 171° .

And if the curve of no variation extends to N. lat. $37^{\circ} 27'$. W. long. $70^{\circ} 40'$, the easterly variation in that parallel will only measure $158^{\circ} 16'$.

These different distances point out, under different parallels of latitude, the direction which the curve of no variation at present assumes; and we may perhaps conclude, that the variation of the magnetic needle is caused by two different and distinct systems of magnetic forces; the one producing a westerly variation in the northern hemisphere, over the space of $200^{\circ} 44'$; and in the southern hemisphere, in the same parallel of latitude, of $143^{\circ} 10'$: and the other an easterly variation in the northern hemisphere, over a space of $159^{\circ} 16'$; and on the southern, of $216^{\circ} 50'$.

From these facts it would seem, that the north end of the curve, which passed Cape Aguillas in 1600 north-westward, was in 1804 found to extend from S. lat. 60° . W. long. $13^{\circ} 10'$, to N. lat. $37^{\circ} 27'$. W. long. $70^{\circ} 40'$, intersecting the 13th degree of north latitude, and the 21st, 30th, and 35th of south latitude; whence the medium rate of its motion is found about $26\frac{1}{2}$ annually: but it is extremely probable, that the south end of this curve has during the same period remained stationary; and this difference in the motion of the two extremes of the curve in the southern hemisphere, may perhaps point out to us the reason why the quantity of variation should have continued the same off Cape Horn during 133 years, while at the Cape of Good Hope, Paris, and London, it should have increased 25° or 27° in the same period.

The curve of no variation which passed through London eastward, about the same time the curve in the southern hemisphere passed the meridian of Greenwich westward, appears to have been lost among the smaller magnetic powers at present found in the continent of Europe and Asia.

The view which we have given of this perplexing subject, deduced from actual observation, renders it obvious that all attempts, by *theory*, to fix on charts the exact positions of the curves of no variation, or lines of given variation, must prove, as they have always hitherto done, entirely abortive. There are indeed places in the world, such as Spitzberger, Cape Horn, Chili, and Mexico, the great Asian archipelago, the coast of Coromandel, Peru, Brasil, &c., where the curve of variation, and the variation itself, has not undergone any perceptible change since first observed; but we have good reasons to believe, that at all the above-mentioned places the variations are regulated by incidental magnetic attractions, which are lost or merged in the two great powers already described, at a little distance from their respective spheres. In all other places of the globe, it is continually undergoing a regular and progressive change; but it is impossible accurately to determine when this change may cease, or to foresee what quantity our present westerly variation may attain, though there is some reason to believe it has very nearly or entirely arrived at its maximum.

At present, we have spoken only of those great and in some measure continued changes in the variation which takes place, and become very obvious after a long period; but there are others of a more minute quantity, and of daily,

and we might add of hourly occurrence, to which it will be proper to refer in the present article.

Mr. George Graham made several observations of this kind in the years 1722 and 1723, professing himself altogether ignorant of the cause of the variation which he observed. Phil. Transf. N^o 383, or Abr. vol. vii. p. 290, &c.

About the year 1750, Mr. Wargentín, secretary of the Royal Academy of Sciences in Sweden, took notice both of the regular diurnal variation of the needle, and also of its being disturbed at the time of the aurora borealis, as recorded in the Phil. Transf. vol. xlvii. p. 126, &c.

About the year 1756, Mr. Canton commenced a series of observations, amounting to nearly 4000, with an excellent variation-compass, of about nine inches diameter. The number of days on which these observations were made was 603, and the diurnal variation on 574 of them was regular; *i. e.* the absolute variation of the needle westward was increasing from about eight or nine o'clock in the morning till about one or two in the afternoon, when the needle became stationary for some time; after that, the absolute variation westward was decreasing, and the needle came back again to its former situation, or near it, in the night, or by the next morning. The diurnal variation is irregular when the needle moves slowly eastward in the latter part of the morning, or westward in the latter part of the afternoon; also when it moves much either way after night, or suddenly both ways in a short time. These irregularities seldom happen more than once or twice in a month, and are always accompanied, as far as Mr. Canton observed, with an aurora borealis.

Mr. Canton lays down and evinces by experiment the following principle, *viz.* that the attractive power of the magnet (whether natural or artificial) will decrease while the magnet is heating, and increase while it is cooling. He then proceeds to account for both the regular and irregular variation. It is evident, he says, that the magnetic parts of the earth in the north on the east side, and the magnetic parts of the earth in the north on the west side of the magnetic meridian, equally attract the north end of the needle. If then the eastern magnetic parts are heated faster by the sun in the morning than the western, the needle will move westward, and the absolute variation will increase: when the attracting parts of the earth on each side of the magnetic meridian have their heat increasing equally, the needle will be stationary, and the absolute variation will then be greatest; but when the western magnetic parts are either heating faster, or cooling slower than the eastern, the needle will move eastward, or the absolute variation will decrease; and when the eastern and western magnetic parts are cooling equally fast, the needle will again be stationary, and the absolute variation will then be least.

By this theory, the diurnal variation in the summer ought to exceed that in winter; and accordingly it is found by observation, that the diurnal variation in the months of June and July is almost double that of December and January.

The irregular diurnal variation must arise from some other cause than that of heat communicated by the sun; and here Mr. Canton had recourse to subterranean heat, which is generated without any regularity as to time, and which will, when it happens in the north, affect the attractive power of the magnetic parts of the earth on the north end of the needle. That the air nearest the earth will be most warmed by the heat of it, is obvious; and this has been frequently taken notice of in the morning, before day, by means of thermometers at different distances from the ground. Phil. Transf. vol. xlviii. p. 526.

Mr. Canton has annexed to his paper on this subject a complete

complete year's observation; from which it appears that the diurnal variation increases from January to June, and decreases from June to December. Phil. Transf. vol. li. p. 398, &c.

It has also been observed, that different needles, especially if touched with different load-stones, will differ a few minutes in their variation. See Poleni Epist. Phil. Transf. N° 421.

We shall here subjoin a method practised by M. Du Hamel, who was one of those who attempted, and succeeded in the preparation of artificial magnets, for enlarging the scale of the variation. At each extremity of the needle, composed of two magnetic bars, and which is fourteen inches long, a slender pointed piece of steel is erected perpendicularly; and at the distance of fifty-two feet, in the direction of the needle, he has placed on two pillars, and in a line perpendicular to that direction, a graduated limb six feet long; being a segment of a supposed circle, described from the centre on which the needle turns. The observer, placing himself so as to bring the two pieces of steel at the extremities of the bar into a line with the eye, observes where that line prolonged, or the visual ray, points to the graduated arc. As, at this distance, each of these degrees measures a foot, the true direction of the needle is ascertained with the greatest precision; and lest the observer's eyes may not be good enough to enable him to see distinctly the particular divisions at that distance, an assistant occasionally moves a certain index, conformably to his direction. Hist. de l'Acad. Roy. des Science. Paris, for 1772, part ii. Mem. 2.

On the Effect of the local Attraction of the Ship upon the Variation of the Needle.—We have already had occasion to notice the necessity of attending to the direction of the ship's head, in observations made on ship-board relative to the direction of the compass; and that this may have a very sensible effect will appear very obvious, when we recollect the quantity of iron with which a ship of war, in particular, is generally loaded; and that this is mostly forward, while the compass is generally aft. The great attraction between the iron and the needle is generally known; and consequently, if we could imagine the magnetic power of the earth to cease entirely, we should have no difficulty in conceiving that the attraction of the guns, &c. would incline the needle to assume a direction coinciding with that of the vessel; and consequently, when the magnetic meridian and the direction of the ship are the same, that is, when the vessel lies north and south, both forces acting in the same manner, the position of the needle will be the same as if no such local attraction existed. But if the ship's head is put over to the east or the west, then the local attraction of the ship will incline the needle to the east and west, while the terrestrial attraction will draw it towards the north; and it will, therefore, assume a direction which corresponds with the resultant of these two distinct forces: and we may observe, that the direction of this resultant would furnish, if well observed, most important data towards determining the intensity of this mysterious power.

Simple and obvious as this idea is, it does not appear to have been formed till Mr. Wales, the astronomer in captain Cook's voyages, was struck with certain irregularities, which he could in no way at first account for, and of which we have the following account in the Introduction to the astronomical observations in the Second Voyage.

“In the English Channel, the extremes of the observed variation were from $19\frac{1}{2}^{\circ}$ to 25° ; and all the way to the Cape of Good Hope, I had frequently observed differences nearly as great, without being able in any way to account for them; the difference in the situation being by no means

sufficient. These irregularities continued after leaving the Cape, which at length put me upon examining into the circumstances under which they were made. In this examination it soon appeared, that when most of these observations were made, wherein the greatest variation had happened, the ship's head was *north* and *easterly*; and that when those where it was the least had been taken, it was *south* and *westerly*. I mentioned this to captain Cook, and some of the officers, who did not at first seem to think much of it; but as opportunities happened, some observations were made under those circumstances, and very much contributed to confirm my suspicions; and throughout the whole voyage, I had good reason to believe that variations observed, with the *ship's head in different positions, and even in different parts of her*, will differ very materially from one another, and much more will observations made on board different ships, which I now find fully verified, on comparing those made on board the Adventure with my own, made about the same time in the Resolution.”

Mr. Wales again recurs to this subject, in the course of his astronomical observations made in Cook's third voyage, and points out the quantity of the deviation in several cases; yet the true cause of these anomalies does not appear to have suggested itself to this able astronomer: he merely states the results, but offers no explanation of them. Nor does it appear that they were afterwards particularly noticed by any navigator, till captain Flinders's attention was called to the subject in the early part of his last voyage. Here that experienced navigator found such unaccountable differences in the quantity of variation, deduced from the different observations he occasionally made, that he determined on instituting an inquiry into their causes; and, if possible, to ascertain the laws by which they were regulated.

“Several instances,” he observes, “have been mentioned in the course of this voyage, where the compass shewed a different variation, on being removed from one part of the ship to another. Thus, observations on the binnacle gave $29\frac{1}{2}^{\circ}$ off the Start, where the true variation was $25\frac{1}{2}^{\circ}$; whilst others taken from the booms before the main-mast, 68 miles lower down the Channel, gave only 24° ; and in the experiments made with five compasses, the mean variation on the binnacle was $4^{\circ} 37'$ greater than on the booms.

“It soon became evident, however, that keeping the compass to one spot was not alone sufficient to secure accuracy: a change in the direction of the ship's head was also found to make a difference in the needle; and it was necessary to ascertain the nature and proportional quantity of this difference, before a remedy could be applied. This inquiry was attended with many difficulties, and no satisfactory conclusion could be drawn, until a greater variety of observations was collected. It then appeared, that when the ship's head was on the east side of the meridian, the differences were mostly one way; and when on the west side, they were the contrary: whence I judged that the iron in the ship had an attraction on the needle, which drew it forward. But there was this remarkable distinction: in the northern hemisphere, it was the north end of the needle which was attracted; and in the southern hemisphere, it was the south end. In the instances off the Start, before cited, when the ship's head was *west*, the north end of the needle had been drawn forward, or to the left of the north, nearly 4° , and the west variation thereby increased to $29\frac{1}{2}^{\circ}$; with the head at *east*, it would be drawn to the right of its natural position, and the variation diminished to about $21\frac{1}{2}^{\circ}$; but at *north*, the attraction of the ship was in the same line with the magnetic poles of the earth, and would, therefore, produce no change.

VARIATION.

change. The same thing took place at *fouth*, for the two attractions were still in the same continued line, though on opposite sides of the compass; and throughout the voyage, I found the variation, taken with the head at north and fouth, agreed very nearly in themselves, and with the ob-

servations themselves near the same place, when such observations were not affected by local attractions."

The following table contains a few of the instances, where the change in the variation was observed by captain Flinders.

TABLE of Variations observed in a Voyage of Discovery to Terra Australis, in 1801 and 1802, by Captain Flinders, in His Majesty's Ship Investigator.

Time.	Latitude.		Longitude.		Ship's-Head.	Variation.		Difference.		Remarks.

32	23	132	39	E. by N.	2	49					
		132	56	S. $\frac{1}{2}$ W.	0	19					

After various other observations, and much examination, (for the needle was not always deflected the same quantity, when the position of the ship was the same,) captain Flinders found that the errors had a close connection with the dip. When the north end of the needle had dipped, it was the north point of the compass that had been attracted by the iron of the ship; and as that dip diminished, so had the attraction, until at the magnetic equator; where the dipping-needle stands horizontal, there seemed to have been no attraction; and, upon the whole, it seemed probable that "the error produced at any direction of the ship's head would be to the error at east or west, at the same dip, as the sine of the angle between the ship's head and the magnetic meridian was to the sine of eight points or radius."

After captain Flinders's arrival in England, he made application to the lords commissioners of the Admiralty to have experiments tried on board some of his majesty's ships, that the observations made during his voyage might be verified;

and a series of observations was accordingly made on board five different ships at Sheerneck and Portsmouth, which fully established the accuracy of his former conclusions.

Should this rule, upon farther trial, be found to answer under all circumstances, we must consider it as a most important acquisition to our present knowledge of navigation; but those who wish fully to appreciate all the consequences of this discovery, should consult Bain's treatise on the "Variation of the Compass," to which work we have been much indebted in the composition of this article, and where they will find every information of a practical kind connected with the subject.

Theory of the Variation of the Needle.—Dr. Halley, as we have already stated, was the first who attempted any theory relative to the variation of the compass; and from the observations which he collected, many of which are included in our preceding remarks, he conceived "that the whole globe of the earth is one great magnet, having four mag-
netical

VARIATION.

netical poles, or points of attraction; near each pole of the equator two; and that in those parts of the world which lie nearly adjacent to any one of these magnetical poles, the needle is governed thereby; the nearest pole being always predominant over the more remote."

The pole which at present is nearest to us, he conjectures to lie in or near the meridian of the Land's-End of England, and not above 7° from the Arctic pole: by this pole the variations in all Europe and Tartary, and the North sea, are principally governed; though still with some regard to the other northern pole, whose situation is in the meridian passing about the middle of California, and about 15° from the north pole of the world, to which the needle has chiefly respect in all North America, and in the two oceans on either side thereof, from the Azores, westwards, to Japan, and farther.

The two southern poles, he imagines, are rather farther distant from the south pole of the world; the one about 16° , in a meridian 20° to the westward of Magellan's straits, or 95° west from London: this commands the needle in all South America, in the Pacific sea, and the greatest part of the Ethiopic ocean. The other seems to have the greatest power, and the largest dominion of all, as it is the most remote from the pole of the world, being distant from it little less than 20° , in the meridian which passes through New Holland, and the island Celebes, about 120° east from London; this pole is predominant in the south part of Africa, in Arabia, and the Red sea, in Persia, India, and its islands, and all over the Indian sea, from the Cape of Good Hope eastwards, to the middle of the Great South sea that divides Asia from America.

Such appears to have been the disposition of the magnetic attraction in the time of Dr. Halley; and from these data this author draws the following conclusions; *viz.*

1. Then, it is plain that, as our European north pole is in the meridian of the Land's-End of England, all places more easterly than that will have it on the west side of the meridian; and, consequently, the needle, respecting it with its northern point, will have a westerly variation, which will still be greater as you go to the eastward, till you come to some meridian of Russia, where it will be the greatest, and from thence will decrease again. Accordingly, in fact, we find, that at Brest the variation is but $1\frac{3}{4}^{\circ}$; at London, $4\frac{1}{2}^{\circ}$ (in 1683); and at Dantzic, 7° west. Again, to the westward of the meridian of the Land's-End, the needle ought to have an easterly variation, were it not that, by approaching the American northern pole, (which lies on the west side of the meridian, and seems to be of greater force than this other,) the needle is drawn thereby westward, so as to counterbalance the direction given by the European pole, and to make a small west variation in the meridian of the Land's-End itself. Yet, about the isle of Terceira, it is supposed our nearest pole may so far prevail as to give the needle a little turn to the east, though but for a very little space; the counterbalance of those two poles admitting no considerable variation in all the eastern parts of the Atlantic ocean, nor upon the west coasts of England and Ireland, France, Spain, and Barbary. But to the westward of the Azores, the powers of the American pole overcoming that of the European, the needle has chiefly respect to this, and turns still more and more towards it as we approach it. Whence it happens, that on the coast of Virginia, New England, Newfoundland, and in Hudson's straits, the variation is westward, that is, it decreases as you go from thence towards Europe; and that it is less in Virginia and New England than in Newfoundland and Hudson's straits.

2. This westerly variation, again, decreases as you pass

over North America; and about the meridian of the middle of California, the needle again points due north; and from thence westward to Yedzo and Japan, it is supposed the variation is easterly, and half-sea over, not less than 15° ; and that this east variation extends over Japan, Yedzo, Tartary, and part of China, till it meets with the westerly, which is governed by the European north pole, and which is the greatest somewhere in Russia.

3. Towards the south pole the effect is much the same, only that here the south point of the needle is attracted. Whence it will follow, that the variation on the coast of Brasil, at the river of Plata, and so on to the straits of Magellan, should be easterly, if we suppose a magnetical pole, situated about 20° more westerly than the straits of Magellan. And this easterly variation extends eastward over the greatest part of the Ethiopic sea, till it be counterpoised by the virtue of the other southern pole, as it is about mid-way between the Cape of Good Hope and the isles of Tristan d'Alcunha.

4. From thence eastwards, the Asiatic south pole becoming prevalent, and the south point of the needle being attracted thereby, there arises a west variation, very great in quantity and extent, because of the great distance of this magnetical pole from the pole of the world. Hence it is, that in all the Indian sea, as far as Hollandia Nova, and farther, there is constantly a west variation; and that, under the equator itself, it rises to no less than 11° , where it is most. And that, about the meridian of the island of Celebes, being likewise that of this pole, this westerly variation ceases, and an easterly one begins, which reaches to the middle of the South sea, between Zelandia Nova and Chili, leaving room for a small west variation, governed by the American south pole.

5. From the whole it appears, that the direction of the needle, in the temperate and frigid zones, depends chiefly upon the counterpoise of the forces of two magnetical poles of the same nature; as also why, under the same meridian, the variation should be in one place $29\frac{1}{2}^{\circ}$ west, and in another $20\frac{1}{2}^{\circ}$ east.

6. In the torrid zone, and particularly under the equinoctial, respect must be had to all four poles, and their positions must be well considered, otherwise it will not be easy to determine what the variation shall be, the nearest pole being always strongest; yet not so as not to be counterbalanced, sometimes, by the united forces of two more remote. Thus, in sailing from St. Helena, by the isle of Ascension, to the equator, on the north-west course, the variation is very little easterly, and in that whole tract is unalterable; because the South American pole, (which is considerably the nearest in the aforesaid places,) requiring a great easterly variation, is counterpoised by the contrary attraction of the North American and the Asiatic south poles; each of which singly, is, in these parts, weaker than the American south pole: and upon the north-west course, the distance from this latter is very little varied; and as you recede from the Asiatic south pole, the balance is still preferred by an access towards the North American pole. In this case, no notice is taken of the European north pole; its meridian being a little removed from those of these places, and of itself requiring the same variations which we here find.

After the same manner may the variations in other places, under and near the equator, be accounted for, upon Dr. Halley's hypothesis.

But in order to account for the *variation of the variation*, it was observed, that from many of the observed phenomena, it seemed to follow that all the magnetic poles have a motion

motion westward: but if it be so, it is evident that it is not a rotation about the axis of the earth; for then the variations would continue the same in the same parallel of latitude (the longitude only changed), as much as the motion of the magnetical poles: but the contrary is found by experience; for there is no where, in the latitude of $51\frac{1}{2}^{\circ}$ north, between England and America, a variation of 11° east, at this time; as it was once here at London. Wherefore it seems, that our European pole is become nearer the Arctic pole than it was heretofore; or else, that it has lost part of its virtue.

But whether these magnetic poles move altogether with one motion, or with several; whether equally, or unequally; whether circular, or libratory: if circular, about what centre; if libratory, after what manner; are things yet unknown.

This theory seems yet somewhat obscure and defective: to suppose four poles in one magnetical globe, in order to account for the variation, is a little unnatural; but to conceive those poles to move, and that by such laws as to solve the variation of the variation, is still more extraordinary. In effect, the solution appears not much less implicit and arbitrary than the problem.

The learned author of the theory, therefore, found himself under a necessity to solve the phenomena of his solution; and with this view, he presented the following hypothesis. The external parts of the globe he considers as the shell, and the internal as a nucleus, or inner globe; and between the two, he conceives a fluid medium. That inner earth, having the same common centre and axis of diurnal rotation, may turn about with our earth each twenty-four hours. Only the outer sphere having its turbinating motion some small matter either swifter or slower than the internal ball; and a very minute difference in length of time, by many repetitions, becoming sensible; the internal parts will, by degrees, recede from the external; and not keeping pace with one another, they will appear gradually to move either eastward or westward, by the difference of their motions.

Now, suppose such an internal sphere, having such a motion, the two great difficulties in the former hypotheses are easily solved; for if this exterior shell of earth be a magnet, having its poles at a distance from the poles of diurnal rotation; and if the internal nucleus be likewise a magnet, having its poles in two other places, distant also from the axis; and these latter, by a gradual and slow motion, change their place in respect of the external, we may then give a reasonable account of the four magnetical poles afore-mentioned, as likewise of the changes of the needle's variation.

The period of its motion being wonderfully great, and there being hardly a hundred years since these variations have been duly observed, it will be very hard to bring this hypothesis to a calculus; especially since, though the variations do increase and decrease regularly in the same place, yet in different places at no great distance, there are found such casual changes thereof, as can no ways be accounted for by a regular hypothesis; but seem to depend upon the unequal and irregular distribution of the magnetical matter within the substance of the external shell, or coat of the earth, which deflect the needle from the position it would acquire from the effect of the general magnetism of the whole. Of which the variations at London and Paris give a notable instance; for the needle has been constantly about $1\frac{1}{2}^{\circ}$ more easterly at Paris than at London: though it be certain that, according to the general effect, the difference ought to be the contrary way; notwithstanding which, the variations, in both places, do change alike.

Hence, and from some other things of like nature, it

seems plain, that the two poles of the external globe are fixed in the earth, and that if the needle were wholly governed by them, the variations thereof would be always the same, with some irregularities, upon the account just now mentioned. But the internal sphere having such a gradual translation of its poles does influence the needle, and direct it variously, according to the result of the attractive or directive power of each pole, and, consequently, there must be a period of the revolution of this internal ball; after which the variations will return again as before. But if it shall in future ages be observed otherwise, we must then conclude that there are more of these internal spheres, and more magnetical poles, than four; which, at present, we have not a sufficient number of observations to determine, and particularly in that vast Mar del Zur, or South sea, which occupies so great a part of the whole surface of the earth. If, then, two of the poles be fixed, and two moveable, it remains to ascertain which they are that keep their place.

The author thinks it may be safely determined, that our European north pole is the moveable one of the two northern poles, and that which has chiefly influenced the variations in these parts of the world; for, in Hudson's Bay, which is under the direction of the American pole, the change is not observed to be near so fast as in these parts of Europe, though the pole be much farther removed from the axis. As to the south poles, he takes the Asiatic pole to be fixed, and, consequently, the American pole to move.

This granted, it is plain that the fixed poles are the poles of this external shell, or cortex, of the earth; and the other the poles of the magnetical nucleus, included and moveable within the other. It likewise follows, that this motion is westwards, and, by consequence, that the afore-said nucleus has not precisely attained the same degree of velocity with the exterior parts in their diurnal revolution; but so very nearly equals it, that, in 365 revolutions, the difference is scarcely sensible. That there is any difference of this kind arises hence, that the impulse by which the diurnal motion was impressed on the earth, was given to the external parts; and from thence, in time, communicated to the internal; but not so as yet perfectly to equal the velocity of the first motion impressed on, and still conserved by, the superficial parts of the globe.

As to the precise period, we want observations to determine it, though the author thinks we may, with some reason, conjecture, that the American pole has moved westward 46° in ninety years, and that the whole period thereof is performed in about seven hundred years.

Mr. Whiston, in his "New Laws of Magnetism," raises several objections against this theory. See **MAGNETISM**.

M. Euler, the son of the celebrated geometrician of that name, has also controverted and censured the above theory: he thinks that two magnetic poles placed on the surface of the earth will sufficiently account for the variation; and he then endeavours to shew, how we may determine the declination of the needle, at any time, and on every part of the globe, from this hypothesis. But we must refer for the particulars of this reasoning to the *Histoire de l'Academie Royale des Sciences et Belles Lettres de Berlin*, for 1757.

Various other theories have been suggested by later authors, but most of these have been already alluded to under our articles **MAGNETISM**, **DIPPING-Needle**, &c.; we shall, therefore, here conclude this article, by referring the reader for a more minute account of the various theories, particularly that of Coulomb, to Haüy's "Elementary Treatise on Natural Philosophy," translated by Gregory, and to the first chapter of the third volume of Biot's "Traité de Physique."

VARIATION.

VARIATION of Declination of the Needle. To observe the.— Draw a meridian line, as directed under MERIDIAN, then, a style being erected in the middle of it, place a needle thereon, and draw the right line which it hangs over. Thus will the quantity of the variation appear.

Or thus: as the former method of finding the declination cannot be applied at sea, others have been thought of, the principal of which follow: suspend a thread and plummet over the compass, till the shadow pass through the centre of the card; observe the rhumb, or point of the compass, which the shadow touches when it is the shortest. For the shadow is then a meridian line; consequently the variation is shewn.

Or thus: observe the rhumb in which the sun, or some star, rises and sets; bisect the arc intercepted between the rising and setting; the line of bisection will be the meridian line; consequently the declination is had as before. The same may be had from two equal altitudes of the same star, observed either by day or night.

Or thus: observe the rhumb in which the sun, or a star, rises and sets; and from the latitude of the place find the eastern or western amplitude, for the difference between the amplitude, and the distance of the rhumb observed, from the eastern rhumb of the card, is the variation sought.

Or thus: observe the altitude of the sun, or some star, SI (Plate II. Navigation, fig. 7.) whose declination is known; and note the rhumb in the compass to which it then corresponds. Since then, in the triangle ZPS, we have three sides; viz. PZ, the complement of the elevation of the pole PR; SP, the complement of the declination DS; and ZS, the complement of the altitude SI; the angle PZS is found by spherical trigonometry; the contiguous one to which, viz. AZS, measures the azimuth HI. The difference, then, between the azimuth, and the distance of the rhumb observed from the south, is the variation sought. See AZIMUTH COMPASS.

Note, to have the eastern or western amplitude accurately, regard must be had to the refraction. See REFRACTION.

For the more commodious observing in what rhumb of the compass the sun, or a star, is seen, it will be proper to have two little apertures, or glass windows, opposite to each other, under the limit of it, with a telescope-sight fitted to one of them, and to the other a fine thread.

The use of the variation is to correct the courses a ship has steered by the compass: *e. g.* given the course set, and the variation of the compass, and let it be required to find the true course the ship steers: if the variation is west, call the N.W. quarter the 1st, the S.W. the 2d, the S.E. the 3d, and the N.E. the 4th; but if the variation be east, call the N.E. quarter the 1st, the S.E. the 2d, the S.W. the 3d, and the N.W. the 4th. Then, if the course be set in the 1st or 3d quarters, add the variation to the points or degrees in the given course; but if in the 2d or 4th quarters, subtract, and the sum in the former, or the difference in the latter case, will be the course corrected by the variation.

VARIATION of Curvature, in Geometry, is used for that inequability, or change, which happens in the curvature of all curves, except the circle. And this variation or inequability constitutes the quality of the curvature of any line.

Sir Isaac Newton makes the index of the inequability or variation of curvature, to be the ratio of the fluxion of the radius of curvature to the fluxion of the curve: and Mr. Maclaurin, to avoid the perplexity that different notions, connected with the same terms, occasion to learners, has adopted the same definition; but he suggests, that this ratio

gives rather the variation of the ray of curvature, and that it might have been proper to have measured the variation of curvature rather by the ratio of the fluxion of the curvature itself to the fluxion of the curve; so that the curvature being inversely as the radius of curvature, and, consequently, its fluxion as the fluxion of the radius itself directly, and the square of the radius inversely, its variation would have been directly as the measure of it, according to Sir Isaac Newton's definition, and inversely as the square of the radius of curvature.

According to this notion, it would have been measured by the angle of contact contained by the curve and circle of curvature, in the same manner as the curvature itself is measured by the angle of contact contained by the curve and tangent. The reason of this remark may appear from this example: The variation of curvature, according to Sir Isaac Newton's explication, is uniform in the logarithmic spiral, the fluxion of the radius of curvature in this figure being always in the same ratio to the fluxion of the curve; and yet, while the spiral is produced, though its curvature decreases, it never vanishes, which must appear a strange paradox to those who do not attend to the import of Sir Isaac's definition. Newton's Meth. of Flux. and Inf. Series, p. 76. Maclaurin's Fluxions, art. 386. Phil. Trans. N^o 468. sect. 6. p. 342.

The variation of curvature at any point of a conic section, is always as the tangent of the angle contained by the diameter that passes through the point of contact; and the perpendicular to the curve at the same point, or to the angle formed by the diameter of the section, and of the circle of curvature. Hence the variation of curvature vanishes at the extremities of either axis, and is greatest when the acute angle, contained by the diameter, passing through the point of contact and the tangent, is least.

When the conic section is a parabola, the variation is as the tangent of the angle, contained by the right line drawn from the point of contact to the focus, and the perpendicular to the curve. See CURVATURE.

VARIATION of Ratios. In the investigations of the relation which varying and dependent quantities bear to each other, conclusions are frequently more readily obtained by expressing only two terms in each proportion, than by retaining the four. But although in considering the variation of such quantities two terms only are expressed, it will be necessary to bear constantly in mind that four are supposed, and that the operations by which our conclusions are in this case obtained, are in reality the operations of four proportionals.

1. One quantity is said to vary directly as another, when their magnitudes depend wholly upon each other, and in such a manner, that if the one be changed, the other is changed in the same proportion: thus, let A and B be mutually dependent upon each other in such a way, that if A changes to any other value *a*, B is changed to another value *b*, such that $A : a :: B : b$; then A is said to vary directly as B, which is denoted by the symbol of general proportion \propto placed between the two quantities. Thus, for example, while the altitude of a triangle remains constant, the area varies directly as the base, or the *area* \propto *base*; for if the base be increased or diminished, the area is increased or diminished in the same proportion.

2. One quantity is said to vary inversely as another, when one cannot be changed in any manner; but the reciprocal of the other is changed in the same proportion.

A varies inversely as B, or $A \propto \frac{1}{B}$, if when A is changed

to a , B is changed to b , in such a manner, that

$$A : a :: \frac{1}{B} : \frac{1}{b}; \text{ or } A : a :: b : B.$$

For example, if the area of a triangle be given, the base varies inversely as the perpendicular altitude; for let A and a represent the altitude of two triangles of equal areas, and B and b their two bases; then

$$\frac{A \times B}{2} = \frac{a \times b}{2}; \text{ or } A \times B = a \times b :$$

therefore,

$$A : a :: b : B; \text{ or } A : a :: \frac{1}{B} : \frac{1}{b}.$$

3. One quantity is said to vary as two others *jointly*, if, when the former is changed in any manner, the product of the other two is changed in the same proportion: that is, A varies as B and C jointly, or $A \propto BC$, when A cannot be changed to a , but BC is changed to bc , such that $A : a :: BC : bc$. The area of a triangle, for example, varies as the base and altitude jointly; for let A, P, B , represent the area, perpendicular, and base of one triangle, and a, p, b , the corresponding quantities in another; we know

that $A = \frac{1}{2}PB$, and $a = \frac{1}{2}pb$; consequently $\frac{A}{a} = \frac{PB}{pb}$,

or $A : a :: BP : bp$.

4. One quantity is said to vary *directly* as a second, and *inversely* as a third, when the first cannot be changed in any manner; but that the second, multiplied by the reciprocal of the third, is changed in the same proportion. That is, A

varies as $\frac{B}{C}$, or $A \propto \frac{B}{C}$, when $A : a :: \frac{B}{C} : \frac{b}{c}$; A, B, C , and a, b, c , being corresponding values of these quantities.

For example, the base of a triangle varies as the area directly, and as the altitude inversely; for as in the preceding example,

$\frac{BP}{pb} = \frac{A}{a}$; if we multiply both sides by

$\frac{p}{P}$, we have $\frac{B}{b} = \frac{pA}{Pa}$, whence $B : b :: \frac{A}{P} : \frac{a}{p}$.

The following are some of the principal propositions relating to the ratio of variable quantities.

If $A \propto B$, and $B \propto C$; then $A \propto C$.

If $A \propto B$, and $B \propto \frac{1}{C}$; then $A \propto \frac{1}{C}$.

If $A \propto C$, and $B \propto C$; then $A \pm B \propto \sqrt{BA} \propto C$.

If $A \propto B$, and m is any given number, $A \propto mB$.

If $A \propto B$; then $A^n \propto B^n$, or $A^{\frac{1}{n}} \propto B^{\frac{1}{n}}$.

If $A \propto a$, and $M \propto m$; then $AM \propto am$.

If $A \propto BC$; then $B \propto \frac{A}{C}$, and $C \propto \frac{A}{B}$.

If AB be constant; then $A \propto \frac{1}{B}$, and $B \propto \frac{1}{A}$.

If $A \propto B$, and $C \propto D$; then $AC \propto BD$.

Wood's Algebra.

VARIATION, *Calculus of*, is a department of the modern analysis, which we owe, as a distinct branch, to the inventive genius of Lagrange, who published his first memoir on this subject in the second volume of the Transactions of the Academy of Sciences of Turin, in 1762; and his second memoir, published in the fourth volume of the same Transactions, in 1770, gave to this theory a perfection and general-

ization far beyond what it was supposed capable of possessing. This method was also in the interval illustrated in the most simple and elementary manner by the celebrated Euler, in the Memoirs of the Academy of Sciences at Peterburgh for 1764, as it was afterwards in the third volume of his *Calcul Integral*, and again in the *Acta Petro.* for 1771. Since that time it has been treated of by different authors at greater or less extent; and to Mr. Woodhouse, of Cambridge, we are indebted for a very neat little volume, in which this subject is handled in a very clear and conspicuous manner, from which work we have already given a few extracts under the article ISOPERIMETRY. Bossut, also, in vol. ii. of his "*Traité de Calcul Differential et de Calcul Intégral*," has a very perspicuous chapter on the calculus of variations, of which we shall avail ourselves in the present instance.

Let there be any indefinite expression or function compounded of variable and constant quantities, which changes its value by the increase or diminution of one or more of the elements which it contains: it will thus undergo a variation, and the method of finding this is what is called the *calculus of variations*.

In the same manner as \dot{x} is made to denote the fluxion of x , and $d x$ the differential of x ; so δx is used to indicate the variation of x ; and the fundamental rules of this calculus are founded on the same principles as those of the differential calculus: at the same time, however, it is necessary to guard against confounding the one with the other. A very simple example will shew clearly the distinction that must be made between the two cases.

Let us suppose the equation $y^2 = ax$, which denotes the relation between the absciss $A P = x$, and ordinate $P M = y$, of a parabola $A M$ (*Plate XIII. Analysis, fig. 1.*), a being the parameter. By drawing pm indefinitely near to PM , and Mr parallel to the axis AV ; the line Pp , or Mr , will represent the differential dx , and Mr the differential dy ; and the relation of these differentials is found by the differentiation of the equation $y^2 = ax$, which gives

$$2y dy = a dx, \text{ or } dy = \frac{a dx}{2y}, \text{ or } dy = \frac{a dx}{2\sqrt{ax}}.$$

Let us conceive now that the equation $y^2 = ax$, vary by the indefinitely small augmentation of its parameter a , which is one of its elements; and let us construct a second parabola $A N$, which has $a + \delta a$ for its parameter. Then supposing the absciss $A P$ to continue the same for both parabolas, it is obvious that the ordinate $P N$, of the parabola $A N$, will have for its value the primitive ordinate $P M$, augmented by the small quantity $M N$, which therefore represents the variation that the ordinate $P M$ undergoes in consequence of the variation of the parameter a ; hence, in representing by δy the variation of y , as that of a is denoted by $a + \delta a$, the new equation will be $(y + \delta y)^2 = (a + \delta a)x$; from which subtracting the original equation $y^2 = ax$, we shall have (neglecting, as in the differential calculus, the variations

of the second order) $2y \delta y = x \delta a$, or $\delta y = \frac{x \delta a}{2y}$, or δy

$$= \frac{x \delta a}{2\sqrt{ax}}, \text{ an equation which exhibits the relation of the}$$

variations δa and δy .

If, also, we make the absciss $A P$ vary by the indefinitely small quantity $Pp = \delta x$, the corresponding ordinate for the parabola $A N$ will be qn , and the line sn will represent the variation of the primitive ordinate $P M$. Now to find the relation between the variations δa , δx , δy , we must substitute in the equation $y^2 = ax$, $(a + \delta a)$ for a ,

$(x +$

VARIATION.

$(x + \delta x)$ for x , and $(y + \delta y)$ for y , and the equation becomes

$$(y + \delta y)^2 = (a + \delta a)(x + \delta x);$$

from which subtracting $y^2 = ax$, we shall have

$$2y\delta y = x\delta a + a\delta x;$$

therefore,

$$\delta y = \frac{x\delta a + a\delta x}{2y} = \frac{x\delta a + a\delta x}{2\sqrt{ax}};$$

which is an expression for the variation s_n , of the ordinate P M.

In this example, (and the same has place for all similar equations,) the parameter a , and its variation δa , are constant quantities for the entire parabolas, while those of the co-ordinates P M and A P continually change; the changes, therefore, relative to the same parabola belong to the differential calculus, and those which result from the passage of one parabola to another, to the calculus of variations. Any one of the variations δa , δx , δy , may be arbitrarily assumed; as, for example, we may suppose $\delta x = dx$, but this supposition being once made, the values of the other variations must be subordinate to this, and we cannot therefore afterwards make $\delta y = dy$, or $\delta y = \delta a$.

There is no difficulty in determining the variations of every order for algebraical and circular quantities, and common exponentials; the operations being exactly the same as in the differential calculus; we therefore obtain the variations by the same rules, and have only to write δ instead of d , and in this respect the calculus of variations return again to the differential calculus; but this latter will not be sufficient when it is required to determine the variation of formulae, which contain in themselves the sign of integration: thus, for example, let the integral formula be $\int V dx$, where V is any function of x , y , and z , and constant quantities; we difference this by omitting the sign \int ; that is, $d(\int V dx) = V dx$; but the expression $\delta \int V dx$ is very different, as we shall see in what follows.

Now the principal object of the calculus of variations, is to determine the variation of these sorts of integral formulae; let us, therefore, endeavour to establish the principles which are to serve as the basis of this research.

First Principle.—The variation of a differential is equal to the differential of a variation, and reciprocally; that is, we shall have $\delta d\pi = d\delta\pi$.

For let us suppose that the variable π represent the ordinate of a curve; then this ordinate will change by *differentials* while it belongs to the same curve, and by *variations* in passing from the proposed curve to the curve indefinitely near to the first. In the primitive curve, let π' be the consecutive value to π , and consequently $\pi' = \pi + d\pi$, or $d\pi = \pi' - \pi$. Now taking the variation of this last equation, we shall have $\delta d\pi = \delta\pi' - \delta\pi$; and in the same manner as π and π' are consecutive values in the series of π 's, we may consider $\delta\pi$ and $\delta\pi'$ as consecutive values in the series of $\delta\pi$'s, so that $\delta\pi' = \delta\pi + d\delta\pi$, or $d\delta\pi = \delta\pi' - \delta\pi$; thus in equating these two values of $\delta\pi' - \delta\pi$, we shall have $\delta d\pi = d\delta\pi$.

Hence if we have an expression which contains any number of d 's and δ 's affecting one and the same variable, we make these characteristics change place at pleasure; for we have seen that $\delta d\pi = d\delta\pi$; and in the same manner, we may for $\delta d^2\pi$ write $d\delta d\pi$, or $d^2\delta\pi$; and for $\delta d^3\pi$ we may write $d\delta d^2\pi$, or $d^2\delta d\pi$, or $d^3\delta\pi$, and so on of others.

Second Principle.—The variation of an integral formula is equal to the variation of its differential; that is, $\delta f\xi = f\delta\xi$.

Let $f\xi = z$, and consequently $\xi = dz$, we shall have by taking the variations $\delta\xi = \delta dz$, or $\delta\xi = d\delta z$; and integrating this last equation, we obtain $\int \delta\xi = \delta z = \delta f\xi$.

Hence in repeated integrations, we change at pleasure the signs f and δ ; for we have seen that $\delta f\xi = f\delta\xi$; and in the same manner, $\delta f f\xi = f\delta f\xi = f f\delta\xi$; so also $\delta f f f\xi = f\delta f f\xi = f f f\delta\xi$; and so on of others.

On the Method of determining the Variations of indefinite integral Formulae.—By indefinite integral formulae, is here to be understood those expressions which contain the sign \int , and such at the same time that the integration cannot be effected: these formulae are said to be *simple*, when they contain only one sign \int , and *compounded*, when they contain two or more such signs, or when they are any function of simple integral formulae, combined or not with algebraical quantities, by addition, multiplication, or division.

Let us begin by considering those formulae which contain only two variable quantities x and y , and between which we shall always suppose the relation $dy = p dx$, $dp = q dx$, $dq = r dx$, $dr = s dx$, &c. a supposition which it will be very necessary to bear in mind.

PROBLEM I.

To investigate a general rule for determining the variation of any indefinite integral formula $\int \pi dx$.

Whatever may be the quantity π , we have always from the second principle given above, $\delta \int \pi dx = \int \delta(\pi dx)$; but $\delta(\pi dx) = dx\delta\pi + \pi\delta dx$; and the first principle gives $\delta dx = d\delta x$; whence $\delta \int \pi dx = \int dx\delta\pi + \int \pi d\delta x$. Now by the method of integrating by parts, the last term

$$\int \pi d\delta x = \pi \delta x - \int \delta \pi dx;$$

whence by substitution,

$$\delta \int \pi dx = \pi \delta x + \int dx \delta \pi - \int \delta \pi dx, \text{ or}$$

$$\delta \int \pi dx = \pi \delta x + \int (dx \delta \pi - d\pi \delta x)$$

Now the different values that we may attribute to π , will give rise to different general problems; of which we shall develop a few of most common use, and which will open the way to others of a higher kind.

PROB. II.

To determine the variation of the indefinite simple integral $\int V dx$, V being a given function of x , y , z , p , q , r , &c.

First, by the preceding problem we have

$$\delta \int V dx = V \delta x + \int (dx \delta V - dV \delta x) \dots (A)$$

Again, the quantity V being a function of x , y , z , &c. we shall have, by taking the differentials and the variations, the two equations

$$dV = M dx + N dy + P dp + Q dq + R dr + \&c.$$

$$\delta V = M \delta x + N \delta y + P \delta p + Q \delta q + R \delta r + \&c.$$

in which the co-efficients M , N , P , Q , R , &c. (which are the same for both equations) represent given functions of x , y , p , q , r .

Multiply the first of these equations by δx , the second by dx , and subtract the first product from the second, and we shall have

$$dx \delta V - dV \delta x = N (dx \delta y - dy \delta x)$$

$$+ P (dx \delta p - dp \delta x)$$

$$+ Q (dx \delta q - dq \delta x)$$

$$+ R (dx \delta r - dr \delta x)$$

$$+ K$$

VARIATION.

If now we put for $dy, dp, dq, dr, &c.$ their values $p dx, q dx, r dx, s dx, &c.$ we shall find

$$d x \delta V - d V \delta x = \left\{ \begin{array}{l} N d x (\delta y - p \delta x) + P d x (\delta p - q \delta x) + \\ Q d x (\delta q - r \delta x) + R d x (\delta r - s \delta x) + \&c. \end{array} \right.$$

Consequently our equation (A) becomes

$$\delta \int V d x = V \delta x + \int \left\{ \begin{array}{l} N d x (\delta y - p \delta x) + \\ P d x (\delta p - q \delta x) + Q d x (\delta q - r \delta x) + \\ R d x (\delta r - s \delta x) + \&c. \end{array} \right\} = \\ V \delta x + \int N d x (\delta y - p \delta x) + \int P d x (\delta p - q \delta x) \\ + \int Q d x (\delta q - r \delta x) + \int R d x (\delta r - s \delta x) \dots (B)$$

This being established, let us make $\delta y - p \delta x = \delta w$, (a substitution that will be employed in what follows,) and differencing, we shall have

$$d \delta y - d p \delta x - p d \delta x = d \delta w.$$

But the formula $dy = p dx$ gives, by taking the variations,

$$\begin{aligned} d \delta y &= d x \delta p + p d \delta x, \text{ or} \\ d \delta y &= d x \delta p + p d \delta x, \text{ or} \\ d \delta y - p d \delta x &= d x \delta p. \end{aligned}$$

$$\begin{aligned} \int P d \delta w &= P \delta w - \int d P \delta w \\ \int \frac{Q d^2 \delta w}{d x} &= \frac{Q d \delta w}{d x} - \int \frac{d Q d \delta w}{d x} = \frac{Q d \delta w}{d x} - \frac{d Q \delta w}{d x} + \int \frac{d^2 Q \delta w}{d x} \\ \int \frac{R d^3 \delta w}{d x^2} &= \frac{R d^2 \delta w}{d x^2} - \int \frac{d R d^2 \delta w}{d x^2} = \frac{R d^2 \delta w}{d x^2} - \frac{d R d^2 \delta w}{d x^2} + \int \frac{d^2 R d^2 \delta w}{d x^2} = \\ &= \frac{R d^2 \delta w}{d x^2} - \frac{d R d^2 \delta w}{d x^2} + \frac{d^2 R \delta w}{d x^2} - \int \frac{d^3 R \delta w}{d x^2}; \text{ and so on.} \end{aligned}$$

Whence, making the necessary substitutions, we obtain finally

$$\delta \int V d x = \left\{ \begin{array}{l} \int d x \delta w \left(N - \frac{d P}{d x} + \frac{d^2 Q}{d x^2} - \frac{d^3 R}{d x^3} + \&c. \right) \\ + V \delta x + \delta x \left(P - \frac{d Q}{d x} + \frac{d^2 R}{d x^2} - \&c. \right) \\ + \frac{d \delta w}{d x} \left(Q - \frac{d R}{d x} + \&c. \right) \\ + \frac{d^2 \delta w}{d x^2} \left(R - \&c. \right) \\ + \&c. \dots \dots \dots (D) \end{array} \right.$$

a formula in which dx is supposed constant.

It will be seen from this expression for the variation $\delta \int V d x$, that it includes two distinct orders of terms, the one affected with the sign \int , and the other free from it. And farther, that the integration by parts necessarily introduces certain constant quantities which must be annexed

But

$$\delta t = \delta \int V d x = V \delta x + \int (d x \delta V - d V \delta x);$$

therefore,

$$\begin{aligned} d x \delta Z - d Z \delta x &= T V d x \delta x + T d x \int (d x \delta V - d V \delta x) - T d t \delta x \\ &= T d x \int (d x \delta V - d V \delta x); \end{aligned}$$

because $T V d x \delta x = T d t \delta x$.

Consequently we have

$$\delta \int Z d x = Z \delta x + \int T d x \int (d x \delta V - d V \delta x) \dots \dots (F)$$

Now integrating the last term by parts, and representing the integral $\int T d x$ by h , for the sake of abridging, the preceding equation becomes (F)

$$\delta \int Z d x = Z \delta x + h \int (d x \delta V - d V \delta x) - \int h (d x \delta V - d V \delta x).$$

Whence, by substitution, we have

$$d x \delta p - d p \delta x = d \delta w.$$

Now putting for dp its equivalent $q dx$, we shall have

$$d x \delta p - q d x \delta x = d \delta w, \text{ or}$$

$$\delta p - q \delta x = \frac{d \delta w}{d x};$$

and as the quantity δw has for its value $\delta y - p \delta x$, by hypothesis we have again $\delta p - q \delta x = \frac{d(\delta y - p \delta x)}{d x}$. And

a calculation exactly similar to the preceding gives also,

$$\delta q - r \delta x = \frac{d(\delta p - q \delta x)}{d x} = \frac{d^2 \delta w}{d x^2}$$

$$\delta r - s \delta x = \frac{d(\delta q - r \delta x)}{d x} = \frac{d^3 \delta w}{d x^3}$$

$$\&c. = \&c.$$

Consequently the equation (B) becomes

$$\begin{aligned} \delta \int V d x &= V \delta x + \int N d x \delta w + \int P d \delta w \\ &+ \int \frac{Q d^2 \delta w}{d x} + \int \frac{R d^3 \delta w}{d x^2} + \&c. \dots (C) \end{aligned}$$

Now by the method of integrating by parts, we find, by making dx constant,

to the terms of the latter species. The aggregate of the terms affected with the sign \int extends through all the variation, *viz.* from its commencement to its termination, while the other quantities answer only to the beginning and end of the variation. This remark finds its application in treating of the *maxima* and *minima* of quantities.

PROB. III.

To determine the variation of the indefinite compound integral $\int Z d x$, Z being a given function of the indefinite simple integral formula $\int V d x$, where again V is a function of $x, y, z, p, q, r, &c.$ as in the preceding problems.

First by Prob. I.

$$\delta \int Z d x = Z \delta x + \int (d x \delta Z - d Z \delta x) \dots (E)$$

And supposing $\int V d x = t$, or $V d x = dt$; since Z is by hypothesis a function of t , we shall have $dZ = T dt$, T being a given function of t , and we shall thus have $\delta Z = T \delta t$; therefore

$$d x \delta Z - d Z \delta x = T d x \delta t - T d t \delta x.$$

VARIATION.

This being premised, and making here for the values of dV and δV the same suppositions, and the same calculations as in the preceding problem, we shall obtain

$$\begin{aligned}
 & b f (d x \delta V - d V \delta x) = \\
 & b f d x \delta w \left(N - \frac{d P}{d x} + \frac{d^2 Q}{d x^2} - \frac{d^3 R}{d x^3} + \&c. \right) + \\
 & b \delta w \left(P - \frac{d Q}{d x} + \frac{d^2 R}{d x^2} - \&c. \right) \\
 & \frac{b d \delta w}{d x} \left(Q - \frac{d R}{d x} + \&c. \right) \\
 & \frac{b d^2 \delta w}{d x^2} (R - \&c.) (G)
 \end{aligned}$$

And we shall find in the same manner, by putting bN for N , bP for P , bQ for Q , $\&c.$

$$\begin{aligned}
 & f b (d x \delta V - d V \delta x) = \\
 & f d x \delta w \left(b N - \frac{d (b P)}{d x} + \frac{d^2 (b Q)}{d x^2} - \frac{d^3 (b R)}{d x^3} + \&c. \right) \\
 & + \delta w \left(b P - \frac{d (b Q)}{d x} + \frac{d^2 (b R)}{d x^2} - \&c. \right) \\
 & + \frac{d \delta w}{d x} \left(b Q - \frac{d (b R)}{d x} + \&c. \right) \\
 & + \frac{d^2 \delta w}{d x^2} (b R - \&c.)
 \end{aligned}$$

$$\delta f Z d x = \left\{ \begin{aligned}
 & f d x \delta w \left(k N - \frac{d (k P)}{d x} + \frac{d^2 (k Q)}{d x^2} - \frac{d^3 (k R)}{d x^3} - \&c. \right) \\
 & + Z \delta x + k \delta w \left(k P - \frac{d (k Q)}{d x^2} + \&c. \right) \\
 & + \frac{k d \delta w}{d x} \left(k Q - \frac{d (k R)}{d x} + \&c. \right) \\
 & + \frac{k d^2 \delta w}{d x^2} (k R - \&c.) (H)
 \end{aligned} \right.$$

PROB. IV.

To determine the variation of the indefinite integral formula $\int Z d x$, Z being a function of $x, y, p, q, r, \&c.$; and of the indefinite simple integral formula $\int V d x$, where V is the same as before.

First, we have

$$\delta \int Z d x = Z \delta x + f (d x \delta Z - d Z \delta x) (I)$$

Let us suppose $\int V d x = t$, or $V d x = dt$. The quantity Z being given in $t, x, y, p, q, \&c.$ we shall have

$$\begin{aligned}
 d Z &= L' d t + M' d x + N' d y + P' d p + Q' d q + \&c. \\
 \delta Z &= L' \delta t + M' \delta x + N' \delta y + P' \delta p + Q' \delta q + \&c.
 \end{aligned}$$

expressions in which the quantities $L', M', \&c.$ are functions of $t, x, y, p, q, \&c.$

Whence we draw, by a proceeding similar to that which has been employed in the second problem,

$$\begin{aligned}
 d x \delta Z - d Z \delta x &= L' (d x \delta t - d t \delta x) + N' d x (\delta y - p \delta x) \\
 &+ P' d x (\delta p - q \delta x) + Q' d x (\delta q - r \delta x) \\
 &+ R' d x (\delta r - s \delta x) + \&c.
 \end{aligned}$$

But $d t = V d x$, and $\delta t = \delta \int V d x = V \delta x + \int (d x \delta V - d V \delta x)$; therefore

$$L' (d x \delta t - d t \delta x) = L' d x (d x \delta V - d V \delta x);$$

Finally, substituting in Equation (G), instead of $b f (d x \delta V - d V \delta x)$ and $f b (d x \delta V - d V \delta x)$, their values, which we have found above, we shall have the expression for the variation of $\delta \int Z d x$.

As in these sorts of problems, it is required to find the variation which answers to a given absciss a , it is evident that in denoting by H the integral $\int T d x$, corresponding to this absciss, we may regard H as a given constant quantity relative to the total variation, while b constantly represents the indefinite integral $\int T d x$, that is to say, the integral for an indeterminate part of the absciss a .

Then, in writing H for b in the part

$$b f (d x \delta V - d V \delta x),$$

and passing H under the sign of integration, the expression

$$b f (d x \delta V - d V \delta x) - f b (d x \delta V - d V \delta x)$$

will become

$$\begin{aligned}
 & \int H (d x \delta V - d V \delta x) - f b (d x \delta V - d V \delta x) = \\
 & \int (H - b) (d x \delta V - d V \delta x).
 \end{aligned}$$

If, for the sake of abridging, we make $H - b = k$, which gives $d(H - b) = d k$, H being constant: now, making conformably to these remarks, and to these abbreviations, the substitutions indicated at the end of the preceding article for equation G, we shall find that this equation becomes

and thus Equation I. becomes

$$\begin{aligned}
 \delta \int Z d x &= Z \delta x + f \left\{ L' d x f (d x \delta V - d V \delta x) \right\} \\
 &+ f \left\{ N' d y f (\delta y - p \delta x) \right\} \\
 &+ P' d x (\delta p - q \delta x) + Q' d x (\delta q - r \delta x) \\
 &+ R' d x (\delta r - s \delta x) + \&c. . . . (K)
 \end{aligned}$$

Now if we represent by b' the integral $\int L' d x$, and take, by parts, the integration of the second term, we shall have

$$\begin{aligned}
 & \int L' d x f (d x \delta V - d V \delta x) = \\
 & b' f (d x \delta V - d V \delta x) - f b' (d x \delta V - d V \delta x).
 \end{aligned}$$

Let us suppose now that the value of the integral $\int L' d x$, for any determinate absciss a , is H' , and that b' still continues to represent the indeterminate integral $\int L' d x$; then, by passing H under the sign of integration, the term

$$\int \left\{ L' d x f (d x \delta V - d V \delta x) \right\}$$

becomes

$$\int (H' - b') (d x \delta V - d V \delta x):$$

or if $H' - b' = k$, then

$$\int k' (d x \delta V - d V \delta x).$$

VARIATION.

If now, as in the second problem, we make

$$dV = M dx + N dy + P dp + Q dq + \&c.$$

we shall have

$$dx \delta V - dV \delta x = N dx (\delta y - p \delta x) + P dx (\delta p - q \delta x) + Q dx (\delta q - r \delta x) + R dx (\delta r - s \delta x) + \&c.$$

$$\begin{aligned} \delta fZ dx &= Z dx + f \left\{ N'' dx (\delta y - p \delta x) + P'' dx (\delta p - q \delta x) \right. \\ &\quad \left. + Q'' dx (\delta q - r \delta x) + R'' dx (\delta r - s \delta x) + \&c. \right\} \\ &= Z \delta x + fN'' dx (\delta y - p \delta x) + fP'' dx (\delta p - q \delta x) \\ &\quad + fQ'' dx (\delta q - r \delta x) + fR'' dx (\delta r - s \delta x) + \&c. \end{aligned}$$

An equation which, being of the same kind as Equation (B), Prob. II. will give in the same manner, by making $\delta y - p \delta x = \delta w$, and supposing dx constant,

$$\delta fZ dx = \begin{cases} f dx \delta w \left(N'' - \frac{dP''}{dx} + \frac{d^2 Q''}{dx^2} - \frac{d^3 R''}{dx^3} + \&c. \right) \\ + Z \delta x + \delta w \left(P'' - \frac{dQ''}{dx} + \frac{d^2 R''}{dx^2} - \&c. \right) \\ + \frac{d \delta w}{dx} \left(Q'' - \frac{dR''}{dx} + \&c. \right) \\ + \frac{d^2 \delta w}{dx^2} (R'' - \&c.) + \&c. \dots (L) \end{cases}$$

It may be remarked here, the same as in Problem II., that the expression of this variation includes two distinct species of terms; *viz.* those which are affected with the sign f , and those that are free from it; and moreover, that the integrating by parts introduces certain constant quantities, which are additive to the terms of the second species; and that the aggregate of the terms affected with the sign f , extends through all the variation, *viz.* from the place where it commences to that where it finishes; while the other terms answer only to the beginning and end of the variation.

PROB. V.

To determine the variation of the indefinite simple integral $\int V dx$, where V is any given function of three variables x, y , and z , and their differentials.

We shall have at first, the same as in the formula of two variables,

$$\delta \int V dx = V \delta x - \int (dx \delta V - dV \delta x) \dots (M)$$

Let us suppose $dy = p dx$, $dp = q dx$, $dq = r dx$, $dr = s dx$, &c. $dz = p' dx$, $dp' = q' dx$, $dq' = r' dx$, &c. the letters p, q, r, s , &c. p', q', r' , &c. expressing functions of x, y, z , and their differentials.

Now making

$$dV = \begin{cases} M dx + N dy + P dp + Q dq + R dr + \&c. \\ + F dz + G dp' + H dq' + I dr' + \&c. \end{cases}$$

and hence, also,

$$\delta V = \begin{cases} M \delta x + N \delta y + P \delta p + Q \delta q + R \delta r + \&c. \\ + F \delta z + G \delta p' + H \delta q' + I \delta r' + \&c. \end{cases}$$

expressions in which N, M, P, Q, R , &c. F, G, H, I , &c. are given functions of x, y, z, p, q, r , &c. p', q', r' , &c. we shall find

$$\begin{aligned} dx \delta V - dV \delta x &= \\ N dx (\delta y - p \delta x) &+ P dx (\delta p - q \delta x) \\ + Q dx (\delta q - r \delta x) &+ R dx (\delta r - s \delta x) + \&c. \\ + F dx (\delta z - p' \delta x) &+ G dx (\delta p' - q' \delta x) \\ + H dx (\delta q' - r' \delta x) &+ I dx (\delta r' - s' \delta x) + \&c. \end{aligned}$$

Substituting, in equation (K), instead of $\int L' dx (dx \delta V - dV \delta x)$, its actual value $\int L' (dx \delta V - dV \delta x)$, and instead of $dx \delta V - dV \delta x$, the value assumed above, reuniting the several parts, and for the sake of abridging, making $L' N + N' = N''$, $L' P + P' = P''$, $L' Q + Q' = Q''$ &c. this equation will become

Now let $\delta y - p \delta x = \delta w$, and $\delta z - p' \delta x = \delta w'$; and supposing dx constant, we shall have, by precisely similar operations to those performed in Prob. II.

$$\begin{aligned} \delta \int V dx &= \\ f dx \delta w \left(N - \frac{dP}{dx} + \frac{d^2 Q}{dx^2} - \frac{d^3 R}{dx^3} + \&c. \right) &+ f dx \delta w' \left(F - \frac{dG}{dx} + \frac{d^2 H}{dx^2} - \frac{d^3 I}{dx^3} + \&c. \right) \\ + V \delta x + \delta w \left(P - \frac{dQ}{dx} + \frac{d^2 R}{dx^2} - \&c. \right) &+ \frac{d \delta w}{dx} \left(Q - \frac{dR}{dx} + \&c. \right) \\ + \frac{d^2 \delta w}{dx^2} (R - \&c.) &+ \delta w' \left(G - \frac{dH}{dx} + \frac{d^2 I}{dx^2} - \&c. \right) \\ + \frac{d \delta w'}{dx} \left(H - \frac{dI}{dx} + \&c. \right) &+ \frac{d^2 \delta w'}{dx^2} (I - \&c.) \\ + \&c. \quad \&c. &+ \&c. \quad \&c. \end{aligned}$$

To which it will be necessary to add certain terms, in order to complete the integral, as stated in the conclusion of our second and last problem.

The formulæ above considered are the simplest of their kind, and the solution of them is found by a calculation comparatively direct and easy to perform; but it may happen, that in the general expression $\int Z dx$, of which the variation is required, the quantity Z is a function of many variables, consisting of algebraical expressions and various indefinite simple integrals; or the quantity Z may depend upon the integration of an equation of any order; it may also, in some cases, be required to find the variation of a formula under a double

VARIATION.

a double or triple, &c. sign of integration, as $\iint Z dx dy$, in which Z is any function of x and y , and f of others. In all these cases, except the last, the variations are determined in the same manner, but the calculus of course becomes more long and intricate, which our limits will not allow of our entering upon in this place. On this head, therefore, the reader is referred to the several works mentioned in the introduction to the present article. We only propose giving here one problem, by way of illustrating the preceding calculus; *viz.*

To determine the curve OMD (*Plate XIII. fig. 2.*) through which a body will pass from the point O to D , not in the same vertical line, in the shortest time possible.

Let AV represent the vertical plane, in which are situated the two given points O and D ; AV the axis of the absciss; and the horizontal line AF that of the ordinates. Also, let us suppose any absciss $AP = x$, the ordinate $PM = y$, and consequently the element of the arc $Mm = \sqrt{(dx^2 + dy^2)} = dx \sqrt{(1 + p^2)}$, making $dy = p dx$.

Now whatever may be the nature of the curve OMD , the velocity of the body along and in the direction of the element of the curve Mm , is equal to that which it would have acquired in falling from a certain vertical height; all these heights deriving their origin in the same horizontal line, which we may suppose to be the axis of the ordinates AZ , the position of this axis being arbitrary.

Thus, calling g the gravity of the body, the velocity along Mm will be expressed by $\sqrt{2gx}$, and consequently

the time in passing $Mm = \frac{M}{\sqrt{2gx}} = \frac{dx \sqrt{(1 + p^2)}}{\sqrt{2gx}}$; therefore we shall have

$$\int \frac{dx \sqrt{(1 + p^2)}}{\sqrt{2gx}} = a \text{ minimum,}$$

or, simply

$$\int \frac{dx \sqrt{(1 + p^2)}}{\sqrt{x}} = a \text{ minimum.}$$

Now generally, when a quantity becomes a maximum or a minimum, its variation is equal to zero; consequently we shall have

$$\delta \int \frac{dx \sqrt{(1 + p^2)}}{\sqrt{x}} = 0.$$

Now this agrees with our formula $\int V dx$ in the second problem; *viz.* in the present case $V = \frac{\sqrt{(1 + p^2)}}{\sqrt{x}}$; consequently we shall have $dV = -\frac{\sqrt{(1 + p^2)}}{2x\sqrt{x}} \cdot dx + \frac{p}{\sqrt{x} \cdot \sqrt{(1 + p^2)}} \cdot dp$; an expression which, being compared with the general value

$$dV = M dx + N dy + P dp + \&c.$$

gives here

$$M = \frac{-\sqrt{(1 + p^2)}}{2x\sqrt{x}}; N = 0;$$

$$P = \frac{p}{\sqrt{x} \cdot \sqrt{(1 + p^2)}}; Q = 0, R = 0, \&c.$$

Now the expression of the variation $\delta \int V dx$ comprehends generally, as we have seen in Equation (D), two parts, the one indefinite, containing the sign \int , and the other definite, in which that sign is not found; and it is evident that these two parts are wholly independent of each other; and conse-

quently, if the whole is equal to zero, these two parts are each also equal to zero; thus the equation $\delta \int V dx = 0$, gives in general the two following equations, of which the one is definite, and the other indefinite; *viz.*

$$(1) 0 = \int dx \delta w \left(N - \frac{dP}{dx} + \frac{d^2Q}{dx^2} - \&c. \right)$$

$$(2) 0 = \begin{cases} V \delta x + \delta w \left(P - \frac{dQ}{dx} + \frac{d^2R}{dx^2} - \&c. \right) \\ + \frac{d \delta w}{dx} \left(Q - \frac{dR}{dx} + \&c. \right) \\ + \frac{d^2 \delta w}{dx^2} (R - \&c.) \\ + \&c. \\ + C, \text{ correction.} \end{cases}$$

Equation (1) is that on which depends the nature of curves, since the second member of this equation is an indeterminate expression, which being made equal 0, gives to the curve OMD the character of a maximum or a minimum. As to Equation (2), it belongs only to the extreme points of the curve OMD , which may be subject to particular conditions, wholly independent of the nature of the curve.

Now differencing Equation (1), and dividing the whole by $dx \delta w$, we shall have

$$(3) 0 = N - \frac{dP}{dx} + \frac{d^2Q}{dx^2} - \frac{d^3R}{dx^3} + \&c.$$

which gives generally the solution of the problem, where only the nature of the curve is required, that renders $\int V dx$ a maximum, or a minimum; V being a function of the perpendicular co-ordinates x and y of the curve, and of the quantities $p, q, r, \&c.$ which are given by the hypothesis $dy = p dx, dp = q dx, \&c.$ remembering that the differential dx has been supposed constant.

Now to apply these general results to our problem; since

we have $N = 0$, and $P = \frac{p}{\sqrt{x} \cdot \sqrt{(1 + p^2)}}$; also $Q = 0$,

$R = 0, \&c.$ our Equation (3) becomes

$$0 = \frac{-1}{dx} d \left(\frac{p}{\sqrt{x} \cdot \sqrt{(1 + p^2)}} \right), \text{ or,}$$

$$0 = d \left(\frac{p}{\sqrt{x} \cdot \sqrt{(1 + p^2)}} \right);$$

which is the differential equation of the curve OMD ; consequently, by integrating we shall have $\frac{p}{\sqrt{x} \cdot \sqrt{(1 + p^2)}}$

$= \frac{1}{\sqrt{a}}$, a being an arbitrary constant quantity. Now

substitute for p its value $\frac{dy}{dx}$, and we shall have

$$\frac{dy}{\sqrt{x} \cdot \sqrt{(dx^2 + dy^2)}} = \frac{1}{\sqrt{a}};$$

which gives

$$dy = dx \sqrt{\frac{x}{a - x}};$$

the equation of the reversed cycloid, its base being horizontal, and its generating circle having for its diameter the constant quantity a .

This equation being integrated, will receive a second arbitrary constant b ; and we shall have then, in the final equation, two constants, a and b , which will be determined from the condition that the cycloid passes through the two points, O and D ,

O and D, given in position. For other examples illustrative of this calculus, see the article ISOPERIMETRY.

VARIATION, in *Music*, is the different manner of playing or singing the same air, tune, or song, either by subdividing the notes into several others of less value, or by adding graces, in such a manner, however, as that the tune itself may still be discovered through all its embellishments, which the French call *broderies*.

Thus, great masters of the last century, flattering the bad taste of the public, have condescended to make variations to old tunes; as Corelli to Farinel's ground, or "All Joy to great Cæsar," which the Italians call "La Follia d'Espagna," and which he has made the theme of his whole twelfth solo. Handel and Tartini have composed simple airs on purpose to be the ground-work of variations. The late John Christian Bach, Fischer, Giardini, &c. have varied Scotch and Irish tunes to corrupt the public taste, instead of improving it by new compositions, which would have done them more credit, and given them less trouble. See THEME and DOUBLE.

"All Paris," says Rousseau, "used to go to the concert spirituel, to hear the variations of Messrs. Guignon and Mondoville; and still at a more recent period, those of Messrs. Guignon and Gaviniès, to the tunes of the Pont-neuf, which had no other merit than that of being trifled with by the two greatest performers on the violin in France."

VARICA, in *Ancient Geography*, a town of Asiatic Iberia, according to Ptolemy.

VARICELLA, in *Medicine*, a diminutive of *Variola*, (the small-pox,) signifying a vesicular eruption, accompanied with slight febrile symptoms, and occurring but once in the period of human life, which is popularly termed *chicken-pox* and *swine-pox*.

It will not be matter of surprise that this disease should bear the name of a *lesser small-pox*, and that it should have been described by the older writers as a modification of that distemper, under various similar appellations, such as *variola pusilla*, *volatica*, *spuria*, &c.; when we are informed by a late acute investigator of diseases, Dr. Willan, that, from the year 1800, to the time of the publication of his essay on vaccination, in 1806, he had seen *seventy-four* cases of chicken-pox that had been mistaken for small-pox, after vaccine inoculation. It is true, indeed, that the distinction has been rendered somewhat more difficult, in consequence of the milder degree, shorter duration, and modified form, which the small-pox itself has been made to assume by the influence of the previous cow-pox, in the few cases where it has occurred after this disease. Nevertheless, the resemblance is sufficient at all times to mislead ordinary observers; and the foreign nosologists, from Sauvages down to Burserius, have considered the disease as a species of *variola*. (See Sauvages Nosol. Method. class. iii. gen. 2. Vogel, De Cognoscend. et Curand. Hominum Morbis, § 128. Burserius, Inst. Med. vol. ii. cap. 9.) It is singular, however, that not only some of the earliest Italian writers on the small-pox, who lived three centuries ago, have distinctly described the chicken-pox under a specific name, *crystalli*, and with the mention of the scarcely perceptible fever, and absence of all danger (see Vidus Vidius, De Crystallis; and Ingrassias de Tumoribus præter Naturam, lib. i. cap. 1.); but that the vulgar, in several countries of Europe, had distinguished it by popular appellations, even while physicians were regarding it as a modification of small-pox. Thus Daniel Sennert, who was a professor at Wittemberg at the commencement of the seventeenth century, observes, in his Treatise on Small-pox and Measles, that there are other varieties, "præter communes variolas et morbillos," which are popularly known in Germany by the terms *scheffsblattern* (*sweep-pox*, or *sweep-*

blebs or *blains*) and *windboßen* (*wind-pox*). (See his Med. Pract. lib. iv. cap. 12.) And Riverius, who was professor at Montpellier at the same period, speaks of it as familiarly known by the common people in France by the name of *veirolette*. (See his Praxis Med. cap. ii.) In Italy it was also known to the vulgar under the appellation of *ravaglione*. Again, in our country, Fuller, who published his "Exanthematologia" in 1730, acknowledges himself indebted to the old women for his appellation. "I have adventured to think," he says, "this is what among our women goeth by the name of chicken-pock." (P. 161.) Other popular names have been given to the disease in different parts of this country. Thus it is in many places called *swine-pox*; in some, *bives*; and at Newcastle and Sunderland, *water-jags*. (See Dr. Wood in the Med. and Phys. Journal, vol. xiii. p. 58.) In some places, however, the different forms which the disease itself assumes, three of which have been distinctly described by the late ingenious Dr. Willan, are designated by the terms *chicken-pox*, *swine-pox*, and *bives*, respectively.

The character of each of these varieties, under which the varicella occasionally appears, we shall copy from the work of that excellent observer of diseases, as there is no other description of them extant of equal accuracy; and it is highly necessary to be able to discriminate between this eruption and the milder forms of small-pox, and especially that modified and altered *variola* which sometimes succeeds vaccination. The only other account of the chicken-pox in our language, which bears the stamp of observation, is a paper of the late excellent Dr. Heberden, another physician of the true Hippocratic school, written in the year 1767, and published in the first volume of the Transactions of the College of Physicians, and which we shall have occasion also to quote, on the point of diagnosis, in the sequel of this article.

Dr. Willan observes, "there are three varieties of the varicella, which, from the different forms of the vesicles, may be entitled the *lenticular*, *conoidal*, and *globate*." And he adds, in a note, "In the northern parts of England, and in some counties of Scotland, these varieties are denominated the chicken-pox, the swine-pox, and the hives. In the south, both the latter varieties are called swine-pox.

1. "The *lenticular* varicella exhibits, on the first day of eruption, small red protuberances, not exactly circular, and having a flat shining surface, in the centre of which a minute vesicle is soon formed. This, on the second day, is filled with a whitish lymph, and it then somewhat resembles a miliarial vesicle, but is not so prominent, so tense, or so regularly circumscribed: its diameter is about the tenth of an inch. On the third day, the extent of the vesicles continues the same, but the lymph they contain becomes straw-coloured. On the fourth day, many of the vesicles are broken at the most prominent part; the rest begin to shrink, and are puckered at their edges. Few of them remain entire on the fifth day, but the orifices of several broken vesicles are closed, or adhere to the skin, so as to confine a little opaque lymph within the puckered margins. On the sixth day, small thin brown scabs appear universally in the place of the vesicles. The scabs, on the seventh and eighth days, become yellowish, and gradually dry from the circumference towards the centre. On the ninth and tenth days they fall off, leaving for a time red marks in the skin, without depression.

"The eruption is generally first observed on the breast and back, and afterwards on the face and extremities. As fresh vesicles arise during two or three successive days, and go through the same stages as the first, the duration of the disease is sometimes longer than I have stated above.

2. "In the *conoidal* varicella, the vesicles rise suddenly, and have a hard inflamed border. They are, on the first day of their

VARICELLA.

their appearance, acuminated, and contain a bright transparent lymph. On the second day they appear somewhat more turgid, and are surrounded by more extensive inflammation than on the preceding day; the lymph contained in many of them is of a light straw-colour. On the third day, the vesicles are shrivelled; those which have been broken exhibit at the top slight gummy scabs, formed by a concretion of the exuding lymph. Some of the shrivelled vesicles, which remain entire, but have much inflammation round them, evidently contain on this day purulent fluid. Every vesicle of this kind leaves, after scabbing, a durable cicatrix or pit. On the fourth day, thin dark-brown scabs appear intermixed with others, which are rounded, yellowish, and semi-transparent. These scabs gradually dry and separate, and fall off in four or five days.

"A fresh eruption of vesicles usually takes place on the second and third day, and as each set has a similar course, the whole duration of the eruptive stage in this species of varicella is six days; the last-formed scabs, therefore, are not separated till the eleventh or twelfth day.

3. "In the swine-pox, or hives, the vesicles are large and globated, but their base is not exactly circular. There is an inflammation round them, and they contain a transparent lymph, which, on the second day of eruption, resembles milk-whey. On the third day, the vesicles subside, and, as in the two former species, become puckered or shrivelled. They likewise appear yellowish, a small quantity of pus being mixed with the lymph. Some of them remain in the same state till the following morning, but, before the conclusion of the fourth day, the cuticle separates, and thin blackish scabs cover the bases of the vesicles. The scabs dry and fall off in four or five days.

"The eruption is usually completed in three days, but I have sometimes observed a few fresh vesicles on the fourth day; in which case, therefore, the eruptive stage occupied eight days.

"The fever in varicella commences two or three days before the eruption appears, and it sometimes continues to the third day of the eruption, but is generally very slight. Its symptoms are, languor, with disposition to sleep, loss of appetite, thirst, heat of the skin, occasional flushing of the cheeks, a severe cough, soreness of the throat, a white fur on the tongue, a quick but unequal pulse, pains in the head, back, and limbs, sometimes pain in the stomach and bowels, with nausea, or vomiting of bile.

"The eruption usually commences on the breast and back, appearing next on the face and scalp, and lastly on the extremities. It is attended, especially in children, with an incessant tingling or itching, which leads them to scratch off the vesicles, so that the characteristics of the disease are often destroyed at an early period. Many of the vesicles, thus broken and irritated, but not removed, are presently surrounded by inflammation, and afterwards become pustules, containing thick yellow matter. These continue three or four days, and finally leave pits in the skin. The eruption is usually fullest in the conoidal form of varicella: I have seen the vesicles close together, or coherent, but seldom confluent. When they are numerous on the scalp, some of the glands below the base of the cranium are enlarged.

"The incidental appearance of pustules among the vesicles sometimes occasions a doubt respecting the nature of the eruption." See Dr. Willan's "Treatise on Vaccination," page 86.) Dr. Heberden says, "the principal marks by which the chicken-pox is distinguished are:

1. "The appearance, on the second or third day from the eruption, of the vesicle full of serum upon the top of the pock. The pustules which are fullest of the yellow liquor

resemble what the genuine small-pox are on the fifth or sixth day, especially when there happens to be a larger space than ordinary occupied by the extravasated serum. It happens to most of them, either on the first day that the little vesicle arises, or on the day after, that its tender cuticle is burst; a thin scab is then formed at the top of the pock, and the swelling of the other part abates, without its ever being turned into pus, as it is in the small-pox.

2. "Slight scabs cover the chicken-pox on the fifth day; at which time the small-pox are not at the height of their suppuration.

3. "The inflammation round the chicken-pox is very small, and the contents of them do not seem to be owing to suppuration, as in the small-pox, but rather to what is extravasated immediately under the cuticle by the ferous vessels of the skin, as in a common blister. No wonder, therefore, that this liquor appears so soon as on the second day, and that upon the cuticle being broken, it is presently succeeded by a slight scab. Hence too, as the true skin is so little affected, no mark or scar is likely to be left." See Med. Transf. of the Coll. of Physicians, vol. i. art. 16.

To these remarks Dr. Willan adds, that "variola pustules, on the first and second day of their eruption, are small, hard, globular, red, and painful. The sensation of them to the touch, on passing the finger over them, is similar to that which one might conceive would be excited by the pressure of small round seeds under the cuticle. In the varicella almost every vesicle has, on the first day, a hard, inflamed margin, but the sensation communicated to the finger in this case, is like that from a round seed, flattened by pressure." He also observes that, "on the third and fourth days, the shrivelled or wrinkled state of the vesicles which remain entire, and the radiating furrows of others, whose ruptured apices have been closed by a slight incrustation, fully characterise the varicella, and distinguish its eruption from the firm and durable pustules of small-pox. As the vesicles of the chicken-pox appear in succession during three or four days, a partial examination will not always discover the characteristic here specified. In order to form a proper judgment, practitioners should inspect the eruption on the face, breast, and limbs, attending more especially to the places in which it was first observed. If the whole eruption be viewed on the fifth or sixth day, every gradation of the progress of the vesicles will appear at the same time. This circumstance may be added to the diagnostics of varicella, as it cannot take place in the slow and regulated progress of the small-pox.

"The globated vesicles not having any resemblance to variolous pustules, distinguish the varicella from the small-pox, whenever they appear; for it is to be remembered, that these large vesicles are occasionally intermixed, both with the lenticular and conoidal vesicles of the chicken-pox. It may be said, that an acknowledged co-existence of different sets of vesicles in the same person tends to abrogate the distinctions I have made. The vesicles, however, are, in many cases, all of the same kind; or, where they are intermixed, one sort greatly predominates. I do not contend for the perfect accuracy of nosological arrangement, but I adopt it because it is in many respects convenient. Systems of botany and zoology are useful, though they have not been yet brought to perfection, for we find some species which break the order of every classification proposed." Loc. cit. p. 95.

With respect to the treatment of varicella, under any of its forms, very little need be said: since it is seldom attended by any severe indisposition, and often by scarcely any perceptible disorder of any of the functions, except a little lassitude and inability for the usual exertions, a whitish tongue,

tongue, and some loss of appetite. In these cases, the treatment consists rather in avoiding all causes of irritation, especially in the way of diet, than in the actual administration of medicines. Where the fever is more considerable, however, not only are these cautions necessary, but it will be proper also to evacuate the bowels, by gentle means, as by a little rhubarb, or neutral salts, to take diluent drinks, and gently diaphoretic medicines.

VARICOCELE, in *Surgery*, derived from *varix*, a dilated vein, and *κνίλη*, a tumour, sometimes denotes a varicose enlargement of the veins of the spermatic chord; but, more commonly, a similar disease of the veins of the scrotum; the term *circoccele* being usually applied to the other affection.

Varicocele, or a varicose enlargement of the veins of the scrotum, is a subject of but little importance; because these vessels are never thus affected, except in consequence of some other more serious disease of the testicle and its coats. Indeed the varicocele is to be regarded as the mere effect of another complaint, the removal of which is the only necessary indication. This having been attended to, the swelling of the scrotal veins, which was never itself a source of much inconvenience, always subsides without farther trouble.

Varicocele, considered as a varicose enlargement of the spermatic veins, is a disease that demands greater attention; but as it has been explained in a previous volume (see *CIRSOCELE*), we do not mean to detain the reader with it in the present place. One remark, however, appears to merit particular attention: a varicose swelling of the spermatic veins is more frequently than any other disease mistaken for an omental hernia. Mr. Astley Cooper has given the following rule, by which the two diseases may be distinguished. Place the patient in a horizontal posture, and empty the swelling by pressure upon the scrotum: then put the fingers firmly upon the upper part of the abdominal ring, and desire the patient to rise: if it be a hernia, the tumour cannot reappear as long as the pressure is continued at the ring; but if it be a circoccele, the swelling returns with increased size, on account of the return of blood into the abdomen being prevented by the pressure. See Cooper on Inguinal Hernia.

VARICOSE VEINS. The term *varix* is applied by surgeons to the permanently dilated state of a vein, attended with an accumulation of dark-coloured blood, the circulation of which is materially retarded in the affected vessel. When veins are varicose, they are not only dilated, but they are also evidently elongated, presenting a cylinder larger than natural, irregular, and in several places studded with knots. They likewise make a variety of windings, and, coiling themselves, form actual tumours from the assemblage of their convolutions in one particular place. The trunk and branches of a vein, thus dilated and elongated, constitute a very distinct swelling, when they are numerous, and confined to a certain part of the body. Indeed, when the diseased vessels are situated near the integuments, the surgeon can feel, and even see the outlines of their tortuous course. These things, for instance, are remarkably obvious in the *vena saphæna interna*, where the affection is particularly common. This vessel may be observed to form in its course several of these swellings, in the interspaces of which it runs in a very serpentine tortuous manner.

Varices are most commonly observed in the lower extremities, reaching sometimes even as far up as the abdomen. They have, however, been noticed in the upper extremities, and it is probable that the whole venous system is susceptible of the affection. As a well-informed writer observes, "the great venous trunks sometimes become varicose. When the disease is situated near the heart, it is attended with pulsation, which

renders it liable to be mistaken for aneurism. Morgagni observed that the jugular veins were occasionally very much dilated, and possessed a pulsation. (Letter xviii. art. 9, 10, 11.) He also relates a case in which the *vena azygos*, for the length of a span, was so much dilated, that it might be compared with the *vena cava*. The patient died suddenly in consequence of the rupture of this varix into the right side of the chest. (Letter xxvi. art. 29.) A similar case is related by Portal, who also mentions an instance, in which the right subclavian vein was excessively dilated, and burst into the chest. (Cours d'Anatomie Medicale, tom. iii. pp. 354. 373.) Mr. Cline described in his lectures the case of a woman who had a large pulsating tumour in her neck, which burst, and proved fatal by hemorrhage. A sac proceeded from the internal jugular vein; the carotid artery was lodged in a groove at the posterior part of this sac. The veins of the upper extremity very rarely become varicose. Excepting cases of aneurismal varix, the only instance of this disease with which I am acquainted is mentioned by Petit. (Traité des Maladies Chir. tom. ii. p. 49.) In this case a varix was situated at the bend of the arm: the patient was so fat, that no other vein could be found for the purpose of venesection, which operation Petit repeatedly performed by puncturing this varix. The superficial epigastric veins sometimes become varicose; but the most frequent seats of this disease are the *venæ saphenæ*, the spermatic and hemorrhoidal veins." (See Hodgson's Treatise on the Diseases of Arteries and Veins, pp. 538, 539.) The deep-seated veins of the extremities seldom become varicose.

The disease rarely occurs before the adult period of life, and its progress is extremely slow. It is very frequently remarked in pregnant women, who have passed a certain age; but it is particularly unusual for it to happen in young women, even during a series of repeated pregnancies. Surgeons have not hitherto made out any very precise information respecting the places, climates, and kinds of constitution which promote the occurrence of a varicose enlargement of the veins. Nor has it been well proved, that the disease often proceeds from swellings of the abdominal viscera, or any other species of tumour capable of mechanically obstructing the venous circulation. One or more veins of the same limb are at first most commonly affected with a slight degree of dilatation, without pain, or any sensation of uneasiness. This beginning change ordinarily advances with great slowness, except in cases where it accompanies pregnancy, in which circumstance one or both the lower extremities, as early as the first months, are frequently seen covered with largely dilated veins, or even with tumours formed by an assemblage of varices. The veins gradually become more and more distended, lengthened, coiled up, and tortuous. The patient then begins to complain of a sense of heaviness, numbness, and sometimes of very acute wandering pain through the whole of the affected limb. In a more advanced stage, in proportion as the varices increase, and especially when the dilated veins actually form tumours, the limb swells, and becomes more or less œdematous, according to the extent of the disease, and the time which it has existed. M. Delpech thinks, however, that the œdema in this case is not such as to justify the conclusion, that the increased size of the veins, and the way in which they distend the integuments, produce a mechanical interruption of the function of the absorbent system. For, says he, we meet with, though not often, enormous varices, which are not attended with any swelling of the cellular substance; and we still more frequently see cases, in which there is a considerable degree of œdema, while the varices are scarcely remarkable. When the latter have prevailed a long while, and made

VARICOSE VEINS.

much progress, the coats of the affected veins are not unfrequently thickened, swelled, and indurated, forming a sort of half canal, or solid tube, which has been regarded as an excavation made by the pressure of the varix against the neighbouring bone. But the same phenomena are equally observable, when varicose veins lie at a distance from any bone, against which it can be pressed.

As Mr. Hodgson remarks, "the blood occasionally deposits frings of coagulum in varicose veins: when this is the case, the vessel is incapable of being emptied by pressure, and is firm to the touch. The deposition does not in general fill the vessel, but, by diminishing its calibre, it retards the flow of blood, and causes the dilatation to increase in the inferior portion of the vein, and in the branches which open into it." (On the Diseases of Arteries and Veins, p. 541.) This gentleman has seen four cases, in which the coagulum accumulated to such an extent, that the canals of the dilated vessels were obliterated, and a spontaneous cure was the consequence.

The excessive distension of the coats of a superficial vein produces an inflammatory irritation, at first in the adjoining cellular membrane, and afterwards in the integuments. These organs become at first connected together by the adhesive inflammation; and if the distension continue to operate, they may at length ulcerate, and burst, and hemorrhage be the consequence. In such cases, the effusion of blood has sometimes been very considerable; but, says M. Delpech, we have no example of its having proved dangerous. The syncope following it, or a moderate compression, has sufficed for its stoppage. A more common occurrence than bleeding, is the coagulation of the blood in the cavity of a varicose vein. The vessel then becomes hard and incompressible, and it loses that elastic yielding softness, which renders it capable of being diminished by gentle pressure. If the parts be already inflamed, Delpech conceives, that the clot in the diseased vein may act as an extraneous body, and bring on ulceration, by the effects of which it is at last brought into view. In this sort of case, it is extremely uncommon for hemorrhage to occur; for, in general, the vessel has been already obliterated by the preceding inflammation. But the ulcer itself is very difficult to heal, and may be kept up a long while by the œdematous swelling of the limb. Varices, or rather the œdema which is the consequence of them, has the same effect upon every other species of ulcer, and even upon the most simple solution of continuity. While the swelling of the limb cannot be dispersed; while the edges of a solution of continuity are kept asunder by the tense state of the skin; and while the divided parts are irritated by this painful tension; every thing is unfavourable to cicatrization. Thus, we see the most simple wounds, which have been allowed to suppurate, and ulcers, which should have healed rapidly, continue uncured a great many years, merely because the limbs, on which they are situated, are affected with an œdematous swelling, the consequence of varices. Such is the condition of things in the case which has been improperly named the *varicose ulcer*. Delpech *Traité des Maladies Chir.* tom. iii. sect. 8. art. 3.

In the investigation of the causes of varices, it is usual to dwell very much upon the mechanical obstructions which may affect the circulation of the blood in the veins. Surgeons have thought themselves justified in regarding this as the only cause, because a circular, moderate compression incontrovertibly retards the course of the blood in these vessels, and produces a temporary dilatation of them. The opinion has seemed also to derive confirmation from the knotty appearance of varicose veins, a circumstance which has been

accounted for by supposing, that the distension is greatest in the situation of the valves. Lastly, the idea is further supported on the well-known fact of the frequent occurrence of varices during the state of pregnancy. But it has not been remembered, that the use of garters, for example, is extremely common; but varices of the legs infinitely less frequent; that very large varices are met with in persons who have never employed any kind of ligatures, to which the origin of the complaint can be imputed; that when the dilatation of the veins extends to the thighs and parietes of the abdomen, no causes of this description even admit of suspicion; that varicose veins are observable round several kinds of tumours, especially scirrhi, when there is no possibility of pointing out any mechanical obstruction to the circulation of the blood; that varices sometimes make their appearance at the commencement of pregnancy, and long before the enlargement of the womb can impede the free return of the blood through the veins in the pelvis; that nothing is more unusual than a varicose dilatation of the veins of the lower extremities, in consequence of swellings of the abdominal viscera; and lastly, it has been forgotten that the knots of the dilated veins are far too numerous to admit of being ascribed to the resistance of the valves. It cannot be denied, that pressure applied in the track of the vessels, tends to promote their dilatation; but it can neither be considered as the only cause, nor as the principal one. The foregoing observations made by Delpech, render it probable, that some unknown general cause is concerned in producing varices, the formation of which may also be facilitated by the impediments to the free return of the blood, occasioned by certain attitudes, and particular articles of clothing.

Mr. Hodgson conceives it probable, that in some instances, the valves are ruptured in consequence of muscular exertions, or external violence, in which cases, the pressure of the column of blood is the first cause of the dilatation of the veins. Sometimes, also, the disease appears to arise from preternatural weakness in the coats of the veins, as in those instances in which, without any evident cause, it exists in various parts of the same person. *Treatise on the Diseases of Arteries and Veins*, p. 537.

Experience proves, says Delpech, that there is no certain mode of curing *varices*, strictly so called, which he thinks cannot be wondered at, since the nature and causes of the disease are completely unknown. The same source of knowledge, however, also proves, that the increase in the dilatation of varicose veins may be retarded, and that the œdematous swelling attendant on the complaint may be beneficially opposed. But these effects cannot be produced by resolvent, tonic, astringent applications, nor by aperient, diuretic, and purgative remedies, as some even of the latest writers so inconsiderately assert; but only by means of methodical and permanent compression. When the whole of a limb affected with varices is subjected to this last mode of treatment, the dilated veins subside, the circulation is more regularly performed, and the œdema and pain cease. There is not, says Delpech, any better method of healing the solutions of continuity in the soft parts produced or kept up, by the varicose state of the limb and its consequences. But as soon as the compression is discontinued, the varices make their appearance again, the pain recurs, the œdema returns, and the ulcers which were healed break out afresh. Compression, therefore, which absolutely required to be constantly employed, can be regarded only as a palliative, the more useful indeed, inasmuch as the changes which it brings about in the state of things are nearly equivalent to a perfect cure.

Inflammation of the integuments covering a varix, or varicose tumour, cannot invariably be prevented by compression, nor will this treatment always succeed even in removing the intolerable pain which sometimes attends numerous clusters of varicose veins. In the first case, rest and relaxing applications will often succeed; and in the second, the topical use of sedatives frequently gives relief. It has been proposed to puncture and empty varicose veins; but if a temporary emptiness and relaxation of these vessels, which are rendered painful by their distension, could remove the pain for a time, things would fall into the old state again in the course of a few days. If it should appear also, that the clotted blood had the effect of keeping up the unfavourable symptoms, it would be necessary to make a very considerable opening into the dilated vein, in order that the coagulum might be extracted. In such a case, it would be useless to tie the vessel above and below the opening, as has been recommended: the slightest compression is afterwards sufficient for the stoppage of the bleeding, and by the subsequent inflammation the vessel is certain of being obliterated.

We learn from Celsus, that the ancients were accustomed to remove varices by excision, or destroy them with the cautery. (*De Rê Medica*, lib. vii. cap. 3.) When the vein was much convoluted, extirpation with the knife was preferred; but in other cases, the dilated vessel was exposed by an incision, and then cauterized. Petit, Boyer, and many surgeons in this country, have also sometimes practised the operation of cutting out clusters of varicose veins.

Delpech remarks, that the extirpation of tumours composed of numerous varices, has been practised either for the purpose of removing the pain in the situation of the disease, or other inconveniences. This operation has been successfully performed; but it appears also not to have constantly had the effect of preventing the formation of new varices, and it has sometimes proved tedious, difficult, and severely painful in its execution. In fact, an erroneous judgment must necessarily be formed of the extent of these swellings, when they are judged of only from the appearance which they present under the skin. When we attempt to operate, says Delpech, we may be led to organs which ought not to be meddled with, and a long and extremely painful dissection may be found requisite. Besides, varices are not always confined to the superficial veins, and a relapse would be inevitable. These reflections tend to the conclusion, that operations of this sort should never be undertaken, except when the disease is accompanied with perilous symptoms, or nearly deprives the patient of the use of his limb.

It has been thought, that one of the established principles in the treatment of aneurisms might be advantageously extended to the cure of varicose veins. By tying the principal venous trunk above the point to which the varicose affection reaches, it is said that the course of the blood in the morbid vessels may be totally stopped; the column of this fluid contained in them made to coagulate; and the consequent obliteration of the vessels themselves accomplished.

The practice of tying veins for the cure of varices appears to have been employed in the days of Paré and Dionis, (*Cours d'Opérations de Chirurgie*, p. 610.) who have accurately described the operation of tying and dividing the vein between the two ligatures. Sir Everard Home has related many cases of varicose veins in the leg, some of them being accompanied with tedious ulcers, in which, after tying the vena saphæna major, where it passes over the inside of the knee, not only the dilatation of the veins of the leg was relieved, but the ulcers were readily healed. This proceeding has unquestionably been sometimes followed

with success; but it has also had its failures. Amongst other evils, an inflammation of the tied vein has been observed extending very far in the vessel, and succeeded by convulsions and death. Indeed, the dangers arising from an inflammation of the internal coat of the veins are now generally acknowledged, and every endeavour should be made to avoid them. A case which lately happened in one of the large hospitals of this metropolis, has fully proved them: we allude to the example, in which the femoral vein happened to be wounded in the operation for aneurism, and had a ligature applied round the small aperture accidentally made in it. Inflammation of its internal coat took place to a considerable extent, and the patient is supposed to have died of the indisposition resulting from it.

As Mr. Brodie observes, it seems to be now established by the experience of modern surgeons, that a mechanical injury inflicted on the trunk of one of the larger veins, is liable to be followed by inflammation of its internal membrane, and a fever of a very serious nature: and the occasional occurrence of these symptoms after the ligature, or even the simple division of the vena saphæna, has made surgeons less confident than formerly, of the propriety of attempting these operations for the relief of a varicose state of the branches of that vessel in the leg. Certain reflections, however, induced Mr. Brodie to think, that the same ill effects would not follow a similar operation performed on the branches themselves. "Where the whole of the veins of the leg are in a state of morbid dilatation, and the distress produced by the disease is not referred to any particular part, there seem to be no reasonable expectations of benefit, except from the uniform pressure of a well-applied bandage. But not unfrequently, we find an ulcer which is irritable, and difficult to heal, on account of its connection with some varicose vessels; or without being accompanied by an ulcer, there is a varix in one part of the leg, painful and perhaps liable to bleed, while the veins in other parts are nearly in a natural state, or at any rate are not the source of particular uneasiness. In some of these cases, I formerly applied the caustic potash, so as to make a slough of the skin and veins beneath it; but I found the relief which the patient experienced from the cure of the varix, to afford but an inadequate compensation for the pain to which he was subjected by the use of the caustic, and the inconvenience arising from the tedious healing of the ulcer, which remained after the separation of the slough.

"In other cases, I made an incision with a scalpel through the varix and skin over it; this destroyed the varix as completely as it was destroyed by the caustic, and I found it to be preferable to the use of the caustic, as the operation occasioned less pain, and as, in consequence of there being no loss of substance, the wound was cicatrized in a much shorter space of time. I employed the operation, such as I have described it, with advantage in several instances; but some months ago I made an improvement in the method of performing it, by which it is much simplified, rendered less formidable, not only in appearance, but also in reality; and followed by an equally certain, but more speedy cure.

"It is evident," says Mr. Brodie, "that the extensive division of the skin over a varix, can be attended with no advantage. On the contrary, there must be a disadvantage in it, as a certain time will necessarily be required for the cicatrization of the external wound. The improvement to which I allude consists in this; the varicose vessels are completely divided, while the skin over them is preserved entire, with the exception of a moderate puncture, which is necessary for the introduction of the instrument with which the incision

incision of the veins is effected. Thus the wound of the internal parts is placed under the most favourable circumstances for being healed, and the patient avoids the more tedious process, which is necessary for the cicatrization of a wound in the skin above.

“For this operation, I have generally employed a narrow sharp-pointed bistoury, slightly curved, with its cutting-edge on the convex side. Having ascertained the precise situation of the vein, or cluster of veins, from which the distress of the patient appears principally to arise, I introduce the point of the bistoury through the skin on one side of the varix, and pass it on between the skin and the vein, with one of the flat surfaces turned forwards, and the other backwards, until it reaches the opposite side. I then turn the cutting-edge of the bistoury backwards, and in withdrawing the instrument, the division of the varix is effected. The patient experiences pain, which is occasionally severe, but subsides in the course of a short time. There is always hemorrhage, which would be often profuse if neglected, but which is readily stopped by a moderate pressure, made by means of a compress and bandage carefully applied.” Mr. Brodie particularly enjoins the necessity of keeping the patient quietly in bed for four or five days after the operation, and removing the bandage and first dressings with the utmost care and gentleness. He also cautions surgeons not to make the incision more deeply than absolutely necessary. Inflammation of the coats of the veins has not occurred in any of the cases in which Mr. Brodie has adopted this method of treatment. This gentleman wishes it to be understood, however, that he does not recommend the practice indiscriminately, but with a due attention to the circumstances of each individual case. “The cases for which it is fitted, are not those in which the veins of the leg generally are varicose, or in which the patient has little or no inconvenience from the complaint; but those in which there is considerable pain referred to a particular varix; or in which hemorrhage is liable to take place from the giving way of the dilated vessels; or in which they occasion an irritable and obstinate varicose ulcer.” See *Medico-Chir. Trans.* vol. vii. p. 195, et seq.

On the subject of cutting through veins affected with varix, it is proper to observe, that even this plan has been known to bring on severe and fatal symptoms. Cases confirming this fact are recorded in a valuable modern work, which should be in the hands of every practical surgeon. (See Hodgson's *Treatise on the Diseases of Arteries and Veins*, p. 555, et seq.) It is but justice to state, however, that in these examples, Mr. Brodie's manner of doing the operation was not adopted.

As we have already noticed, cases of spontaneous varix in the veins of the arm are rarely observed. When these vessels become varicose, it is almost always in consequence of a communication being formed, in the operation of venesection, between the brachial artery and one of the veins at the bend of the arm. The superficial veins in this situation then become more or less dilated by the impulse of the stream of arterial blood which is thrown into them. There is, however, a good deal of difference between those accidental varices actually induced by a mechanical cause, and those which originate spontaneously, or from causes not very clearly understood. The former never acquire the size which the latter often attain; they never exceed a certain magnitude, whether pressure be employed or not; they never form tumours composed of an assemblage of varicose veins; they are never filled with tough coagula of blood; their coats are never thickened, nor constitute the solid half canal remarked in the other species of varices; the

skin which covers them is not disposed to inflame and ulcerate; they are not subject to occasional hemorrhage; and the limb is not affected with any œdematous swelling. (See Delpech *Traité des Maladies Chir.* tom. iii. p. 261.) These circumstances must render it sufficiently evident that all surgical interference in such a case would be entirely unnecessary.

For additional observations connected with the subject of varicose veins, see the article ANEURISM, where the aneurismal varix is described; CIRSOELE, where the varix of the spermatic cord is treated of; HEMORRHOIDS, where the diseased and enlarged veins of the rectum are considered; and VARICOELE, where those of the scrotum are noticed. Delpech *Précis Elementaire des Maladies réputées Chirurgicales*, tom. iii. Hodgson's *Treatise on the Diseases of Arteries and Veins*. Cooper's *Dictionary of Practical Surgery*.

VARICOSE Ulcer. See the preceding article, and ULCERS.

VARICOSE, or *Varicous*, a term applied to a kind of soft puffy swelling, or particular sort of ulcer in animals, mostly about the legs. See ULCERS, in *Animals*.

VARICULA, (diminutive of *varix*,) in *Surgery*, a varicose enlargement and dilatation of the veins of the tunica conjunctiva of the eye; a frequent consequence of chronic ophthalmia.

VARJEAS, in *Geography*, a town of Portugal, in the province of Beira; 14 miles S.E. of Lamego.

VARIEGATED LEAVES, in *Botany and Vegetable Physiology*, *folia variegata*, or more properly *variata*, are such as are irregularly blotched with white or yellow, constituting a variety, for the most part permanent, and which is not uncommon in several species of shrubs, trees, or herbs. The white variegation is most usually seen in Elder, some kinds of Elm, Round-leaved Mint, or *Mentha rotundifolia*, and Striped Grass, or *Phalaris arundinacea*; the yellow one in Jasmine, White Lily, and in many evergreens, as Holly, *Rhamnus Alaternus*, *Phillyrea latifolia*, *Aucuba japonica*, and many others. We have seen an accidental, very beautiful, specimen, in *Rumex obtusifolius*, but it was not permanent. A romantic garden, among some very uncommon and whimsical rocks at Plumpton, near Harrogate, was originally planted with nothing but variegated shrubs, of every species that could be procured. It might have delighted a Chinese, but the effect was not picturesque.

This change in the colour of leaves, more or less extended occasionally to the rest of the herbage, can be considered but as a sort of disease. The plants affected with it are much more tender, and difficult of cultivation, than in their natural state, as well as less luxuriant; witness *Antirrhinum Cymbalaria*, *Fritillaria imperialis*, and many others. Variegated Oaks are rare, and sickly. We do not recollect to have seen any Willow in this state, nor any Cherry, Plum, Currant, or Gooseberry. The Holly assumes different shades of yellow, sometimes accompanied with pink. *Prunus Lauro-cerasus* now and then puts forth an entirely white or colourless shoot, and we have several times met with the same circumstance in *Rosa canina*, but we do not know that either of these shrubs is permanently variegated.

The cause of these blotches in leaves is probably among those secrets of Nature, hardly, if ever, to be discovered. That it must consist in some quality of the soil, in which the original stock vegetated, is a probable conjecture, but no more. The variety commonly continues unimpaired, in offsets or cuttings from this original stock, in whatever soil they may be planted. Nevertheless, a shrub thus marked, or diseased, will now and then, from luxuriance of health, return to the pristine and natural verdure of its species,

making shoots of extraordinary vigour, which soon overtop and exclude the variegated parts of the same individual.

VARIETIES, in *Natural History*, a word used to express an accidental change in some body, which is not essential to it, and therefore does not constitute a different species.

The naturalists of former ages have run into great errors, in mistaking the accidental varieties of plants, animals, and minerals, for distinct species. Many of them have called a plant a new species, because its flower, which should have been blue or red, is white, on account of the poorness of the soil, or some other such reason. Mr. Ray has established a very good test for varieties in botany; he allows every thing to be a distinct plant, which will propagate itself in its own form by its seeds; but such as, when sown, lose their difference, and run back to the old standard, he accounts varieties, however great their distinctions may appear.

In the history of fish, as much confusion has been introduced, by mistaking varieties for distinct species, as in botany. Artedi is the only author who has rationally attempted to bring this part of natural history into order in this respect, and to settle regularly the rules by which to distinguish real and essential from accidental differences.

The principal grounds of the error of supposing varieties distinct species of fish have been these: the variable and inconstant colour of fish hath been mistaken for a specific difference; in this manner Rondeletius has described many varieties of the turdi, labri, and other fish, under the names of distinct genera.

Others have paid the same too great regard to the more constant varieties of colour, which are found only to differ in degree in the several individuals of the same species, and their differences to be only in the degrees of the same colour, which is much more intense in some, and more remiss in others. These differences can only make varieties of the same fish, the species remaining always the same. Of the same kind are the mistakes of those who esteem size or magnitude a specific character; and thus, out of the varieties of the same fish, occasioned by scarcity or plenty of food, or other such occasions, make larger or smaller species. The place where fish are caught is also another cause of making new species with these authors: thus, though the *perca fluviatilis* of Bellonius, and the *perca marina* of other authors, be the same fish, yet they are pretended to be different species. The time of spawning is also with some made a distinction of species; and thus we find the common pike divided into three species, according to its spawning, in spring, summer, and autumn, which it does according to the heat or coldness of the climate. See SPECIFIC NAMES.

All these differences are false and frivolous, and the utmost they can do is to make what are properly called varieties, though few of them are sufficient even for that. A salmon caught at sea is not different from one of the same brood caught in a river; and if the *perca marina*, falsely so called, be a little different from the *perca fluviatilis*, yet if its spawn will produce regular *perca fluviatilis*, its difference can only amount to a variety, not a distinct species.

The time of spawning is no essential difference; for we daily see the change of climate make changes of that kind in all creatures; and even in the same climate, and under the same circumstances, the same species of birds will afford some individuals much earlier or later in laying their eggs than others. Artedi Ichthyol.

VARIETIES, in *Botany and Vegetable Physiology*, are certain differences between individuals of the same species, which are not sufficiently important to constitute a specific

distinction, nor, however important or striking, are they permanent, except in offsets, buds, cuttings, or layers of the same individual. Even these are observed, sooner or later, to wear out; while, on the other hand, some varieties do appear to be continued, by seed, through successive generations, at least in annual plants; but a very slight degree of observation will shew that these gradually return to their original nature; sometimes very speedily. Varieties amongst eatable fruits seem to be the most numerous and the most lasting; but whether they are more so than others, which, being unimportant to mankind, pass unnoticed, as in the *Fungus* tribe, may be doubted. Mr. Knight, the learned and experienced President of the Horticultural Society, has convinced himself, and we believe most of his intelligent readers, that varieties of Apples and Pears have only a limited duration. (See SPECIES OF PLANTS.) Thus the most valuable, perhaps, of all, the Golden Pippin, and particularly the russet-coated kind of that fruit, is generally wearing out. It may be propagated by grafting; but the young trees, thus obtained, quickly canker, and cease to bear any fruit worth notice. Numbers of Apples and Pears, celebrated in the horticultural works of the French, and many known to have existed formerly in England, are no more to be found. Those who plant orchards draw out admirable plans upon paper, buy trees, and wait with great complacency for the produce, till they find themselves miserably deceived. Half their trees, possibly, bear something different from what was promised. So far they have a right to complain of an ignorant, careless, or dishonest nurseryman. The greater part of their whole stock, whether the fruit be good or bad in quality, cankers, turns mossy, or dies, in a few years. Some few hardy trees only, of ordinary fruits, perhaps remain. The soil is concluded to be unfit for apples, and the possessor bears his disappointment as well as he can. This is the literal history of several orchards, which have passed under our observation. We have also seen fine trees of Golden Pippins and Nonpareils, which twenty years ago bore full crops of excellent fruit, canker and die, without any apparent cause, so that "the places which knew them, know them no more." Such is the melancholy history of our orchards. But it is still more grievous to observe, that new varieties, which Mr. Knight, and some other patriotic cultivators, are obtaining every year from seed, prove far more transient than their predecessors, cankering and disappearing in four or five years. Some, however, we hope and trust, will remain, and that our descendants will not be destitute of the most valuable of all English fruits. With this important end in view, we cannot sufficiently recommend, to those who have the means, the raising of apple-trees from seed, every year, on a large scale. It has usually been the practice of such experimentalists to select the kernels of good apples, for their purpose; thinking such more likely to yield something analogous to their parent fruit. Perhaps they may inherit too much of the same constitution, and this may be the latent cause of their own short existence. Might it not be worth while to sow the seeds of healthy wild crab-trees, whose vigour might remain in their offspring? From such, doubtless, all our valuable varieties must, at first, have originated. Who can tell that the degeneracy so prevalent among the new-raised stocks, as to duration, may not be owing to the repeated cross impregnation of diseased worn-out varieties, which must take place in a garden? The ornaments of our courts and drawing-rooms may descend from the heroes of Cressy and Agincourt, but our modern heroes commonly rise from the ranks, and the quarter-deck.

In the ornamental department of horticulture, varieties

VARIETIES.

are much attended to. Cape Geraniums are raised, by crosses impregnation, which often excel their parents in size and beauty, and for a while are continued by cuttings, if not by seed. Nothing, however, can be more transitory than these ephemeral productions. We have adverted to some of them under the article *PELARGONIUM*. Double-flowered varieties are produced from time to time, either by nature or by some accident of cultivation, for which we cannot in any manner account. Thus, if we sow an hundred seeds of the common Annual Stock, *Cheiranthus annuus*, one, or perhaps many, of the plants may bear nothing but completely double flowers, all the rest being quite single. When such a variety occurs in any perennial, or shrubby, species of plant, it is justly prized, being capable of multiplication by cuttings, layers, &c.; and when variations of colour are superadded, as in the favourite *Camellia japonica*, the treasures of the conservatory are still more multiplied. We must be content, in the present state of knowledge at least, to seize each vegetable Proteus as it comes in our way, without attempting to explain, or to imitate, the cause of its transformation.

Colour is, of all things, most liable to vary in the petals of flowers. Almost every blue flower is capable of changing to white, and it appears that in several instances the seeds of the white variety more generally produce their like, than those of the natural-coloured flowers change to white. But this rule is not invariable. The seeds of Canterbury Bells, *Campanula Medium*, whether taken from a white or blue flower, appear, as far as we can judge, to produce a great majority of blue-flowered plants, with a few white ones. The elegant varieties of the Sweet Pea, *Lathyrus odoratus*, seem more constant; but they are comparatively of recent introduction amongst us, and it is probable they may in time wear out, like other more short-lived beauties.

Varieties in the luxuriance or flavour of annual herbs, or their seeds, which make the riches of a kitchen garden, require, of all things, the most assiduous attention of a cultivator. These are the most casual and fugacious of all things. They do, however, appear to be more within the control of a skilful gardener, than many above-mentioned; especially with regard to soil, or manure. An eminent London seedsmen assured the writer of this, that he found it expedient to send lettuce seed to a remote country, the south of France, for instance, one season, and its produce to Holland, or Germany, perhaps, the next, in order to preserve or improve its quality. Change of crops every body knows to be essential in farming, as well as change of seed. What are the various degrees of excellence in Wheat, Barley, or other grain, but varieties, in what possibly, when originally wild, resembled but an ordinary grass. These excellencies are kept up by culture, that is, by attention to the circumstances just detailed. Such attention is infinitely more requisite in the cultivation of high-fed, pampered, and delicate culinary vegetables, which, if at all neglected, soon return to their original kind, or more frequently vanish altogether. Varieties of Peas, obtained by crosses impregnation, are a late improvement in horticulture, which promises a more durable success. For this acquisition to our tables we are indebted to the skill and indefatigable exertion of Mr. Knight, who has also extended his philosophical inquiries and experiments to Strawberries. It is much to be wished that the test of distinction between a variety and a species, which this gentleman has assumed, or rather adopted from animal physiologists, may hold good. This is, their power of generating together, without limitation. That unquestionably distinct species in the vegetable king-

dom will, like the horse and the ass, produce a mule; and that such mules will, for a longer or shorter period, continue to propagate themselves, as the animal mule is said occasionally to do, we cannot deny. It is sufficient for the preservation of order in nature, that such bastard progenies are limited; nor have we any doubt that, if they were all diligently watched, their termination, sooner or later, might always be observed. But we are not the less aware of the hazard of drawing conclusions on this subject, without a sufficiently long course of observation; analogy, always in philosophy to be followed with caution, being in the present case peculiarly treacherous.

In practical botany, varieties often cause no small trouble. Linnæus was among the first who, upon sound principles, distinguished them from species. Tournefort, and most of his followers, enumerated all the different appearances of plants that fell in their way, without regard to their permanency, or specific distinction. Hence a plant with a blue or a white flower stands, in the works of these authors, as two different species; though manifestly the same in every other character, and perhaps produced from seed out of one and the same capsule. Linnæus blames Micheli for making sixteen species out of the common Dutch Clover. (See *TRIFOLIUM repens*.) Of these, some indeed prove more certainly distinct species than Linnæus imagined; but the rest are, many of them, distinguished by casual marks, that may or may not exist, in the same individual plant, the following season. Some botanists contend that the red and the white *Lychnis dioica*, so different in colour, must constitute two species. We have found the larger kind, which is usually white, with a pink flower, and thinking we had made a great acquisition, transplanted it into a garden. Next year the same root bore pure white flowers, and no others. All cultivators know how Tulips, Hyacinths, Anemones, and the garden Ranunculus, differ and vary in colour, from the same seed, and even on the same root at different seasons. The same plant of *Hydrangea hortensis* will produce pink or blue flowers according to the time of year, or the manner in which it is treated as to soil and watering. Bog-earth generally induces the blue tint. To multiply instances of this sort, would lead us beyond all bounds.

Pubescence has been thought to afford a good specific distinction, and in some cases it unquestionably does. Its direction is certainly very material, and has been applied by the writer of this to discriminate species of *Mentha*, as it has by Dr. Roth to establish distinct species of *Myosotis*. But the quantity of hairiness on a plant is very variable, and can hardly be said to mark even a variety. A perfectly smooth wild plant of *Mentha hirsuta*, the calyx and flower-stalk excepted, being transplanted into a garden, proved as hairy all over as any of its brethren, the very next season. On the subject of the specific characters, as opposed to mere varieties, we have already been sufficiently explicit, under the head *SPECIES of Plants*, nor need we here add any further illustrations.

Some botanical writers, even of the present day, are curious to mark varieties under each species. This may on some occasions, and in gardening books, be useful; but if their specific distinctions be well founded, each variety will of itself fall into its proper place. To dwell upon them is a trifling study, except so far as their different qualities may lead to any practical utility; or their various origins and changes, to any physiological instruction. With the latter intention, the ingenious Mr. R. Brown has, for some time past, been attentive to every strange deformity or mon-

strosity,

strosity, that has fallen in his way, in the parts of fructification; nor can it be doubted that, under so acute an inspector, new secrets of Nature are likely to be discovered. We shall conclude this subject with one remark, that, as in the establishment of generic or specific characters, no rule whatever is perfectly absolute; so there are several distinctions, in most instances decidedly indicative of a species, that in others hardly mark a variety. Such are, the leaves being opposite or alternate, simple or compound, serrated or entire: the flowers terminal or lateral, with or without petals. Examples of such differences, on the same individual plant, will occur to the recollection of every botanist; yet every one knows that, under the direction of common sense and the most trivial degree of observation, nothing can afford more clear and absolute specific characters.

VARIETIES, in *Gardening*, the different variations of plants of the same general nature from that of the parent or particular sort from which they came. They are, of course, the offspring of certain peculiar determinate sorts, which vary in some accidental particular of their habits of growth, or some other circumstance, from the natural original sort, or parent plant. But although this is the case, as their variations are, for the most part, confined to some particular part or parts, they still retain the specific mark or marks of distinction of the parent plant, which discriminates them from those of other different sorts. Consequently there are frequently numerous varieties from the same sort, all of which differ from it, either in their manners of growth, foliage, flowers, the economical qualities which they possess, or some other particular of a similar nature. All kinds of plants, both of the annual, biennial, and perennial descriptions, as well as those of the herb and tree sort, are liable to vary in this way. This is effected by different modes and kinds of culture, by the nature of the climate, by that of the soil, by the use of particular sorts of manure and other materials, by frequent changes in their situation, by age, and in many other methods, and respects their differences in size and magnitude, their luxuriant, dwarfish, erect or trailing growths, their being smooth or prickly; the nature and shape of their leaves, as broad, narrow, entire, divided, curled, spotted, variegated, round, oval, sharp, blunt, &c.; smooth, hairy, downy: in their flowers, as single, double, proliferous, white, red, blue, yellow, variegated, &c.: in their smell, as sweet-scented, rank-scented, &c.: also in the form, size, colour, taste, quality, &c. of the fruit, in some cases, as round, oval, oblong, smooth, furrowed, warted, hairy, downy, large, small, red, green, sour, sweet, compact, pulpy, &c. as in the cucumber, melon, apple, pear, gooseberry, currant, &c.: likewise, in particular instances, in the shape and appearances of the roots, as in the carrot, the radish, the turnip, the potatoe, &c.: in the manner of their producing their seeds, fruits, &c.; as in the hop, spinach, hemp, &c.; and the cucumber, melon, &c. And it takes place in many other circumstances.

However, notwithstanding these different modes of variation in the particular parts of the varying plants of a peculiar sort, if those of each such sort still all maintain the same specific mark of distinction as that which characterizes and discriminates the respective natural sorts from all others, it shews them all the offspring, or varieties, of the same original sort. For as every different and distinct sort, in any particular kind of plants, is discriminated by some peculiar, uniform, constant mark or appearance in some part of its growth, all the plants of the same particular kind unchangeably bearing exactly the same, are, notwithstanding their accidental variation in other parts of their growth, all

varieties of one sort. Consequently all the plants which are produced from the seed of the same particular sort, however they may put on different forms and appearances, are to be considered as the real varieties of it.

The difference betwixt any particular sort and that of a variety, is, that a really true sort, raised from seed, will, though it may sport into many variations, still retain and keep its true and invariable mark of distinction through all its varieties; and although there may be varieties of that particular sort with different sized leaves, and colours of the flowers, &c.; if the seed of any one be sown, it will probably produce young plants of all these kinds, each having the characteristic discriminating mark of the parent.

It is, indeed, in a great measure, from plants of the seedling kind, that the different varieties of particular sorts were first obtained, as in the case of the auricula, polyanthus, &c. each being a distinct sort of the same kind, and each of which consists of innumerable varieties, in the colours and variegations of the flowers, first gained in this way, the seed of the same plant often producing a great diversity in this respect, each variation of colour, &c. forming a real variety; but probably not one of them with a flower exactly like that of the original parent plant: yet each variety retains the specific difference of its respective particular sort, the auricula, for instance, never changing to the polyanthus, nor that to the auricula, but the varieties of each keep their proper distinction; as the auricula, in all its varieties, continues its *smooth fleshy serrated* leaves; and the polyanthus, its *rough-toothed* leaves. And the same is the case with the carnation, the ranunculus, the anemone, the tulip, and a great number of other flower-garden plants.

The tree kind, especially those for the production of fruit, are particularly disposed to form varieties, equally in their modes of growth, their foliage, and the fruit: for instance, one original sort of apple-tree is only admitted, but which furnishes an almost endless variety of fruit, in regard to shape, size, colour, taste, quality, &c. as well as in the growth of the trees, so far as respects their size or magnitude, the dimensions and colours of the foliage, &c.; the specific distinction of which is, *serrated leaves, and close-setting flowers in the form of an umbel*, which runs through all the numerous varieties, however different the trees may be in size, growth, leaves, and fruit. And the same takes place in the pear, the plum, the common cherry, the peach, and many others, there being only one principal sort of each of these, but the varieties of the fruit are many in number, which, in all these sorts of trees, were originally obtained from seedling plants, that is, such trees as were raised by setting the stones or kernels of the fruit. Almost all the fruit-tree kind sport greatly in their seedling plants, so that out of hundreds of trees raised from the seeds of the best fruits, very few, if any, will produce fruit exactly like that of the parent plant, or which possess any good perfection. Therefore, on account of the uncertainty of producing and continuing the approved sorts of fruit from seedling plants, recourse is constantly necessary to be had, in the practice of gardening, to the modes of grafting, budding, and, in some instances, the making of layers and cuttings, in order to propagate the intended and desired sorts, or to continue and increase any good newly acquired variety.

The greater number of varieties in herbaceous plants, as well as many kinds of fruit and other trees, are of a variable and sporting nature, so that when raised from seed, there is no dependance on having the seedling plants coming again of the same sort, but varying into different sorts of one another. In cases of this nature, the propagation of such of them as

VARIETIES.

are perennial, to continue them with certainty, is to be accomplished either by means of planting their suckers, or the offsets or slips of the roots, and in some by layers and cuttings, or in the woody descriptions by layers, cuttings, grafting, and budding; but in the annual tribe there is no other means than by sowing or setting the seed, except in some few sorts, by the planting of their cuttings, as in the chrysanthemum, nasturtium, and some others; however, in a great number of kinds, where particular attention has constantly been bestowed in saving the seeds from only the most perfect, they will continue tolerably permanent, and frequently come again the same, or with but very little variation.

In many sorts of plants of the kitchen-garden and annual flower kind, though there be a number of varieties in each, yet by good care, and constantly saving seed from the most perfect plants, which shew no signs of degenerating, they remain, year after year, permanent from seed.

But most of the perennial tribe, the herbaceous as well as the woody sorts, as being in general more variable from seed, afford great opportunities of continuing the permanency of any particular variety, by making use of the offsets from their roots, the suckers, layers, and cuttings, as well as by grafting and budding, as has been already seen.

It sometimes occurs, however, that plants, although not immediately raised from seed, will, on account of some accidental cause, vary materially from their usual natural growths, and assume quite different appearances, arising in consequence either of culture, climate, exposure, soil, age, disease, abundance, or deficiency of nourishment, contusions, or other similar circumstances; and by such means produce accidental varieties in some particular parts of their growth.

The ascertaining of the reality of the varieties is, in many sorts, readily and easily accomplished by a comparison of the variable plant with the specific distinctions of the natural sort; and the variations of growth of the variety with the same parts in the natural plant. But still there are many varieties that require all the skill and knowledge of the most expert gardener to fully distinguish and ascertain them. It is, however, of material importance, in many cases of practical gardening, to have a nice and correct notion of the varieties of the plants which are to be cultivated, as the work can thereby be performed with greater certainty and advantage, as well as with more and better effect.

In the first volume of the Transactions of the Horticultural Society, T. A. Knight, esq., makes the following conclusions on the means of raising new and early varieties of fruits: after stating that "variation is the constant attendant on cultivation, both in the animal and vegetable world;" and that "in each the offspring are constantly seen, in a greater or less degree, to inherit the character of the parents from which they spring:" that as every particular sort of fruit acquires its greatest state of perfection in some peculiar sort of soil or situation, and under some similar mode of culture; the proper choice of such "must be the first object of the improver's pursuit; and that nothing should be neglected which can add to the size, or improve the flavour of the fruit which it is intended to propagate. Due attention to these points will, it is contended, in almost all cases, be found to comprehend all that is necessary to insure the introduction of new varieties of fruit, of equal merit with those from which they spring;" but that, at the same time, "the improver, who has to adapt his productions to the cold and unsteady climate of this country, has still many difficulties to contend with; he has to con-

bine hardiness, energy of character, and early maturity, with the improvements of high cultivation. Nature has, it is maintained, however, in some measure, pointed out the path he has to pursue; and that, if it be followed with patience and industry, no obstacles will be found, which may not be either removed or passed over."

Thus, "if two plants of the vine, or other tree, of similar habits, or even if obtained from cuttings of the same tree, were placed to vegetate, during several successive seasons, in very different climates; if the one were planted on the banks of the Rhine, and the other on those of the Nile, each would adapt its habits to the climate in which it was placed; and if both were subsequently brought, in early spring, into a climate similar to that of Italy, the plant which had adapted its habits to a cold climate, would instantly vegetate, whilst the other would remain perfectly torpid. Precisely the same thing occurs in the hot-houses of this country, where a plant accustomed to the temperature of the open air, will vegetate strongly in December; whilst another plant of the same sort, and sprung from a cutting of the same original stock, but habituated to the temperature of a stove, remains apparently lifeless. It appears, therefore, that the powers of vegetable life, in plants habituated to cold climates, are more easily brought into action than in those of hot climates; or in other words, that the plants of cold climates are most excitable: and as every quality in plants becomes hereditary, when the causes which first gave existence to those qualities continue to operate, it follows that their seedling offspring have a constant tendency to adapt their habits to any climate in which art or accident places them." But it is remarked, that "the influence of climate on the habits of plants, will depend less on the aggregate quantity of heat in each climate, than on the distribution of it in the different seasons of the year." Where it comes on suddenly and violently after the plants have been long exposed to severe and intense cold, and their capability of being excited is, of course, greatly increased, or become abundant, the progress of vegetation will consequently be extremely rapid. But, on the contrary, where it takes place in a slow and irregular manner, and increases only in a tardy moderate way on plants which have been little affected with the preceding cold, and in which the powers of life have scarcely at any time been suspended, the progress is much more gradual and restrained. Thus the crab, which is a native of Russia as well as of England, has adapted alike its habits to each: the Siberian variety, when introduced into the climate of this country, retains its habits, expands its leaves, and blossoms on the first approach of spring, vegetating strongly in the same temperature, in which the native tree of that sort hardly displays any signs of life; and its fruit acquires a degree of maturity, even in the early part of an unfavourable season, which the variety of this country is rarely or ever seen to attain.

It is likewise suggested, that "similar causes are productive of similar effects on the habits of cultivated annual plants," but that "these appear most readily to acquire habits of maturity in warm climates; for it is in the power of the cultivator to commit his seeds to the earth at any season; and the progress of the plants towards maturity will be most rapid where the climate and soil are most warm." This knowledge is not only of great utility in many cases of gardening, but of much practical advantage in the business of agriculture.

It is added, that "the value to the gardener of an early crop has attracted his attention to the propagation and culture of the earliest varieties of many particular sorts of our esculent plants; but in the improvement of these, he is

more often indebted to accident than to any plan of systematic culture; and contents himself with merely selecting and propagating from the plant of the earliest habits, which accident throws in his way, without inquiring from what causes those habits have arisen; and few efforts have been made to bring into existence better varieties of those fruits which are not generally propagated from seeds, and which, when so propagated, of necessity exercise during many years the patience of the cultivator, before he can hope to see the fruits of his labour, industry, and attention." The attempts which the writer has made to produce early varieties of fruit are, it is believed, all that have yet been made; and though the result of them is by no means sufficiently decisive to prove the truth of the hypothesis he is endeavouring to establish, or the eligibility of the practice he has adopted, it is amply sufficient to encourage future experiment on the subject.

It is noticed, that the first sort of fruit which was subjected to experiment in this way, was the apple; some young trees of the desired varieties of which for propagation were trained to a south wall, until they afforded buds containing blossoms. The branches of which then, in the following winter, were detached from the wall, and removed to as great a distance from it as possible, in which state they continued till so far advanced in their blossoms in the following spring, as to be in danger from frost. Then the branches were trained to the wall, where each blossom allowed to remain quickly expanded, and formed fruit, that in a few months attained perfect maturity; and the seeds produced plants that have ripened the fruit much earlier than other trees raised at the same time from seeds of the same fruit grown in the orchard. In this trial, the blossoms of each variety were fecundated by the farina of another kind; from which is supposed to have been attained in this as well as other similar instances a greater vigour and luxuriance of growth; but no earlier ripening of the fruits than in the plants grown by the ordinary modes of culture. The early maturity of those mentioned, is consequently ascribed to the other peculiarity of circumstances under which the fruit and seeds ripened from which they sprang.

By the same method of culture, several new varieties, that are the offspring afforded by the Siberian crab and the richest apples of this country, were obtained in the intention of providing fruits for the presses that might ripen well in cold and exposed situations. The plants furnished in this manner possess a remarkable hardness and luxuriance of growth, appearing in every way perfectly suited to answer the intended purpose. In each of these trials, some of the new varieties inherited the character of the male, and others of the female parent, in the greatest degree; and of some varieties of fruit, especially of the golden pippin, a better example was obtained by the introduction of the farina into the blossom of another apple, than by sowing their own seeds. The new variety of the Downton pippin, obtained in this manner from the farina of the golden pippin, will, it is believed, be found, in a favourable season and situation, little if at all inferior to the golden pippin, when first taken from the tree; but it is a good deal earlier, and probably cannot be preserved so long in a perfect state.

The next trials were on the grape, which, though less successful than the above in producing new varieties, were not less favourable to these conclusions. After supposing a vine without fires in the winter, to afford a climate to the vine similar to that afforded by the southern parts of Siberia to the apple or crab-tree; the same extensive variation of temperature taking place in it, and the sudden transition

from great comparative cold to excessive heat, as productive of the same rapid progress in the growth of the plants and the advancement of the fruit to maturity; he states that his first attempt was to combine the hardness of the blossom of the black cluster, or Burgundy grape, with the large berry and early maturity of the true sweetwater, often confounded with the white chasselas and white muscadine. In this case, the seedling plants produced fruit in his vinery at the age of three or four years, and in some of them it was very early; but the bunches were short and ill-formed, and the blossoms did not set by any means so well as he had expected.

On substituting the white chasselas for the sweetwater, many varieties were obtained whose blossoms appeared perfectly hardy, and capable of setting well in the open air; and the fruit of some of them ripening a good deal earlier in the year than that of either of the parent plants. But the berries are smaller than those of the chasselas, having less tender and delicate skins: and though not without much merit for the desert, they are generally better calculated for the press. In the latter intention, in a cold climate, it is supposed that one or two of them possess very great excellence. From the white chasselas and sweetwater, plants have since been obtained, the appearance of which is greatly more promising: and the earliest variety of the grape he has ever yet seen was produced from a seed of the sweetwater, and the farina of the red Frontignac. It is a very fine grape, resembling the Frontignac in colour and the form of the bunch; but it is feared that its blossoms will prove too tender to succeed in the open air in this country; a single bunch consisting of a few berries is, however, all that has yet existed of this kind. Two new varieties of the vine, with striped fruit and variegated autumnal leaves, have also been produced from the white chasselas and the farina of the Allipo vine: one of these has ripened extremely early, and is thought a good grape. As in all attempts to obtain new varieties of fruit, the propagator is at a loss to know the kinds which are best suited to answer his purpose, those varieties of the grape which he has employed with the most success are mentioned. In short, the facts which he has obtained on this subject, leave no doubt in his mind that varieties of the grape capable of ripening perfectly in our climate, when trained to a south wall, as well as of other fruits better suited to this climate than those which are now cultivated, may be readily produced; but whether the method of cultivation which he has adopted and advised be the most eligible, must be left to the decision of future and more extensive practice and experience.

Trials similar to these have been made on the peach; but it is stated that nothing more can yet be said of the result of them, than that the plants are perfectly healthy and luxuriant in their growth, affording sufficient evidence in their leaves of the good quality of the future fruit. And though he is uncertain at what age plants of this sort become capable of producing blossoms, the sudden changes in the character of the leaves and growth of those raised by him, which are now in their third year, lead him to believe that they will be in a state to produce fruit at the age of three or four years.

Upon the whole, from these and a close attention to the subject for years, it may be maintained that new varieties of every particular sort of fruit will in general be better obtained from the introduction of the farina of one variety of it into the blossoms of another, than by propagating from any single kind. Where trials of this nature are made between varieties of different size and character, the farina of the

VARIETIES.

the smaller kind should be introduced into the blossoms of the larger, as under these circumstances it has generally, though with some exceptions, been found that there is a prevalence in the fruit of the character of the female parent, probably on the following account. The seed-coats are wholly generated by the female parent, and these regulate the bulk of the lobes and plantula; and it has been noticed, in raising new varieties of the peach, that when one stone contained two seeds, the plants these afforded were inferior to others. The largest seeds, procured from the finest fruit, and from that which ripens most perfectly and most early, should constantly be chosen. When it is intended to propagate new varieties in this manner, it will be necessary for the gardener to extract the stamina of the blossoms from which he purposes to propagate some days before the farina begins to shed. After young trees have risen from seed, a certain time must elapse before they become capable of bearing fruit, which, it is believed, cannot be shortened by any means of cultivation. Pruning and transplanting are equally hurtful; and no alteration in the character or merits of the future fruit can be effected during this length of time, either by manure or any sort of culture. The young plants should be suffered to extend their branches in every direction, in which they do not interfere with each other in a hurtful manner; and the soil be just sufficiently rich to promote a moderate degree of growth, without exciting the plant to preternatural exertion, which constantly brings on diseases. The soil of an old garden is particularly destructive in this way. The length of time that different sorts of fruit-trees require to attain the age of puberty, admits of great variation. The pear demands from twelve to eighteen years; the apple, from five to twelve or thirteen; the plum and cherry, from four to five years; the vine, three or four; and the raspberry, two years. The strawberry, if its seeds be sown early, affords an abundant crop in the following year; and he has produced several new and excellent varieties of this fruit; but the hautboy strawberry does not seem to propagate readily with the other varieties, possibly belonging to an original distinct sort. He has, however, obtained several offspring from its farina; but they have all afforded a feeble and abortive blossom, and been of little value.

In another paper in the same volume, the same writer, in speaking of raising new and early varieties of the potatoe, says that those who have cultivated early varieties of this plant, must have noticed that they never afford seeds or even blossoms, and that the only mode of propagating them is by the division of their tuberous roots. Also farther, that each variety has been found by experience, when long propagated, to gradually lose some of those good qualities which it possessed in the early stages of its culture; the duration of a variety in the state of perfection, being limited to about fourteen years. A good new variety of an early potatoe is, of course, considered highly valuable by the person who raised it; and as such early varieties, according to any method of culture heretofore practised, can only be gained by chance from seeds of late kinds, they are not very frequently produced. But by the method here directed, seeds are readily obtained from the earliest and best varieties; and the seeds of these may possibly, in successive generations, finally afford much earlier and better varieties than have yet appeared.

The cause of the constant failure of the early potatoe to produce seed has been suspected, and found "to be the preternaturally early formation of the tuberous root, which draws off for its support that portion of sap, which in other

plants of the same sort affords nutriment to the blossoms and seeds."

After taking several methods of placing the growing plants so as readily to prevent this, he found the following to be the best. He fixed strong stakes into the ground, and raised the mould in a heap round the bases of them, in perfect contact with their bottom parts; and then planted on their south sides the potatoes from which seeds were desired. As soon as the young plants were about four inches high, they were fastened to the stakes by means of shreds and nails, and the mould washed away, by a strong current of water, from the bases of their stems, so that the fibrous roots only of the plants entered into the soil. As the fibrous roots of this plant are perfectly distinct organs from the runners, which give existence and subsequently convey nutriment to the tuberous roots; and as the runners spring from the stems only of the plants, which are, in this mode of culture, placed wholly out of the soil, the formation of tuberous roots is easily prevented. Whenever this is therefore done, numerous blossoms will soon appear, and almost every blossom will afford fruit and seeds. It is also suggested as not improbable, that by introducing the farina of the small and very early varieties into the blossoms of those of larger sizes, and somewhat later habits, moderately early varieties, adapted to field culture, and winter use, may be obtained; the value of which to the farmer in the colder parts of the kingdom, whose crops of this root are followed by one of wheat, would be extremely great.

It is likewise stated by Mr. Biggs, in the above work, that the different varieties of the apple-tree may be raised in a ready manner by means of cuttings, and that the trees so produced, "from healthy one-year old branches, with blossom-buds upon them, will continue to go on bearing the very finest possible fruit, in a small compass, for many years. Such trees are also peculiarly proper for forcing, by way of curiosity or luxury, and, it is believed, that they are less liable to canker than when raised by grafting. This has been more than once experienced in the golden pippin, cuttings of which have remained seven years in perfect health, when grafts, taken not only from the same tree, but from the very branch, part of which was divided into cuttings, cankered in two or three years. This mode of raising young apple-trees was discovered by accident, from sticking cuttings of these kinds of trees into the ground, as flower-marks during a wet season, which took root.

In raising new varieties of carnations, much advantage has lately been found from ripening the feed of the old plants by means of placing them in the artificial heat or warmth of some sort of house, frame, or other contrivance of these kinds, as they naturally flower late in the season, and, of course, fully ripe seed can seldom be procured in that way for the purpose.

VARIETIES of Land, in Agriculture, the different sorts or qualities of it, as they relate to the nature and manner of its cultivation, or the uses to which it is applied. Though no general principles are probably yet capable of being laid down in regard to the comparative value or utility of different modes or plans of cultivation, or of the different methods of proceeding in respect to crops that are had recourse to in different cases and situations, as the real nature of it, and the particular circumstances to which it is exposed and liable, in every instance, are not sufficiently known; it is evident that all the less firm, close, and solid sorts of land are not so greatly benefited by much working over, as those of the stiff and cohesive kinds, in which minute division of their parts and full aeration are essentially necessary,

necessary, effects which are produced in the most extensive manner, under the drill practice of culture; but the labour, trouble, and expenditure attending its use, in some cases, may not be adequate to its benefits. Thus, the former and all the dry and less moist sorts of land are commonly well suited for the purposes of tillage and those of sheep-pasture; while the latter and those of the more wet and retentive kinds are more fitted to the raising broad-leaved crops, and those of the artificial and natural grass sorts. Stiff clayey or aluminous lands are mostly best suited for wheat crops, and those of the lime-stone or calcareous descriptions for producing sainfoin and clover crops. The varieties of land, too, are considerable, as they relate to different practices, such as those of draining, watering, and many others. See SOIL, SPRING and SURFACE-Draining, TILLAGE, and WATERING of Land.

VARIGNON, PETER, in *Biography*, was born at Caen, in France, in 1564, and originally intended for the church; but imbibing an early taste for the mathematics, this kind of science became the object of his attention, in the prosecution of which he was discouraged by his relations, who obliged him to devote some part of his time to theology. With the abbé St. Pierre, who studied philosophy in the same college, he formed an intimacy; and they mutually encouraged and aided each other in their favourite studies. The abbé took him to his house, and in order to render him more independent, bestowed upon Varignon out of his own income, which was only 1800 livres a-year, 300. In 1686 the abbé took him to Paris, where he wholly employed himself in the study of mathematics, and where he formed an intimacy with Du Hamel, Du Verney, and De la Hire. From Du Verney he acquired a considerable knowledge of anatomy, whilst in return he taught him the application of mathematical reasoning to that subject. In 1687 Varignon became known by his "Projet d'une nouvelle Mécanique," dedicated to the Academy of Sciences. This treatise was much admired, and served to introduce him to two considerable places, viz. that of geometrician to the Academy of Sciences, and that of professor in the college of Mazarine. In 1690 he published "Nouvelles Conjectures sur la Pesanteur;" and he became one of the most early cultivators of the science of infinitesimals. Of his application and industry we have ample evidence in the volumes of the Academy of Sciences; his papers are numerous, and contain complete theories on the laws of motion, central forces, and the resistance of different media. In 1703 he suffered much from his intense application, which impaired his naturally strong constitution, and reduced him for three years to a very languishing state. His physicians prohibited study, from which, however, he could not totally abstain. Having censured Dr. Wallis for asserting that there are certain spaces more than infinite, ascribed by this celebrated geometrician to hyperbolas, whilst Varignon maintained that they were finite, his criticism was shewn to M. Carré, and by him caused to be printed in the Memoirs of the Academy, without his knowledge. After his recovery, he resumed his application, by republishing his "Projet d'une nouvelle Mécanique" in a new and enlarged form, by an extensive correspondence, and by reading lectures to his scholars in the college of Mazarine, as well as in the royal college, in each of which he occupied a professor's chair. In the latter part of his life, much as he valued peace, he was engaged in a scientific dispute with an Italian monk on the subject of tangents, and the angle of contact in curves. In the two last years of his life he laboured under an asthmatic complaint, which baffled all remedies. At length,

having finished his lecture at the Mazarine college, on the 22d of December 1722, he died suddenly on the following night. His character, says Fontenelle, was as simple as his superior understanding could require. He had no jealousy of the fame of others; for, indeed, he was at the head of the French mathematicians, and one of the first in Europe. In the discharge of every personal and social duty he was conscientiously strict. On the theory of the mathematics few mathematicians have laboured more successfully than Varignon; introducing into this science that mode of generalization which characterises it, simplifying many of its principles, and resolving many questions that had not before been considered; such, especially, as relate to the doctrine of motion. His works, published separately, were "Projet d'une nouvelle Mécanique," 4to. Paris, 1687; "Des nouvelles Conjectures sur la Pesanteur," 12mo. 1692; "Nouvelle Mécanique," 2 tom. 4to. 1725; and his papers in the different volumes of the Academy of Sciences are very numerous. Montucla Hist. des Mathem. Fontenelle's Eloges des Académiciens.

VARILHES, in *Geography*, a town of France, in the department of the Arriège; 10 miles W.S.W. of Mirepoix.

VARILLAS, ANTONY, in *Biography*, was born in 1624 at Gueret, in the Upper La Marche, and upon his settlement at Paris, Gaston, duke of Orleans, made him his historiographer; and in 1655 he obtained a place in the royal library, very favourable for the prosecution of his historical studies. Huet says of him, that no man ever brought to the illustration of French affairs so rich a provision of valuable observations, or so copious a store of domestic narrative. But he adds, that his excellent qualifications were disparaged by his immoderate assurance, which led him to confide in his own conjectures and suspicions, and to relate with as bold assertion things for which he had no authority, and which were altogether fictitious, as if he had been an eye-witness of them. In fact, Varillas was destitute of the most essential and estimable quality of an historian, a love of truth; and this has rendered his voluminous labours of inferior value. His leading object seems to have been the gratification and amusement of his readers. In the prosecution of this object he at first succeeded; his books were much read, and Colbert gave him a pension, which was afterwards withdrawn. In lieu of this, he contented himself with a pension which the French clergy granted him, as the reward of his services to the Catholic cause, obtained for his "Histoire des Révolutions arrivées en Europe en Matière de Religion," a mere party performance, concerning which Menage said to the author, "You have given a history of heresy full of heresies." Bishop Burnet published a critique on part of it, which is said to have prevented Dryden from translating it; a task which was proposed to him, after his conversion to Popery, by James II. Bayle, and many others, have detected the errors and falsifications of Varillas. As his writings, which chiefly relate to French and Spanish history, are scarcely ever read or cited, it is needless to copy their titles. Varillas died in 1696, in easy circumstances, so that he left few legacies for pious purposes. Moreri. Huet. Nouv. Dict. Hist. Gen. Biog.

VARINAS, in *Geography*, a province and city of South America, which in the year 1787 was detached from the government of Maracaibo, and made a separate government, constituted at the expense of those of Venezuela and Maracaibo. The chief has only the title of political governor, although his functions, in the district assigned to him, are the same as those of other governors, in the civil, military, and

religious departments. He has also, like them, a salary of 1000 dollars a-year. In order to secure its defence, a militia was raised in 1803, and a garrison allotted to the city of Varinas, consisting of a company of 77 men. Varinas has been long known in the European markets, from the reputed quality of the tobacco which its territory produces; though it is in fact inferior to that which is raised elsewhere, particularly at Cumanacoa, in the province of Cumana. However, sugar, coffee, cotton, indigo, and in general all the fruits of the torrid zone, find here a soil adapted to each, and their quality is unrivalled. The commodities of this district are transported chiefly by water to Guiana; the shipping-place being five leagues below the city, at a spot called Tocunos. Within the jurisdiction of Varinas are also very large commons, furnishing a number of beeves and mules, that are exported by the Oronoko, or consumed in the province. This city enjoys a tolerably pure air, and its inhabitants are reckoned at 6000. The public edifices consist of one parish church and an hospital. It lies in N. lat. 7° 40', 100 leagues S.E. of Caraccas.

VARIN-KEY, a small island in the Spanish Main. N. lat. 11° 10'. W. long. 83°.

VARIOLA, in *Surgery*, the small-pox. See INOCULATION and SMALL-POX.

VARIOLA *Vaccina*, the cow-pox, sometimes termed by modern medical writers *vaccinia*. See COW-POX and VACCINATION.

VARIOLARIA, in *Botany*, a genus of the *Lichen* family, (see LICHENES,) named from the eruptive aspect of its fructification, resembling the small-pox, or measles, *variole* of modern medical writers.—Perfoon in *Ul. Annal. fasc. 7. 23.* Achar. *Prodr. 27.* Meth. 12. *Lichenogr. 67. t. 5. f. 1—9.* Syn. 129. *Sm. Engl. Bot. 2400.* *Prodr. Fl. Græc. Sibth. v. 2. 305.*—Class and order, *Cryptogamia Algæ. Nat. Ord. Algæ, Lichenes.*

Eff. Ch. Receptacles cup-shaped, with a torn border from the crust, powdery, with a fertile disk beneath.

The whole of this genus was confounded by Linnæus under his *Lichen fagineus*, and *L. lacteus*, so far at least as its species were then noticed. They now amount, in the last work of Acharius, to ten, all of a crustaceous nature, found, some on the trunks of trees, others on rocks or walls, one on the ground. We have several, of British origin, to add to this list.

1. *V. velata*. Veiled Variolaria. Achar. n. 1. (*Lichen velatus*; *Engl. Bot. t. 2062.* *Parmelia velata*; *Turn. Tr. of Linn. Soc. v. 9. 143. t. 12. f. 1.*)—Crust limited, tartareous, thin, rugged, greyish, with a pale edge. Receptacles small, crowded; disk yellowish, veiled with a white membrane; border thick, even, of the substance of the crust.—Found by Mr. W. Borrer, but rarely, on the bark of ash-trees in Suffex. The *crust* is thin, spreading in roundish patches, two or three inches broad, of a greenish-grey, corrugated in the disk, minutely fibrous at the edge. Receptacles numerous, sessile, shield-like, about a line in diameter, pale salmon-coloured, with a thick smooth border, from which a white membrane is drawn across the disk, so as entirely to conceal that part.

2. *V. multipuncta*. Many-dotted Variolaria. *Turn. Tr. of Linn. Soc. v. 9. 137. t. 10. f. 1.* Achar. n. 2. (*Lichen multipunctus*; *Engl. Bot. t. 2061.*)—Crust ash-coloured, warty, rugged, tartareous, thin, with a fibrous edge. Receptacles hemispherical, with a white, aggregate, powdery disk, and smooth, lobed border.—Found, not uncommonly, on the trunks of beeches in Suffex, by Mr. W. Borrer.—Nearly akin to the last, but the *crust* is more of a grey hue, and less uneven, though becoming rugged and

warty by age. It changes nearly to white in drying. *Fructifications* the size of the last, but essentially differing in the want of a separate membranous covering, and in having each *receptacle* marked with three or four depressions, making so many distinct disks, in one thick lobed border. The surface of these disks is white and powdery; their inside pale chestnut.

3. *V. globulifera*. Vesicle-fruited Variolaria. *Turn. Tr. of Linn. Soc. v. 9. 139. t. 10. f. 2.* Achar. n. 3. *Prodr. Fl. Græc. n. 2432.* (*Lichen globuliferus*; *Engl. Bot. t. 2008.*)—Crust spreading, faintly bordered, rugged, greyish with white powdery warts. Receptacles spherical, closed; at length bursting, with a thin ragged border, and blackish disk.—This also was discovered by Mr. W. Borrer, growing on the trunks of beeches and oaks in Suffex, but rarely. Dr. Sibthorp met with it in Greece. The *crust* agrees in appearance with the following, but the globular vesicles, of the size of small peas, scattered over the disk, and each lodging a blackish *receptacle* of seeds, are peculiar to the present species.

4. *V. faginea*. Common Bitter Variolaria. *Perf. in Uff. Ann. fasc. 7. 24.* Ach. Meth. 12. *Prodr. Fl. Græc. n. 2433.* (*V. communis*; Achar. n. 4. *Lichen fagineus*; *Linn. Sp. Pl. 1608.* Achar. *Prodr. 27.* Hoffm. *Enum. 18. A. t. 2. f. 4.*)—Crust cartilaginous, rugged, polished, greyish, bordered with brown. Receptacles prominent, hemispherical, mealy, very white, with a pale, flattish, at length naked, disk.—Very common on the trunks of beech, sycamore, oak, &c. throughout Europe, from Sweden to Greece. The *crust*, in a perfect state is circular, grey or greenish when young, corrugated, but with a smooth polished surface, and circumscribed by a thin border, elegantly coloured with concentric shades of brown. Numerous, prominent, almost stalked, tubercular *receptacles* are scattered over the central part, which are very white, especially in wet weather; powdery and somewhat convex in their disks, with a clumsy indistinct kind of border. By age these, like the *crust*, become of a dirty white. Mr. W. Borrer has first observed a very bitter taste in this species, not immediately perceptible, but after a while very strong, disagreeable and permanent, like the flavour of the *Cyclamen* root. No other species of *Variolaria* has been found to have this bitterness. We know not by what accident the learned Acharius, generally so accurate, has transferred it to our *discoidea*, which he has therefore called *amara*. His specific characters of the two species leave no doubt of what he intends under each, though we do not presume to decide on all his synonyms. This being the case, we do not feel authorized to change the old Linnæan name, though we readily allow that Linnæus here confounded two species.

5. *V. discoidea*. Flat-cupped Variolaria. *Perf. in Uff. Ann. fasc. 7. 23.* Achar. Meth. 14. (*V. amara*; Achar. n. 5. *Lichen discoideus*; Achar. *Prodr. 28.* *Engl. Bot. t. 1714.* *L. fagineus*; Hoffm. *Enum. 19. B, C, D. t. 7. f. 2, 5.* *L. albelcens*; Hudf. 529. *L. carpineus*; Lightf. 807. *Lichenoides candidum et farinaceum, scutellis ferè planis*; *Dill. Musc. 131. t. 18. f. 11.*)—Crust cartilaginous, cracked, somewhat rugged, polished, greyish, bordered with brown; at length powdery. Receptacles flattish, mealy, very white; at length concave, depressed, with a dilated torn border.—This is probably as common as the preceding, with which it has been confounded. The chief mark of distinction consists in the little elevation of its *receptacles*, which, after discharging their powdery contents, become quite concave, with a thin expanded margin. Hence the present plant has been separated by several botanists from *fagineus*, even without their adverting to its insipidity, remarked by Mr.

Borrer, and which obliges us to retain the old name *discoideus*, that of *amara* being only applicable to the former, where it is not wanted. On the trunks of old trees, particularly in wet weather, *V. discoidea* is very conspicuous for its whiteness. No proper *receptacle*, of a different colour from the frond, has been detected in this species.

6. *V. conglobata*. Conglobate Variolaria. Achar. n. 6.—“Crust tartareous, thick, milk-white, plaited and conglomerated, with a smooth cartilaginous surface. Warts of the receptacles close-pressed, of the same colour. Disk powdery. Margin elevated, tumid. Nucleus thick, included, yellowish; flattened above.”—Native of France. This appears by its colour, and the different habit of its parts, to be distinct from all the other known species. *Acharius*.

7. *V. griseo-virens*. Greyish-green Variolaria. Turner and Borrer Lich. Brit. v. 1. 54, unpubl. Engl. Bot. t. 2400.—Crust elliptical, thin, slightly tartareous, rugged, grey, scarcely limited. Receptacles roundish, with a narrow border. Powder greenish.—Gathered by Mr. Borrer, on the smooth cuticle of the bark of birch and cherry trees, in Norfolk. The patches, about an inch or two in length, and half as broad, look like a dirty stain, or some decayed *Lepraria*; but when accurately examined, prove to consist of a continued, rugged, though thin, *crust*, of a dirty greenish-grey, bearing very distinct mealy *receptacles*, of a yellowish rather bright green when wet, bordered with white.

8. *V. Cinchona*. Smooth Green Variolaria.—Crust elliptical, thin, cartilaginous, polished, nearly even, olive-coloured, slightly bordered with black. Receptacles round, white, mealy, with a smooth pale border.—Found on the bark of *Cinchona floribunda* from the island of St. Lucia. Our only specimen is above an inch in diameter, of a brighter more olive-brown than the bark, but otherwise scarcely distinguishable therefrom. The whitish *fructifications*, scattered all over it, smaller than pins' heads, are very conspicuous.

9. *V. aspergilla*. Sprinkled Variolaria. Achar. Meth. 13. Turn. and Borr. Lich. Brit. v. 1. 67. Engl. Bot. t. 2401. (*V. communis* g; Achar. Syn. 131. Lichen aspergillus; Achar. Prodr. 28, excluding the reference to Perfoon.)—Crust orbicular, tartareous, thickish, dull white, wrinkled, with a smooth, white, polished edge. Receptacles scattered, elevated, hemispherical, with an obsolete border. Powder very white.—Found by Mr. Borrer in Suffex, more commonly on rails than on trees. This gentleman and Mr. Turner have, on the authority of an original specimen, determined the synonym of *Acharius*. That learned botanist has sent us, under the same name, what has a different aspect, being whiter and full of cracks; and such may perhaps have induced him to refer his plant to *V. communis* (*faginea*) as a variety. However this may be, our *aspergilla* is infipid, and surely distinct from *faginea*; yet, though like *discoidea* devoid of bitterness, it cannot be confounded with this latter. The edge is polished and white; the rest of a pale greyish or blueish hue, unaltered by moisture. *Receptacles* neither numerous nor crowded, but scattered, convex, very prominent; their border minute, and soon obliterated; their internal *disk*, or *nucleus*, pale flesh-coloured, concealed by the copious white powder, which forms a dense mass, and turns greenish by rubbing.

10. *V. cinerea*. Ash-coloured Variolaria. Engl. Bot. t. 2411.—Crust orbicular, tartareous, thin, ash-coloured, cracked; its circumference indeterminate. Receptacles orbicular, very small, white, with an elevated margin, and a flesh-coloured concealed disk.—Discovered by the Rev. Mr. Harriman, on whinstone rocks, in the county of Durham. We conceive it to be of all things most distinct from the following, with which it is said to have been confounded.

The colour and great tenuity of the *crust*; the want of an expanded or zoned border; the more evident red *nucleus*; and the much smaller *receptacles*; all mark it with precision. The white powder of the latter is easily abraded, and then the *disk* or *nucleus* becomes conspicuous.

11. *V. lactea*. Milky-white Variolaria. Perf. in Uft. Ann. fasc. 7. 24. Achar. n. 7. Meth. 14. t. 1. f. 6. Engl. Bot. t. 2410. Turn. and Borr. Lich. Brit. v. 1. 69, unpubl. (Lichen lacteus; Linn. Mant. 131. Hudf. 526. Wulf. in Jacq. Coll. v. 3. 107. t. 4.)—Crust orbicular, tartareous, thick, white, cracked; thin, polished, zoned and flesh-coloured in the circumference. Receptacles orbicular, very white, with an elevated margin when young.—Found on rocks in the north of Europe. Mr. Harriman's specimen, on whinstone, from Durham, figured in Engl. Bot., shews this elegant species in great perfection. Its diameter is often from three to five inches. The finely granulated, tartareous, cream-coloured central part, is bordered by a broad thin circumference, polished almost like satin, marked with many concentric lines or plaits, and tinged with a delicate flesh-colour at the extreme edge. *Fructification* when young small, and shield-like, with a thick border; but the disk becomes very white, powdery, and much elevated. Mr. Turner found a pale brown *nucleus*, which we have not seen.

12. *V. dealbata*. White-wash Variolaria. Decand. Franco. v. 2. 525? Engl. Bot. t. 2519. (*V. corallina*; Achar. n. 8. Lich. Univ. 319. t. 5. f. 6. Lichen dealbatus; Achar. Prodr. 29. *Ilidium corallinum*, a supposed variety; Achar. Meth. 138. t. 3. f. 7, D, E, bad. *I. paradoxum*; Turn. and Borr. Lich. Brit. v. 1. 97.)—Crust tartareous, thickish, greyish-white, cracked, tumid, papillary and rugged; obscurely zoned at the circumference. Receptacles orbicular, prominent, white, with an aggregate internal disk.—Not rare on rocks in mountainous countries. Differs from the last in having a very narrow, imperfectly zoned, border, and especially in the cylindrical, papillary, erect processes, sometimes in pairs, scattered over the crust. The *receptacles* when young are small, concave, powdery, white cups; but the few which arrive at maturity become raised, convex, the size of hemp-seed, their surface still white and powdery, but finally displaying several little, concave, brownish or flesh-coloured, separate disks. We are not quite free from doubts, as to the plant of *Acharius* being the same as our's, and therefore we would not hastily follow him in altering the name, by which we have already adopted this most distinct and curious species in the English Botany.

13. *V. tiflea*. Georgian Variolaria. Achar. n. 9.—“Crust somewhat tartareous, unequal, white. Receptacles minute, hemispherical, powdery, very white; nucleus lenticular, concealed, afterwards exposed, furrowed with a margin from the crust, and finally deciduous.”—Found on the ground, near Tiflis in Georgia. A minute species. *Nucleus* slightly convex, at length nearly globose. *Acharius*.

14. *V. gaditana*. Spanish Variolaria. Achar. n. 10.—“Crust nearly orbicular, tartareous, continued, rugged, grey, slightly powdery; its circumference somewhat crenate, or partly cylindrical, crowded in the centre, and of the same colour.”—Gathered on walls near Cadiz, by Don Simon de Roxas Clemente. The *warts*, or *receptacles*, whether hemispherical or somewhat cylindrical, become concave with age.

VARIOLITE, in *Mineralogy*, a name given by some mineralogists to porphyritic rocks, in which the imbedded substances

substances are imperfectly crystallized, or are rounded, giving the stone a spotted appearance.

VARIORUM, in *Matters of Literature*, a term or phrase of abbreviation, used for an edition of a classic author, printed in Holland, with the notes of divers authors upon it: *Cum notis variorum*, or *cum selectis variorum observationibus*.

In this sense we say, *Plautus variorum*; a set of Dutch *variorums*, &c. Many of the *variorums* are valuable editions.

The word is the genitive plural of the Latin *varius*, *different*, *divers*.

VARIS, in *Ancient Geography*, a place of the isle of Albion, on the route from Segontium (Caernarvon) to Deva (Chester), between Conovium (Caer-Rhyn) and Deva; supposed to be Bodvay; 32 miles from Deva, or Chester.

VARIUS, in *Ichthyology*, a name used by most authors for a small fresh-water fish, common in brooks and running waters, and well known in England by the name of the *minnow*.

VARIUS *Mus*, in the old authors of *Zoography*, a name used for the same creature they otherwise called *mus ponticus*; which seems to have been no other than the European flying squirrel.

VARIX, from *varius*, *irregular*, in *Surgery*, denotes an uneven swelling of a dilated vein. The tumour is softish, generally not painful, and presents an appearance as if studded with several knobs, or tubercles, which correspond to the valves in number and situation. The diseased vein is also elongated as well as dilated, and describes in its course a variety of windings or convolutions. A particular account of the symptoms, causes, and treatment of this common disease, will be found under the head of **VARICOSE Veins**.

VARIX, in *Animals*, a sort of puffy dilatation or enlargement in some part of a vein, forming a kind of knot. It mostly happens in the veins of the legs, and is of the nature of spavin. It may readily be removed, on its first appearance, by the use of cold solutions, and applications of that sort, frequently applied, and suitable bandages.

VARLER, in *Geography*, a town of Germany, in the bishopric of Munster; 4 miles N.N.W. of Coesfeld.

VARLET. See **VALET**.

VARMAT, in *Geography*, a town of Hungary; 12 miles N.N.W. of Zatmar.

VARMO, a river of Italy, which runs into the Tajaumento, 2 miles N. of Latisfana, in the country of Friuli.

VARNA, in *Ancient Geography*, a town of Asia, in the interior of Media. Ptolemy.

VARNA, in *Geography*, a sea-port town of European Turkey, in Bulgaria, situated on a gulf or bay of the Black sea, to which it gives name, at the mouth of the river Vrana; the see of a Greek archbishop. In the year 1444, Ladislaus, king of Hungary, was defeated and slain by Amurath I. emperor of the Turks, near this town; 144 miles N. of Constantinople. N. lat. 43° 14'. E. long. 27° 10'.

VARNA. See **VRANA**.

VARNAVA, a mountain of Greece, near Athens.

VARNAVIN, a town of Russia, in the government of Kostrom, on the Vetluga. N. lat. 57° 16'. E. long. 45° 14'.

VARNI, in *Ancient Geography*, a people of Asia, in Bactriana. Ptolemy.

VARNISH, or **VERNISH**, *Vernix*, a thick, viscid, glossy liquor, used by painters, gilders, and various other artificers, to give a gloss and lustre to their works, as also to defend them from the weather, dust, &c.

There are divers kinds of varnishes; some of the principal of which are as follow:

VARNISH, *Amber*, is prepared in the following manner: Put four ounces of amber into a crucible, and melt it with a small degree of heat, and pour it out upon an iron plate; when cold, reduce it to powder, and add to it two ounces of drying oil, that is, linseed oil thickened by boiling it up with litharge, and one pint of oil of turpentine, and dissolve the whole together into a liquid varnish.

This simple amber varnish is of great use for many purposes, and is said to be the basis of the fine varnishes which we see on coaches, and may be prepared without drying oil, by boiling the powder of amber in linseed oil, or in a mixture of linseed oil and oil of turpentine. Drying oil is commonly used by the workmen; but Dr. Lewis thinks it more eligible to take the oil unprepared, that the boiling requisite for giving it the drying quality may be employed at the same time in making it act upon the amber. It has generally been thought, that amber will not at all dissolve in oils, till it has suffered a degree of decomposition by fire. But Hoffman relates an experiment, in his *Observationes Physico-Chemicæ*, which discovers the solubility of this concrete in its natural state. Powdered amber, with twice its quantity of oil olive, was put into a wide-mouthed glass; and a digester, or strong copper vessel, being filled about one-third with water, the glass was placed in it, the cover of the digester screwed down tight, and a moderate fire continued an hour or more: when cold, the amber was found dissolved into a gelatinous, transparent mass. In Dr. Stockar's *Specimen Inaugurale de Succino*, printed at Leyden in 1760, we have an account of other experiments made by himself, in conjunction with M. Ziegler of Winterthur; from which we learn, that by continuing a simmering heat twelve hours, and confining the vapour as much as stone-ware vessels would bear without burbling, (the danger of which was avoided by making a small notch in the cork-stoppers,) powdered amber dissolved perfectly in expressed oils, in turpentine, and in balsam of copaiba: a strong copper vessel, with a cover screwed on it, seems most eligible; and for the greater security, a valve may be made in the cover, kept down by a spring, that shall give way before the confined vapour is of sufficient force to endanger burbling the vessel. Moreover, by digestion for a week in close-stopped glass vessels, in which the compressure could not be very great, solutions equally perfect were obtained. The solution in rape-seed oil, and in oil of almonds, was of a fine yellowish colour; in linseed oil, gold-coloured; in oil of poppy-seeds, yellowish-red; in oil olive, of a beautiful red; in oil of nuts, deeper coloured; and in oil of bays, of a purple-red. The solutions made with turpentine and with balsam of copaiba, were of a deep red colour, and on cooling, hardened into a brittle mass of the same colour. All the solutions mingled perfectly well with spirit of turpentine. Those made with the oils of linseed, bays, poppy-seeds, and nuts, and with balsam of copaiba and turpentine, being diluted with four times their quantity of spirit of turpentine, formed hard, tenacious, glossy varnishes, which dried sufficiently quick, and appeared greatly preferable to those made in the common manner from melted amber.

An amber varnish may also be made by boiling down some colophony, or turpentine, till it becomes black and friable, and melting this in a glazed earthen vessel, sprinkling in, by degrees, thrice as much amber in fine powder, with the addition of a little spirit or oil of turpentine now and then. When the amber is melted, sprinkle in the same quantity of sarcocolla, continuing to mix them, and to add more spirit of turpentine, till the whole becomes fluid; then strain out the

clear through a coarse hair bag, pressing it gently between hot boards. This varnish, mixed with ivory-black in fine powder, is applied, in a hot room, on the dried paper paste of which the *papier mâché* is made; which is then set in a gently heated oven, next day in a hotter oven, and the third day in a very hot one, and let stand each time till the oven is grown cold. The paste thus varnished is hard, durable, glossy, and bears liquors hot or cold. Lewis's Com. Phil. Techn. p. 367.

An amber varnish may be otherwise made by melting eight ounces of Chio turpentine, and when fluid, pouring into it, by degrees, a pound of fine powdered amber, and stirring it; and when it is properly mixed, setting it on a fire for half an hour, taking it off, and stirring it well, and adding to it two ounces of the white colophony. It is again to be put on a brisk fire, and covered close; when the mass is perfectly fluid, and taken off to cool, a pound of linseed or poppy oil, made drying, is to be poured in boiling hot, and stirred till it be incorporated with the mass; and then a quart of hot turpentine is to be added, and the whole well stirred. Let it then cool, and strain it off for use; when, if it has been properly made, it will be quite clear. See GILDING on *Enamel and Glass*.

VARNISH, *Black*, for japanning on wood or leather, is prepared by mixing lamp-black or ivory-black with a proper quantity of a strong solution of gum lac in spirit of wine. (See JAPANING.) The lamp-black is commonly preferred to the ivory-black, on account of its uniting better with the fluid, and working smoother. The thicker part of the varnish, which settles at the bottom, is used with the lamp-black for the first coatings, and the mixture applied at different times, in a hot room, one layer after another, is dry, till a full body of colour is obtained; after which, the piece is washed over in the same manner several times, with the finer part of the varnish, just tinged with the black, so as to make a coating of sufficient thickness to bear polishing with tripoli. Iron snuff-boxes, mourning buckles, &c. are coloured black, by making them considerably hot, and applying on them in this state a thick mixture of lamp-black, with a certain varnish called gold-size, consisting of drying oil, turpentine, and the pigment called Naples yellow; but the yellow might be omitted, and the varnish formed at once by mixing lamp-black with a proper quantity of turpentine and drying oil. The workmen, as Dr. Lewis says, frequently employ, as varnish for metals, a mixture of lamp-black, with the scummings, &c. of different oil paints; the mixture is applied with a pencil, and the piece afterwards baked in an oven with a heat somewhat greater than is used for the *papier mâché*. Naples yellow, a superfluous ingredient in the black varnish, is the basis of the dark-brown which we see on some iron snuff-boxes; this pigment changing to a brown in baking with the varnish. Lewis. See LACQUER.

The excellent black varnish of China and Japan, which has been hitherto but imperfectly imitated in Europe, and which was formerly thought to be an artificial composition of resinous bodies coloured with black pigments, has been discovered by the later travellers into those countries, to be a native juice, exuding from incisions made in the trunks of certain trees. Mr. Miller, in consequence of a letter from the abbé Mazeas to Dr. Hales, containing a communication of the discovery of a plant by the abbé de Sauvages, which he calls *toxicodendron Carolinianum foliis pinnatis, floribus minimis herbaceis*, and the black juice of which adheres, without the least acrimony, to cloth with more force than any other known preparation, takes occasion to shew, that this American toxicodendron is the same species of plant from which

the inhabitants of Japan procure the varnish with which they stain all their utensils; adding, that the Calicuts are also painted with the juice of this shrub. This American toxicodendron (see *Poison-Tree*) is the same plant, as he affirms, which is mentioned by Kämpfer, in his *Amœnitates Exoticæ*, by the title of *arbor vernacifera legitima, folio pinnato juglandis, fructu racemoso cicicis facie; i. e.* the true varnish-tree, with a walnut-tree leaf, and a branching fruit like cicers. It is called by the inhabitants of Japan *sitz*, or *lesitz-dju*, and also *urus*, or *urus-noki*. Kämpfer has also described the wild or spurious varnish-tree, called *safi-no-ki* by the natives, which he says agrees with the other in every part, except that the lobes of the leaves are narrower; but Mr. Miller is of opinion that this is a distinct species, if not a different genus, from the true sort; and says, that the varnish yielded by it is of little esteem. The account which the Jesuits at China have given of the manner in which the varnish is procured, is as follows: they first slit the back of the branches of the shrub, in different places, with a knife; and thus there flows out a white clammy juice, which is received into wooden vessels; and when these become dry, they tap the stems of the shrubs near the roots, so that all the juice is drawn out of them. The shrubs are then cut down to the ground, and from their roots new stems arise, which in three years will be fit for tapping. The juice turns black when exposed to the air; it heats without turning sour; but being of a poisonous nature, it is dangerous to handle it. This native varnish wants hardly any preparation; but if any dirt should happen to mix with it, it is cleansed by being strained through coarse gauze, put into wooden vessels, and covered with an oil called *toi*, and a skin, in order to prevent its evaporating. In this state it is carried over to China and Japan for sale. The shrub is chiefly cultivated in the provinces of Tsi-kocko and Figo; and the best varnish, according to Kämpfer's account, is produced about the city Jassino; but there is an ordinary sort of varnish, called *nam-rak*, brought from Siam, which is collected in the province of Corfama, and in the kingdom of Cambodia, from the tree *anacardus*, called by the inhabitants *tong*, or *tue-rak*, the fruit of which is called in our shops *anacardium*. To collect this liquor, they bore a hole in the trunk, and insert a tube. By this method they procure as much of it as is sufficient, not only to varnish all the utensils of China, Tonquin, and Japan, but it is even exported in close wooden vessels to Batavia, and other parts of India. This varnish, says Kämpfer, is not only sold quite pure, but likewise coloured, with Chinese native cinnabar, and a kind of red earth, which the Dutch formerly, but now the Chinese bring them, and also with the materials of which they make their common Japan ink. Mr. Ellis has controverted the opinion of Mr. Miller, and endeavoured to shew that the American toxicodendron is not the same with Kämpfer's *arbor vernicifera legitima*; alleging, that Kämpfer's description of the true varnish-tree does not agree with this toxicodendron; and he inclines to the opinion, that the Carolina pinnated toxicodendron, or poison-ash, is the same with the *safi-no-ki*, or spurious varnish-tree of Kämpfer. Mr. Ellis also thinks it is not improbable, that the varnish mentioned by Kämpfer, as obtained from the oriental *anacardium*, is the same with that mentioned by father d'Incarville, in the *Phil. Trans.* vol. xlvi. p. 254, called *toing-yeou*; which is so universally used in China for preserving and ornamenting their furniture. See this controversy between Mr. Miller and Mr. Ellis at large, in *Phil. Trans.* vol. xlix. part i. p. 157—166. part ii. p. 806—876. vol. l. p. 430—456. See POISON-TREE, LINEN, and JAPANING.

VARNISH, *Brown*, for Metals. See *Black VARNISH*, supra.

VARNISH,

VARNISH.

VARNISH, Copal Oil, called in France *vernis martin*, is made by pouring into a well-glazed strong earthen pot, in shape resembling a chocolate pot, and in size large enough to hold about a gallon, and made warm, four ounces of Chio or Cyprus turpentine, and when this is dissolved, eight ounces of finely powdered amber; mingling them well, and setting them on the fire for a quarter of an hour; take off the pot, and pour gently into it a pound of copal, finely bruised, but not powdered; stir the mass, and add four ounces of Chio turpentine, and a gill of warm turpentine oil; then set it on a brisk fire for about half an hour, and taking it off, stir the contents well, and add two ounces of the finest and whitest colophony. Let the pot be put on a very brisk fire, and remain till the whole is dissolved, and become as fluid as water; let it be removed from the fire, and remain for a few minutes, and then gradually pour in twenty-four ounces of poppy, nut, or linseed-oil, made drying, and boiling hot, and stir the mass with a deal stick. When the gums and oil are thoroughly incorporated, set them over the fire for a few minutes, still stirring them about, and let them boil once up; and having taken off the pot, pour into it a quart of hot turpentine; stir them together, and give them one boil up; take off the pot, and pour into it a pint more of hot turpentine, still stirring it well. If the gums are thoroughly melted, and well incorporated, the varnish is made; which, being cool, is strained through a close cloth into another vessel, and, if it be too thick, thinned with oil of turpentine, till it becomes of the consistency of linseed-oil; strain it a second time, bottle it for use, and let it stand a month, at least, before it is used. This varnish is used for coaches, cabinets, &c.; and the piece, whatever it be, after having been varnished smoothly, and dried in the intervals half a dozen times, and suffered thoroughly to dry, must be rubbed with a wet coarse rag, dipped in pumice-stone, powdered and sifted, till the streaks of the brush and all blemishes are removed. When it is perfectly smoothed, washed, and dried, the coats of varnish are to be repeated, for ten or twelve times, till there be a sufficient body. After having again used the powdered pumice-stone, and washed it off as before, let it be rubbed with fine emery, till the surface becomes even and smooth as glass; then with powder of fine rotten stone, till by passing the palm of the hand two or three times over the same place, you discover a gloss equal to that of glass: having dried it clean, dip a rag, or piece of flannel, in sweet oil, and rub the surface a few times over, and clear it off with fine dry powder, flour, or the hand; and a piece of fine flannel, dipped in flour, and rubbed over it, when cleared of the oil, will give it an excellent lustre. Between every coat of varnish it will be advisable, if the subject admits of it, to set it in a warm oven; or to heat the varnished pieces by stoves. See **COPAL**.

VARNISH, Gold-coloured. See **LACQUER**.

The composition of a gold-coloured varnish, used by the English artists for brass and silver, was communicated to some of the French academicians in 1720, by Mr. Scarlet, and in 1738 by Mr. Graham, and published in the volume of the French Memoirs for 1761. It is as follows: Take two ounces of gum lac, two ounces of yellow amber, forty grains of dragon's blood in tears, half a drachm of saffron, and forty ounces of good spirit of wine: infuse and digest in the usual manner, and then strain through a linen cloth. The piece to be varnished must be heated before the liquid is applied: it receives from the varnish a gold colour, and may be cleaned, when sullied, with warm water.

VARNISH for preserving polished Iron from Rust. See **IRON**.

Many methods have been used for preserving iron utensils from rust, as animal fats, oils, boiled oil mixed with melted lead, &c. Hornberg's salve for this purpose consists of two pounds of hog's-lard, an ounce of camphor, and as much black lead as will render the mixture of an iron-colour; when this is used, the iron must be previously heated. M. Reaumur has discovered a better composition for this purpose: it is oil, inspissated by being exposed to the air in flat shallow vessels, so as just to cover the bottom, mixed with a solution of copal in spirit of wine: this forms an elegant hard varnish, which, rubbed on polished iron, made a little hotter than the hand can bear, will cover it with a solid, thin, transparent coat, without any injury to its colour or appearance. See **RUST**.

VARNISH, Lacca, is made of gum lacca and spirit of wine, frequently shaken till the gum be dissolved, then strained, and the clear liquor decanted off.

The lacca ought to be of the kind called seed lacca. (See **LAC**.) Three ounces of this, well purified by repeated ablution of water, dried and powdered grossly, should be put into a bottle with a pint of rectified spirit of wine, so as to fill about two-thirds of it, and the bottle placed in a gentle heat; proceeding as above: though for varnishing ordinary woods, shell lacca is often used. For this purpose, five ounces of the best shell lacca should be grossly powdered, and put into a bottle, holding about three pints or two quarts, with one quart of rectified spirit of wine; and placed in a gentle heat: the mixture must be filtered through a flannel bag. To this varnish, the colours used in varnish painting may be added, and properly diluted with rectified spirit, and kept in phials, or tin vessels closely stopped for use. But this will not stand against the weather.

For various preparations of this kind, see **JAPANING** and **LACQUER**.

VARNISH, Mastich, is made by putting five ounces of powdered mastich into a proper bottle, with a pound of spirit of turpentine, and setting them to boil in balneo Mariæ, till the mastich be dissolved, and straining the solution through flannel. This varnish may be converted into a proper varnish for painting, by grinding one ounce of gum anime on a stone with water, till it becomes an impalpable powder; then drying it, and grinding it again with half an ounce of turpentine, and afterwards with the proper colours, and moistening it with the mastich varnish, till the mixture be of a due consistence for working with the pencil. It must then be kept in phials or tin vessels, and diluted, as there may be occasion, with spirit of turpentine.

VARNISH for preserving Paintings. See **PICTURE**.

For this purpose some have recommended the following composition: viz. half a pound of gum sandarac; an ounce and a half of Venice turpentine; three-quarters of an ounce of each of the gums anime and copal; half an ounce of mastich; benzoin, gum elemi, and white resin, each two drachms, and one pound of rectified spirit. The benzoin and gum anime powdered, are put with the Venice turpentine into a phial, with eight ounces of the spirit of wine; the copal and resin powdered are also put in a phial with six ounces, and the powdered gum elemi, with two ounces of spirit of wine. The several phials are frequently shaken, till the gum, &c. are dissolved; then the solutions are strained through a fine linen in one bottle, and when the mixture has stood some days, it is decanted off clear, and kept in a separate bottle for use. Some have substituted the sarcocolla for the copal. Another composition is formed, by dissolving mastich and sandarac, grossly powdered,

dered, of each six ounces, and Venice turpentine half an ounce, in a quart of highly rectified spirit of wine, and straining off the solution. If it be required harder, an equal weight of the gums anime and copal may be added, and the quantity of spirit of wine doubled. In the use of this varnish, the painting should be thoroughly dry, and it should be spread very gently with a pencil. The varnish should be laid on in a very warm place, or the picture itself warmed to a moderate degree, in order to prevent the *chilling* of the varnish; in which case another coat should be added. And, indeed, two or three coats are necessary to preserve the painting, and to bring out a due effect of its colours, if they are in that state called *sunk in*, occasioned by the attraction of the cloth on the oils mixed with them. An oil of turpentine varnish may be added by grossly powdering mastich and sandarac, of each four ounces; two ounces of white resin; and sarcocolla, anime, copal, and olibanum, of each one ounce; and putting them into a phial with two pounds of oil of turpentine, stopping the phial gently, and placing it in any heat, so that the mass may not boil, and straining off the solution for use. Or, a varnish more simple, and equally good, may be made by powdering two ounces of sandarac, mastich and olibanum, of each an ounce and a half; or three ounces of mastich, and Venice turpentine half an ounce; and dissolving them in half a pound of oil of turpentine, and proceeding as before. *Handmaid to the Arts*, vol. ii. p. 227, &c.

VARNISH for Paper-hangings. See PAPER-Hangings.

VARNISH for Printers' Ink. See PRINTING-Ink.

VARNISH, *White*, is usually made of gum sandarac and gum mastich, dissolved in spirits, left to settle two days, then strained through a linen cloth, and, after standing some time, the clear poured off, and bottled for use.

The more curious artists dissolve the two gums separately; and having made a separate varnish of each, mix them occasionally, as their work requires a stiffer or a softer varnish.

But for the *best* white varnish more gums are required; *viz.* Venice turpentine, gum copal, elemi, benzoin, anime, and white resin.

Besides these, there are *hard* and *soft* varnishes, or grounds, used by the etchers and engravers. See ETCHING.

VARNISH is also used for a kind of glossy coat, with which potter's-ware, Delf-ware, China-ware, &c. are covered, to give them a smoothness and lustre. Some preparation of lead is the varnish ordinarily used for the first; and earths for the second. See GLAZING and POTTERY.

The true varnish used by the Chinese and Japanese, to give that inimitable lustre to their porcelain, is one of the grand secrets in that manufacture; and is one of the great things wanting, to make Delf and French ware vie with the Chinese. Several have described the preparation of it, particularly Kircher: but none ever succeeded in the trial. See PORCELAIN and VARNISH, *supra*.

VARNISH is also a term applied to the colours which antique medals acquire in the earth.

The value of a medal is heightened by a beauty, which nature alone was able to give, and art has never yet attained to counterfeit: we mean the colour or varnish with which certain soils tinge the medal; some with a blue, almost as beautiful as that of a turcois; others with an inimitable vermilion colour; and others with a glossy shining brown, infinitely beyond any of our figures in bronze.

The most usual varnish, however, is a fine green, which hangs to the most delicate strokes without effacing them; much more accurately than the finest enamel does on metals. Brass alone is susceptible of it; for as to silver, the green

rust that gathers on it, always spoils it; and it must be scoured off with vinegar, or lemon juice.

There is also a *false*, or *modern* varnish; which the falsifiers of medals give to their counterfeits, to give them the air of antiquity: it is discovered by its being softer than the natural varnish, which is as hard as the metal itself.

Some lay their spurious medals under ground, where they contract the degree of varnish, that they impose on the less knowing: others use sal ammoniac, mixed with vinegar; others the acid spirit of nitre, &c.

VARODOPA, or VERODOPA, in *Ancient Geography*, a province in the environs of Macedonia, according to Eutropius. Ortelius makes it a country of Thrace, writing it *Rodopa*.

VAROE, in *Geography*. See VÆIROE.

VAROLI, COSTANZO, in *Biography*, was born at Bologna in 1542, and became a professor of physic and surgery in his native city. In 1572 he was invited by pope Gregory XIII. to settle at Rome as his first physician, and professor in the college of Sapienza. He was advancing in reputation by his anatomical discoveries, as well as in his practice of medicine and surgery, when a premature death cut him off in 1575, in the 33d year of his age. He was particularly distinguished in the anatomy of the brain, which he described in his work "De Nervis Opticis nonnullisque aliis præter communem Opinionem in Humano Capite observatis Epistola ad Hieronymum Mercurialem," Patav. 1570. Among the parts of the brain which he discovered, or more accurately described, was that known by his name, the "Pons Varoli," formed by the union of the crura cerebri and cerebelli, and the place whence several nerves originate. After his death was published "De Resolutione Corporis Humani," a work which is a compendium of anatomy, chiefly according to the ancients, but with several new observations by himself. Haller. Eloy.

VAROLI Pons, in *Anatomy*. See PONS.

VARORE, in *Geography*, a town of Hindoostan, in Baramaul; 14 miles N.N.W. of Darempoury.

VAROTARI, DARIO, in *Biography*. See PADUANINO.

VARPA, in *Geography*, an island near the N.E. coast of Sumatra, about 30 miles in circumference. S. lat. $0^{\circ} 36'$. E. long. $103^{\circ} 25'$.

VARRO, MARCUS TERENCE, in *Biography*, the most learned of the ancient Romans, received from Pompey the Great, in the piratical war, a naval crown, and joined this chief in the civil war against Cæsar; but afterwards submitting to the latter, he was employed by him in making a collection of books for the public library which he proposed to establish at Rome. The death of Cæsar prevented the accomplishment of this design; and Varro, being involved in the proscription by the triumvirates, escaped with his life, but with the loss of his library. After the restoration of tranquillity, he retired for the prosecution of his studies, and composed books till his 88th year. His life was prolonged to the age of 90, and he died about the year B. C. 27. He is highly extolled for his various talents and literary performances by ancient writers, and particularly by Cicero in his "Academics." Aulus Gellius cites a passage from Varro, in which he declares of himself, that to the 78th year of his life he had composed 490 books, and he continued to write to his 90th year. The subjects on which he wrote, as we learn from Fabricius, were grammar, eloquence, poetry, the drama, history, antiquities, philosophy, politics, agriculture, nautical affairs, architecture, and religion. He was also the first Latin author of that species of satire called the Menippean, from Menippus, a Greek, its inventor, which was written in prose, with a mixture of verse in different measures. (See MENIPEAN.)

MENIPEAN.) Such and so pre-eminent was the reputation of Varro, that when Afinius Pollio, in the reign of Augustus, opened the first public library at Rome, and placed in it the effigies of various learned persons, he was the only living writer who had the honour of this distinction. The only relics of his numerous works are six books, in an imperfect state, out of twenty-four, which he composed on the Latin language, with three books on agriculture, and a few fragments of his satires and epigrams. The former are printed among the "Auctores de Lingua Latina," and the latter among the "Auctores de Re Rusticâ."

A contemporary of the preceding, named P. TERENTIUS VARRO ATACINUS, has been confounded with him. He was a native of Atace in Gallia Narbonnensis, and wrote an esteemed poem "De Bello Sequanico," and translated into Latin verse the "Argonautics of Apollonius Rhodius." Some fragments of his poetry are published in the "Corpus Poet. Latin." Vossius. Tiraboschi. Gen. Biog.

VARRONIA, in Botany, is so called in memory of MARCUS TERENTIUS VARRO, (see that article,) whose treatise *De Re Rusticâ* has procured him this botanical tribute. The name originated with Browne, but was speedily adopted by Linnæus and Jacquin.—Browne Jam. 172. Linn. Gen. 102. Schreb. 140. Willd. Sp. Pl. v. 1. 1079. Mart. Mill. Dict. v. 4. Jacq. Amer. 40. Ait. Hort. Kew. v. 2. 11. Juss. 129. Lamarck Dict. v. 4. 262. Illustr. t. 95.—Class and order *Pentandria Monogynia*. Nat. Ord. *Asperifolia*, Linn. *Borragineæ*, Juss.

Gen. Ch. Cal. Perianth of one leaf, inferior, tubular, with five long, slender, recurved teeth, permanent. Cor. of one petal, tubular; tube cylindrical; limb in five deep spreading segments. Stam. Filaments five, awl-shaped, the length of the corolla, inserted into its tube; anthers oblong, incumbent. Pist. Germen superior, ovate; style thread-shaped, the length of the corolla; stigmas four, bristle-shaped. Peric. Drupa ovate, of one cell, inclosed in the swelling calyx, but not connected with it. Seed. Nut roundish, of four cells.

Eff. Ch. Corolla five-cleft. Calyx tubular. Drupa superior, covered with the permanent calyx. Nut of four cells.

A West Indian genus of shrubby plants, with simple, alternate, rarely almost opposite, rough leaves; and terminal, aggregate, rather ornamental, flowers. They are little known in our stoves, nor has any one species as yet been exhibited in our popular periodical works. *Varronia* is next akin to *TOURNEFORTIA* (see that article); but the less deeply divided calyx, and four slender stigmas, are sufficient to mark the present genus, without adverting to their fruits, which are not in all cases well understood.

1. *V. lineata*. Round-spiked *Varronia*. Linn. Sp. Pl. 275. Willd. n. 1. Ait. n. 1. Swartz Obs. 87. (*V. fruticosa*, foliis rugosis, ovatis, subhirsutis, ferratis, alternis, capitulis subrotundis; Browne Jam. 172. t. 13. f. 2. *V. humilis*; Jacq. Amer. 41. Ulmi angustifoliae facie Bacifera jamaicensis, foliis supernè scabris subtis villosis, floribus flavis perpusillis, fructu botryoide monospermo; Pluk. Almag. 393. Phyt. t. 328. f. 5.)—Leaves lanceolate, minutely hairy, marked with straight depressed veins. Flower-stalks mostly axillary, combined with the footstalks. Spikes globose.—Common in the lower woody lands of Jamaica. The stem is three or four feet high, with many slender, round, downy, crooked, entangled, leafy branches. Leaves spreading, or rather dependent, two inches long, taper-pointed, distantly and irregularly ferrated; roughish, like a very fine file, with minute rigid hairs, above; densely downy and hoary beneath. Footstalks hairy, a quarter of

an inch long, united for half their length, to the base of each simple, solitary, downy flower-stalk, which is about half the length of the leaf, and bears a round head of small whitish or yellowish flowers. Plukenet's figure is a much better representation of the Linnæan specimen from Browne himself, than his own plate, particularly with respect to the situation of the flowers. We cannot but suspect some error, and that the said plate may represent a species not hitherto well defined.

2. *V. bullata*. Blistered *Varronia*. Linn. Sp. Pl. 276, excluding Jacquin's synonym. Am. Acad. v. 5. 394. Willd. n. 2. Swartz Obs. 88?—Leaves ovate, veiny, rugose, rough with callous tubercles and bristles. Spikes globose, on long rough stalks, from the forks of the stem.—Native of Jamaica. The Linnæan specimen is from Browne, but does not answer to the description of either of his species. The branches are forked, extremely rough with minute warts, and rigid ascending bristles, as are likewise the footstalks and flower-stalks. Leaves an inch and a half or two inches long, about four times the length of their stalks, nearly elliptical, acute, ferrated, reticulated with copious veins, and minutely blistered in the interstices; besprinkled on the upper side with callous tubercles and bristles, which turn white by age, when the leaf becomes tawny; paler, with hairy veins, beneath. Flower-stalks from the forks of the branches, solitary, from one inch to two inches and a half long, erect, simple, very rough, quadrangular upwards. Spike globose, of six or eight flowers. Calyx corrugated, bristly, with linear recurved teeth. Corolla not much longer than the tube of the calyx, with five plaits in the limb. Fruit tuberculated. Many doubts have arisen respecting this species. What we have here, with all possible precision, described, is certainly the Linnæan authentic specimen, which we should suspect to be the *Lantana Radula* of Swartz, Ind. Occ. 1057. Willd. Sp. Pl. v. 3. 317, to judge at least by the description, not having seen the plant. Nevertheless our's has the calyx and corolla of a *Varronia*, and the habit of the plant is so near *V. mirabiloides*, as figured by Jacquin, that Linnæus may well be excused for supposing them one and the same. In the Linnæan herbarium are two other specimens, sent by Rolander, and marked likewise *V. bullata*. It must be to these that Swartz alludes, when he says, in his Obs. 88, "there is a specimen of *V. globosa* in Herb. Linn. under the name of *bullata*." Whether this be correct or not, these have never been described as *bullata*, though, by mistake, so named.

3. *V. mirabiloides*. Salver-flowered *Varronia*. Jacq. Amer. 41. t. 33. Willd. n. 3. Ait. n. 2. Swartz Ind. Occ. 465.—Leaves ovate, rough, ferrated. Spikes roundish, unequal. Corolla salver-shaped; its tube thrice the length of the calyx.—Native of Hispaniola, even in hedges near the town of Port-au-Prince. Jacquin. The most elegant of its genus, often twelve feet high. Leaves two inches long, rough on both sides. Flower-stalks lateral and terminal, measuring three or four inches, and bearing each a simple or divided round-headed spike, of numerous white inodorous flowers, very handsome, the size of Marvel of Peru. Segments of the calyx small, ovate, ending in long bristles. Drupa red, the size of a pea, full of sweet glutinous pulp. Nut depressed. Such is the plant of Jacquin, and we must suppose Swartz's the same, in spite of some slight incongruities of description. We have never seen either.

4. *V. martinicensis*. Martinico *Varronia*. Jacq. Amer. 41. t. 32. Willd. n. 4. Ait. n. 3.—Leaves ovate, pointed. Spikes oblong, dense. Calyx-teeth linear, half the length

of the tube.—Native of Martinico. Sent to Kew by Sir Joseph Banks, in 1795. It is said to flower in the stove about August and September.—A *shrub* as tall as a man; the young *branches* only roughish with close-pressed hairs. *Leaves* three inches long, sharply serrated; rough above, with minute depressed hairs; soft and downy at the back. *Flower-stalks* solitary, a little above each fork of the branch, silky, an inch and a half long, each bearing a dense *spike*, about an inch long, of many funnel-shaped, probably white, *flowers*. *Calyx* silky, with broader and shorter teeth than any of the foregoing.

5. *V. globosa*. Globose Varronia. Linn. Sp. Pl. 276. Willd. n. 5. Jacq. Amer. 41. — “Leaves lanceolate-oblong. Stem forked. Flower-stalks axillary, elongated, naked. Spikes globose.—Native of the West Indies. An obscure species, of which we can give only the Linnæan specific character, the author of which adds *pedunculus e dichotomiâ nudus*; meaning, probably, that whenever a *stalk* springs from the fork of the *stem*, it is unaccompanied by a leaf. Linnæus further says, that the *calyx-teeth* are long, linear, and recurved. Whether the specimen above-mentioned from Rolander (see n. 2.) be this species or not, we have no authority to say. Sir Joseph Banks has favoured us with what he considers as *V. globosa*, from Von Rohr, which may be the same; the *leaves* and serratures are much blunter, but hardly enough to make a specific distinction.—In this the *leaves* are scarcely above an inch long, rough and rather hoary, especially beneath, as are also the *branches* and *footstalks*. *Flowers* numerous, in dense, globular, silky, stalked heads, either from the forks of the younger branches, or each opposite to a leaf. *Calyx-teeth* as described by Linnæus.

6. *V. curassavica*. Long-spiked Varronia. Linn. Sp. Pl. 276. Willd. n. 6. Jacq. Amer. 40. n. 1. Swartz Obs. 88? (*V. affurgens* farmentosa, foliis et capitulis oblongis; Browne Jam. 172?)—Leaves elliptic-oblong, minutely toothed. Spikes oblong. *Calyx-teeth* triangular, slightly pointed.—Sent by Von Rohr from the West Indies, and given us by the late Mr. Dryander, as the authentic plant of Jacquin, compared doubtless with his specimen. Yet the *calyx-teeth* have less evident points than he describes, and the *spikes* are rather lax. Whatever our intelligent friend Dr. Swartz may have had for *V. curassavica*, we can assert that our's is certainly distinct from *martinicensis*. (See his Obs. 88.) Jacquin describes it fifteen feet high, with round rough *branches*, rusty when old. *Flowers* small, white, without scent, in dense terminal *spikes*, two or three inches long. *Drupa* small, red.

7. *V. angustifolia*. Narrow-leaved Varronia. Willd. n. 7. “West. St. Cruc. 202.”—“Leaves linear, rough, somewhat toothed. Spikes linear-oblong.”—Native of Santa Cruz. A *shrub*. *Leaves* lanceolate-linear, obtuse, revolute, rough above; downy beneath. *Willdenow*.

8. *V. alba*. White-fruited Varronia. Linn. Sp. Pl. 276. Jacq. Amer. 41. Willd. n. 8. (*Mespilus americana*, alni vel coryli foliis, fructu mucaginoso albo; Comm. Hort. v. 1. 155. t. 80.)—Leaves heart-shaped, pointed, flowers cymose.—Native of South America, about Carthagen and in Curassow. A *tree*, often thirty feet high, with an ample spreading head, and a trunk six inches in diameter; though in hedges it is scarcely more than a *shrub*. *Leaves* four or five inches long, serrated, rough; somewhat heart-shaped at the base. *Cymes* large, not uncommonly extending six inches, of numerous, whitish, scentless *flowers*. *Calyx* at first entire, but, as the *corolla* protrudes, it is pushed aside horizontally, splitting into two valves, the upper withering, the under permanent, and the margin is seen to have five

very slight teeth. Limb of the *corolla* bell-shaped. *Drupa* oblong, measuring half an inch, whitish, semipellucid, sweet, but inlipid and glutinous, eaten by the inhabitants of Curassow. *Nut* oblong, striated, black.

9. *V. monosperma*. Single-seeded Varronia. Jacq. Hort. Schoenbr. v. 1. 18. t. 39. Willd. n. 9.—Leaves ovate; entire at the base. *Cymes* lateral. *Flowers* capitate.—Native of the Caraccas. It flowered in the stove at Schoenbrun all summer long, and bore fruit. The *stem* is twelve feet high. *Leaves* three inches in length, stalked, serrated from about the middle only. *Flowers* small, white, in little globular heads, collected into stalked cymes, which spring laterally from the branches, about half way between the leaves. *Calyx-teeth* triangular, scarcely pointed. *Corolla* bell-shaped, abrupt, crenate. *Stigmas* dilated, obtuse. *Drupa* scarlet, the size of a pea. There being but one kernel, is probably owing to the plant not being in a natural situation, and therefore is wisely omitted by Willdenow in the specific character. For the same reason, the name may probably prove exceptionable.

In studying this genus, we cannot but observe that the species are not so distinctly known, nor so well defined, as could be wished, nor do we pretend to have placed them all beyond the reach of uncertainty, our materials being, in several instances, defective on the score of authority.

VARRONIAN SATIRE. See SATIRE.

VARS, in *Geography*, a town of France, in the department of the Charente; 6 miles N. of Angouleme.

VARSAKA, a town of Imiretta; 10 miles S.E. of Cotatis.

VARSETCH, a town of Istria; 8 miles E. of Pedena.

VARSHNEYA, in *Mythology*, a name of the Hindoo deity *Krishna*; which see.

VARSOVIA, in *Geography*. See WARSAW.

VARU, an island in the Caribbean sea, near the coast of South America, about sixteen miles long, and three broad. N. lat. 10° 12'. W. long. 75° 25'.

VARVELS, in *Falconry*, small rings about a hawk's leg, with the owner's name on them.

VARUNA, in *Hindoo Mythology*, is the genius or regent of the waters, corresponding with the Neptune of western heathens. As light is thought to be excluded from the deep, Varunâ is also deemed the governor of the night, or of darkness; in this character, as well as in that of lord of punishment, coalescing with the Hindoo Pluto, who is named *Tama*; which see. Still he is one of the twelve suns, called Aditya, of which see under our article SURYA. As lord of punishment, the wealth of criminals is directed to be offered to him; or, in other words, thrown into the waters; or it may, instead, be bestowed on a learned priest. The latter, we may suppose, is likely, on most occasions, to outshare the deity. In the Institutes of Menu, ch. ix. v. 243, 4, 5, these texts occur. “Let no virtuous prince appropriate the wealth of a criminal in the highest degree; for he who appropriates it through covetousness, is contaminated with the same guilt. Having thrown such a fine into the waters, let him offer it to Varuna; or let him bestow it on some priest of eminent learning in the scripture. Varuna is the lord of punishment; he holds a rod even over kings, and a priest who has gone through the whole Veda, is equal to a sovereign of the world.” In another text, c. ix. v. 308, it is said that “Varuna most assuredly binds the guilty in fatal cords.” Like other Hindoo deities, Varuna has a consort, or fakti, assigned him. She is called *Varuni*; which see. He has likewise a terrestrial palace or paradise, situated far in the West,

West, named *Subhavati*; which see. He has also had a terrestrial incarnation, under the name of Samvarna.

VARUNI, the consort of the Hindoo Neptune, who is named *Varuna*; which see. As well as his consort, she is said to be his daughter; a double relationship not uncommon with the gods both of India and Greece.

VARUS, or VARUM FLUMEN, *the Var*, in *Ancient Geography*, a river, which, in the time of Strabo and Pliny, separated the Gauls from Italy.

VARUSA, a river of Italy, in Gallia Cisalpina, which discharged itself into the Po, near the confluence of this river with the Ticini.

VARUTHA, a town of Asia, in the Greater Armenia. Ptolemy.

VARY, in *Geography*, a town of Hungary; 10 miles S. of Munkacs.

VARZEA, a town of Portugal, in the province of Beira; 9 miles S.S.W. of Lamego.

VARZESKOI, a lake of Russia, in the government of Archangel; 60 miles E. of Mezen.

VARZY, a town of France, in the department of the Nièvre; 7 miles S.S.W. of Clamecy.

VAS, VESSEL. See VESSEL, VESICULA, and ANGIOLOGY.

Hence, in the style of anatomists, the *vasa adiposa, præparantia*, &c.

VAS *Chyliferum*, in *Anatomy*, the thoracic duct. See ABSORBENTS.

VAS *Deferens*, the excretory tube of the testis. See GENERATION.

VASA *Brevia*, the short arterial and venous ramifications proceeding from the splenic trunks to the great end of the stomach. See ARTERY, and VEIN.

VASA *Efferentia* and *Inferentia*; the latter are the lymphatic vessels, which enter an absorbing gland; and the former, those which go out of it. See ABSORBENTS.

The tubes which pass from the upper end of the testis, and unite to form the epididymis, are also called *vasa efferentia*. See GENERATION.

VASA *Lactea*, or *Vena Lactea*, the absorbents which take up the chyle from the small intestine. See ABSORBENTS, and INTESTINE.

VASA *Vasorum*, the vessels which belong to the coats of vessels. See HEART.

VASA *Concordia*, in *Hydraulics*, are two vessels, so constructed, as that one of them, though full of wine, will not run a drop; unless the other, being full of water, do run also. Their structure and apparatus may be seen in Wolfius, *Element. Mathes. tom. ii. Hydraul.*

VASA, in *Geography*, a town of Turkestan, on the Sirt; 70 miles W. of Taraz.

VASA, or *Wasa*. See WASA.

VASAGUDA, or VAZAGUDA, in *Ancient Geography*, a town of Africa, in Mauritania Cæsariensis. Ptol.

VASANTA, in *Hindoo Mythology*, is the name of the bosom friend of their Kama, god of love. Among the Mahrattas and low people he is called Bessant, Bessent, or Bussunt. He is a personification of the season of spring; and songs in his honour are chanted by minstrels of both sexes at vernal and other festivals. See under KAMA for some mention of his inseparable attendant.

VASARHELY, in *Geography*, a town of Hungary, on a small river, which runs into the Theysse; 50 miles N.N.W. of Temeswar. N. lat. 46° 27'. E. long. 20° 33'. —Also, a town of Hungary; 22 miles E. of Caschau. —Also, a town of Transylvania; 40 miles E. of Colosvar. N. lat. 46° 37'. E. long. 25° 5'.

VASARI, GIORGIO, in *Biography*, was born at Arezzo in 1512, and was first instructed in design by a glass-painter, called Il Prete Gallo, but afterwards, being taken to Florence by the cardinal Passerini, studied under M. Angelo and Del Sarto. Another friendly cardinal conveyed him to Rome, the cardinal Ippolito di Medici; and under his protection he acquired riches and honours. In Rome he laboured assiduously, attaching himself particularly to M. Angelo, of whom he appears; by several letters preserved by Bottari, to have been very sincerely esteemed. He was employed in several public works at Rome, both as a painter and an architect, particularly in the Vatican, in the Sala della Cancellaria, where he painted, by the direction of the cardinal Farnese, a series of frescoes, representing the principal actions of Paul III.; and in the church of S. Giovanni Dicollato, he painted for the principal altar the martyrdom of that saint, one of his most highly esteemed performances.

He was invited by Cosmo I. to Florence in 1553, and employed by that prince as superintendent of the important works then going on in the Palazzo Vecchio, where he executed, with the help of numerous disciples, the decoration of the principal apartments. Of his paintings there, pope Clement VII. crowning the emperor Charles V. was the most important, and it was accompanied, in other compartments in the same hall, by representations of the actions of that monarch.

There are many other works of Vasari scattered about Italy, as at Bologna, Arezzo, and Rimini, &c.; but after all he was a tame copyist of Michael Angelo's manner, and a very indifferent colourist. He is far more endeared to us by his writings than his pictures. His work, entitled "Lives of the most excellent Painters, Sculptors, and Architects, from the Period of Cimabue till his own Time," is the fountain of knowledge concerning the greater part of them: and though in many points he appears to have been too facile of belief, and to have related histories without sufficient inquiry into their correctness, yet upon the whole the world is indebted to him for an ingenious and useful work; without which, the history of the art would not now have been so distinctly understood, nor the profession so justly known and honoured. It was first published at Florence, in two volumes, in 1550, and afterwards republished with considerable additions, and heads engraved in wood of most of the artists mentioned, in 1568, and has since been re-edited with copious notes by Bottari. Vasari died at Florence in 1576, at the age of 64.

VASAVA, in *Mythology*, a name of the Hindoo god *Indra*; which see.

VASBARIA, in *Ancient Geography*, a town of Africa, in the interior of Mauritania Cæsariensis. Ptolemy.

VASBUHL, in *Geography*, a town of the duchy of Wurzburg; 4 miles N.E. of Arnstein.

VASCO, or VASTORUM CIVITAS, in *Ancient Geography*, a town of Gallia Narbonensis, according to Ptolemy and Pliny.

VASCONES, a people of Hispania Citerior, at the foot of the Pyrenées. These people, who in later times passed into Gaul, where they assumed the name of Gascons, lay to the east of the Cantabri, in the country now called Navarre: and they extended from the Pyrenées as far as the Iberus towards the south. Their principal towns were Pompelo, Calaguris, and Graccuris.

VASCULAR, VASCULARIS, in *Anatomy*, is applied to any thing consisting of divers vessels, veins, arteries, &c.

We say, the vascular and valvular texture of the lungs.

All the flesh, in an animal body, is found to be vascular, none of it parenchymous, as the ancients imagined.

VASCULAR Glands. See **GLAND.**

VASCULAR, Vascularius, in *Antiquity*, was the denomination of a kind of artificers among the ancient Romans; who made silver and gold vessels without reliefs, or figures embossed on them.

Hence, according to Salmasius, it is, that Cicero, in his sixth oration against Verres, distinguished *vascularius* from *celator*, engraver.

In the art called by the Greeks *εμπαρισμω*, which was the art of superadding ornaments of precious stones, or rich metals, to vases of other metals; the *vascularii* and *celatores* were different; the first being the goldsmiths who made the vase; the second, the sculptors who added the ornaments. But in the art called *τοκευτικη*, or the art of cutting bas-reliefs, or stamping figures on metal, the *vascularii* were also *celators*, or engravers; that is, they who made the vase, made also the reliefs, or figures, with which it was enriched.

VASCULIFEROUS PLANTS, in *Agriculture* and *Gardening*, are all such the seeds of which are contained in vessels, divided in the cells. There are several of these in both these departments. See **SEED.**

VASE, a term of equal import with the Latin *vas*, whence it is formed; and with the English *vessel*; which see.

It is applied to the ancient vessels dug from under ground, or otherwise found, and preserved in cabinets, &c. as vessels of sacrifice, urns, &c.; and to other more modern vessels, which are rather of curiosity and show than use; as those of crystal, porcelain, &c.

In the curious collection of ornamental works, made by Messrs. Wedgwood and Bentley, after the antique, there are vases of various kinds; some formed of a composition of *terra cotta*, resembling agate, jasper, porphyry, and other variegated stones, of the vitrescent or crystalline kind; others of black porcelain, or artificial basalt, highly finished, with bas-relief ornaments; others of the painted Etruscan kind; and others again ornamented with encaustic paintings. The art of painting vases in the manner of the Etruscans has been lost for ages: however, these ingenious manufacturers set themselves to revive it; and, having carefully examined the original Etruscan vases, and having perused with attention the writings of the late count Caylus upon Etruscan antiquities, they were convinced that the colours of the figures could not be successfully imitated with enamel; and that their success must chiefly depend upon the discovery of a new kind of enamel colours, to be made upon other principles, and to have effects essentially different from those that were then in use, and are of the nature of glass: the Etruscan colours being burnt in, smooth and durable, but without any glassy lustre. In consequence of this observation, and by a great variety of experiments, they invented a set of encaustic colours, not only sufficient to imitate the paintings upon the Etruscan vases, but to give the beauty of design the advantages of light and shade in various colours; and to render paintings durable, without the defect of a varnished or glassy surface. These encaustic colours may be applied with great ease and certainty; they change very little in the fire, are not liable to run out of drawing, are perfectly durable, and not glassy, and possess the advantages of enamel, without its essential defects. Catalogue of Cameos, &c. by Wedgwood and Bentley, 1773.

VASES, in *Architecture*, are ornaments of sculpture, placed on foci, or pedestals, representing the vessels of the ancients;

particularly those used in sacrifice, as the *præfericulum simpulum*, incense-pots, flower-pots, &c. and occasionally enriched with basso-reliefs.

They are commonly placed there to crown or finish façades, or frontispieces. They are frequently also called *acroteria*; and are usually insulate.

In forming and decorating vases, fancy has great scope. Many excellent inventions of these ornaments are transmitted to us from the ancients. A vase differs from an urn, as it is in general of a more elegant contour, and is lofty; whereas an urn should be low and wide, and always covered.

Vitruvius mentions a kind of *theatrical* vases, made of brass, or earthen-ware, called *ecbeia*, *ηχηρα*, (see *ECHEDIA* and *VITRUVIUS*); which they disposed in private places, under the steps and seats of the theatres, to aid and increase the reflection and resonance of the actors' voices, &c. It is said, there are also vases of this kind in the cathedral church of Milan.

VASE is particularly used in architecture to signify the body of the Corinthian and Composite capital; called also the *tambour*, or *drum*; and sometimes the *campana*, or *bell*.

VASE is also sometimes used among *Florists*, for what they otherwise call the *calyx*.

The vase, or rather calyx of a tulip, is the top or head of a tulip; the leaves of which form a kind of vase, or cup.

Goldsmiths, brasiers, &c. also use vase for the middle of a church-candlestick; which is usually of a roundish figure, bordering somewhat on that of a vase.

VASE River, in *Geography*, a river of America, which runs into the Mississippi, 55 miles above the mouth of the Ohio.

VASEN. See **WESEN.**

VASH, a river of Grand Bucharia, which gives name to the country it waters; and runs into the Gihon near Termed.—Also, a province of Great Bucharia; which see.

VASHAVAN, a town of Hindoostan; 30 miles S.W. of Dindigul.

VASHGERD, a town of Grand Bucharia, and principal town of a district watered by the Vash; 200 miles S.E. of Samarcand. N. lat. 38° 25'. E. long. 67° 50'.

VASHON'S ISLAND, an island near the west coast of America, at the bottom of the Admiralty Inlet, and eastern branch of the gulf of Georgia. N. lat. 47° 10'. E. long. 237° 25'.

VASIL, a town of Russia, in the government of Nizgorod, on the Volga; 60 miles E. of Niznei Novgorod. N. lat. 56° 16'. E. long. 45° 44'.

VASILICA. See **BASILICA.**

VASILKOV, a fort of Russia, in the government of Kiev; 28 miles S.S.W. of Kiev.

VASINA, a town of the island of Corsica; 4 miles N. of Bastia.

VASIR. See **SIRVENT.**

VASISHT'HA, in *Biography*, is the name of a celebrated person of Hindoo history and mythology: one of a class called Rishi, meaning a sage. Of these divine persons we have given a list, and some remarks, under the articles **RISHI** and **KRITIKA**; the latter being the Pleiades of the Hindoos, who have many very curious tales of their "shedding sweet influences." Vasisht'ha is a character frequently mentioned in the romantic histories of the Hindoos, as being resorted to for advice by royal and other persons requiring spiritual or other consolation. He is, indeed, called the preceptor of the inferior gods. A very celebrated commentary on the Veda, the Hindoo scripture, is ascribed to Vasisht'ha. It is in prose, with poetry intermixed; and is quoted as high law authority. (See **VEDA.**)

His wife, named Arundhati, is represented to have been exemplary in regard to holiness and sanctity, and to have been translated to the skies with her sapient husband : she is still quoted as proverbial for virtue and constancy. Vasisht'ha is a star of the second magnitude, in N. lat. 60° , and Arundhati is a smaller star near it.

In the Agni Purana, a hymn is addressed to Vasisht'ha ; affording some clue to the relative antiquity of the poetical romances bearing the common denomination of *Purana* ; which see.

VASIT, or WASIT, in *Geography*, a town of the Arabian Irak, on the Tigris. This town was built in the beginning of the eighth century, by Al Hejâj, the Arabian general. A mint was established, and in 707, money was coined there by order of the caliph. In 1401 it was plundered by Timur Bec ; 96 miles S.E. of Bagdad. N. lat. $32^{\circ} 18'$. E. long. $45^{\circ} 38'$.

VASKINA, a gulf or bay of Russia, on the south coast of the island of Kalguev.

VASKOVNIA, a town of Russia, in the government of Pskov ; 120 miles S.S.E. of Pskov.

VASLUI, a town of European Turkey, in Moldavia, on the Birlat ; 32 miles S. of Jassy. N. lat. $46^{\circ} 40'$. E. long. $27^{\circ} 45'$.

VASOKY, in Hindoo mythological *Legend*, is a name of a mighty serpent, more commonly called *Seha* ; which see. The name of Vasoky, however, frequently occurs in the extravagant legends of the East. See KALIYA and KURMAVATARA.

VASON, in *Geography*, a town and castle of Hungary ; 20 miles W.S.W. of Stuhl Weissenburg.

VASPINGE, a town of Persia, in the province of Adirbeitzan, containing about 600 houses ; 9 miles from Tauris.

VASQUEZ, a town of the island of Cuba ; 66 miles N.W. of Villa del Principe.—Also, a river of Mexico, which runs into the Spanish Main, N. lat. $11^{\circ} 30'$.

VASSAL, VASSALLUS, in our *Ancient Customs*, a person who vowed fidelity and homage to a lord, on account of some land, &c. which he held of him in fee.

Du-Cange will have the word to come from *vassus*, which anciently signified a *servant* or *domestic* of a prince, and sometimes also the *comites*, or *assessores*, in public trials. Menage, after Cujas, takes vassal to have been formed of *geffel*, an ancient German word, signifying *companion*. Caneuue derives it from the Gaulish *geffus*, a *brave man*, from *geffo*, or *geffum*, or *jesum*, a kind of javelin used among them. Vossius derives vassal from *vas*, *vadis*, *pledge* ; whence also he will have it to be, that they are sometimes called *fideles*.

The vassal was also called *piratus*, *lord's-man*, and *see-man* ; but now the denomination is changed into that of *tenant in fee*.

Accordingly the vassal, or feudatory, was only another name for the tenant or holder of the lands ; though, on account of the prejudices we have justly conceived against the doctrines that were afterwards grafted on this system, we now use the word vassal opprobriously, as synonymous to slave or bondman. The manner of the grant, on the part of the proprietor or lord, who retained the dominion, or ultimate property of the feud, or fee, was by words of gratuitous and pure donation, *dedi et concessi* ; which are still the operative words in our modern infeodations, or deeds of feoffment. This was perfected by the ceremony of corporal investiture, or open and notorious delivery of possession, in the presence of the other vassals, which perpetuated among them the era of the new acquisition, at a time when the art of writing was very little known ; and, therefore, the evidence

of property was reposed in the memory of the neighbourhood : who, in case of a disputed title, were afterwards called upon to decide the difference, not only according to external proofs, adduced by the parties litigant, but also by the internal testimony of their own private knowledge.

They sometimes also used the term *vassour* for vassal ; whence *vavassour*.

If a vassal offended his lord grievously, either in person or in honour, he committed the crime of felony ; which carried with it a confiscation of his fee.

VASSAL, a *Rear*, is he who holds of a lord, who himself is vassal of another lord.

VASSAL was anciently used for soldier ; by reason fees, at first, were given to none but military men.

VASSALAGE, the state of a vassal ; or a servitude and dependency on a superior lord.

Anciently, they distinguished between *liege vassalage*, and *simple vassalage*.

Liege vassalage only belonged to the king ; as carrying with it an obligation on the side of the vassal to serve his lord in war, against all persons whatever. See *LIEGE*.

In all *simple vassalage*, the fealty, or liege vassalage, was still reserved to the king.

Some also distinguish *active vassalage*, and *passive* : the first is the right of fealty residing in the lord ; the second, the service and duties incumbent on the tenant.

VASSALBOROUGH, in *Geography*, a town of the province of Maine, on the Kennebeck ; 204 miles N.E. of Boston.

VASSEN, or WAESSEN, a town of Holland, in the department of Guelderland ; 12 miles S. of Hattem.

VASSIETTE, a river of America, which runs into lake Michigan, N. lat. $44^{\circ} 38'$. W. long. $85^{\circ} 18'$.

VASSY, a town of France, in the department of the Calvados ; 8 miles E. of Vire.—Also, a town of France, and seat of a tribunal, in the department of the Upper Marne. In the year 1562, a bloody persecution against the Protestants began in this town ; 9 miles S. of St. Dizier. N. lat. $48^{\circ} 30'$. E. long. $5^{\circ} 2'$.

VASTAN, a town of Curdistan, on lake Van. In 1386, it was taken by Timur Bec ; 20 miles S.W. of Van.

VASTANFORS, a town of Sweden, in Westmanland ; 32 miles N.N.W. of Stroemsholm.

VASTAUNA, in *Ancient Geography*, a town of Asia, situated in the S.E. part of the lake Arisfa, towards the 38th degree of latitude.

VASTO, in *Law*, a writ that lies against the tenant for life, or years, for making waste.

VASTUS, in *Anatomy*, the name of two very large muscles belonging to the thigh. The body of the femur is completely enveloped, except at the *linea aspera*, by a thick muscular mass : this may be distinguished at its origin into three portions, which soon become blended together, so as not to admit of separation. The part which covers the outside of the bone is called *vastus externus* ; that which covers the inside, *vastus internus* ; and the middle, *cruralis*, or *cruræus*. These have usually been described as three distinct muscles ; but some modern anatomists have more properly considered them as one, under the name of *triceps femoris* : they form the *tri-femoro-rotulien* of Dumas.

The *triceps cruris* then is a very thick fleshy mass, of a rounded or convex figure, covering the thigh-bone, and extending from the hæs of the trochanters to the patella and tibia.

The anterior surface is covered, towards the outside, by the tendon of the *gluteus maximus*, the *tenor vaginæ*, the *fascia*

fascia lata, and the short portion of the biceps; at the middle, by the iliacus internus, rectus extensor cruris, and the external circumflex vessels; on the inside, by the sartorius, the femoral artery, and the fascia. The posterior surface covers the body of the femur, with the exception of the linea aspera; it is attached to the anterior, external and internal surfaces of the bone, from the bases of the trochanters to within four fingers breadth of the knee; then it is separated from the femur by a loose and fatty cellular substance, and lastly, it covers the synovial membrane of the knee-joint.

The outer margin is fixed to the rough line, which descends from the great trochanter to the linea aspera, together with the gluteus maximus, to which it is closely connected: it is then fixed to the external edge of the linea aspera, in its whole length, and to the upper two-thirds of that line, which descends from the linea aspera to the external condyle of the femur, being connected in the latter situation with the fascia lata. The internal edge is fixed to the corresponding inner edge of the linea aspera, from the trochanter minor downwards; and to the upper two-thirds of the line descending from it to the external condyle, being connected here with the tendon of the triceps adductor. Its upper extremity is divided into the three portions already mentioned. The external (vastus externus) and most considerable is fixed to the circumference of the basis of the great trochanter; it descends on the outside of the thigh, increasing in size to the middle of the limb, and then diminishing again. At first it is separated from the middle portion by a thin stratum of cellular substance; but they are soon confounded in one mass. The internal portion (vastus internus) is not in general very distinct from the middle. Commencing at the root of the little trochanter, it descends on the inside of the femur, first increasing in size, and then diminishing again. On its outside it is separated from the middle portion, if at all, by a very slight cellular line, for about an inch or two, after which they are confounded in one mass. The middle and smallest division (cruralis) commences at the basis of the neck of the thigh-bone, by an attachment to the rough line, which reaches from the great to the small trochanter: it descends perpendicularly, increasing in size, separated at first from the lateral portions, but soon inseparably joined with them into one mass, surrounding the body of the femur, and ending in a tendinous extremity, attached to the basis and sides of the patella, and to the tuberosities of the tibia.

The last-mentioned attachment is effected by means of a broad and thick tendon, connected in front to that of the rectus extensor cruris, and expanded laterally into aponeuroses fixed to the tuberosities of the tibia. Of these aponeuroses, the outer is closely connected to the fascia lata. The tendon of the triceps is divided above into three broad portions, which ascend on the three divisions of the muscle. A thick and broad aponeurotic sheet commences from the basis of the trochanter major and the linea aspera, and covers the upper half of the vastus externus: a similar but smaller aponeurosis descends from the linea aspera on the vastus internus. The muscular fibres of the vastus externus pass obliquely downwards and forwards from its superior aponeurosis, and from the aponeurotic septum, which separates it from the short head of the biceps to the inferior tendon. Of these fibres, the upper are the longest and most perpendicular; the succeeding ones become more and more oblique, and the lowest approach to the transverse direction, accompanying the tendon to within an inch of its insertion.

The fleshy fibres of the vastus internus pass with a corre-

sponding obliquity between the two aponeuroses; the inner or anterior being the longest and straightest, the lower shorter, and more transverse. Of the middle portion, the muscular fibres are parallel to the axis of the thigh, arising from the anterior and lateral surfaces of the bone, and terminating in the lower tendon.

A prolongation of the synovial membrane of the knee extends for some distance behind this portion, above the patella, and thus supplies the place of a bursa mucosa. The lateral portions of the inferior tendon adhere very closely to the synovial membrane of the knee.

The triceps femoris straightens the knee-joint, either by moving the leg forwards on the thigh, or the thigh on the leg. These are very important muscles in progression, when they bring the thigh forwards on the leg of the advanced limb. When we are descending an inclined surface, and the heels slip, they make a great effort, by drawing forwards the thighs, to prevent the body from falling: in this exertion the patella is sometimes fractured. In standing, they preserve the thigh-bones perpendicular over the legs. They extend the leg on the thigh, where the limb left behind in progression is advanced in its turn in front of the foot which has just reached the ground.

VASU, in *Hindoo Mythology*, a name of the regent of the winds, more commonly called *Pavana*; which see. But the word occurs more frequently in the plural, when "the Vafus" seem to imply the eight winds collectively; the Hindoos having many fables connected with this number of winds. It is not easy to discriminate at all times between the Vafus and the Maruts of the Hindoos. See *MARUT*.

VASUDEVA is the name of the mortal father of their god Krishna: his mother was Devaky. (See *KRISHNA*.) The name Vasudeva is said to mean *giver of wealth*. Krishna himself is sometimes called by this name.

VASUGAN, in *Geography*, a river of Russia, which runs into the Oby, N. lat. 59°. E. long. 80° 14'.

VAT, in *Commerce*, &c. See *FAT*.

VAT, an oil measure of Holland, containing of oil of olives 717 mingels, and weighing 1730 lbs. avoirdupois. Train-oil is sold in quartels of 18 or 21 stekans; also in vats of 12 stekans, or 192 mingels: the mingel of 2 pints, or 8 musies of rain-water, weighs about 2 lbs. 4½ oz. Amsterdam weight. The aam, by which Rhine and Moselle wine, and also spirits distilled from corn are sold, contains 4 ankers, 8 stekans, 21 viertels, 64 stoops, 128 mingels, 256 pints, or 1024 musies: and holds 8966 Dutch, 7705 French, or 9351 English cubic inches, or about 40½ English wine gallons. A vat of French wine contains 4 oxhoofdens, or 6 tierces. The oxhoofden should hold 200 mingels, but is commonly reckoned at 180 mingels, and the tierce at 120.

VAT, or *Vate*, in *Minerology*, denotes a square hollow place on the back of a calcining furnace, in which they lay the next serving of tin-ore to dry, before it is let down into the furnace, into which it passes through a plug-hole in the bottom of this vat, or *dry*.

VATABLE, or *GASTEBLED*, FRANCIS, in *Biography*, was born at Gamache, a village in Picardy, and having first distinguished himself in Greek literature, and by a translation into Latin of Aristotle's "Parva Naturalia," devoted himself to the study of the Hebrew language, in which he excelled, and which he restored in France. He was appointed Regius professor of Hebrew at Paris by Francis I., in 1531, and the lectures which he made on the Old Testament were delivered to large audiences. His brief and clear explanations of the literal meaning of the texts were preserved

preserved by some of his hearers, collected by Robert Stephens, and added to his publication in 1545, of Leo Judæ's Latin version of the Bible. But as they contained some free passages, they were condemned by the doctors of the theological faculty in Paris, who, imperfectly acquainted with Hebrew, reposed their confidence in the Vulgate. However, the university of Salamanca reprinted the text and notes in Spain, R. Stephens defended them against the Paris theologians, and they have since been approved by men of learning. He not only encouraged Clement Marot to translate the Psalms into French verse, but assisted him in the undertaking. Vatable, though suspected of heresy, was an orthodox Catholic, and opposed the discipline and opinions of the Calvinists. He died in 1547, possessed of the abbacy of Bellocane. Dupin.

VATAN, in *Geography*, a town of France, in the department of the Indre; 11 miles N.W. of Issoudun. N. lat. $47^{\circ} 5'$. E. long. $1^{\circ} 54'$.

VATERIA, in *Botany*, was so named by Linnæus, in honour of Abraham Vater, professor of Medicine at Wittenberg, and author of *Catalogus Horti Wittenbergensis*, (a mere catalogue,) as well as of some botanical dissertations, on the Balsam of Mecca, on *Hippopane*, &c. This gentleman was born in 1684, and died in 1751. He succeeded his father in the professorship, who died in 1732, aged eighty-one, and was also a naturalist.—Linn. Gen. 269. Schreb. 359. Mart. Mill. Dict. v. 4. Juss. 258. Lamarck Illustr. t. 475.—Class and order, *Polyandria Monogynia*. Nat. Ord. akin to *Guttifera*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five acute segments, permanent, at length reflexed. *Cor.* Petals five, ovate, thick, entire, spreading. *Stam.* Filaments numerous, very short; anthers vertical, awl-shaped, much longer than the filaments, with two capillary points. *Pist.* Germen superior, roundish; style simple, short; stigma capitate. *Peric.* Capsule turbinate, coriaceous, seated on the reflexed calyx, marked with three furrows, separating into three valves, with one cell. *Seed* solitary, ovate, with a reddish skin.

Ess. Ch. Petals five, undivided. Calyx five-cleft, permanent. Capsule coriaceous, of three valves and one cell. Seed solitary.

Obs. Retzius and Vahl have removed this plant to *ELÆOCARPUS*, see that article; but without giving any sufficient reason. On the contrary, they describe the *petals* as entire; nor have they thrown any light upon the *fruit*, which, as described in the *Hortus Malabaricus*, cannot accord with *Elæocarpus*. The large figure, on the right hand, in that book, cannot be reconciled with the rest, unless it be a seed vegetating. Jussieu seems staggered as to the character of this fruit, by finding the rudiments of three *seeds* in the germen. But this may very well be, and yet only one may ever come to perfection. The same learned author remarks, that Linnæus, in his *Syſtema*, attributes three *seeds* to *Vateria*. This is true; but we believe it a typographical error, originating in the tenth edition of *Syſt. Nat.* especially as the synoptical table, at the head of the class, remains with the character of a single seed. This contradiction, whichever of the two characters be correct, is heedlessly perpetuated through every following edition. On the whole, there appears more reason to retain than to abolish the genus in question.

1. *V. indica*. Copal *Vateria*. Linn. Sp. Pl. 734. (*Elæocarpus copalliferus*; Retz. Obs. fasc. 4. 27. Vahl Symb. v. 3. 67. Willd. n. 5. Pænoc; Rheede Hort. Malab. v. 4. 33. t. 15.)—Native of Malabar and Ceylon. A tall and handsome tree, generally sixty feet high, with wide extended branches, and a thick bark, which when wounded

discharges a clear, pellucid, fragrant resin, acrid and bitter to the taste, at length becoming yellow and brittle like glass. This, according to Kœnig, is one kind of *COPAL*; see that article. Persons experienced in the use of this gum, so useful for varnishing anatomical preparations, know that there are, as Kœnig says, several different things imported under the same name, which are not all equally soluble, even in oil of lavender. The *leaves* of this tree are alternate, stalked, a span long, elliptical, acute, coriaceous, entire, smooth. *Flowers* in large terminal, downy panicles, white with yellow *stamens*; their scent sweet, like a lily. *Fruit* the size of a walnut in its green coat, swelling and blunt at the extremity, dark purple; its kernel white, bitterish and rather astringent, inclosed in a reddish skin, like that of a filberd. This description, taken from the *Hortus Malabaricus*, is precise; and as nothing is said of any hard shell, we do not see how the *fruit* can agree with that of *Elæocarpus*. The above-mentioned kernel, triturated with hot water, is reckoned strengthening to the stomach, and is given to stop vomiting or nausea.

Having formerly examined at sir Joseph Banks's a specimen of *Vateria*, in order to distinguish this genus from *VATICA*, (see that article,) we have corrected the generic characters from observations then made, particularly respecting the *anthers*, of which Retzius and Vahl have also given a faithful account. Linnæus had no specimen, but described the genus from one in Hermann's herbarium, now at sir Joseph Banks's. Vahl is surely mistaken in saying the *corolla* and *fruit* agree with *Elæocarpus*!

VATES, in *Mythology*, the name of a class of Druids.

VATHI, in *Geography*, a town on the north coast of the island of Samos, in a bay called the Gulf of Vathi. N. lat. $37^{\circ} 40'$. E. long. $26^{\circ} 54'$.

VATHIA, or BERBATHI, anciently *Tyrinx*, a town of European Turkey, in the Morea; 16 miles N.E. of Napoli di Romania.

VATI, a town of the island of Siphanto. N. lat. $36^{\circ} 57'$. E. long. $24^{\circ} 46'$.

VATICA, in *Botany*, an unexplained name of Linnæus, apparently derived from the same source as *vaticinatio*, a prophesying. Hence the writer of the present article ventured to suggest, as a query, whether the plant might have any superstitious use among the Chinese, from whose country it is said to have been brought. This conjecture appears in the form of a general opinion in *De Theis*, strengthened by a reference to Boehmer's *Lexicon*, p. 208, a book not within our reach. Notwithstanding all this, there is great doubt whether the plant comes from China, the specimens being marked India, just like many others, known to have been received from Java by Linnæus. In fact, these specimens are so like *VATERIA* (see that article) in appearance and character, that if it were possible to suppose the anthers could vary so remarkably, we should suspect these plants might be only sexual differences of one species. Having started this difficulty without having the means of overcoming it, we proceed to describe *Vatica*.—Linn. Mant. 2. 152. Schreb. Gen. 318. 831. Willd. Sp. Pl. v. 2. 847. Mart. Mill. Dict. v. 4. Sm. Plant. Ic. 36. Juss. 259. Lamarck Illustr. t. 397.—Class and order, *Dodecandria Monogynia*. Nat. Ord. akin to *Guttifera*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, erect, ovato-lanceolate, acute segments. *Cor.* Petals five, sessile, obovate, entire, thrice the length of the calyx, folded over each other, in some flowers to the left, in others to the right; their inner surface smooth; outer, in the exposed half, hoary. *Stam.* Filaments none; anthers fifteen, sessile, three on the base of each petal, small, ovate, smooth, of four

four obtuse cells, the two outer cells terminated by a small, intermediate, upright spine, the two inner but half as long, without any spine. *Pist.* Germen superior, conical, with five angles, obtuse, hoary; style cylindrical, with five angles, twisted; stigma bluntish, obscurely three-lobed. *Peric.* unknown, but the germen has three cells, with the rudiment of a solitary seed in each.

Eff. Ch. Petals five, undivided. Calyx five-cleft. Anthers fifteen, sessile, of four cells.

1. *V. chinensis.* Chinese Vatica. Linn. Mant. 2. 242. Willd. n. 1. Sm. Plant. Ic. t. 36.—Native of China, according to Linnæus, but his authority, as we have said, does not appear. This seems to be a tree, very near *Vateria indica*, from which it chiefly differs in the number and form of the *stamens*. As to the *fruit*, Jussieu's having found three cells and as many *seeds*, in the *germen* of *Vateria*, renders the supposed distinction in the ripe *fruit* very doubtful. The *leaves*, *inflorescence*, &c. discover no difference, and the *flower-stalks* and *calyx*, as well as *footstalks*, are clothed with the same fine, short, close, hoary pubescence, in both. It is much to be wished that some East Indian botanist would clear up these doubts respecting two very fine, and hitherto little-known plants. We must add, that if this be *Vateria*, nothing can be more distinct in its *petals* from *Eleocarpus*; for instead of the thin texture, and curiously lacinated margin, appropriate to the latter, their thick undivided substance, and partial hoariness at the back, prove that those genera ought never to be confounded together.

VATICA, in *Geography*, a sea-port town of European Turkey, in the Morea, situated in a large bay, to which it gives name; 44 miles S.E. of Misitra.

VATICAN, VATICANUS, is properly the name of one of the seven hills on which Rome stands: on the foot of this is the famous church of St. Peter, hence called the Vatican; and a magnificent palace of the pope, which has the same denomination. Hence arise divers figurative expressions; as *the thunderbolt of the Vatican*, *q. d.* the pope's anathema, &c.

The word, according to Aulus Gellius, is derived from *vaticinium*, *prophecy*; by reason of the oracles and predictions which were used to be delivered there by the inspiration of an ancient deity, called *Vaticanus*; who was supposed to unbind the organs of speech in new-born children; and whom others will have to be no other than Jupiter, considered in that capacity.

VATICAN, *The Library of the*, is one of the most celebrated in the world: it is particularly remarkable for its manuscripts. It was first erected, according to Petavius (*Rat. Temp. lib. ix. cap. 9.*) by pope Nicholas V., who succeeded to the papal chair in 1447. It was re-established, after the books had been dispersed, under the pontificate of Calixtus III., by Sixtus IV.; and after having been almost entirely destroyed by the army of Charles V. it was not only restored to its former state by Sixtus V., but greatly enriched with books and manuscripts. It was finally fixed in the Vatican, under the pontificate of Martin V.

Towards the beginning of the 17th century, it was greatly augmented by the addition of that of the elector palatine. It is open to all the world three or four times a week. In it are shewn a Virgil, Terence, &c. above a thousand years old; as also the manuscript on which the edition of the Septuagint was made; and abundance of rabbinical manuscripts.

VATICAN *Manuscript*, is one of the most celebrated manuscripts of the Greek version of the Bible now extant in the world. It was polished at Rome by cardinal Carafa, at the command of Sixtus Quintus, in 1587; and in the preface, it is said to have been written *ante millesemum ducentum*

tesimum annum, *i. e.* before 387; but Blanchini supposes it a few years later. A Latin edition from this manuscript, with notes, was printed at Rome in 1588, by Flam. Nobilius; and an edition, with the Greek and Latin, with the division of the verses according to the Vulgate, and Nobilius's Latin notes, and the Greek scholia of Carafa, by J. Morinus, at Paris, in 1628. This manuscript is written in large or text letters, and has no distinguishing chapters, verses, words, nor any marks of accents. It is mutilated both at the beginning and end; and wants the first forty-six chapters of Genesis, thirty-two Psalms, *viz.* from the 105th to the 137th, and the latter part of the Epistle to the Hebrews, from chap. ix. ver. 14. with the other Epistles of Paul to Timothy, Titus, and Philemon, and the whole book of Revelation. It appears also, that the whole manuscript has been repaired, with fresh ink laid over the letters which were disappearing through age. In the edition of Carafa, the mutilated passages have been supplied from other copies.

It has been asserted, by two eye-witnesses, that this manuscript has undergone some alterations by a later hand. See *Le Long's Biblioth. Sacra*, cap. 3. sect. 4. and Wetstein's *Prolegomena*, Nov. Test. p. 24.

It is difficult to estimate the comparative value of this and the Alexandrian manuscript, in which thirty Psalms, a few chapters, and a few verses, are now lost, as well as parts of verses in different places; and in which there have been some rasures and insertions, as Grabe allows. If, as Grabe states it, that manuscript be the most respectable, which comes the nearest to the Hexaplar copy, the Alexandrian manuscript seems to claim that merit in preference to its rival. But if it be thought a matter of superior honour to come nearer the old Greek version, unaltered by Origen, that merit seems to belong to the Vatican. For farther particulars, see the *Prolegomena* of Walton, Grabe, Wetstein, Mills, and *Le Long*, *ubi supra*.

VATICANÆ PILULÆ, the name of an old form of medicine, intended as a purge. The recipe is in the old London Pharmacopœia; but the late ones have discarded it.

VATICANO, CAPE, in *Geography*, a cape on the W. coast of Calabria Ultra. N. lat. 38° 40'. E. long. 16° 52'.

VATICINATION, VATICINATIO, the act of prophesying, or divining. See DIVINATION, and PROPHECY.

VATIMONT, in *Geography*, a town of France, in the department of the Moselle; 8 miles W.N.W. of Morhange.

VATISA, or FATISA, a town of Asiatic Turkey, in the government of Sivas; 90 miles N. of Sivas.

VATO, a town on the W. coast of the island of Negropont. N. lat. 38° 20'. E. long. 24° 2'.

VATRANDEL, a town of Hindoostan, in the Carnatic; 4 miles N. of Vellore.

VATTIER, PETER, in *Biography*, an Arabic scholar, was born at Lizieux, in Normandy, and having been educated for the medical profession, was appointed physician and counsellor to Gaston, duke of Orleans, brother of Lewis XIII. To an extensive acquaintance with the ancient naturalists and physicians, both Greek and Latin, he added a peculiar attachment to Arabic writers, and translated many of their works. Among these are "The Mahometan History, or the Forty-nine Caliphs of Elmacin;" "The History of the Great Tamerlane, from the Arabic of Achamed, Son of Guerafpo;" "The Egypt of Mur-tadi;" "The Elegy of Tograi, with some Sentences from the Arabian Poets," &c. He also wrote a work, entitled "Nouvelles Persées sur la Nature des Passions," 1659, 4to. The time of his death is not known. Moreri.

VAVANGA, in *Botany*. See VANGUERIA.

VAVAO, or VAVOU, in *Geography*, one of the Friendly islands, in the South Pacific ocean, seen by Perouse in 1787, who says, "this island, which Capt. Cook never visited, is almost equal in size to Tongataboo, and has the advantage of being never in want of water, with a good harbour." It had been before discovered by the Spanish pilot Maurelle, and with a number of islands almost as considerable as those already explored by Capt. Cook, which he called the islands of Majorca. S. lat. 18° 34' of the western point. See TONGA.

VAVASOR, VALVASOR, *Vavafour*, or *Valvafour*, in our *Ancient Customs*, a diminutive of *vassal*, or *vassour*; signifying a *vassal of a vassal*, or one who held a fee of another vassal.

Yet Camden, and others, hold vavafor to be a dignity, next below that of a baron: he adds, that the word is formed of *vas sortitum ad valetudinem*, a vessel chosen for safety and health. Others derive it à *valvis*, *quasi obligatus sit adflare ad valvas domini, vel indignus sit eas intrare*; as being a person obliged to wait at his lord's door, or as unworthy to enter thereat; but this etymology is ridiculous enough.

Du-Cange distinguishes two sorts of vassals under this denomination: the *great*, called *valvasores*, who held of a king; such were counts and barons: and the *lesser*, called *valvasini*, who held of the former.

The valvasors are mentioned by our ancient lawyers as *virī magnæ dignitatis*; and sir Edward Coke speaks highly of them. But they are now quite out of use; and our legal antiquarians are not agreed upon even their original or ancient office.

VAVASORY, VAVASORIA, the quality of the land, or fee held by a vavafor.

"Quod dicitur de baronia non est observandum in vavatoria, vel aliis minoribus feodis quam baronia, quia caput non habent sicut baronia." Braët. lib. ii. cap. 39.

There are *base* vavafories, and *frank* or *noble* vavafories; according as it has pleased the lord to make his vavafor. *Base* vavafories are those for which the lord of the fee owes fummage, light-horse, rents, or other services. *Free* vavafories are such as are exempt from these services.

VAVASSEUR, FRANCIS, in *Biography*, was born in 1605, at Paray, in the diocese of Autun; and entering into the society of the Jesuits in 1621, and acting as regent in the schools for some years, he was called to Paris to occupy the chair of positive theology, the duties of which he discharged honourably for thirty-six years; and he died in this city in 1681, aged seventy-six years. He has been reckoned one of the most elegant and correct Latin writers, and wrote several theological pieces, some against Janseuism, and one of a singular subject, "On the personal Beauty of Jesus Christ;" and also poems chiefly on sacred subjects. The work which has chiefly distinguished him is a treatise "De Ludicra Dictione," or on the burlesque style, dedicated to Balzac. He also wrote a treatise "On the Epigram;" and "Remarks on the Poetics of Father Rapin." Moreri.

VAUBAN, SEBASTIAN LE PRESTRE, *Seigneur de*, marshal of France, and an eminent engineer, was born in 1633, and began to bear arms at the age of seventeen under the prince of Condé, general of the Spanish army. Being taken prisoner by a French party, he was engaged by cardinal Mazarin on the royal side, and employed in 1653 at the second siege of St. Menchoud, by which it was recovered to France. He also acted as engineer in the five following years at several other sieges. After the peace of the Pyrenées, he was employed in demolishing some places and fortifying others; and he also sug-

gested a variety of ideas, by the maturity and development of which he contributed in a high degree to the improvement of the science of fortification. On the renewal of the war in 1667, he conducted several sieges, at which Lewis XIV. attended in person, and he was commissioned to fortify several places, and in 1668 nominated governor of the citadel of Lille, which he had constructed. After the peace of Aix-la-Chapelle, he visited Piedmont, and gave designs to the duke of Savoy for some important fortresses. In the war of 1672 he again distinguished himself, particularly at the siege of Maeltricht, in which he introduced his famous method of attack by parallels and places of arms; and also on other occasions, when an opportunity offered for the display of his inventive genius. In carrying his schemes into execution he was anxious for saving life, and therefore preferred a slow and regular advance in sieges. The peace of Nimeguen afforded him leisure for fortifying towns; and of these, his master-piece was the port of Dunkirk. On the commencement of war, he again resumed his active services, and had the honour of taking Luxemburg, which was regarded as impregnable. Upon the whole, he fortified one hundred old places, constructed thirty-three new fortresses, and had the principal direction of fifty-three sieges. In recompence of his various exertions, he was advanced to several posts of honour, and in 1703 appointed marshal of France. At Dunkirk, whither he was sent in a state of great alarm, he died of a fluxion in his lungs, in March 1707, at the age of seventy-four years.

The character of Vauban, as a man and a citizen, was no less estimable than his superior talents and achievements in his professional capacity. Loyal and faithful to his sovereign, he studied to serve more than to please, and he manifested on all occasions an inviolable attachment to truth. As a liberal and zealous patriot, he made such observations, and collected such facts in his various travels, as contributed most effectually to the improvement and prosperity of his country. These were comprised in twelve large MS. volumes, which he modestly denominated "Mes Oisivetés;" and Fontenelle observes of him in relation to these, that if all his projects could be executed, his "idleness" would be more useful than his labours. In 1699, he was nominated an honorary member of the Academy of Sciences. The following works were either written by himself, or in consequence of ideas which he suggested: *viz.* "Manière de Fortifier, par M. de Vauban, mise en ordre par le Chevalier de Cambrai," Amst. 1689 and 1692, printed at Paris under the title of "L'Ingenieur François," with notes by Hebert, professor of mathematics; and afterwards with notes by the Abbé du Fay; "Nouveau Traité de l'Attaque et de la Defence des Places, suivant le Systeme de M. de Vauban, par M. Desprez de Saint-Sevin," Paris 1736; "Essais sur la Fortification, par M. de Vauban," Paris 1740; "Projet d'un Dime Royale," Rouen, 1707, often reprinted. This last work is attributed by Voltaire to Bois-Guillebert, author of a "Testament Politique" in the name of Vauban. Fontenelle Eloge. Moreri.

VAUBECOURT, in *Geography*, a town of France, in the department of the Meuse; 9 miles N. of Bar-le-Duc.

VAUCHERIA, in *Botany*, was so named by M. Decandolle, in his *Flore Française*, in honour of the discoverer of the genus, the Rev. M. Vaucher of Geneva, author of an excellent work in quarto, entitled *Histoire des Conservees d'Eau douce*, where this genus is established by the name of *Ethosperma*. The latter appellation has very properly given way to the above, previously chosen by M. Decandolle.—Sm. Engl. Bot. v. 25. 1765. "Decand. Rapport sur les Conservees,

ferves, Soc. Phil. 15." De Theis 478. Vauch. Conf. 25.
—Class and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ*.

Eff. Ch. Anther solitary, awl-shaped, incurved. Capsules adjoining to the anther, ovate, single-seeded, in pairs or solitary.

1. *V. fœffilis*. Sessile-fruited Vaucheria. Engl. Bot. t. 1765. (*Ectosperma fœffilis*; Vauch. Conf. 31. t. 2. f. 7. *Conferva vesicata*; Dillw. Conf. t. 74, without the anther. *Ceramium cœspitosum*; Roth Catal. v. 3. 120.)—Floating. Capsules in pairs and solitary, sessile on each side of the anther.—Found floating on the surface of pools, in large green patches, about February; and consisting of capillary, branched, smooth, rather elastic, tubular filaments, filled with a green pulpy substance, which separates in oblong portions, giving the filament a jointed appearance. Capsules lateral, sessile, pellucid, commonly in pairs, each containing one large green seed, and having next to them an awl-shaped body, asserted by Vaucher to be the anther. Yet sometimes this body seems to shoot out into a branch. Vesicles are often found on the branches, perhaps of the nature of galls, inhabited by the aquatic animalcule called by Muller *Cyclops Lupula*, in considerable numbers, with one dark-coloured animal besides.

2. *V. geminata*. Twin-stalked Vaucheria. Engl. Bot. t. 1766. (*Ectosperma geminata*; Vauch. Conf. 29. t. 2. f. 5.)—Floating. Capsules in pairs and solitary, on opposite partial stalks, growing out of one common stalk with the anther.—Sent by Mr. W. Borrer, along with the preceding, from Suffex. The habit is the same in both, but the *fructification*, furnished with partial stalks, and with a common stalk for both organs, appears to afford a good specific character. Some botanists nevertheless, and among them, if we mistake not, Mr. Dillwyn, consider these two plants as mere varieties of each other.

3. *V. velutina*. Velvet Vaucheria. (*Conferva velutina*; Engl. Bot. t. 1556. Dillw. Conf. t. 77. *Byssus velutina*; Linn. Sp. Pl. 1638. *B. tenerima viridis*, *velutum referens*; Dill. in Raii Syn. 56. Musc. 7. t. 1. f. 14. *B. terrestris viridis herbacea et mollissima*, *filamentis ramosis et non ramosis*; Mich. Gen. 211. t. 89. f. 5.)—Erect, tufted. Filaments beaded, somewhat rigid. Capsules sessile.—This covers the earth, in moist shady places, with a most beautiful fine green velvet carpet, fragrant like several of the *Jungermannia*, even for a long time after it is dried. It appears to be perennial, occurring in summer as well as winter, but has been thought more common than it really is, because Dillenius and others have confounded with this plant a much more general one, *Conferva muralis*, Engl. Bot. t. 1554, which is prostrate, resembling satin rather than velvet, and has no sweet scent. M. Vaucher is our authority for removing this species hither. Micheli has but imperfectly figured the capsules, and in such a manner that they may belong either to those *Confervæ* which make Roth's genus of *Ceramium*, or to *Vaucheria*. Of the anther we know nothing.

We have here limited ourselves to the British species, which may possibly prove but a small part of the genus, when the subject has been sufficiently examined.

VAUCLAIN, LE, in *Geography*, a town of the island of Martinico, situated in a bay on the N.E. coast. N. lat. 14° 36'. W. long. 60° 46'.

VAUCLUSE, a town of France, in the department of the Doubs; 8 miles S.W. of St. Hypolite.

VAUCLUSE, formerly Venaissin, and the principality of Orange, on the left hand of the Rhone, in N. lat. 44°, one of the twelve departments of the S.E. region of France,

bounded on the N. by the departments of the Drôme and Ardèche, on the E. by the department of the Lower Alps, on the S. by the department of the Mouths of the Rhone, and on the W. by that of the Gard. It derives its appellation from the fountain of Vacluse, (see FONTAINE de *Vacluse*;) which is the source of the river Sorgues, and made memorable by the near residence of Petrarch and Laura. Its territorial extent is 3700 kilometres, or 186 square leagues, and its population consists of 190,180 inhabitants. It is divided into 4 circles or districts, 22 cantons, and 150 communes. The circles are, Orange, including 54,293; Avignon, 47,351; Carpentras, 39,714; and Apt, 48,822 inhabitants. According to Hassenfratz, its length in French leagues is 15, and its breadth 10: its circles are 4, its cantons 52, and its population consists of 200,500 persons. Its capital is Avignon. Its contributions, in the eleventh year of the French era, amounted to 1,367,701 francs; and its charges, administrative, judiciary, and for public instruction, were 227,109 francs, 14 cents. This department consists of plains, marshes, gentle eminences, and hills. Mont-Ventoux is upwards of 6000 feet above the level of the sea. The soil is various, and indifferently cultivated. The products are grain, silk, fruits, and roots. In this department are coal impregnated with sulphur, a few metallic substances, potter's-earth, mineral springs, &c.

VAUCOULEURS, a town of France, and principal place of a district, in the department of the Meuse; 8 miles N.E. of Gondrecourt. N. lat. 48° 36'. E. long. 5° 44'.

VAUD, PAYS DE, a country of Switzerland, of which travellers and historians speak with rapture, particularly of that part which borders on the lake of Geneva. It is almost wholly a gradual ascent from the edge of the lake, richly laid out in vineyards, corn-fields, and luxuriant meadows, and chequered with continued hamlets, villages, and towns: the shores are generally of the clearest gravel, and the water of the finest transparency. This country is one of the two great divisions into which the canton of Berne is divided; the other being the German district. The Pays de Vaud, after the decline of the Roman empire, made a part of the kingdom of Burgundy, from which it fell to the empire of Germany, under which the dukes of Zaringen held it as a fief, and at the extinction of that family, it became annexed to the estates of the counts of Savoy. It was conquered from the house of Savoy by the canton of Berne in 1536, and in this year the reformation was introduced. From that period the whole Pays de Vaud, excepting the common bailliages of Grenchon, Orbe, and a small portion of it which was ceded to Friburgh, has been subject to Berne, and forms a part of that canton. The German district was gained by conquest from the estates of the empire. In each of these divisions justice is administered and taxes regulated by peculiar laws and customs. Each division has its treasurer and chamber of appeal resident in the capital; the chamber of appeal belonging to the Pays de Vaud judges in the last resort; but the inhabitants of the German district may appeal to the sovereign council. During the French revolution, the Pays de Vaud was separated from the canton of Berne, and formed into an independent republic under the protection of France, in January 1798. In the new division of Switzerland, it forms the canton or department of Leman, of which Lausanne is the capital. The Pays de Vaud is estimated to be about 60 miles long, and as many broad; bounded on the N. by the county of Neuchâtel, on the E. by the canton of Friburgh, on the S. by the lake of Geneva and the river Rhône, and on the W. by France. It includes the towns and bailiwicks of Lausanne, Yverdon, Moudon, Avenche, Vevey, Morges, and several others.

VAUDEMONT, a town of France, in the department of the Meurte; 4 miles S. of Vezelize.

VAUDEVILLE, a song sung in the streets by ballad-singers, the subject of which is generally jocose or satirical. The origin of this little kind of poem is traced up to the time of Charlemagne. But according to the more general opinion, it was invented by a certain man of the name of Basselin, Foulon de Vere in Normandy; and in order to dance, as people used to assemble in the Val de Vire, they were called Vaux de Vire, and afterwards, by corruption, *Vaudevilles*.

The air of these Vaudevilles is generally very unmusical. But as people merely listen to the words, the tune only helps to enforce the voice and render the words more audible. But, as music, there is in general neither taste, melody, nor measure in their tunes. The Vaudeville, with respect to the words, belongs exclusively to the French, and they are sometimes very piquant and pleasant. Rousseau.

VAUDIER, in *Geography*, a town of France, in the department of the Stura, late in the province of Coni; 5 miles S.E. of Demont.

VAUDOIS, **VALDENSES**, or *Waldenses*, in *Ecclesiastical History*, a name given to a sect of reformers, who made their first appearance about the year 1160.

Of all the sects that arose in this century, none was more distinguished by the reputation it acquired, by the multitude of its votaries, and the testimony which its bitterest enemies bore to the probity and innocence of its members, than that of the *Waldenses*, so called, says Mosheim, from their parent and founder Peter Waldus, or Valdis. They were also called *Leonists*, from Leonz, the ancient name of Lyons, where their sect took its rise. The more eminent persons of that sect manifested their progress towards perfection by the simplicity and meanness of their external appearance: hence, among other things, they wore wooden shoes, which, in the French language, are termed *sabots*, and had imprinted upon these shoes the sign of the cross, to distinguish themselves from other Christians; and on these accounts they acquired the denomination of *Sabbatati* and *Insabbatati*.

The origin of this famous sect, according to Mosheim, was as follows: Peter, an opulent merchant of Lyons, furnished Valdenfis, or Validifius, from Vaux, or Waldum, a town in the marquisate of Lyons, being extremely zealous for the advancement of true piety and Christian knowledge, employed a certain priest, called Stephanus de Evifa, about the year 1160, in translating from Latin into French the four Gospels, with other books of Holy Scripture, and the most remarkable sentences of the ancient doctors, which were so highly esteemed in this century. But no sooner had he perused these sacred books with a proper degree of attention, than he perceived that the religion, which was now taught in the Roman church, differed totally from that which was originally inculcated by Christ and his apostles. Struck with this glaring contradiction between the doctrines of the pontiffs, and the truths of the Gospel, and animated with zeal, he abandoned his mercantile vocation, distributed his riches among the poor (whence the Waldenses were called *poor men of Lyons*), and forming an association with other pious men, who had adopted his sentiments and his turn of devotion, he began, in the year 1180, to assume the quality of a public teacher, and to instruct the multitude in the doctrines and precepts of Christianity.

Beza, and other writers of note, who are followed by Dr. Maclean, the learned translator of Mosheim's History, give different accounts of the origin of the Waldenses; alleging, that it seems evident from the best records, that Valdis derived his name from the true Waldenses of Piedmont,

whose doctrine he adopted, and who were known by the names of Vaudois and Waldenses, before he or his immediate followers existed. If the Waldenses or Waldenses had derived their name from an eminent teacher, it would probably have been from Valdo, who was remarkable for the purity of his doctrine in the eleventh century, and was the contemporary and chief counsellor of Berengarius. But the truth is, that they derive their name from the *valleys* in Piedmont, which in their language were called *vaux*, and hence *Vaudois*, their true name; hence also Peter, or, as others call him, John of Lyons, was called in Latin *Valdis*, because he had adopted their doctrine; and hence the term *Waldenses* or *Waldenses*, used, by those who write in English or Latin, in the place of *Vaudois*. The bloody inquisitor, Reinerus Sacco, who exerted such a furious zeal for the destruction of the Waldenses, lived but eighty years after Valdis of Lyons, and must, therefore, be supposed to know whether or not he was the real founder of the Waldenses or Leonists; and yet it is remarkable, that he speaks of the Leonists as a sect that had flourished above five hundred years; and mentions authors of note to make their antiquity ascend to the apostolic age. See the account given of Sacco's book by the jesuit Gretler, in the *Bibliotheca Patrum*. See also Leger's *Histoire Gen. des Eglises Vaudoises*, cap. 2. 25, 26, 27.

But to return to the history of Peter Valdis. Soon after Peter had assumed the exercise of his ministry, the archbishop of Lyons, and the other rulers of the church in that province, vigorously opposed him. However, their opposition was unsuccessful; for the purity and simplicity of that religion which these good men taught, the spotless innocence that shone forth in their lives and actions, and the noble contempt of riches and honours, which was conspicuous in the whole of their conduct and conversation, appeared so engaging to all such as had any sense of true piety, that the number of their followers daily increased. They accordingly formed religious assemblies in France, and afterwards in Lombardy, from whence they propagated their sect throughout the other provinces of Europe with incredible rapidity, and with such invincible fortitude, that neither fire, nor sword, nor the most cruel inventions of merciless persecution, could damp their zeal, or entirely ruin their cause.

The attempts of Peter Waldus, and his followers, were neither employed nor designed to introduce new doctrines into the church, nor to propose new articles of faith to Christians. All they aimed at was, to reduce the form of ecclesiastical government, and the manners both of the clergy and people, to that amiable simplicity, and primitive sanctity, that characterized the apostolic ages, and which appear so strongly recommended in the precepts and injunctions of the divine Author of our holy religion. In consequence of this design, they complained that the Roman church had degenerated, under Constantine the Great, from its primitive purity and sanctity. They denied the supremacy of the Roman pontiff; and maintained, that the rulers and ministers of the church were obliged, by their vocation, to imitate the poverty of the apostles, and to procure for themselves a subsistence by the work of their hands. They considered every Christian as, in a certain measure, qualified and authorized to instruct, exhort, and confirm the brethren in their Christian course, and demanded the restoration of the ancient penitential discipline of the church, *i. e.* the expiation of transgressions by prayer, fasting, and alms, which the new-invented doctrine of indulgences had almost totally abolished. They, at the same time, affirmed, that every pious Christian was qualified and entitled to prescribe to the penitent the kind or degree of satisfaction or

expiation that their transgressions required; the confession made to priests was by no means necessary, since the humble offender might acknowledge his sins, and testify his repentance to any true believer, and might expect from such the counsel and admonition which his case demanded. They maintained, that the power of delivering sinners from the guilt and punishment of their offences belonged to God alone; and that indulgences, of consequence, were the criminal inventions of fordid avarice. They looked upon the prayers and other ceremonies that were instituted in behalf of the dead, as vain, useless, and absurd, and denied the existence of departed souls in an intermediate state of purification; affirming, that they were immediately upon their separation from the body, received into heaven, or thrust down to hell. These, and other tenets of a like nature, composed the system of doctrine propagated by the Waldenses. It is also said, that several of the Waldenses denied the obligation of infant-baptism, and that others rejected water-baptism entirely; but Wall has laboured to prove, that infant-baptism was generally practised among them. *Hist. of Infant-Baptism*, p. 387, &c.

Their rules of practice were extremely austere; for they adopted, as the model of their moral discipline, the sermon of Christ in the mount, which they interpreted and explained in the most rigorous and literal manner, and, consequently, prohibited and condemned in their society all wars, and suits of law, and all attempts towards the acquisition of wealth, the inflicting of capital punishments, self-defence against unjust violence, and oaths of all kinds.

The government of the church was committed by the Waldenses to bishops, called also *majorales* or elders, presbyters, and deacons; for they acknowledged that these three ecclesiastical orders were instituted by Christ himself. But they thought it absolutely necessary that these orders should resemble the apostles of Christ, and be, like them, unlearned, poor, and furnished with some laborious trade or vocation, in order to gain by constant industry their daily subsistence; and indeed most of the Waldenses gained their livelihood by weaving; whence in some places the whole sect was called the *sect of the weavers*. The laity were divided into two classes, *viz.* the perfect and the imperfect Christians: the former divested themselves of all worldly possessions, manifested in the wretchedness of their apparel, their extreme poverty, and emaciated their bodies by frequent fasting: the latter were less austere, and approached nearer to the method of living generally received, though they abstained from all appearance of pomp and luxury.

The Waldenses were not without intestine divisions; for such of them as lived in Italy differed considerably in opinion from those who dwelt in France, and the other European nations. The former considered the church of Rome as the church of Christ, though much corrupted; they acknowledged, moreover, the validity of its seven sacraments, and solemnly declared they would continue always in communion with it, provided that they might be allowed to live as they thought proper, without molestation or restraint. The latter affirmed, on the contrary, that the church of Rome had apostatized from Christ, was deprived of the Holy Spirit, and was in reality, that whore of Babylon mentioned in the Revelation of St. John. They were also divided in their sentiments concerning the possession of worldly goods. In the fourteenth century, the Waldenses, though they were every where exposed to the fury of the inquisitors and monks, baffled all the attempts that were made to extirpate them. Many of them fled out of Italy, France, and Germany, into Bohemia, and other adjacent countries, where they afterwards associated with the Hussites, and

other separatists from the church of Rome. In the fifteenth century they subsisted in several European provinces, more especially in Pomerania, Brandenburg, the district of Magdeburg, and Thuringia, where they had a considerable number of friends and followers; though, it is said, that many adherents of this sect, in the countries now mentioned, were discovered by the inquisitors, and delivered over by them to the civil magistrates, who committed them to the flames. After the Reformation, in the sixteenth century, the descendants of the Waldenses, who lived shut up in the valleys of Piedmont, were naturally led, by their situation in the neighbourhood of the French, and of the republic of Geneva, to embrace the doctrines and rites of the reformed church. So far down, however, as the year 1630, they retained a considerable part of their ancient discipline and tenets; but being much reduced by the plague in that year, and deprived of many of their clergy, they applied to the French churches for spiritual succour; and the new teachers, sent from thence, introduced several changes into the discipline and doctrine of the Waldenses, and rendered them conformable, in every respect, to those of the Protestant churches in France. In this century they suffered much from the persecution of Philibert Emanuel, duke of Savoy, who at the solicitation of the pope resolved to force his subjects to return to the communion of the church of Rome; and in 1561 sent a Dominican friar, as an inquisitor, with forces to effect his purpose. After ineffectual supplications, they took up arms, and so far prevailed, after enduring very severe distress, as to obtain some degree of liberty and peace.

During the greatest part of the seventeenth century, those of them who lived in the valleys of Piedmont, and who had embraced the doctrine, discipline, and worship of the church of Geneva, were oppressed and persecuted, in the most barbarous and inhuman manner, by the ministers of Rome. This persecution was carried on with peculiar marks of rage and enormity in the years 1655, 1656, and 1696, and seemed to portend nothing less than the total extinction of that unhappy nation. The most horrid scenes of violence and bloodshed were exhibited in this theatre of papal tyranny; and the few Waldenses that survived, were indebted for their existence and support to the intercession made for them by the English and Dutch governments, and also by the Swiss cantons, who solicited the clemency of the duke of Savoy in their behalf. *Mosheim's Eccl. Hist.* vol. ii. iii. iv. *Eng. ed.* 8vo. *Dupin's Eccl. Hist. of the Sixteenth Century*, vol. ii. p. 414.

VAUDREVANGE, in *Geography*, a town of France, in the department of the Meurthe, on the Sarre; formerly a considerable town, but ruined by the wars in Lorraine; 3 miles N. of Sar-Louis.

VAUDREUIL, a town of France, in the department of the Eure. In 1195, the king of France besieged it, and Richard I. king of England, advancing to its relief, a battle ensued, in which the latter had the victory. Vaudreuil had formerly a royal palace; 4 miles N. of Louviers.

VAUGELAS, in *Biography*. See *Claude FAVRE*.

VAUGIRARD, in *Geography*, a town of France, in the department of Paris; 2 miles S.W. of Paris.

VAUGNERAY, a town of France, in the department of the Rhône and Loire; 8 miles W.S.W. of Lyons.

VAULT, FORNIX, in *Architecture*, an arched roof, so contrived, as that the several stones of which it consists, do, by their disposition, sustain each other.

Vaults are to be preferred, on many occasions, to soffits, or flat ceilings, as they give a greater rise and elevation; and, besides, are more firm and durable.

The ancients, Salmafius obferves, had only three kinds of vaults: the firft, the *fornix*, made cradle-wife; the fecond, the *teftitudo*, tortoise-wife, called by the French *cul de four*, or oven-wife; the third, the *concha*, made fhell-wife.

But the moderns fubdivide thefe three forts into a great many more, to which they give different names, according to their figures and ufe; fome are *circular*, others *elliptical*, &c.

The fweeps of fome, again, are larger, and others lefs portions of a fphere: all above hemifpheres are called *high*, or *furmounted* vaults; all that are lefs than hemifpheres, are *low*, or *furbafed* vaults, &c.

In fome, the height is greater than the diameter; in others, it is lefs: there are others, again, quite flat, only made with haunfes; others oven-like, or in form of a *cul de four*, &c. and others growing wider, as they lengthen, like a trumpet.

Of vaults, fome are *single*, others *double*, *cross*, *diagonal*, *horizontal*, *afcending*, *defcending*, *angular*, *oblique*, *pendent*, &c. There are likewife *Gothic* vaults, with *pendentives*, &c.

VAULTS, *Mafter*, are thofe which cover the principal parts of buildings; in contradiftinction to the *lefs*, or fubordinate vaults, which only cover fome little part, as a paffage, a gate, &c.

VAULT, *Double*, is fuch an one as, being built over another, to make the exterior decoration range with the interior, leaves a fpace between the convexity of the one and the concavity of the other: as in the dome of St. Paul's at London, and that of St. Peter's at Rome.

VAULTS with Compartments, are fuch whofe fweep, or inner face, is enriched with pannels of fculpture, feparated by platbands: thefe compartments, which are of different figures, according to the vaults, and are ufually gilt on a white ground, are made with flucco, on brick vaults; as in the church of St. Peter's at Rome; and with plaifter, on timber vaults.

VAULTS, *Theory of*. A femicircular arch, or vault, ftanding on two piedroits, or impofts, and all the ftones that compofe it being cut and placed in fuch manner, as that their joints, or beds, being prolonged, do all meet in the centre of the vault; it is evident, all the ftones muft be in form of wedges, *i. e.* they muft be wider and bigger at top than at bottom; by virtue of which they fustain each other, and mutually oppofe the effort of their weight, which determines them to fall.

The ftone in the middle of the vault, which is perpendicular to the horizon, and is called the *key* of the vault, is fupported on each fide by the two contiguous ftones, juft as by two inclined planes; and of confequence, the effort it makes to fall, is not equal to its weight.

But ftill that effort is greater, as the inclined planes are lefs inclined; fo that if they were infinitely little inclined, *i. e.* if they were perpendicular to the horizon, as well as the key, it would tend to fall with its whole weight, and would actually fall, but for the mortar.

The fecond ftone, which is on the right or left of the key-ftone, is fupported by a third; which, by virtue of the figure of the vault, is neceffarily more inclined to the fecond, than the fecond is to the firft; and, of confequence, the fecond, in the effort it makes to fall, employs a lefs part of its weight than the firft.

For the fame reafon, all the ftones, reckoning from the key-ftone, employ ftill a lefs and lefs part of their weight to the laft; which refting on an horizontal plane, employs no part of its weight; or, which is the fame thing, makes no effort to fall; as being entirely fupported by the impoft.

Now, in vaults, a great point to be aimed at is, that all the feveral ftones make an equal effort in order to fall: to effect this, it is vifible, that as each (reckoning from the key to the impoft) employs a ftill lefs and lefs part of its whole weight; the firft, for inftance, only employing one-half; the fecond, one-third; the third, one-fourth, &c.; there is no other way to make thofe different parts equal, but by a proportionable augmentation of the whole, *i. e.* the fecond ftone muft be heavier than the firft; the third, than the fecond, &c. to the laft; which fhould be vailtly heavier.

M. de la Hire demonftrates what that proportion is, in which the weights of the ftones of a femicircular arch muft be increafed, to be in equilibrio, or to tend with equal forces to fall; which gives the firmeft difpofition a vault can have.

Before him, architects had no certain rule to conduct themfelves by; but did all at random. Reckoning the degrees of the quadrant of the circle from the key-ftone to the impoft; the extremity of each ftone will take up fo much the greater arch, as it is farther from the key.

M. de la Hire's rule is, to augment the weight of each ftone above that of the key-ftone, as much as the tangent of the arch of the ftone exceeds the tangent of the arch of half the key. Now, the tangent of the laft ftone, of neceffity, becomes infinite, and of confequence, its weight fhould be fo too; but as infinity has no place in practice, the rule amounts to this, that the laft ftones be loaded as much as poffible, that they may the better refift the effort which the vault makes to feparate them; which is called the *shoot*, or *drift*, of the vault.

M. Parent has fince determined the curve, or figure, which the extrados, or outfide of a vault, whofe intrados, or infide, is fpherical, ought to have, that all the ftones may be in equilibrio. See ARCH.

VAULT, *Key of a*. See KEY and VOUSOIR.

VAULT, *Reins* or *Fillings-up of a*, are the fides which fustain it.

VAULT, *Pendentive of a*. See PENDENTIVE.

VAULT, *Impoft of a*, is the ftone on which the firft vouffoir, or arch-ftone of the vault, is laid. See IMPOSTS.

VAULT, in the *Manege*. To vault a horfe-shoe, is to forge it hollow, for horfes that have high and round foles; to the end that the shoe, thus hollowed or vaulted, may not bear upon the fole that is higher than the hoof; but after all, this fort of shoe fpoils the feet; for the fole, being tenderer than the shoe, affumes the form of the shoe, and becomes every day rounder and rounder. In Mr. Solleyfel's Complete Horfeman, may be feen the true method of shoeing high and round foles. See SHOE and SHOEING.

VAULT, or *Volte*. See VOLTE.

VAULT, *Going to the*, a term ufed by fportsmen for a hare's taking the ground like a coney, which fhe fometimes does.

VAULT, *Le*, in *Geography*, a town of France, in the department of the Yonne; 3 miles W. of Avallon.

VAULX, a town of France, in the department of the Straits of Calais; 4 miles N.E. of Bapaum.

VAULX Milieux, a town of France, in the department of the Here; 12 miles N.E. of Vienne.

VAUNIA, in *Ancient Geography*, a town of Italy, belonging to the Bechuni. Ptolemy.

VAUNING, in *Mineralogy*. See VAN, VANNING-SHovel, and TIN.

VAUNT, or *VANT*. See VAN.

VAUNT-Lay, among *Hunters*, a fetting of hounds, or beagles, in a readinefs where the chafe is to pafs; and calling them off before the reft of the kennel come in.

VAUQUE-

VAUQUELIN, in *Biography*. See IVETEAUX.

VAUQUELINIA, in *Botany*, a genus dedicated by M. Correa de Serra, now the Portuguese minister to the United States of America, to the honour of the celebrated French chemist M. Vauquelin, whose discoveries have been extended to the vegetable kingdom. Humboldt and Bonpland, *Plantes equinoxiales*, fasc. 6. De Theis 478. We regret that we are furnished with no further account of this genus, nor with any of its characters.

VAUS, in *Geography*, a river of West Florida, which runs into the St. Mark, N. lat. $30^{\circ} 10'$. W. long. $84^{\circ} 36'$.

VAUVENARGUES, a town of France, in the department of the Mouths of the Rhône; 6 miles E.N.E. of Aix.

VAUVERT, a town of France, in the department of the Gard; 9 miles S. of Nismes.

VAUVILLE, a small seaport-town of France, in the department of the Channel, on a bay to which it gives name; 9 miles W. of Cherbourg. N. lat. $49^{\circ} 39'$. W. long. $1^{\circ} 37'$.

VAUVILLERS, a town of France, in the department of the Upper Saône; 12 miles N.W. of Luxeuil.

VAUVINCOURT, a town of France, in the department of the Meuse; 5 miles N. of Bar-le-Duc.

VAUX, LA, a district of Switzerland, in the Pays de Vaud, between Laufan and Vevay, which contains the two pleasant little towns of Lutry and Cully, with the villages of St. Saphorin and Corsier. This district is entirely hilly, rising abruptly from the lake; above the vineyards are rich meadows and a continued forest. In the church of St. Saphorin is an ancient Roman mile-stone with an inscription, which contains two circumstances often questioned; viz. that the banks of the lake of Geneva, which border this part of Switzerland, were comprised within a Roman province, even so early as the time of Claudius, and also that Aventicum was the chief town of this part of Helvetia; for the mile-stones always referred to the capital of the province in which they were placed, and the distance from St. Saphorin to Avenches is nearly 37,000 paces. The inscription is as follows:

TI. CLAUDIUS. DRUSI. F.
CÆS. AUG. GERM.
PONT. MAX. TRIB. POT. VII.
IMP. XII. P. P. COS. III.
F. A.
XXXVII.

VAUXHALL GARDENS, a well-known place of public amusement in the parish of Lambeth and county of Surrey, which belonged, in 1615, to Jane, widow of John Vaux, between whose two daughters the estate was divided, and passed through various hands, till both moieties were purchased, about the middle of the last century, by Jonathan Tyers, esq. It does not appear at what time this place was first opened for public resort; but we are led to conclude from a paper in the *Spectator* (No. 388.), and another in the *Connoisseur* (No. 68.), that it must have been so appropriated in or before the time of queen Anne. Mr. Tyers, who held the premises on lease many years before he bought the estate, opened the Spring Gardens, as they were then denominated, in 1730, and expended large sums in embellishing them. After his death they fell into the possession of several proprietors, of whom the principal is Mr. Barratt. These gardens were, till of late years, opened every evening during a great part of the summer, for the reception of company; but they are now admitted only

three times a week. The entertainments consist of music, vocal and instrumental, illuminations, and fire-works, and other exhibitions. See LAMBETH and TYERS.

VAUZ, in *Geography*, a town of Pennsylvania, on the Susquehanna; 12 miles N.N.W. of Harrisburg.

VAYHINGEN, a town of Wurtemberg, on the Entz, with a castle. This town had formerly counts of its own; 11 miles N.W. of Stuttgart. N. lat. $48^{\circ} 58'$. E. long. $8^{\circ} 59'$.

VAYLOOR, a town of Hindoostan, in Baramaul; 11 miles S.S.W. of Namacul.

VAYPAR, a town of Hindoostan, in the province of Madura; 25 miles E. of Coilpetta.

VAYRÈS, a town of France, in the department of the Gironde; 3 miles S.W. of Libourne.

VAYU, in *Hindoo Mythology*, is a name of the regent of the winds, more commonly called *Pavana*; which see. Vayu is the Eolus of the East. One of the Puranas is named after him, being called Vayu Purana. (See PURANA.) Yah is another of his names.

VAYVODE, or VAIVODE. See WAYWODE.

VAZABU, in the *Materia Medica*, a name by which some authors have called the *acorus Asiaticus*, or Asiatic sweet-flag.

VAZCUSE, in *Geography*, a river of Louisiana, which runs into the Mississippi, N. lat. $38^{\circ} 31'$. W. long. $94^{\circ} 5'$.

VAZUA, in *Ancient Geography*, a town of Africa Propria, between the river Bagradas and the town of Thabraca, according to Ptolemy.

UBALDI, GUIDO, in *Biography*, an eminent mathematician of noble extraction from a branch of the family of Bourbon, studied under Condamine, and made early as well as rapid proficiency. Mathematics and mechanics were his favourite objects; but in the latter science he published a work, entitled "Mecanicorum Liber, in quo hæc continentur:—de Libra, Vestæ, Trochlea, Axe in Peritrochio, Cuneo, Cochlea," Venetiis, 1615, fol. In this work he reduces all machines to the lever, applying the same principle with advantage to some of the other mechanical powers, and particularly to the pulley and its combinations. He also explained the structure of the screw of Archimedes, and its application to the rise of water, in a treatise "De Cochlea, Libri quatuor," Venet. 1615, fol. He illustrated the principles and practice of perspective more fully and clearly than other preceding writers had done, but with needless prolixity, in his "Perspectiva, Libri sex," Pisauri, 1600, fol. His other works, mentioned by Küstner, are "Guidi Ubaldi e Marchionibus Montes (of the Marquisses del Monte) in duos Archimedis Æquiponderantium Libros Paraphrasis, scholiis illustrata," Pisauri, 1588, fol.; "Problematum Astronomicorum Libri septem," Venet. 1508, fol. The time of his birth and also of his death is unknown. Montucla.

UBAMBA, in *Geography*, a town of Brasil, near the coast of the Atlantic; 80 miles S.W. of Rio Janeiro.

UBARCO, CAPE, a cape on the N.W. coast of the island of Iviça. N. lat. $39^{\circ} 5'$. E. long. $1^{\circ} 18'$.

UBATA, in *Ancient Geography*, a town of Africa, S. of Adrumetum. Ptolemy.

UBATUBA, in *Geography*, a river of Brasil, which runs into the Atlantic, S. lat. $23^{\circ} 20'$.

UBAYE, a river of France, which runs into the Durance, near Embrun.

UBEDA, a city of Spain, in the province of Jaen, containing 10 parishes, 8 convents, and about 2900 inhabitants. In 1233, Ubeda was taken from the Moors; 3 miles E. of Jaen. N. lat. $38^{\circ} 3'$. W. long. $3^{\circ} 31'$.

UBENITZ,

UBENITZ, a town of Bohemia, in the circle of Prachatz; 7 miles E. of Prachatz.

UBERAU, a town of Hesse Darmstadt; 6 miles S.E. of Darmstadt.

UBERE, a town of Sweden, in West Gothland; 15 miles S.W. of Skara.

UBERKINGEN, a town of Bavaria, in the territory of Ulm; 13 miles S.W. of Ulm.

UBERLINGEN, a town of Baden, situated on a rock, in a bay of the lake of Constance, which takes its name from it, and its moats are formed of so many stone-quarries. This town is divided into three parts; viz. the Lower Town, the Upper Town, and the Gallenberg; in the last of which are vineyards. It contains in it a collegiate church, a house of the order of St. John, a hospital, three convents, and two other churches. Near the town is a good mineral spring. Uberlingen was an imperial town so early as the time of the emperors of Swabia. Charles IV. and Wenceslaus engaged to maintain it in its immediate independency on the empire; but in 1802, it was given to the duke of Baden; 22 miles N.W. of Lindau. N. lat. 47° 43'. E. long. 8° 49'.

UBERSKO, a town of Bohemia, in the circle of Chrudim; 10 miles E.N.E. of Chrudim.

UBERTI, FAZIO, (BONIFACIO,) *Degli*, in *Biography*, an Italian poet, born at Florence, who flourished in the 14th century. His character is represented as amiable, allowing for his disposition to frequent the courts of tyrants and to pay adulation to the great; but his poverty in a state of exile, as one of the Ghibelline party, has been adduced as an apology for his conduct. He wrote various poems, and according to the account given of him by Villani, he was the first who employed with effect that species of poetical composition called by the vulgar "frottole," or ballads. His principal work, however, written in his advanced age, was a description of the world in verse, intitled "Ditta Mondo." This is divided into six books, but was left in an unfinished state, though written at different periods from the year 1355 to 1364. It was first printed at Verona, and afterwards at Venice in 1501. He is reckoned superior to the Italian poets of his time in energy of style. Some of his Canzone have been published in collections. He died and was interred at Verona.

UBES, St., in *Geography*. (See SETUVAL.) This town would be more considerable if it were not so near to Lisbon, and the trade carried on through Lisbon houses; for here, it is said, there are only fifteen mercantile firms. Its trade consists in wine, of which various kinds are exported. Oranges are likewise exported: but the best commercial article of St. Ubes is salt, which is taken principally by Danish and Swedish ships. The salt-pans lie in great numbers along the Sado or Sandao, and its branches, being called in Portuguese "marinhas." They are dug square, about three feet deep, and salt-water is introduced on one side from the sea, at flood, through canals which extend in innumerable branches, and are shut when the pans are full. The water is often previously collected in large reservoirs called "governos," from which it is afterwards distributed into the marinhas, where being evaporated, the salt is collected in the month of June, and kept either in wooden sheds, or in heaps, which are protected from the rain by rushes. This salt is large-grained, becomes but little moist by the air, and excels in purity the marine salt collected in other provinces of the south of Europe, or in other parts of Portugal. The fishery of St. Ubes was formerly celebrated, but has of late much declined.

Opposite to St. Ubes, on the narrow strip of land that forms the entrance of the harbour, are the remains of an ancient city, called Troya. Tradition reports that this place was buried in sand; and that the inhabitants removed and built St. Ubes on the opposite side.

UBI, or UBY, an island in the East Indian ocean, in the gulf of Siam, near the coast of Cambodia; about 21 miles in circumference, with plenty of wood and good water. N. lat. 8° 26'. E. long. 105° 56'.

UBIGAU, a town of Saxony; 6 miles N.W. of Liebenwerda. N. lat. 51° 34'. E. long. 12° 20'.

UBII, in *Ancient Geography*, a people whose first abode was on the other side of the Rhine, being separated from Gaul by the river. Being afterwards pressed by the Suevi, they had recourse to Cæsar. Agrippa passed the Rhine, according to Dion Cassius, and transported them to the hither bank of the river and established them, with a view to the security of the adjoining frontier of the empire. Under the reign of Claudius, an Agrippine colony was founded among them, and they voluntarily assumed the name of Agrippinenses, as their attachment to the Romans excited the enmity of Civilis. Their territory extended along the Rhine, from the Treveri to the borders of the Gugerni, who had been a branch of the Menapii. The Ubians, on the right bank of the Rhine, were continually harassed by the Sicambri, and in order to avoid the hostility of such neighbours, they were induced to cross the river. Agrippa caused them to build a town, which was called "Civitas Ubiorum," in which he planted a Roman colony, denominated "Colonia Agrippina." This town is the present Cologne. The Ubii formed a part of the Germanic body, which they abandoned in order to enter into a league with the Celtic people. This separation of the Ubians is referred to about the thirty-seventh year before our era. They worshipped the god Mars.

UBIQUISTS, UBIQUITARIES, or UBIQUITARIANS, formed from *ubique*, every where, in *Ecclesiastical History*, a sect of Lutherans, which rose and spread itself in Germany; and whose distinguishing doctrine was, that the body of Jesus Christ is every where, or in every place.

Brentius, one of the earliest reformers, is said to have first broached this error, in 1560. Luther himself, in his controversy with Zuinglius, had thrown out some unguarded expressions, that seemed to imply a belief of the omnipresence of the body of Christ; but he became sensible afterwards, that this opinion was attended with great difficulties, and particularly that it ought not to be made use of as a proof of Christ's corporal presence in the eucharist. (Luther, Oper. tom. viii. p. 375. ed. Jenens.) However, after the death of Luther, this absurd hypothesis was renewed, and dressed up, in a specious and plausible form, by Brentius, Chemnitius, and Andræas, who maintained the communication of the properties of Christ's divinity to his human nature.

Melancthon declared against it; maintaining that it introduced, with the Eutychians, a kind of confusion into the two natures of Jesus Christ; and protested, that he would oppose it as long as he lived.

On the other hand, Andræas, Flacius Illyrius, Schmidelin, Oslander, &c. espoused Brentius's party; and asserted the body of Jesus Christ to be every where.

The universities of Leipzig and Wirtemberg, and the generality of Protestants, set themselves against this new heresy, but in vain: the Ubiquitarians grew stronger and stronger. Six of their leaders, Andræas, Selnecker, Musculus, Chemnitius, Chytræus, and Cornerus, having a meeting in 1576, in the monastery of Berg, they there composed

posed a kind of credo, or formula of faith, called the "Form of Concord;" wherein the ubiquity was established as an article. See *Form of CONCORD*.

Musculus, one of these leaders, and the most zealous advocate of the ubiquity, expressly maintains, that the ascension of Christ into heaven was nothing more than a ceasing to be visible, and that it is not performed by any physical motion, or change of place: and in 1575 he published a book to prove that it is by no means necessary, that the glorious body of Christ should physically fill up any space. And he declares in a sermon in 1564, that they who teach that Jesus Christ died only as to his human nature, belong to the devil, both body and soul; and that the true doctrine is, that he died as to his human and divine nature. Hofpin. *Histor. Sacram. part ii. p. 492. ad ann. 1561. Idem ibid. p. 553. ad ann. 1564. Idem ibid. p. 600. Bayle, art Musculus.*

All the Ubiquists, however, are not agreed: some of them, and among the rest the Swedes, hold that Jesus Christ, even during his mortal life, was every where: others maintain, that it is only since his ascension that his body is every where.

G. Hornius only allows Brentius the honour of being the first propagator of ubiquitism; its first inventor, according to him, was John of Westphalia, or Westphalus, a minister of Hamburg, in 1552.

But according to Hofpinian, Westphalus opposed the opinion concerning the ubiquity advanced by Brentius and Schmidelin. Bayle, art. *Westphalus*.

UBUIST, in the *University of Paris*, is a term applied to such doctors in theology, as are not restrained to any particular house; either to that of Navarre, or Sorbonne.

The Ubiquists are called, simply, *doctors in theology*; whereas the others add, *of the house of Sorbonne*, or *Navarre*, &c. See *SORBONNE*.

UBUIQUITY, OMNIPRESENCE; an attribute of the God-head, whereby he is always intimately present to all things; gives the esse to all things; and knows, preserves, and does all in all things.

For since God cannot be said to exist in all places, as placed therein, (because, then, he would need something to his existence, viz. place; and would have extension, parts, &c.) he must be conceived to be every where, or in all things, as a first, universal, efficient cause, in all his effects.

He is present, therefore, to all his creatures, as a pure act, or an exercise of an active virtue, which knows, preserves, governs, &c. every thing. Nor are even finite minds present otherwise than by operation. See *GOD*.

UBUIQUITY of the King. See *KING*.

UBIRRE, in *Ichthyology*, a name given by some to the anguilla marina, or small sea-eel.

UBIUM, in *Botany*, altered by Rumphius, Herb. Amboin. book 9. 346, from the Malay name *Ubi*, a synonym of some species of *Dioscorea*; see that article. Forster declares all the kinds of *Ubi*, mentioned by Rumphius, to belong to *D. alata*. These differ chiefly in the shape of the roots, and in the stems being furnished or not with fleshy buds, or bulbs, of different forms. These roots constitute one of the most important articles of food, in the remote islands of India and the South Seas.

UBNI, in *Geography*, a town of Walachia; 10 miles N. of Vidin.

UBOA, a town on the west coast of the island of Luçon. N. lat. 16° 57'. E. long. 120° 48'.

UBRAYE, a town of France, in the department of the Lower Alps; 9 miles N.E. of Castellane.

UBRILEN, a town of the Arabian Irak; 5 miles S.E. of Bassora.

UBRIX, in *Ancient Geography*, a town of Africa, on the coast of Libya. Ptolemy.

UCA, a town of Asia, in the interior of Media. Ptolemy.

UCANNO, in *Geography*, a town of Portugal, in the province of Beira; 2 miles N. of Lamego.

UCAYALE, UCAIAL, or YCAYALE, a river of South America, formed by the union of the Apurimac and Ene, in S. lat. 10° 50'. It pursues a northerly course to S. lat. 4° 15', where it joins the Marañon, near St. Joachim de Omaguas, and then takes the name of the Amazons. See *MARAÑON*.

UCENA, in *Ancient Geography*, a town of Asia, in Galatia, belonging to the Trochmi. Ptolemy.

UCENI, a people placed by the inscription on the trophy of the Alps, mentioned by Pliny, near the Medulli and the Caturiges, and supposed by Sanson to be the same with the Siconii or Iconii, mentioned by Strabo.

UCETIA, a town of Gallia Narbonensis.—Also, a town of Gallia Transpadana. Strabo.

UCHALIGES, a people of Africa, in Libya Interior. Ptolemy.

UCHENDGE, in *Geography*, a town of the principality of Georgia, and chief place of a district, situated to the east of Teflis. In 1395, this town was taken by Timur Bee, and the whole garrison put to the sword.

UCHINCHIR, one of the small Kurile islands, in the North Pacific ocean. N. lat. 48° 30'. E. long. 153° 44'.

UCHKILISSA, a town of Persian Armenia; 18 miles N.W. of Erivan.

UCHT, a river of Brandenburg, which runs into the Aland, near Osterburg.

UCHTLHAUSEN, a town of the duchy of Wurzburg; 6 miles E. of Schweinfurt.

UCIBI, in *Ancient Geography*, a town of Africa Pro-pria, in Numidia Nova. Ptolemy.

UCIMATH, a town of Africa, in Libya Interior, upon the northern bank of the river Gir. Ptolemy.

UCKER, in *Geography*, a river of Pomerania, which empties itself into the Frische-Haff, 1 mile N. of Ucker-munde.

UCKER Mark. See *BRANDENBURG*.

UCKER See, a considerable lake of Brandenburg, in the Ucker Mark, situated to the south of Prenzlau.

UCKERMUNDE, a town of Anterior Pomerania, situated on the river Ucker, near its entrance into the Frische-Haff. This town was surrounded with walls in 1190. In the 17th century it suffered greatly by sieges, and the vicissitudes of war; and in 1713, was sacked by the Russians. It has good fisheries, pastures, and woods; 29 miles N.N.W. of Old Stettin. N. lat. 53° 48'. E. long. 13° 57'.

UCKEWALLISTS, in *Ecclesiastical History*, a sect of rigid Anabaptists, so called after its founder Uke Wallis, a native of Friesland. This sectary not only exhorted his followers to maintain the primitive and austere doctrine of Menno, but took it into his head to propagate, in connection with one John Leus, in 1637, a singular opinion concerning the salvation of Judas, and the rest of Christ's murderers; alleging, that the period of time, which extended from the birth of Christ to the descent of the Holy Ghost, and was, as it were, the distinctive term that separated the Jewish from the Christian dispensation, was a time of profound ignorance, during which the Jews were destitute both of light and divine succour; and that, consequently,

quently, the sins and enormities, that were committed during this interval, were in a great measure excusable, and could not merit the severest displays of the divine justice. This idle fiction met with no indulgence either from the Mennonites, who excluded its inventor from their communion, or from the magistrates of Groningen, who banished him from the city. In East Friesland he drew after him a considerable number of disciples, whose descendants still subsist in the neighbourhood of Groningen, Friesland, and also in Lithuania and Prussia, and have their own religious assemblies, separate from those of the other Mennonites. They re-baptize all who leave other Christian churches to embrace their communion: they studiously avoid every appearance of elegance or ornament; suffering their beards to grow to an uncommon length, and their hair to lie uncombed over their shoulders: their countenances are marked with melancholy; and their houses only adapted to answer the demands of necessity. Their inspectors or bishops, whom they distinguish from the ministers whose office is to teach, are chosen by an assembly composed of all the congregations of the sect. The ceremony of washing the feet of strangers is considered by them as a rite of divine institution. They carefully avoid even the aspect of learning and science, and thus prevent all attempts to alter or modify their religious discipline. Mosheim's *Eccles. Hist.* vol. v. 8vo.

UCLES, in *Geography*, a town of Spain, in New Castile. In 1108, a battle was fought near this place between the Christians and the Moors, in which the former were defeated with great loss; 20 miles S.W. of Huete.

UCO, a town of Chili; 9 miles E.S.E. of St. Yago.

UCRIA, a town of Sicily, in the valley of Demona; 8 miles W.S.W. of Pati.

UCRIANA, in *Botany*, so called by Willdenow, in honour of Signor Bernardi di Ucria, a distinguished botanist of Palermo.—Willd. *Sp. Pl.* v. 1. 961. (Tocoyena; *Publ. Guian.* 131. *Juss.* 201. Lamarck *Illustr.* t. 163.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Rubiaceae*, *Juss.*

Gen. Ch. *Cal.* Perianth superior, of one leaf, short, cup-shaped, with five angles, and five small, erect, acute teeth, permanent. *Cor.* of one petal, tubular; tube extremely long and slender, cylindrical, pervious; limb bell-shaped, with five rather short, ovate, acute, equal, slightly spreading, marginal segments. *Stam.* Filaments five, very short, inserted into the limb between the segments; anthers incumbent, oblong, pointed, of two cells. *Pist.* Germen inferior, elliptical; style the length of the tube of the corolla, thread-shaped; swelling and hairy at the top; stigma of two rounded lobes. *Peric.* Berry elliptical, fleshy, of two cells, crowned by the permanent calyx. *Seeds* numerous, roundish, inserted into the middle of the partition at each side, and surrounded with viscid pulp.

Eff. Ch. Calyx superior, with five teeth, permanent. Corolla with a very long cylindrical tube, and five-cleft, bell-shaped limb. Anthers nearly sessile. Style club-shaped, hairy. Stigma of two flat lobes. Berry of two cells, with many seeds.

1. *U. speciosa*. Willd. n. 1. (Tocoyena longiflora; *Aubl.* t. 50.)—Native of woods in Guiana, bearing flowers as well as fruit in August. *Stem* shrubby, simple, about three feet high, obtusely quadrangular, leafy. *Leaves* opposite, stalked, fifteen inches long, lanceolate, acute, entire, smooth, contracted at the base, with one rib and many transverse veins. *Stipulas* in pairs, intrafoliaceous, ovate. *Flowers* about fourteen, crowded at the top of the stem, sessile, opposite, erect, very fragrant, white, with a yellowish tube, nine inches and a half long, the thickness of a goose-quill. *Calyx* very small. *Berry* yellow, an inch in length.

This plant comes very near to *Gardenia*, or at least to Thunberg's *Rotmannia*. (See *GARDENIA*.) We do not profess to have had sufficient opportunities of comparing them and their allies, to form an accurate judgment. Willdenow has changed the specific name without any authority or reason.

UCUBIS, in *Ancient Geography*, a town of Spain, in Bætica.

UDA, in *Geography*, a river of Russia, which runs into the Velika, 12 miles N.W. of Onegka, in the government of Pskov.—Also, a river of Russia, which joins the Tchiuna, N. lat. 55° 50'. E. long. 99° 22'.—Also, a river of Russia, which runs into the Selenga, near Verch Udiuk.—Also, a river of Russia, which runs into the sea of Ochotz, N. lat. 55° 15'. E. long. 136° 44'.

UDACENSES, in *Ancient Geography*, mountains of Asia, in Corduena, south of the lake Arsilisa, lat. 37° 30'.

UDAL. See *ODHAL*.

UDASSA, in *Geography*, a town of Hindoostan, in Goondwana; 12 miles N.W. of Nagpour.

UDAWANTANAGUR, a town of Hindoostan, in Bahar; 5 miles S.S.W. of Arrah.

UDDALAKA, in *Hindoo Mythology*, is the name sometimes given to a theologian, who is said to be the son of Aruna, the charioteer of the sun. He is not often read of. Respecting his parent, who corresponds with the Aurora of western fable, notice will be found under our article *SURVA*, the common name of the Hindoo Phæbus.

In the theogonies of the Puranas (see *PURANA*), when describing the process of churning the ocean, as mentioned in our article *KURMAVATARA*, a goddess, named Jyeshtha, was produced. She is deemed the goddess of poverty and misfortune, and having rose from the sea earlier than Lakshmi, the goddess of riches and fortune, is called her elder sister. Vishnu, enamoured of the latter, wished to espouse her; but she objected, saying her elder sister, agreeably to the injunctions of the Veda, ought to be married first. And this we may remark, in passing, is a rule in force at this day, though not invariably observed. Vishnu, after much difficulty, prevailed on Uddalaka the Rishi, who was unmarried, to take the undesirable damsel to wife; and Sagara, her father, sealed the nuptial ceremony by pouring water into the hands of the Rishi. (See *SAGARA*.) Jyeshtha, like Lakshmi, is called the daughter of the ocean, and is celebrated as being ever faithful to her consort. She is sometimes called Sreshta.

Under the article *RISHI* will be found an account of the holy men so designated. One of them taking the goddess of poverty to wife, means, we may suppose, the usual profession of poverty by pious persons. It was no small sacrifice of comfort to be linked to such a rib: for Jyeshtha is described to have arisen in black garments, with yellow hair, red eyes, wanting many teeth, those remaining of repelling appearance, her tongue lolling out of her mouth, pot-bellied, &c. &c.; so that gods and demons were amazed at the sight of such a figure. Such a one is described, from an image in the East India House, in our article *KALI*. Her younger sister, on the contrary, is described as superlatively fascinating, but fickle; being a personification of Fortune.

UDDEN, in *Geography*, a town of Arabia, in the province of Yemen; 44 miles E.S.E. of Zebid. N. lat. 13° 58'. E. long. 43° 50'.

UDDER, in *Rural Economy*, a term applied to the glandular organ which is destined for the preparation and secretion of the milk in cows, mares, ewes, fows, or any other kinds of domestic animals, and which is often much subject to disease.

It is to be noticed, that the udders of young cows which are in a high condition, are sometimes very greatly swollen and inflamed for several days before they calve; in which cases, it is mostly proper to milk them frequently in repetition, and alternately to anoint the distended parts, in some severe instances, with a saturnine cooling ointment, and brandy, or some other quickly evaporating spirit; as, by such means, these swellings are often speedily removed, without much danger or inconvenience. But, besides these sorts of swellings, the udders of cows are liable to injuries, which are often of a more serious consequence, as from falls, blows, the wounds of sharp instruments, or such as are pointed, and the violent sucking of calves, as well as from the injudicious or rough treatment of harsh and inexperienced milkers. In all such cases, while the inflammation in the glands remains in a hard and indolent state, the parts so affected should be repeatedly anointed in the course of the day with some gentle cooling substance, such as fresh lard, or with a solution consisting of one ounce of Castile soap, dissolved in a pint and a half of new milk, over a moderate fire, constantly stirring it until it becomes thoroughly mixed and incorporated. An ointment, too, prepared from the juice of the leaves of the common thorn-apple, by mixing it with fresh hog's-lard, is said by some to be an excellent application in cases of this nature. Such tumours may likewise, in many instances, be anointed with a little of a composition, consisting of camphor dissolved in spirit and blue ointment, with great benefit; and about half a drachm of calomel may be given in a hornful of treacle and warm beer, three or four mornings together, if the swelling should continue to increase. Where, however, the udder and teats are considerably inflamed and swelled, other internal remedies may be had recourse to; for which purpose, it has been recommended to mix four ounces of nitre with one pound of common salt, and to give two table spoonfuls of the powder in a gallon of thin water-gruel every three hours. But in case the affection, in such instances, should have made, from neglect, such progress as to display large hardish tumours in the parts, fomentations of the sort given below may often be applied with advantage. Boil in a sufficient quantity of water one handful of the leaves of common hemlock, the same quantity of the dwarf or round-leaved mallow, and an equal proportion of common melilot, and diligently apply the liquid, by means of cloths wrung out of it, to the part or parts, as warm as the beast can bear it. As soon as the tumour or tumours, in this case, bursts or opens, the wound should be well and properly cleaned, and then covered with a pledget of lint, and a plaster of common cerate or basilicon laid over all.

The remedy directed below, it is said, has been employed with great success in very obstinate cases of ulcerated cattle udders: one ounce of gum ammoniacum, the same quantities each of gum galbanum, Castile soap, and extract of hemlock; reduce the gums into powder, and form them with the soap and extract into eight small balls, one of which is to be given to the beast every night and morning. In cases where the teats only are sore, they may first be washed well with clean warm soap-suds, and then rubbed with an ointment, composed of finely powdered ceruse or white lead, which has previously been saturated with brandy, and well mixed and united with a proper quantity of elder ointment or goose-grease.

In the case of sheep too, these parts are often much affected, when the lambs are yeaned in the ewes, the lactiferous ducts in the udders of which are liable to become attacked with various obstructions, which are the consequence of hard tumours or swellings being formed, which are accompanied with inflammation, and which, if not speedily relieved, will terminate in mortification, not unfrequently in the course of twenty-four hours. As soon as such swellings or tumours are discovered, the wool should be shorn off closely in a careful manner, and the part affected be frequently wetted and rubbed well with camphorated spirit of wine. If, however, suppuration should ensue, the part should be laid open by a strong lancet or sharp knife, and the matter be discharged, when a pledget of lint should be laid over the part, and secured by a plaster spread with some soft ointment, or the common cerate rubbed with a little oil. Ewes, when thus affected, should be kept separate from the rest of the flock, and though one of the nipples may be lost, they may be allowed to suckle their lambs; but in cases where both are affected, there is, of course, no alternative but that of fattening them off for sale, and to bring up their lambs by hand in the best manner possible.

The udders and nipples of ewes are likewise very apt to be heated, chafed, and fretted, by which the lambs are prevented from being let suck in a proper and ready manner; consequently, in all such cases, the parts so affected should be kept as cool as possible, and be well washed with a weak solution of white vitriol in rain-water, or be anointed with some mild softening ointment, such as that of elder, or common cerate softened with oil, once or twice in the day; care being taken to have them well removed by the use of warm water and a little soft soap, before the lambs be again admitted to them for suckling.

The diseases of the udders, in the other sorts of domestic animals, are, for the most part, to be treated in a similar manner, according as the nature of them may be; always having the parts carefully cleaned, before the young are suckled.

UDDER-Locking, a term used in the management of sheep, to signify the practice of clearing away the locks of wool from about the udders, and other parts, where the lambs suck, in ewes. Some sheep-farmers have a very high opinion of the necessity and utility of this custom, while others as strongly condemn it, and consider it to be quite unnecessary, as well as dangerous and hurtful both to the ewes and the lambs. It may, however, be useful in different cases and circumstances. The former, or those in favour of the practice, recommend that, immediately before the ewes begin to drop their lambs, they should be carefully driven into the yards, folds, or pens, and have a small part of the locky wool pulled off from about their udders, in order to give the lambs more easy and ready access to the teats or nipples, by which they come forward faster, and succeed better. But the latter, or those who object to the custom, think that they have seen instances where it occasioned not only the death of nearly one-twentieth part of the ewes, but that many of those which survived it lambed dead lambs at the danger and hazard of their own lives. They suppose that there is naturally a sufficient space left bare about these parts, so as to enable the young lambs to find the dugs or nipples; and that the uncovering more, or or a larger extent of parts, serves only to starve and expose the ewes in the most tender and delicate parts; as, although they have been engaged among sheep the whole of their lives, they have never seen a single lamb die from the want of its dam or mother being udder-locked, even though she

may have been ever so young, or ever so rough in such parts: nor have they ever met with any persons who could be certain that they had seen any. How far some breeds of sheep, as those of the Cheviot, may have their lambs more readily or more easily killed or destroyed in this way, or whether it may not be owing to the shape of the udders in their dams, which being more full and exposed in such parts, is not by any means well known; but far less injury or exposure, in this or in any other way, will make that breed of sheep lamb dead lambs, it is said, than in the forest, or probably some other breeds.

But though this practice may often be found prejudicial in the more northern parts of the kingdom, in the southern sheep districts it may not unfrequently be had recourse to with very considerable utility and advantage in different respects.

UDDEVALLA, in *Geography*, a sea-port town of Sweden, in the province of Bahus, with a strong fort and convenient harbour. The inhabitants carry on a considerable trade in iron, planks, and herrings; their number is about 9000; 205 miles W.S.W. of Stockholm. N. lat. $58^{\circ} 21'$. E. long. $11^{\circ} 45'$.

UDEBODE, a town of the island of Ceylon; 60 miles S. of Candi.

UDEGHERRY, a town of Hindoostan, in the Carnatic; 43 miles N.W. of Nellore. N. lat. $14^{\circ} 43'$. E. long. $79^{\circ} 16'$.

UDEM, a town of France, in the department of the Roer; 7 miles S.S.E. of Cleves.

UDERIPCONDA, a town of Hindoostan, in Myfore; 20 miles N.W. of Anantpour.

UDERWANGEN, a town of Prussia, in Natangen; 12 miles S.S.E. of Konigsberg.

UDI, a town of Egypt; 10 miles N. of Atfieh.

UDJARMA, a town of the principality of Georgia, in the province of Kaketi; 24 miles E. of Teflis.

UDICA denotes the projecting part of a barge's stern, on which its name, &c. is printed.

UDINA, or UDINE, in *Geography*, a town of Italy, and capital of Friuli; to which, on the decline of Acquileia, the patriarch removed his seat. It has several churches, convents, and hospitals, a college for the study of law, and a military academy: and it is said to contain between 17,000 and 18,000 inhabitants; 35 miles N.W. of Trieste. N. lat. $46^{\circ} 10'$. E. long. $13^{\circ} 14'$.

UDINE, GIOVANNI DA, in *Biography*, was the cognomen of an assistant of Raffaele in the works of the Vatican, whose real name was Nanni. His family resided at Udine, (where he was born in 1494,) and had there followed the occupation of embroiderers with so much excellence, as at length almost to have lost their own name in that of Ricamatori, by which Vafari often calls him. His father, become rich, amused himself with hunting; and his son Giovanni found his sport, at a very early period of his life, in drawing the animals, birds, &c. brought him from the chase. This indication of taste for painting was encouraged, and the youth was placed under the tuition of Giorgione, at Venice, with whom he acquired a knowledge of colour and chiaro-scuro. About the time of the death of Giorgione he went to Rome, and being furnished by his protector, the patriarch Grimani, with letters to count Baldisare Castiglione, he was introduced to Raffaele, who admitted him into his school, and employed him in painting the grotesque and ornamental accessories of his larger works. The imagination of his master Raffaele, and of himself, was led to the introduction of this species of ornament, by the discovery of the painted chambers in the baths of Titus, then recently

opened, when Giovanni was employed in making designs of the beautiful ornaments in stucco found there, and thence denominated *grotesque*. In pursuing these studies, he discovered the composition of the stucco upon or rather in which they were painted; and with the same materials he, by order of Raffaele, prepared the walls and ceilings of the Loggia, and painted upon it the beautiful series of ornamental combinations of flowers, fruit, animals, vases, &c. since then so much employed in adorning the dwellings of the rich and great. This part of the work was entirely entrusted to Giovanni da Udine, under whose directions a number of ingenious young men were employed; and the taste and ability, the freedom and truth, without minuteness, with which the whole is managed, has ever since been a constant subject of praise and admiration. After the death of Raffaele, he was employed by Clement VII., in conjunction with Pierino del Vaga, to ornament that part of the Vatican called the Torre di Borgia. When he was compelled to leave Rome by the sacking of that city, he was employed for a time at his native place, and afterwards was engaged at Florence in adorning the palace of the Medici; and returning to Rome in the pontificate of Pius IV., left in various places there mementos of his admirable ingenuity. He died there, at the age of seventy, in 1564, and had the honour to be buried in the church of La Rotonda, (the Pantheon,) near the tomb of his renowned master.

UDINE, MARTINO DA, called Pellegrino di San Daniello, was born at the castle of San Daniello, near Udine, about the year 1480, and was a disciple of Giovanni Bellini. He pursued the style of that master in the many religious subjects he treated for altar-pieces at Udine and his native place, where his works are principally to be found; though it is said, in addition to his fame, that something of Giorgione's breadth may be discovered in his latter productions. He died about 1545.

UDINSK, NIZNEL, in *Geography*, a town of Russia, in the government of Irkutsk, situated on the river Uda; 260 miles N.W. of Irkutsk. N. lat. $54^{\circ} 15'$. E. long. $98^{\circ} 50'$.

UDINSK, *Verchnei*, a town of Russia, in the government of Irkutsk, on the Selenga; 88 miles E. of Irkutsk. N. lat. $51^{\circ} 50'$. E. long. $107^{\circ} 20'$.

UDINSKA, a town of Russia, in the government of Irkutsk, at the conflux of the Uda and the Angara; 140 miles W.N.W. of Irkutsk. N. lat. $54^{\circ} 12'$. E. long. $103^{\circ} 14'$.

UDINSKA, *Nov*, a town of Russia, in the government of Irkutsk, on the Uda; 24 miles S.E. of Udinsk.

UDITTA, in *Ancient Geography*, a town of Africa Pro-pria, between the Two Syrtes. Ptolemy.

UDNON, in *Botany*, the name by which Theophrastus and Dioscorides have called the truffle commonly used at table in their times; but we find that they were not acquainted with a better kind of truffle, which we cultivate at present.

This smooth reddish-coated truffle is common in Italy at this time, and is esteemed of no value, and called the wild truffle: the sort that is eaten there, and in all other parts of Europe, is the blackish and rough-coated kind. In Africa they have a yet finer kind than our's: it has a white coat, and is of the most delicious flavour. The Greeks were also acquainted with this, and denominated it Cyrenean, as they did almost all the things they had from Africa: they also gave it the name *nissy*.

UDO, in the *Materia Medica*, a name given by the Portuguese to the lignum aloes.

It seems only a corruption of the monosyllable *ud*, by which

which the Arabian physicians have called that drug; and even this *ud* possibly was only a contraction of the orthography of the word *heud*; which seems to have been the original name of this drug among the Arabs.

UDO, in *Geography*, a town of Japan, in the island of Niphon; 60 miles W.N.W. of Jedo.—Also, a town of Japan, in the island of Ximo. N. lat. $32^{\circ} 30'$. E. long. $132^{\circ} 30'$.

UDON, in *Ancient Geography*, a river of Asiatic Sarmatia; the mouth of which, according to Ptolemy, was in the Caspian sea, between that of Alontas and that of Rha.

UDRIGILL HEAD, in *Geography*, a cape of Scotland, on the W. coast of the county of Ross. N. lat. $57^{\circ} 54'$. W. long. $5^{\circ} 31'$.

UDSL, a town of Japan, in the island of Niphon; 15 miles S.W. of Meaco.

UDSKOI, a town of Russia, in the government of Irkutsk, on the Uda; 1100 miles E.N.E. of Irkutsk. N. lat. $55^{\circ} 16'$. E. long. $135^{\circ} 50'$.

UDSTEIN, a small island near the coast of Norway; 9 miles N.W. of Stavanger.

UDUAR, a town of the island of Ceylon; 26 miles S.S.E. of Colombo.

UDVARHELY, a town of Transylvania; 22 miles N.E. of Schesburg. N. lat. $46^{\circ} 30'$. E. long. $24^{\circ} 54'$.

UDUMNAEVSKOI, a fort of Russia, in the government of Irkutsk; 88 miles S.W. of Nertchinsk.

UDURA, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Taccetani. Ptolemy.

VEA, in *Geography*, a town of Persia, in the province of Segestan; 52 miles N. of Zareng.

VEADAR, in *Chronology*, the thirteenth month of the Jewish ecclesiastical year, answering commonly to our March: this month was intercalated, to prevent the beginning of Nisan from being removed to the end of February.

VEAGUES, in *Geography*, a town of France, in the department of the Cher; 6 miles S.W. of Sancerre.

VEAL TOWN, a town of New Jersey; 14 miles N.N.W. of New Brunswick.

VEAS, a town of Spain, in the province of Seville, on the Odier; 8 miles N.N.E. of Gibrleon.

VEASCIUM, in *Ancient Geography*, a town of Italy, allied to the Romans: it was attacked by the Gauls on their departure from Rome, but they were surpris'd and routed by Camillus. Plutarch says, that the Gauls, on leaving Rome, encamped eight miles from this town in Latium.

VEBRON, in *Geography*, a town of France, in the department of the Lozere; 6 miles S. of Florac.

VECCHI, ORAZIO, in *Biography*, born at Milan, and many years maestro di capella at Mantua, gained great reputation, not only as an able musician, but a poet. His numerous canzonets for three and four voices, published at Milan and Venice, from 1580 to 1613, were reprinted and sung all over Europe. Our countryman, Peacham, who had received instructions in music from this composer, during his residence in Italy, speaks of him in the following manner: "I bring you now mine own master, Horatio Vecchi, of Modena, who, beside goodness of aire, was most pleasing of all other for his conceipt and variety, wherewith all his works are singularly beautified, as well his madrigals of five and six parts, as those his canzonets, printed at Norimberge." (Complete Gentleman, p. 102.) He then instances and points out the beauties of several of his compositions, that were most in favour during that time. Besides secular music,

Vecchi composed two books of sacred songs, in five, six, seven, and eight parts; masses of six and eight voices; and four-part lamentations.

Vecchi has been erroneously supposed by many of his countrymen the inventor of the burletta or comic opera in Italy; and it was the opinion of the learned Muratori (La Perfetta Poesia, lib. iii. cap. 4.), that a musical drama or farce, called Anfiparnaso, written and set by the celebrated Orazio Vecchi, and acted and printed at Venice, 1597, was the origin of the OPERA Buffa; which see.

VECCHIA, PIETRO, born at Venice in 1605, was a painter, educated in the school of Paduanino, but more an imitator of Giorgione and Pordenone; and some of his pictures have been mistaken for works of those masters. Sandrardt relates a story of his having been deceived by a picture of Vecchia, which he mistook for one by Giorgione. From this talent of imitating others, the doge and senate of Venice employed him to copy the ancient works in mosaic which are preserved in the church of St. Marc. And in that church are also two original and very able pictures by him, representing the Crucifixion, and Christ driving the money-changers from the temple. His colouring is rich and warm, and his execution free and full, but sometimes apt to be incorrect. He died in 1678, aged seventy-three.

VECELLI, TIZIANO. See TITIAN.

VECELLI, ORAZIO, son of Titian, born at Venice in 1540, practis'd the art of painting under his father's tuition, but became distinguished only as a painter of portraits, some of which were esteemed as little inferior to those of his father. He died in the same year with his father, 1576.

VECELLI, MARCO, called Marco da Tiziano, was the nephew and disciple of Titian, and born at Venice in 1545. He appears to have been regarded by his great instructor with peculiar favour, and certainly his talent gave him the fairest claim to such distinction; for he approached the nearest to Titian, both in colour and composition, of all his disciples, and has left several original works, very deservedly esteemed, in the Palazzo di San Marco. He also executed several considerable works for the churches in Venice, Trevigi, and in the Friuli. He died in 1611, leaving a son, known by the name of Il Tizianello, who obtained much repute by his paintings, but they are in a loose and mannered style: his best productions are his portraits.

VECHT, in *Geography*, a river which rises in the bishopric of Munster, about six miles N.E. of Coesfeld, crosses Bentheim and Overissel, and runs into the Zuyder See at Gelmuyden.—Also, a river which passes by Utrecht, and runs into the Zuyder See at Mnyden.

VECHTA, a town and fortrefs of Germany, in the bishopric of Munster; 60 miles N.E. of Munster. N. lat. $52^{\circ} 43'$. E. long. $8^{\circ} 18'$.

VECS, a town of Transylvania; 16 miles E.S.E. of Bistritz.

VECTIS, in *Ancient Geography*, an island of the British ocean, S. of the Portus Magnus, or Great Haven, according to Ptolemy and Pliny.

VECTIS, in *Mechanics*, one of the powers, more usually called the lever; which see.

VECTIS, *Heterodromus*. See HETERODROMUS.

VECTOR, in *Astronomy*, a line supposed to be drawn from any planet moving round a centre, or the focus of an ellipsis, to that centre, or focus.

This, by some writers of the new astronomy, is called *vector*, or *radius vector*, because it is that line by which the planet

planet seems to be carried round its centre; and with which it describes areas proportional to the times.

VEDA, the name by which the Hindoos designate the collective body of their scripture. They enumerate eighteen parts of true knowledge, as follow: four Vedas, four Upavedas, six Angas, and four Upangas. The prefixure *up* infers a work deduced from its principal; like our *sub*, implying inferiority.

The first four, according to a native writer, quoted by Sir W. Jones, are the immortal Vedas, evidently revealed by God, which are entitled, in one compound word, *Rig-yajushsamatharva*; or, in separate words, *Rig*, *Yajush*, *Saman*, and *Atharvan*. The Rigveda consists of five sections; the Yajurveda, of eighty-six; the Samaveda, of a thousand; and the Atharvaveda, of nine; with eleven hundred *shuklas*, or branches, in various divisions and subdivisions. The Vedas in truth are infinite; but were reduced by Vyasa to this number and order. The principal part of them is that which explains the duties of man in a methodical arrangement; and in the fourth is a system of divine ordinances.

From these are deduced the four Upavedas; viz. *Ayush*, *Gandharva*, *Danush*, and *Sthapatya*. The first of which was delivered to mankind by Brahma, Indra, Dhanwantari, and five other deities; and comprises the theory of disorders and medicines, with the practical methods of curing diseases. The second, on music, was invented and explained by Bharata: it is chiefly useful in raising the mind by devotion to the felicity of the divine nature. The third Upaveda was composed by Viswamitra, on the fabrication and use of arms, and implements handled in war by the tribe of Kshetriya. Viswakarma revealed the fourth, in various treatises on sixty-four mechanical arts, for the improvement of such as exercise them. Of the personages named above, viz. Brahma, Indra, Viswakarma, Viswamitra, and Vyasa, see under those words respectively. Of Dhanwantari, some mention is made under our article KURMAVATARA.

The six Angas, or bodies of learning, are also, according to the same native authority, derived from the same source. We omit their names and contents: their subjects chiefly are, 1. Of the pronunciation of vocal sounds. 2. Detail of religious acts and ceremonies. 3. Grammar. 4. Prosody. 5. Astronomy. 6. On the signification of difficult words and phrases in the Vedas.

Lastly, continues the same author, there are four Upangas, called *Purana*, *Nyaya*, *Mimansa*, and *Dhermafaitra*. (See PURANA, NYAYA, and MIMANSA.) Eighteen Puranas were composed by Vyasa, for the instruction and entertainment of mankind in general. *Nyaya* is a collection of treatises in two parts, on metaphysics, logic, philosophy, &c. *Mimansa* is similarly divided into two parts; the latter, abounding in questions on the divine nature, and other sublime speculations, was composed by Vyasa in four chapters and sixteen sections. It may be considered as the spring of all the Angas; it exposes the heretical opinions of sophists; and, in a manner suited to the comprehension of adepts, it treats on the true nature of *Ganefa*, *Bhaskara* or the sun, *Nilakantha*, *Lakshmi*, and other forms of *One Divine Being*. Of *Ganefa*, the god of prudence and sagacity, see under POLLEAR. *Bhaskara* is a name of *Surya*. *Nilakantha* is a name of *Siva*, the same as *Shitakoonta*. *Lakshmi* is the consort of *Vishnu*.

The body of law, called *Smriti*, consists of eighteen books, &c. delivered for the instruction of the human species by *Menu*, and other sacred personages. As to

ethics, the Vedas contain all that relates to the duties of kings, the Puranas, what belong to the relation of husband and wife; and the duties of friendship and society (which complete the triple division) are taught succinctly in both. This double division of Angas and Upangas may be considered as denoting the double benefit arising from them in theory and practice.

To the above native account of the Vedas, Sir W. Jones adds an ingenious commentary. He says that the Vedas consist of three *kandas*, or general heads; viz. *Karma*, *Jnyana*, and *Upasana*; or works, faith, and worship. To the first of which, the author of the *Vidyaderasa*, or *View of Learning*, a rare Sanscrit book, wisely gives the preference; as *Menu* himself prefers universal benevolence to the ceremonies of religion.

After all, continues this instructive writer, the books on divine knowledge, called *Veda*, or what is *known*, and *Sruti*, or what has been *heard* from revelation, are still supposed to be very numerous; and the four here mentioned are thought to have been selected as containing all the information necessary for man. It must not be omitted, that the commentaries on the Hindoo scriptures, among which that of *Vasistha* (see VASISTHA) seems to be reputed the most excellent, are innumerable.

From the Vedas are immediately deduced the practical arts of surgery and medicine, music and dancing; archery, which comprises the whole art of war; and architecture, under which the system of mechanical arts is introduced.

Next in order to these are the six Vedangas: three of which belong to grammar; one relates to religious ceremonies; a fifth, to the whole compass of mathematics; and the sixth, to the explanation of obscure words or phrases in the Vedas. Subordinate to these Angas, though the reason of the arrangement is not obvious, are the series of sacred poems (see PURANA), the body of law, and the six philosophical *sastras* or *shastras*. See PHILOSOPHY of the Hindoos, and SHASTAH.

In the commentary whence we quote parts of this article, Sir William Jones gives some of the reasons that induced him and Mr. Wilkins to believe, notwithstanding the mythological fable of Brahma's four mouths, each of which uttered a Veda, that the fourth, or Atharva, was written or collected after the other three; but Mr. Colebrooke, in the eighth volume of the Asiatic Researches, after noticing some texts and arguments on which that belief might be reasonably grounded, gives his own reasons and proofs in support of a contrary opinion. He thinks it probable that some portion at least of the Atharvana, is as ancient as the compilation of the three others; and its name, like theirs, is anterior to Vyasa's arrangement of them; but the same, he adds, must be admitted of the portion called *Itahava* and *Purana*, which constitute a fifth Veda, as the Atharvana does a fourth.

The Hindoos believe that the original Veda was revealed by Brahma, and to have been preserved by tradition until it was arranged in its present form by a sage, who thence obtained the name of Vyasa, or the compiler; or Vedavyasa, that is, compiler of the Vedas. He distributed the Indian scripture into four parts, as already enumerated; each bearing the common denomination of Veda.

With the Hindoos it is an article of their creed, that the Vedas were composed by no human author. It must be understood, therefore, that in affirming the primeval existence of their scripture, they deny these works to be the original composition of the editor (Vyasa), but believe them to have been gradually revealed to inspired writers.

It appeared to Mr. Colebrooke from several other passages, and from the received opinion of the Hindoos themselves, that the Rich, Yajush, and Saman, are the three principal portions of the Veda; and the Atharvana is commonly admitted as a fourth; and that divers mythological poems, entitled Itahafa and Purana, are reckoned a supplement to the scripture, and as such constitute a fifth Veda.

The Vedas are a compilation of prayers, called Mantra; with a collection of precepts and maxims, entitled Brahmana: from which last portion, that called Upanishad is extracted. The prayers are properly the Veda, and apparently preceded the Brahmana. Each Veda consists thus of two parts, the Mantras and the Brahmanas; or prayers and precepts. The complete collection of the hymns, prayers, and invocations belonging to one Veda, is called its Sanhita: every other portion of Indian scripture is included under the general head of divinity (Brahmana): this comprises *precepts*, which inculcate religious duties; *maxims*, which explain those precepts; and *arguments*, which relate to theology. But in the present arrangement of the Vedas, the portion which contains passages called Brahmana, includes many which are strictly prayers, or Mantras. The theology of the Indian scripture, comprehending the argumentative portion entitled Vedanta, is contained in the tracts denominated Upanishad; some of which are portions of the Brahmana, properly so called: others are found only in a detached form; and one is a part of a Sanhita.

Prayers, employed at solemn rites, called Yajnya, have been placed in the three first Vedas: those in prose are named Yajush; such as are in metre are denominated Rich; and some which are intended to be chanted are called Saman; and those names, as distinguishing different portions of the Vedas, are anterior to their separation in Vyasa's compilation. But the Atharvana, not being used at the religious ceremonies above-mentioned, and containing prayers employed at lustrations, at rites conciliating the deities, and as imprecations on enemies, is essentially different from the other Vedas. This is adduced by Mr. Colebrooke as the true reason why the three first Vedas are often mentioned without any notice of the fourth; which must be sought, he says, not in their different origin and antiquity, but in the difference of their use and purport. The fourth, or Atharvana, is known to contain many forms of imprecation for the destruction of enemies. These are called *Mantra* (see that article), but it must not be inferred that such is the chief subject of that Veda; for it contains also a great number of prayers for safety, and for the averting of calamities; and, like the other Vedas, numerous hymns to the gods, with prayers to be used at solemn rites and religious ceremonies, excepting, as above-mentioned, such as are named Yajnya.

Mr. Colebrooke gives a passage from that part of the second, distinguished by the title of the *White* Yajurveda, the other being called the *Black*, confirming his opinions as above indicated, and important, as containing an enumeration of the Vedas, and of the various sorts of passages which they comprise: "As smoke and various substances separately issue from fire lighted with moist wood, so from this Great Being were reformed the Rigveda, the Yajurveda, the Sama-veda, and the Atharva and Angiras; the Itahafa and Purana; the sciences and Upanishads; the verses and aphorisms; the expositions and illustrations: all these were breathed forth by Him."

The commentators remark, that four sorts of prayers (Mantra), and eight kinds of precepts (Brahmana), are here stated. The fourth description of prayers comprehends such as were revealed to, or discovered by Atharvan and Angiras, meaning the Atharvana Veda. The Itahafa designate such

passages, in the second part of the Vedas, as narrate a story. The Purana intends those which relate to the creation, and similar topics. "*Sciences*" are meant of religious worship; "*verses*" are memorial lines; "*aphorisms*" are short sentences in a concise style; "*expositions*," interpret such sentences; and "*illustrations*" elucidate the meaning of the prayers.

The Puranas here meant are not the mythological poems bearing the same title; but, as already mentioned, certain passages interspersed throughout that part of the Vedas called Brahmana, or divine precepts. This distinction is important. Under our article PURANA a pretty full account of those mythological romances will be found.

The subjects and uses of the prayers contained in the Vedas, differ more than the deities which are invoked, or the titles by which they are addressed: every line is replete with allusions to mythology, and to the Indian notions of the divine nature and of celestial spirits. For the numerous ceremonies to be performed by a householder, and still more for those endless rites enjoined to hermits and ascetics, a choice of prayers is offered in every stage of the celebration. It may be here sufficient to observe, that Indra, or the firmament, fire, the sun, the moon, water, air, the spirits, the atmosphere, and the earth, are the objects most frequently addressed; and the various and repeated sacrifices with fire, and the drinking of the milky juice of the moon-plant, or acid asclepias (see SOMALATA), furnish abundant occasions for numerous prayers adapted to the many stages of those religious rites.

In describing the Vedas so replete with mythological allusions, Mr. Colebrooke does not mean a mythology which avowedly exalts deified heroes, as in the Puranas; but one which personifies the elements and planets; and which peoples heaven, and the world below, with various orders of beings. He observed, however, in many places, the groundwork of legends which are familiar in mythological poems; such, for example, as the demon Vritra, slain by Indra, who is thence surnamed *Vritraban* (which see,) but he did not remark any thing, except some detached portions, the genuineness of which appeared doubtful, that corresponds with the favourite legends of those sects which worship either the Linga or Sakti, or else Rama or Krishna. Such portions, he reasonably suspects to have been composed in more modern times, when compared with the other parts of the Vedas. This suspicion is chiefly grounded on the opinion, that the sects which now worship Rama and Krishna as incarnations of Vishnu, are comparatively new: he did not find in any other part of the Vedas the least trace of such a worship. The real doctrine of the whole Indian scripture is the *Unity of the Deity*, in whom the universe is comprehended; and the seeming polytheism which it exhibits, offer the elements, and stars, and planets as gods. The three principal manifestations of the Divinity, with other personified attributes and energies, and most of the other gods of Hindoo mythology, are indeed mentioned, or at least indicated, in the Vedas. But the worship of deified heroes is no part of that system; nor are the incarnations of deities suggested in any other portion of the text which he had seen, though such are hinted at by the commentators.

On the point of unity in doctrine, inculcated with great sublimity and purity, we may refer to some translations from the Vedas by sir W. Jones, in the last volume of his Works.

After giving strong reason for believing the Vedas to be genuine compositions, in opposition to some assertions of their being forgeries, or grossly interpolated, Mr. Colebrooke avows his opinion, that the greater part of the books received by the learned among the Hindoos will assuredly be found genuine;

mine; and has no doubt but the Vedas will appear to be of this description. In pronouncing them genuine, he means to say that they are the same compositions, which, under the same title of Veda, have been revered by Hindoos for hundreds, if not thousands of years. He thinks it probable they were compiled by Dwapayana, the person who is said to have collected them; and who is thence named Vyasa, or the compiler. See VYASA.

The following is the concluding paragraph of Mr. Colebrooke's very instructive paper on the Vedas, in the eighth volume of the Asiatic Researches, to which we have already acknowledged our obligations for a portion of this article.

"The preceding description may serve to convey some notion of the Vedas. They are too voluminous for a complete translation of the whole; and what they contain would hardly reward the labour of the reader; much less that of the translator. The ancient dialect in which they are composed, especially that of the three first Vedas, is extremely difficult and obscure; and though curious, as the parent of a more polished and refined dialect (the classical Sanscrit), its difficulties must long continue to prevent such an examination of the whole Vedas as would be requisite for extracting all that is remarkable and important in those voluminous works: but they deserve to be occasionally consulted by the Oriental scholar." See SHANSKRIT.

We shall now proceed to notice, as briefly as we can, the fabled and believed origin of the Vedas; the reverence in which they are held by Hindoos; their supposed antiquity; and some other points that may incidentally arise in the course of such considerations.

In the Institutes of Menu, chap. i. v. 23, it is laid down, that "from fire, from air, and from the sun, He (the Supreme Ruler) milked out, as it were, the three primordial Vedas, named Rich, Yajush, and Saman, for the due performance of the sacrifice."

Chap. iv. 124. "The Rigveda is held sacred to the gods; the Yajurveda relates to mankind; the Samaveda concerns the manes of ancestors; and the sound of it, when chanted, raises therefore a notion of something impure."

A commentator on the first of these texts explains it by remarking, that the Rigveda opens with a hymn to fire, and the Yajurveda with one in which air is mentioned. Another commentator has recourse to the popular notions respecting the renovations of the universe, at the end of the periods called Kalpa. "In one Kalpa the Vedas proceeded from fire, air, and the sun; in another, from Brahma at his allegorical immolation." See KALPA and PARUSHA.

The most general belief is, that the four Vedas issued from the four mouths of Brahma, as the like number of individuals did in whom originated the four grand civil sects, from appropriate parts of his body (see SECTS of Hindoos); the Brahman, or divine, from his mouth. Now Brahma is fabled to have once had five heads, and in this article we have noticed a fifth Veda. Siva, in one of his forms, is also five-headed; hence called *Panchamuki*; which see. (See also SIVA.) Some authorities attribute the Vedas generally to Pavaka, the god of fire. (See PAVAKA.) Others to Saraswati, the goddess of literature, &c. consort of Brahma. (See SARASWATI.) No female, however, is permitted to read the holy volumes. Sir W. Jones tells us (Af. Ref. vol. iii.), that "the Veda is called also *Agama*; but this title refers more particularly to a mysterious book, or set of books, so named from having come from the mouth of Siva, as the Vedas proceeded severally from the four mouths of Brahma. The same word means also the Veda." The word *Agama*, and similar words in other tongues, seem to imply something mysterious. See OGHAM and O'M.

The idea of impurity arising from the chanting of the Samaveda, is not uniformly held. Mr. Colebrooke informs us, "that a peculiar degree of holiness seems to be attached, according to Indian notions, to the Samaveda, if reliance may be placed on the inference suggested by the etymology of its name, which is expounded as denoting something which *defroys sin*." And this inference, we may remark, is countenanced by the circumstance of Krishna, when enumerating, in the Bhagavat Gita, various orders of beings and things, to the chief of which he compares himself, declaring, that "among the Vedas, I am the Saman." It may be said, however, that this Veda more especially relating to music, over which Krishna, the Hindoo Apollo, presides, he may advert only to its harmonious pre-eminence.

iv. 125. "Let the learned," Menu commands, "read the Veda on every lawful day, having first repeated in order the pure essence of the three Vedas, namely, the Pranava, the Yajhritis, and the Gayatri." Of these see under O'M.

xi. 262. "A priest who should retain in his memory the whole Rigveda, should be absolved from guilt, even if he had slain the inhabitants of the three worlds, and had eaten food from the foulest hands."

263. "By thrice repeating the Mantras and Brahmanas of the Rig, or those of the Yajush, or those of the Saman, with the Upanishads, he shall perfectly be cleansed from every possible sin."

264. "As a clod of earth, cast into a great lake, sinks into it, thus is every sinful act submerged in the triple Veda."

266. "The primary trilateral syllable, in which the three Vedas themselves are comprised, must be kept as secret as another triple Veda: he knows the Veda, who knows the mystic sense of that word." Of which see under O'M.

In the above texts from Menu, we see the propensity of the Hindoos to bring every thing into a ternary arrangement. The three Vedas, and the triple Veda, are ever recurring. In a hymn by Sir W. Jones to the sun, or rather to its ruler, Surya, he says,

"Nor e'en the Vedas three to man explain
Thy mystic orb triform, though Brahma tun'd the strain."

See SURYA. See also TRIMURTI for many instances of this disposition for triune classification.

The philosophical writers and their disciples, who profess to adhere closely to the doctrines of the Veda, are called *Vedantia*; which see.

On the age of the Vedas, we have to observe, that Sir W. Jones (Af. Ref. vol. i.) rejects their claim to the very high antiquity that some warm advocates were disposed to assign to them: he could never believe that they were actually written before the flood; but ventures to assert, that they are far older than any other Sanscrit composition. And in vol. ii. he says, that he "firmly believes, from internal and external evidences, that three of the Vedas are more than three thousand years old." And in vol. iii. that they appear to stand next in antiquity to the five books of Moses. In the preface to the Institutes of Menu, the learned translator deems the three first Vedas to have been composed about three hundred years before the Institutes, and about six hundred before the Puranas, which he is fully persuaded were not the production of Vyasa. The Institutes he supposes to have received their present form about 880 years before Christ's birth. By one mode of reckoning, the highest age of the Yajurveda is carried to 1580 years before the birth of our Saviour, (which would make it older than the Pentateuch,) and the Institutes must then be assigned to about 1280 years before the same epoch: but Sir W. Jones deemed the former date of 880 years
B. C.

B. C. for the Institutes the more probable. This would give the Yajurveda an age, in 1815, of about 2995 years.

Mr. Colebrooke (As. Ref. vol. vii.) infers, from several data there given, the probability that the Vedas were not arranged in their present form earlier than the 14th century before the Christian era; but cautiously marks the inference as vague and conjectural: about 3200 would hence be assumed as the maximum of elapsed years since the present arrangement of the Vedas. And deducing, by Sir William Jones's method, the comparative age of the Puranas, they will be 2500 or 2600 years old at most; and the Institutes 2800. See PURANA and MENU.

As to the relative age of the different Vedas, some differences of opinion will have been seen to exist. We shall only remark farther, that Mr. Wilkins, in the preface to the Gita, observes, that Krishna throughout the whole makes mention of three Vedas only; and those, the three first in their present order; the fourth, proving itself a posterior work, mentions him. On this being noticed to some Pandits who assisted in the translation, they expressed great astonishment at it, as it had escaped all the numerous commentators on the Gita. It may be remarked, in passing, that Menu is often mentioned in the Veda, and the Veda by Menu; a proof of interpolation somewhere.

It is evident that the Vedas are anterior to the heresy or reformation of Budha; one of his leading innovations being the condemnation of the practice of killing and eating animals, as enjoined in the Veda, and by Menu. See SECTS of *Hindoos*, and SRADHA.

So holy are the Vedas esteemed by the Brahmans, that no individual of the fourth, or servile tribe of Sudra, is permitted to read them. In this interdiction are included several other divine works. Both the poems entitled "Mahabarat" and "Ramayana," are likewise esteemed to contain passages and descriptions too awful for the eye of a Sudra: he may bear them read by a Brahman, who is likely to be careful as to what he communicates. Of this see under MAHABARAT, RAMAYANA, SECTS of *Hindoos*, SUDRA, and VAIDYA.

The Yajurveda is declared by Menu, in a text quoted above, to "relate to mankind." It is, as already noticed, ascribed to a celestial physician: it contains an entire Upanishad on the internal parts of the human body; with an enumeration of nerves, veins, and arteries, a description of the heart, spleen, and liver, and various disquisitions on the formation and growth of the fœtus. From this, and from many texts of Menu, we may perceive that the ancient Hindoos were fond of reasoning, in their way, on the mysteries of animal generation; and on the comparative influence of the sexes in the production of perfect offspring. The physiological disputes on this latter point exacerbated, by mythological warmth, appear to have led to violent schisms in religion, and even to bloody wars. See SARASWATI and YONI.

There can be little doubt but the learned world would thankfully receive a faithful uninterpolated translation of such portions of the Vedas as tend to throw light on the state of knowledge among a people who so early engaged in such disquisitions as are contained in the Yajurveda, above indicated. These would, doubtless, be valuable, and are, indeed, necessary to complete the history of universal philosophy, and to supply the scholars of Europe with authentic materials for an account of the opinions anciently formed on this head by the philosophers of Asia. We will not say how far the Atharvana Veda may deserve the honour of translation. It contains a most complete system of

incantations and magical devices; and would be so far curious, as to evince that, both in antiquity and ingenuity, the demagogues of Europe are vastly outstripped by their sapient brethren of the East.

We are not able to state the exact size or extent of the Hindoo scripture, or Veda. The following is as near an estimate as can be made.

The first, or Rig-Veda, contains about 10,000 verses, or rather stanzas, of various measures. The second, or Yajur-Veda, is divided into two; the *white* and the *black* together, they include about 9000 verses. The third, or Sama-Veda, about 3000. The fourth, or Atharva-Veda, about 6000. Of glosses, or commentaries, it is not easy to form any but a vague estimate: but we are, we think, warranted in the opinion, that, supposing the whole could be collected and printed in the manner of our dictionary, they would form a work larger than this!

In all Hindoo writings connected in the least with theology, and, indeed, in many others, extracts from, and allusions to, the Veda, frequently occur. Several articles in this work contain such, and are farther explanatory of the contents of those revered volumes. Those, therefore, desirous of more information hereon, are referred to the following; IDOLATRY, KRISHNA, MATSYAVATARA, SARASWATI, (in which is an extract of some length descriptive of the powers or energies of that goddess,) SHASTAH, SUTTEE, SECTS of *Hindoos*, SITANTA, SRADHA, SUDRA, SURYA, SURYA, TRIMURTI, UPANISHAD.

Veda is the correct way of writing the title of the Hindoo scripture collectively. In different parts of India it is variously pronounced; and it is variously spelt by European writers. Vedam and Bedam are occasionally seen: these are the modes of pronunciation in the Carnatic. Among the Mahrattas, Bede, or Bhade, is not uncommon: and its reputed compiler is called Beafs, and Beafs Muni. (See MUNI.) The Bengal alphabet having no *v*, Bed or Beda is the usual pronunciation in that quarter.

VEDAM, a name sometimes given to the *Veda*; which see.

VEDANGA, in *Hindoo Mythology*, a name of the sun, more commonly called *Surya*; which see. The name of Vedanga seldom occurs, as of the sun; but it is applied to certain portions of books of divine knowledge, as they call them, derived from the Vedas. Of this see under our article VEDA.

VEDANTA, in *Philosophy*, a sect among the Hindoos, so named from their theory being professedly founded on the doctrines contained in the Veda, or scripture, in a degree exceeding that of any other of the philosophical schools or systems. (See VEDA.) The fundamental tenet of this school consists, not in denying the existence of matter, but in correcting the popular notion of it; and in contending that it has no existence independent of mental perception; that existence and perceptibility are convertible terms; that external appearances and sensations are illusory, and would vanish into nothing, if the divine energy, which alone sustains them, were suspended but for a moment. This opinion seems to have been adopted by Epicharmus and Plato, and was maintained in the last century by a writer of our own nation. The founder of this school is named *Vyasa* (which see), and his theory is comprised in a little treatise in four chapters. An attempt has been made to elucidate the obscurity of this writer by the judicious and learned Sankara, in his commentary on the Vedanta. (See some account of him under the article SANKARACHARYA.) His esteemed work is entitled "Bashea." Sir W. Jones, after reading this commentary with great attention,

tion, affirms that it is not possible to speak in too high terms of so excellent a work; and that until an accurate translation of it shall appear in some European language, the general history of philosophy must remain incomplete. See MIMANSA.

The elegant author whom we have already named, touching on the Indian metaphysics of *natural bodies*, according to the most celebrated of the Asiatic schools, from which the Pythagoreans are supposed to have borrowed many of their opinions, remarks, that as the old sages of Europe had, as we learn from Cicero, an idea of centripetal force, and a principle of universal gravitation, which indeed they never attempted to demonstrate; so he would venture to affirm, without meaning to pluck a leaf from the never-fading laurels of our immortal Newton, that the whole of his theology, and part of his philosophy, may be found in the Vedas, and even in the works of the Sufis. (See SUFI.) That *most subtle spirit*, which he suspected to pervade natural bodies, and, lying concealed in them, to cause attraction and repulsion; the emission, reflection, and refraction of light; electricity; calcification; sensation and muscular motion, is described by the Hindoos as a *subtle element*, and endued with those very powers. The Vedas abound with allusions to a force universally attractive, which they chiefly ascribe to the sun, thence called "Aditya," or the *Attractor*.

Sir W. Jones, in his instructive essay on the philosophy of the Asiatics, proceeds to observe, that from all the properties of men and of nature, from all the various branches of science, from all the deductions of human reason, the general corollary admitted by Hindoos, Arabs, and Tartars, by Persians and by Chinese, is the supremacy of an all-creating and all-preserving spirit, infinitely wise, good, and powerful, but infinitely removed from the comprehension of his most exalted creatures. Nor are there in any language (the ancient Hebrew always excepted) more pious and sublime addresses to the Being of beings, more splendid enumerations of his attributes, or more beautiful descriptions of his visible works, than in Arabic, Persian, and Sanscrit, especially in the four Vedas, and in many parts of the Puranas. But supplication and praise would not satisfy the boundless imagination of the Vedanti and Sufi theologists; who, blending uncertain metaphysics with undoubted principles of religion, have presumed to reason confidently on the very nature and essence of the Divine Spirit, and asserted in a very remote age, what multitudes of Hindoos and Mussulmans assert at this hour, that all spirit is homogeneous; that the spirit of God is in *kind* the same with that of man, though differing from it infinitely in *degree*; and that, as material substance is mere illusion, there exists in this universe only one generic spiritual substance, the sole primary cause, efficient, substantial, and formal, of all secondary causes, and of all appearances whatever; but endued, in its highest degree, with a sublime providential wisdom, and proceeding by ways incomprehensible to the spirits which emanate from it.

This doctrine, as it is grounded on the belief of an immaterial Creator supremely wise, and a constant preserver supremely benevolent, differs widely from the pantheism of Spinoza and Toland. Our limits will not allow our enlarging on the principles of the Vedanta philosophy.

We have already noticed the admirable commentary by Sankaracharya on the Vedanta doctrines of Vyasa. In Bengal this work is highly esteemed; but on the western side of India, it is rivalled, in the estimation of the learned, by a more concise gloss, entitled Panchadahi, thought to be not inferior in clearness and accuracy to the *Baheea* of Sankara.

From a statement of the fundamental doctrine maintained by the disciples of the Vedanta school, it has been inferred that their philosophy is founded on the contemplation of one infinite Being, existing under two states or modifications. The first is that of a pure, simple, abstract Essence, immovable and quiescent; the second is that of a Being displaying motion or active qualities. Under the first modification he is called *Brimh*, or the Great Being, and *Kutasth*, or He who sitteth on high; under the second, he is named *Eesh*, the Lord, or *Jiv*, the Soul: or we may say, that *Brimh* is Being in its state of simple essence; *Eesh* is Being exerting energy, and causing the phenomena of the material universe; *Kutasth* is Being existing in sensitive creatures in its pure simple state; and *Jiv* is Being in a sentient active state.

It is rare to find in Vedanta works any attempt to establish its doctrines by any process of reasoning. The authors announce the principles of their sect in a dogmatical authoritative style, as indubitable truths; or establish their assertions by the authority of the sacred text alone, and attribute disbelief to passion and ignorance. Sometimes, indeed, we do perceive an appearance of reasoning and argument, in support of the denial of a material world.

It will be perceived by those who investigate the Vedanta philosophy, that it does not correspond closely either with the Berkeleyan, or with any other system known in the western world. (See BERKELEY.) It does not teach that the Supreme Being is the soul of the universe, as was taught by Virgil (see MAYA); that animate beings are separate detached portions of his essence, or that the visible extended material frame of things is God; but it affirms that the world is one living, unextended, indivisible Being, who puts forth his energy, and excites in himself the phenomena of sensible things, as well as of sensation, passion, &c. In explaining this system, however, the writers frequently make use of such figures as may mislead one who reads only detached passages of Vedanta works, without examining closely the nature of their doctrines. Hence the Vedantas have been supposed to teach the doctrine of *emanations*; and it must be admitted that passages occur, even in the Vedas, apparently countenancing this supposition. (See MURTY.) In the fourth or Atharva Veda it is said, that "as the sparks proceed from fire, so various kinds of animate and inanimate beings proceed from the incorruptible Being." But the best commentators say, that these expressions do not mean that these are separate individual beings, but only whatever is beheld or perceived is the Divine Essence. The Vedanta opinions cannot be represented by any figure: they must be deduced from plain and simple declarations.

The Vedanta philosophy will be found to correspond with the Berkeleyan in this important particular: both deny a material world, referring sensible things to the energy of a living Being. But the analogy appears to extend no farther. In another important particular they are strongly opposed: in maintaining and denying the existence of separate beings, upon whom this energy operates, exciting in their minds the ideas of external things. See more on this subject under our articles *MYSTICAL Poetry*, and *SUFI*.

Having offered this sketch of the Vedanta theory, the practical maxims of this very extended sect will be easily understood. They teach that perfection consists in rest; that motion or action is the origin of the moral distinctions of good and evil, both of which must be renounced, as they involve and imply each other. To the attainment of this sublime state, it is required that the active faculties be annihilated, and the passions and affections subdued; that the individual be totally indifferent to external things, animate and inanimate, to parents, wives, children, relations, goods,

or to whatever causes pleasure, pain, &c. This furnishes a reason why, in some Vedanta works, language very disrespectful is held towards such relatives and friends; so different to the general rule and usage of the Hindoos. When by the practice of rigid austerity, retirement from the world, and contemplation, this quiescent state is attained, the soul perceives that it is Being, and that Being is all things; and thus the soul becomes the one Infinite Essence. Some branches of this rigid austerity and contemplation are called TAPAS and JAP. (See under those words for some account of these practices; and under SECTS of Hindoos, and YOGI, of those who practise them.) Action, say the Vedantis, or religious performances, do not conduct the soul to the state of the Eternal but to *Swergra* (which see), where it continues, until the holiness it hath accumulated be nearly expended by the enjoyment of happiness; when it returns to earth, and takes a body corresponding to its remnant of virtue. Agreeably to this notion, action is condemned, as it tends to retain the soul in the prison of passion and affection. Still, while a person continues to perform the common acts of life, it is incumbent on him to attend to religious duties and rites.

It has been found expedient farther to modify the doctrine, in such a manner as to reconcile it with the ordinary avocations of life, on which depend the existence of society. Accordingly it is held, that the renunciation of the world does not require that a person cease or depart from those avocations; but only that he preserve his mind in a state of perfect indifference and tranquillity. "If it be alleged that the Puranas declare, that Bharata and others did not perform the acts of life; we would ask," says the Panchdashī, "why do you not listen to the Vedas, which declare that wise men eat, act, and procreate?"

It will be necessary to keep in mind that the Vedanta is a philosophical, not a religious system; and that a profession of its tenets is compatible with all the religious sects who admit the authority of the Veda. This may be said likewise of the Sankya, Nyayai, and other philosophical systems. The religious distinctions of the Hindoos result from the peculiar or exclusive veneration paid to a particular deity; and the adoption, as a spiritual guide, of those books which celebrate that deity as the great Being. On this point the reader may consult our articles KRISHNA, SARASWATI, SECTS of Hindoos, SANKYA, SIVA, and others thence referred to, connected herewith.

VEDENSKAIA, in *Geography*, a town of Russia, in the government of Irkutsk, on the Irkut; 34 miles W. of Irkutsk.

VEDENSKOI, a town of Russia, in the government of Vologda, on the Uria; 66 miles E.S.E. of Vielsk.—Also, a town of Russia, in the government of Archangel, on the Voksha; 200 miles E.S.E. of Archangel. N. lat. $58^{\circ} 45'$. E. long. $46^{\circ} 44'$.—Also, a town of Russia, in the government of Tobolsk; 36 miles S.E. of Tomsk.

VEDETTE, in the *Military Art*, a sentinel on horseback, detached from the main body of the army, to discover and give notice of the enemy's designs.

VEDIANTII, according to the orthography of Pliny, written *Vesliantii* by Ptolemy, in *Ancient Geography*, the name of a people, whose capital was Cæmelion (Pliny), or Cemenelium (Ptolemy), situated in the province of the Maritime Alps, according to the Notitia of the provinces of Gaul.

VEDRA, a river of Britain, the mouth of which is placed by Ptolemy on the south-east side, bounded by the German ocean. Horsley differs in opinion concerning this river from Camden and Baxter: he supposes it to be the river Tyne, and they conjecture it to be the Were.

VEDRA, *Cape*, in *Geography*, a cape of Spain, on the coast of Galicia. N. lat. $42^{\circ} 19'$. W. long. $8^{\circ} 51'$.

VEDRO, or WEDDRA, in *Commerce*, a liquid measure in Russia. The cask, farokowoi, or pipe of wine, contains 40 vedros; the vedro, 8 osmuchki or kruschkas; and the kruschka, 11 tscharkays or cups. The vedro in Petersburg contains 621 French, or 752 English cubic inches; hence 1 vedro = $3\frac{1}{4}$ English wine gallons, and 3 kruschkas = 1 English ale gallon. Kelly's Un. Camb.

VEÈNE, in *Geography*. See VEHNE.

VEER, in *Sea Language*, is variously used. *Veering out the rope*, denotes the letting it go by hand, or letting it run out of itself: thus, they say, *Veer more cable*; that is, let more run out.

VEER is also used in reference to the wind: for when it changes often, and suddenly, they say, *the wind veers*.—Or, the wind is said to *veer and haul*, when it alters its direction, and becomes more or less *fair*: thus it is said, to *veer aft*, and to *haul forward*.

VEER and haul, *To*, is to pull a rope tight, by drawing it in and slackening it alternately, till the body to which it is applied requires an additional motion, like the increased vibration of a pendulum, so that the rope is frightened to a greater tension with more facility and dispatch. This method is particularly used in hauling the bow-lines. Falconer.

VEERAPATCH, in *Geography*, a town of Hindoostan; 18 miles W.N.W. of Dindigul.

VEERE, or VERE, or *Terwer*, a sea-port town of Zealand, situated on the northern coast of the isle of Walcheren, communicating with Middelburg by means of a canal. The name given it signifies, in the language of the country, "Passage," and was probably acquired by its being the place from whence they ordinarily pass over to North Beveland. Its ancient name was Kamp Vere. The place is regularly fortified towards the land with strong bastions, and a broad ditch; and towards the sea is a strong wall. The harbour is very good, but lies much exposed to inundations. The arsenal is one of the best in Zealand, and furnished with all manner of stores for a considerable fleet. This is the third walled town in the island of Walcheren, and has the sixth place in the assembly of the states of Zealand. It has three gates towards the land, and one towards the sea, where vessels come from Dort, Zirczee, and other places. The inhabitants are chiefly occupied in the herring-fishery, which is their harvest. There is little to be observed in the town but the stadthouse, began in 1704, and the great church the steeple of which is low and unfinished; 4 miles N. of Middelburg. N. lat. $51^{\circ} 37'$. E. long. $3^{\circ} 35'$.

VEERE Channel, a channel between the Dutch islands of Walcheren and Schouwen.

VEERING, in *Sea Language*, denotes the operation by which a ship, in changing her course from one board to the other, turns her stern to windward. Hence it is used in opposition to *tacking* (which see), wherein the head is turned to the wind, and the stern to leeward. A ship, having made the necessary dispositions to veer, bears away gradually before the wind, till it blows obliquely upon the opposite side, which was before to leeward; and as the stern necessarily yields to this impression of the wind, assisted by the force of the helm, and the action of the waves upon the same quarter, the side which was before to leeward soon becomes to windward. Since, by this movement, a ship loses ground considerably more than by tacking, it is rarely practised except in cases of necessity or delay; as, when the violence of the wind and sea renders tacking impracticable; or when her course is slackened to wait for a pilot, or some other ship in company, &c.

When it becomes necessary to veer the ship, the sails towards the stern are either furled or brailed up, and made to shiver in the wind; whilst those near the head are spread abroad, so as to collect the whole current of air which their surfaces can contain. Hence, while the whole force of the wind is exerted in the fore-part of the ship to turn her about, its effect is considerably diminished, or altogether destroyed, on the surfaces of the after-sails. The fore-part, accordingly, yields to the above impulse, and is put in motion; and this movement, conspiring with that of the wind, pushes the ship about as much as is necessary to produce the effect required. When she is turned so that the wind will act upon that quarter, which was formerly to leeward, her circular motion will be accelerated by extending some of the sails near the stern, as the mizen, and by placing those at the prow more obliquely, which will wheel the vessel round with her bow to the windward; in the same situation, with regard to the wind, as when close-hauled, or tacking. When the tempest is so violent as to prevent the use of sails, the effort of the wind operates almost equally on the opposite ends of the ship, so that the masts and yards situated at the head and stern counter-balance each other. The effect of the helm is also considerably diminished, because the head-way, which gives vigour to its operations, is at this time feeble and ineffectual. Hence it is necessary to destroy this equilibrium which subsists between the masts and yards afore and abaft, and to throw the balance forward, in order for veering. This is accordingly performed by bracing the foremoft yards across the direction of the wind, and arranging those on the main-mast and mizen-mast directly in the line of the wind. If this expedient proves unsuccessful, and it is absolutely necessary to veer, in order to save the ship from destruction, by oversetting or running ashore, the mizen-mast must be instantly cut away, and even the main-mast, if she yet remains incapable of answering the helm by bearing away before the wind. Falconer.

VEERING, in *Husbandry*, a term borrowed of the sailors, and used for the turning of two furrows toward each other, as they must do to begin a ridge; they therefore call the top of a ridge a *veering*; and they call the two furrows that are turned from each other at the bottom between two ridges, a *venting*, that is, an ending, because it makes an end of plowing ridges.

VEERSE, in *Geography*, a town of Germany, in the county of Verden; 10 miles E.N.E. of Rotenburg.

VEGA, **LOPEZ DE LA**, or **LOPE-FELIX DE VEGACARPIO**, in *Biography*, a celebrated and voluminous Spanish poet, was born of a noble family at Madrid, in the year 1562. Having been educated in the university of Alcalá, he occupied several honourable posts, and served on board the grand armada destined against England. After the death of his second wife, he took holy orders at Toledo, and obtained admission into the congregation of priests at Madrid; acting as president, and professing himself as one of the third order of Franciscans. By favour of pope Urban VIII. he was honoured with the insignia of the knights of Malta, and with the title of doctor of theology. He died in 1635, at the age of 73. He was eminently distinguished as a poet, and regarded as the father of the Spanish drama, excelling, as some have asserted, all poets, ancient and modern, in this kind of composition. His "Theatre" occupies twenty-five volumes, each of which contains twelve plays of various descriptions. One of his biographers says of him, that "the inundation of Vega's fancy seems to have been no more than a deluge of very ordinary matter, in which there is little to be praised but an easy eloquence of language, and a faculty of dramatising,

after a manner, stories of every kind. Three hundred pieces could not possibly have been composed otherwise. Nor was this the principal portion of his literary labour; for he has himself affirmed, that upon a calculation it would appear, that he wrote five leaves of MS. for every day of his life." The high degree of admiration he inspired in his own country appeared from the numerous eulogies of which he was the subject after his death. Moreri. Gen. Biog.

VEGA, in *Geography*, a town of Spain, near the N. coast of Asturias; 34 miles N.W. of Oviedo.

VEGA, **La**, a town of the island of Hispaniola; 24 miles S.E. of St. Jago de los Caballeros.—Also, a town of the island of Hispaniola; 62 miles N. of St. Domingo.—Also, a town of Spain, in the province of Leon; 40 miles W.N.W. of Astorga.—Also, a town of Spain, in the province of Leon; 18 miles N.N.E. of Leon.

VEGAMAN, a town of Spain, in the province of Leon; 24 miles N.N.E. of Leon.

VEGENOE, a small island in the North sea, near the coast of Norway. N. lat. 65° 45'.

VEGESELA, in *Ancient Geography*, a town of Africa, in Numidia, upon the route from Theveste to Sitifis, between Mascula and Timphadis, according to the Itinerary of Antonine.—Also, a town of Africa, in the Byfacene territory, on the route from Thenæ to Theveste, between Sufetula and Menegefes. Itin. Anton.

VEGETABLES, in *Agriculture and Gardening*, are all such plants as are found capable of affording useful products as food for man, and different sorts of live-stock. They are constituted and composed of soft and fleshy and solid parts, the latter of which are formed and arranged in such a manner as to afford proper firmness and support in their different growths; and from which proceed those which are often considered as, in some measure, distinct and different in their nature and uses, as the roots, the stems, the leaves, the flowers, the fruits, the seeds, and some others.

The first of these, which differ greatly in different sorts of vegetables, are the parts which connect them with the earth or soil, and the main source of their nourishment and support. They are, in all cases, more or less fibrous in some of their parts; and the more perfectly this takes place, the more capable they are of drawing nourishment from the ground on which they grow. It is, consequently, the fibrous radicles and the leaves that constitute the media through which the growth and increase of vegetables are effected. The fixing of these parts in the earth, too, by the ramifications which they send forth, prevents the vegetables from being overturned by winds and other causes. The form or shape and uses of these parts in different kinds of vegetables differ very materially, having in some cases a branching lateral growth, in others a knobby, and sometimes that which is directly downward, in some instances is fleshy and eatable, and in others woody or sticky, and of no value.

They are very similar in the nature of the different divisions of their parts to the stem or trunk and branches; and may, indeed, be said to be a sort of continuation of the former, terminating in minute ramifications and filaments, and not in leaves; as by burying the branches of certain trees, as the willow, in the earth or soil, as practised by Woodward, and since repeated by many others, and elevating the roots in the atmosphere, there is, as it were, an inversion of the functions of them, the roots producing and becoming buds and leaves, and the branches shooting out into radical fibres and tubes, and forming roots. See **ROOT**.

The second of these parts are those which stand next in importance in vegetables, when considered merely as such, and which include the branches as well as all the more solid parts of them, consisting principally of different coats, as bark, flesh or wood, according to the nature of the vegetable, and pith, or the middle part. These coats or coverings are differently formed, modified, and constituted, so as to be of different uses in their economy. The part, or layer, which is placed next to the wood, is composed, in vegetables of the tree kind, of a soft white substance, not easily discernible in some sorts of trees, but harder and more apparent in others. It is, as it were, an imperfect wood, or in the state between bark and wood. The wood is the compact, fibrous, hard part or substance which is disposed in the middle of trees, which in annual and biennial vegetables is called the flesh, as has been seen already. Between the above coat and the wood, a new ring of a softer nature is formed every year, which gradually loses its softness as the cold season advances, and which towards the middle of winter is converted into a solid ring of wood. These annual rings, which are visible in most trees when cut through transversely, serve as marks by which to determine their ages in some cases. They seem to decrease in breadth as the trees advance in age; and as they are found to be very unequal throughout in their dimensions, their breadth probably varies as the season may be favourable or otherwise. The wood, however, does not only differ from the coats or bark in the degree of hardness, but likewise in its structure, which is essentially different; and the seeming conversion of bark into wood, is imagined by some to be entirely a deception.

Thus, if the branch, stem, or the root of a tree be cut in a transverse manner, it usually displays three distinct bodies or parts: the bark, the wood, and the pith; each of which is again susceptible of a new division. The bark, where perfectly formed, has a thin covering, that may easily be separated; is in laminæ or scales, which, in old trees, are mostly in a loose and decaying state. It is not vascular, but merely defends the interior parts from injuries. It is supposed to be a part of little importance in forest-trees, and the larger shrubs, the bodies of which are firm and of strong texture; but in the reeds, the grasses, and the plants which have hollow stalks, it is of great use, is of very great strength, and appears constituted of a sort of glassy network, which is chiefly siliceous earth, as has been lately ascertained. This is the case in wheat, in the oat, and in different other plants; in some of which it exists in large quantities, and is general in this part of those of the hollow kind. It is serviceable as a support as well as protection from insects in such cases.

The most interior part of the bark is composed of layers, the numbers of which vary with the age of the tree; so that on cutting this part of a tree of several years standing, the productions of different periods may be distinctly seen, though the layer of every particular year can rarely be exactly defined or ascertained. The functions of the different parts of the bark are of great importance to vegetables.

In regard to the wood in trees, it is composed of an external or living part, called sap-wood, and of an internal or dead part, termed heart-wood; the former of which is white, and full of moisture, and in young trees and annual shoots reaches even to the pith. It is the great vascular system of the vegetable through which the sap-juice rises, the vessels in it extending from the leaves to the most minute filaments in the roots. Its structure has different important uses in producing new arrangements, and forming new wood.

In respect to the arrangement of the fibres of the wood, there are two distinct appearances in them: as the series of white shining laminæ, which shoot from the centre towards the circumference, and which constitute what is termed the *silver grain* of the wood; and the numerous series of concentric layers, which are commonly denominated the *spurious grain*, the number of which denotes the age of the tree, as already suggested. The former has many important functions, and is the most distinct in forest-trees; though annual shrubs have even a system of fibres similar to it. See **TIMBER, SAP, and ALBURNUM.**

The stem parts of some vegetables are quite hollow; partly, it is supposed, from such vegetables requiring a more than ordinary supply of air in their support, as they are generally those which are of a quick growth.

The pith is the soft, white, innermost substance of vegetables of the tree and other kinds, that is situated in the centres of the stems.

In the very infancy of the vegetable it occupies but a small space, but gradually dilates; and in shoots of the annual kind, and in young trees, offers a considerable diameter. Being acted on by the heart-wood, as pressed by the new layers of the sap-wood, in the more advanced age of the tree, it begins to diminish, and in very old forest-trees wholly disappears. As it has lately been wholly removed in different young trees, which continued to live and increase; it is evidently only an organ of secondary importance. In early shoots, in vigorous growth, it is filled with moisture, and is a reservoir of fluid nourishment, perhaps, at the time when it is most wanted. As the heart-wood forms, it is more and more separated from the living part, the sap-wood; its functions become extinct, it diminishes, dies, and ultimately disappears. See **STALK and TRUNK.**

The third, or the leaves, are parts which are essential to the existence of vegetables; as when, either of the plant or tree kind, wholly divested, or only stripped of a considerable part of them, they do not shoot in a vigorous manner. They are produced from the coats of the stalks or stems, and are of the soft fleshy thick kind, or the more thin, barked, or woody sort. They are capable of affording nourishment, and of being of use to vegetables, by the nutrient fluid matters which they hold in reserve in their soft substances, and by the dew, air, and moisture, which they take in and throw off.

In all cases the leaves are similar in their interior organization, and perform the same functions as the above parts, only their structure is finer and more minute. The sap-wood spreads and extends itself from the footstalks into the very extremities of the leaves; it preserves a vascular system, and its living powers; some parts of the former of which may be distinctly seen in the leaf. A material use of the leaves is, the exposure of the sap to the influence of the air, heat, and light: for which their surface is extensive, the tubes and cells very delicate, and their texture porous and transparent. In the leaves, much of the water of the sap is evaporated; it is combined with new principles, and fitted for its organizing functions, and probably passes, in its prepared state, from the extreme tubes of the sap-wood into the ramifications of the cortical tubes, and then descends through the bark. On the upper surface of leaves, which is exposed to the sun, the external covering is thick but transparent, and is said to be composed of matter possessed of little organization, which is either principally earthy, or consists of some substance of the homogeneous chemical kind. That in the grasses it is partly siliceous, in the laurel resinous, and in the thorn and maple principally constituted by a substance analogous to wax.

VEGETABLES.

By these arrangements, any evaporation, except from the appropriate tubes, is, it is thought, prevented. On the lower surface of them, the external coat is a thin transparent membrane full of cavities; and it is probably altogether by this surface, it is said, that moisture and the principles of the atmosphere necessary to vegetation are absorbed or taken up.

The leaves in the greater number of plants annually decay, and are reproduced; their decay takes place either at the close of the summer, as in very hot climates, when they are no longer supplied with sap, on account of the dryness of the soil, and the evaporating powers of heat; or in the autumn, as in the northern climates at the commencement of the frosts. In common cases, the leaves preserve their functions no longer than there is a circulation of fluids through them. The colour assumed in the decay of the leaf, seems, it is said, to depend upon the nature of the chemical change; and that as acids are generally developed, it is usually either reddish-brown or yellow; yet there are great varieties. Thus, in the oak it is a bright-brown; in the beech, orange; in the elm, yellow; in the vine, red; in the lycamore, dark-brown; in the cornel-tree, purple; and in the woodbine, blue. The cause of the preservation of the leaves of evergreens during the winter is not well known. It is found that the force of the sap is much less in vegetables of this sort, and there is probably a certain degree of circulation throughout the winter season; their juices are less watery than those of other plants, and probably less liable to be congealed by cold, and they are defended by stronger coatings from the action of the elements. The production of the other parts of the plant may be noticed to take place at the time the leaves are most vigorously performing their functions. If the leaves of a tree be stripped off from it in the spring, it uniformly dies; and when many of those of forest-trees are injured by blasts, the trees are said always to become stag-headed and unhealthy in their growth.

The leaves, it is said, are necessary for the existence of the individual tree; the flowers, noticed below, for the continuance of the species.

In the flowers there are several different organs or parts, the forms, vascular nature, texture, and organization of which serve different important uses and functions. That which contains the rudiments of the seed has it never formed as reproductive, without the aid of the influence of the pollen, or fecundating dust provided for the purpose. This mysterious impregnation is, of course, necessary to the continued succession of the different vegetable tribes.

It has been noticed, that all the parts of a vegetable seem to contribute to the formation of the flowers and fruits of plants; as, although the latter do not swell and ripen until after the former have fallen, their rudiments or first beginnings are in the flowers, of which they properly make a part. These last are consequently temporary parts of vegetables, allotted to the purposes of generation, terminating, as it were, the old vegetables, and beginning the new ones. Fruits consist of nearly the same parts as the stems of vegetables, as a sort of skin or fine coat, which is a production or continuation of that of the bark of an outer soft pulpy substance, and is the same as that continued from the bark, only that its vessels or cells are larger, and it is more succulent and juicy. There is commonly an inner pulp, which is next to the core; and the core itself is nothing more than a hard woody covering, that includes the seed. It is to be noticed, however, that the formation of the fruit is very various: in some cases, the seeds are dispersed through the pulpy substance; in some, instead of a core, a strong woody material is met with, inclosing the seed or kernel, which,

from its great hardness, is termed a stone; in some, there is a number of seeds; and in others, only a single seed, inclosed in a large mass of pulpy matter. See FRUIT.

The seeds are the deciduous parts of vegetables, each seed including the rudiment of a new plant, imbued with the vital principle, which it is capable of retaining for a vast length of time. A seed consists of different parts, as that which is necessary to the production of the new plant or vegetable within the seed, termed the corcule; which is divided and distinguished into the scaly ascending part, named the plumule, and the plain descending part, called the roset; with different others of less importance, some of which are perishable. It has been commonly supposed, and not without probability, that the perfect plant, or the organization necessary to it, exists in the seed, surrounded by a quantity of farinaceous matter, which serves to absorb moisture, and to furnish nourishment to the corcule, until its parts are sufficiently unfolded to draw support from the soil in which it is placed. This is finely illustrated in the dwarf kidney bean, which, when steeped some time in water, and it begins to swell, may be easily separated into its two lobes, between which is seen the nascent plant or vegetable. The stem, and its connection with the lobes, too, are clearly seen; and numberless vessels ramify through the lobes, which directly communicate with the embryo plant or vegetable. And on the external surface of the seed are absorbent vessels, that take up moisture, by which a sort of fermentation is produced, and a liquid material formed, elaborated and prepared by a particular process, which is proper for the nourishment and support of the plant or vegetable, in its first tender growth. In this early growth, the lobes of the seed, which are provided with a mealy material, are likewise found necessary. And the first leaves, or those which are called seminal, are thought to appear not less necessary than the lobes to the perfection of the plant or vegetable; as, if they happen to be broken off or destroyed, the plant or vegetable experiences a proportional loss of strength and vigour in its growth.

There is, therefore, to be distinguished in every seed an organ of nourishment, a nascent plant, and a nascent root. The first of these, in wheat and many grasses, is a single part; in other instances, it consists of more than two parts; but in the greater number, it is simply divided into two.

The seed, which is the last production of vigorous vegetation, is wonderfully diversified in form. That being of the highest importance to the resources of nature, it is defended above all other parts of the plant, it is said, by soft pulpy substances, in the esculent fruits; by thick membranes, in the leguminous vegetables; and by hard shells, or thick external coverings, in the palms and grasses. Though the matter of the seed, in its common state, may appear wholly inert and inactive; when acted upon by moisture, heat, and air, it soon distinctly develops itself, and becomes a complete plant in root and stem.

The above observations have been chiefly taken from the works of Hooper and Davy, to which the reader may be referred. See SEED.

As vegetables are supplied with proper vessels, those of the absorbent kind on the surfaces of them take up the nutritious fluid or material, and convey it to the different parts. The surface of a plant has two sets of absorbents, as already seen, which constitute the absorbent organ of vegetables; as the mouths of the vessels of the radicles of the roots, and those on the surfaces of the leaves. The root, as long as it remains soft and tender, imbibes and takes up the nutritious juices from the earth, by means of the absorbent mouths of its vessels; but as soon as it be-

VEGETABLES.

comes lignous, it emits radicles on every side, which continue the absorption, and convey the matters first to the root, and then to the whole plant or vegetable. Thus, if a plant or tree be transplanted, it succeeds with greater certainty, the more absorbent radicles are preserved with the root. The leaves absorb matters from the surrounding atmosphere, in the same manner as the radicles do from the earth, and convey them to the other parts of the plant or vegetable. It is supposed that, by means of the absorbents, water is distributed to every part of the plant or vegetable, and constitutes its principal aliment; as, deprived of this universal fluid, it droops and dies; but, by its influence, is not only nourished, and the vascular parts of the whole fabric dilated, but it contributes greatly to excite the languishing fibres, and in this way to increase the vital power of the vessels. By means of this system of vessels, too, the atmospherical air, which is essential to the growth of vegetables, is absorbed or taken up; as plants *in vacuo* cannot be evolved from the seed, nor can they afterwards vegetate. This is most probably the reason why seeds, buried very deep in the earth, do not vegetate, but die. See SAP and VEGETATION.

There are many matters or principles in different kinds

of vegetables, which render them particularly useful in the way of food, or beneficial in the products which they afford. The starchy and saccharine principles are particularly important, as possessing the qualities of fattening animals in a high degree. See STARCH, SACCHARINE Matter, and VEGETO-ANIMAL Matter.

The bitter principle prevails very extensively in vegetables, and the natural sort of it is of great importance and utility in the art of brewing, as checking fermentation, and preserving fermented liquors, &c. And there are many other principles in them, which contribute to different useful purposes in several ways. See OIL, VOLATILE Oil, WAX, &c.

The particular nature and properties of the several different principles or parts of vegetables may be seen explained in Davy's Elements of Agricultural Chemistry.

The quantities or proportions of nutritive or soluble matters, which are contained in different vegetables, or substances of that kind, are very different, as shewn in the table given below from the above work, which comprehends the quantities of this sort of matters which are afforded by a thousand parts of different vegetable substances, when submitted to experiment, green, and in their natural states.

TABLE.

Vegetables or Vegetable Substances.	Whole Quantity of nutritive or soluble Matter.	Mucilage or Starch.	Saccharine Matter or Sugar.	Gluten or Albumen.	Extract or Matter rendered insoluble during Evaporation
Middlesex wheat, average crop	955	765	0	190	0
Spring wheat	940	700	0	240	0
Mildewed wheat of 1806	220	178	0	32	0
Blighted wheat of 1804	650	520	0	130	0
Thick-skinned Sicilian wheat of 1810	955	725	0	230	0
Thin-skinned Sicilian wheat of 1810	961	722	0	239	0
Wheat from Poland	950	750	0	200	0
North American wheat	955	730	0	225	0
Norfolk barley	920	790	70	60	0
Oats from Scotland	743	641	15	87	0
Rye from Yorkshire	792	645	38	109	0

Fiorin cut in winter	76	64	8	1	3

VEGETABLES.

These substances comprise some of the most important articles of food in different intentions, and it is suggested as probable, that the excellence of them in this view will be found, in a great measure, to be in proportion to the quantities of this sort of matters they yield or afford; though they cannot be regarded as absolutely denoting their value in this way. Some of the matters have the characters of animal substances, as the albuminous and glutinous; sugar is more nourishing, and extractive matter less so, than any other principles composed of carbon, hydrogen, and oxygen. Certain combinations of these substances, too, may be more nutritive than others. It is stated likewise, on the authority of Sir Joseph Banks, that the miners in Derbyshire, during winter, prefer oat-cakes to wheat bread, as they find that this kind of nourishment enables them to support and keep up their strength, and perform their labour better at that season. But that in summer, they say that oat-cake heats them, and they then consume the finest wheat bread they can procure. It is supposed, that even the skin of the kernel of oats has probably a nourishing power, and is rendered partly soluble in the stomach with the starch and gluten. It is noticed, that in most countries of Europe, except Britain, and in Arabia, horses are fed with barley mixed with chopped straw; and that the straw in this state seems to act the same part as the husk of the oat. Hard thin-skinned wheats are preferred in some parts to those of the soft thick-skinned kinds, as containing a larger quantity of gluten and nutritive matter. See *WHEAT*.

In regard to vegetables of the grass kind, the only substances which have been detected in the soluble matters procured from them, are mucilage, sugar, bitter extract, a substance analogous to albumen, and different saline matters; with feeble indications of the tanning principle in some products from after-math crops. The albumen, sugar, and mucilage, probably, it is thought, when cattle feed on grass or hay, are, for the most part, retained in the body of the animal; and the bitter principle, extract, saline matter, and tannin, when any exists, are probably in common voided in the dung, with the woody fibre. From the great similarity of the extractive matter procured from the fresh dung of cows, to that existing in the soluble products from grasses, and some other facts of the same nature, it appears probable, it is said, that the bitter extract, though soluble in a large quantity of water, is very little nutritive; but probably serves the purpose of preventing, to a certain extent, the fermentation of the other vegetable matters, or in modifying or assisting the function of digestion, and may thus be of considerable use in forming a constituent part of the food of cattle. A small quantity of bitter extract and saline matter is probably all that is needed, and beyond this quantity, the soluble matters must be more nutritive in proportion as they contain more albumen, sugar, and mucilage, and less so in proportion as they contain other substances.

In comparing the composition of the soluble products afforded by different crops from the same grass, it was constantly found, that the largest quantity of truly nutritive matter, was in the crop cut when the seed was ripe, and least bitter extract and saline matter; most extract and saline matter in the autumnal crop; and most saccharine matter, in proportion to the other constituent parts, in the crop cut at the time of flowering. It is supposed that the greater proportion of leaves in the spring, and particularly in the late autumnal crop, accounts for the difference in quantity of extract; and the inferiority of the comparative quantity of sugar in the summer crop, probably depends upon the agency of light, which always tends in plants to convert saccharine matter into mucilage or starch.

No differences have been found in the nutritive produce of the crops of different grasses cut at the same season, which could render it possible to establish a scale of their nutritive powers, but probably the soluble matters of the after-math crop are always from one-sixth to one-third less nutritive than those from the flower or feed crop. In this crop, the extractive and saline matters are certainly usually in excess; but the after-math hay, mixed with summer hay, particularly that in which the fox-tail and soft grasses are abundant, would, it is thought, produce an excellent food or fodder.

In the clovers, the soluble matter from the Dutch clover is said to contain most mucilage, and most matter analogous to albumen: all the clovers contain more bitter extract and saline matter than the common proper grasses. When pure clover is to be mixed as fodder, it should, it is said, be with summer hay, rather than after-math hay.

Other observations on this interesting subject may be seen in the appendix to the above work.

In cultivation, much use and advantage may, in many cases, be derived from changing the natural habits of vegetables, by sowing the seeds of them or planting them at unusual seasons, by placing them in more dry and warm, or more cold and moist situations, and by altering the time of their flowering, or the length of their duration, by cutting parts of them, or in other ways; as by such means some of them, though annual in their nature, may be made to last and afford crops for two or for several years. Others may furnish two or three green crops the same season, and an early one in the succeeding; and so on in a variety of instances in the garden as well as in the field.

VEGETABLES, Injuries or Destruction of Parts of, the affections and mischiefs which are produced in them by different causes, as those of frost, lightning, insects, and some others. It is well known, that trees of the apple and some other kinds, in field fruit-grounds, orchards, and gardens, have their buds, blossoms, and other parts, often affected or destroyed by a sort of blight or canker induced by such causes; in consequence of which there are great failures in the crops of them. The mischievous effects of frost in this way may frequently be clearly traced, though they are seldom greatly injurious, when it is of the dry kind, unless it be very severe; but most certainly so, when it succeeds to large falls of rain. Sudden transitions from heat to cold are hurtful to vegetables: by warmth the vessels of them are expanded, and their juices flow freely: a sudden application of cold causes a sudden contraction of their parts, without a proportionate diminution of the fluids which they contain, which being thus unnaturally checked in their current, become stagnant and diseased. Rain is congenial to the growth of vegetables; and while Nature disposes them to open all their pores, by which its influence can be received, when overtaken by frost in such a situation, the consequence must be injurious or fatal. It has been said by a philosophical writer, in speaking of the action of cold or frost, that besides its opposition to the adequate fluidity of the vegetable juices, it must be unfriendly to the animation of the solids, causing either local canker, or death of the whole vegetable. That when the vegetable fluids are chilled, and converted into ice, their bulk is vastly enlarged, and this enlargement sometimes takes place with such extreme violence as to rend them in pieces. In this way, frost, it is thought, destroys those parts of vegetables which are most succulent, particularly in that form of it which is called hoar-frost, or rime, so common in the spring season. The moisture of fog too is said to be equally mischievous, as far as it extends. Thus, in a fruit district, in one night at this season, a most promising

8
ing

ing blossom has been cut off; the elm, oak, and ash, being injured at the same time: the line of devastation was precisely marked, proceeding in a horizontal manner through a certain vale tract, to the height of about thirty-five feet; the trees that grew on higher ground not being touched. The explanation of this circumstance seems, it is said, to be, that the fog, which rises more or less every evening, especially after a warm day, was, during the night, in this instance, suddenly succeeded by a smart frost, which seized the moistened parts to the point of elevation of the fog, and produced the mischief. Cold winds coming on after a day or two of sun-shine, may likewise prove destructive of the blossom in such cases of apple-trees in these fruit-grounds. On this account, in a northern exposure, the fruit is not unfrequently preserved, while in others it is destroyed; for the sun, not having much influenced the trees in this situation, they are left to the prevailing temperature of the season, and thus enabled to bear the cold north-easterly blasts of the night without being hurt.

Though the second of the above causes is much believed to be hurtful to the trees in fruit-grounds by those engaged in them, the opinion has been considered as unfounded by some. If, however, the partial manner in which some trees and hedges are affected be considered, it will be difficult, it is thought, to account for the effect in any other way. This cause, like that of frost, may affect vegetables by its expansive power, bursting their vessels as it passes through them. In some cases, a single limb of a tree, in one night, loses all its foliage, and ceases to vegetate: in others, one tree of many in a fruit-ground; or a row of trees in the same direction; and sometimes whole fruit-grounds are affected in the same manner, and are difficult of recovery. The mischief is mostly done in a night, and with great uncertainty, as neighbouring trees in the very same directions often escape.

In respect to the last of these causes, it has been observed, that frosty nights, with a north-east wind, in the spring, succeeding a warm day, are particularly injurious to the blossom of the apple; the warmth of the day hatches the ova or eggs of the insect which breeds in it, while the coldness of the night, by checking the progress of the sap, keeps the blossom in its half-expanded state, to form a nidus for them. The opinion of apple-growers, too, is in support of this in most districts and situations. But whether insects are caused in this way, or by the diseased state of the trees, the most promising mode of preventing the ravages and destruction which they commit on the leaves, buds, and blossoms of such trees, is that of smoking them well by means of some proper substance, to which a little sulphur has been added. In this way they may mostly be got the better of without much trouble.

The other causes of mischief have been noticed under their proper heads.

Many other sorts of vegetables of the tree and other kinds are likewise liable to be affected, injured, or destroyed in their parts by these causes, the prevention of which may be attempted by similar means. See *Diseases of Plants* in Smith's Introduction to Botany.

VEGETABLE Acid. See ACID, and VINEGAR.

VEGETABLE Ashes, in *Agriculture*, the substances of this sort which are produced from vegetables of different kinds by incineration. They differ much in their nature and quantities as afforded by different vegetables. In general, those of the herb sort furnish four or five times, and those of the shrub kind two or three times as much ashes as those of trees. The leaves in common produce more than the branches, and the branches more than the trunks. Those

burnt in a green state afford more ashes than such as are consumed in a dry condition. The quantities of ashes that are afforded by some common vegetables are, in 10,000 parts of the thistle, 53 of ashes; in the same number of fern, 62; in that of the sow-thistle, 196; in wormwood, 730; in vetches, 275; in beans, 200; and in fumitory, 790: while in the same number of parts of the poplar-tree, 7 of ashes are only afforded; in the beech, 12; in the oak, 15; in the elm, 39; and in the vine, 55. Such vegetable ashes as contain alkalies, are capable of being applied to land with advantage in some cases. The oxyds of metals are sometimes found in the ashes of vegetables, but only in very minute quantities. In cases where the vegetable ashes are of a reddish-brown appearance, they are mostly impregnated with the oxyds of iron; but where they have a black or purple cast, with that of the oxyd of manganese; and where these different colours are blended, they contain both such substances of the oxyd kind.

The different saline compounds contained in vegetables, or afforded by the incineration of them, are extremely various, and have been considered under their several proper heads. See *SULPHATE of Potassa*, &c. *PHOSPHATE of Lime*, &c.

The quantities of soluble saline matters, metallic oxyds, and other substances which are afforded by the ashes of different vegetables, may be seen in a table inserted in the "Elements of Agricultural Chemistry."

These points may serve to direct and assist the farmer in the preparation and application of vegetable ashes in the most economical and beneficial manner, where they can be had recourse to with propriety as a dressing on land or over crops of some kinds. See *ASHES and WOOD-Ashes*.

VEGETABLE Earth, or Mould, that sort of fine reduced earthy material, which is formed and produced by the destruction and decay of different vegetable productions and matters, either upon the surface, or in the more interior parts of the land. The term is, however, more generally applied to the peculiar earthy substance, or body, which constitutes the superficial layer of fine black or dark coloured mould, in which plants, for the most part, strike or take root, and grow in every sort of ground or soil, and which varies very greatly in different situations and circumstances, in consequence of the variations that happen in respect to its depth, and the progress it has made towards the state of perfect decomposition and destruction, as well as from the nature of the vegetable substances and matters of which it is constituted and composed. It has been suggested too, as acquiring some diversity or difference of quality on account of its being more intimately or more loosely mixed and incorporated with the other bodies and materials that are found to constitute land: and, likewise, that the earthy matter which is formed from the destruction of some particular sorts of vegetable materials, may be better suited for the purposes of vegetation than that which proceeds from others. It is an earthy material, which, besides being produced both by the dissolution and reduction of vegetable matters, as above, may probably be partly too acquired from the air, water, and light; by the process of vegetation, and partly from the properties of the lands in or on which it exists. In some cases it is of very considerable depth, while in others it forms merely a thin superficial coat or covering of the land; and there are still other cases, in which it is scarcely visible, or met with at all.

It may be noticed, that vegetables, in consequence of their having in their composition a large proportion of mucilaginous matter in a state of mixture with their other materials or substances, especially in some sorts, are in some degree

VEGETABLES.

gree capable of being dissolved in water, though the external coats or coverings of living plants, principally on account of the resinous material that enters into their composition, are preserved from its action and effects. It is plain, that in consequence of the first of these circumstances, and that of earthy matters being contained in them, which had been taken up in the state of solution or diffusion with their fresh fluids or juices while growing, that considerable quantities of vegetable earth or mould must be continually formed and deposited on lands by the natural dissolution and decay of such bodies. But its formation and provision are much more abundantly effected by means of the putrefaction and destruction of such vegetable productions as are cut down, or otherwise destroyed, on the surface of the land, and the laying of different kinds of manures and compost materials upon it. In cases where these have been in great abundance for a long time, there is mostly, it is said, a deep rich surface bed of this earth or mould; but that where few vegetable products, and those of the less luxuriant kind, have been left to undergo the above processes, or little assistance given by means of manures, the crust of surface earth or mould is commonly very thin and poor. In all cases, it is evident that the dissolution and decay of vegetable materials must be greatly promoted and expedited by a proper degree of moisture, and suitable state of heat; the atmosphere being at the same time in a proper condition for the purpose. The close and stagnated state of different sorts of luxuriant tall growing crops of the grass, herb, plant, or other kinds, have likewise much effect in the forming and elaborating of this mouldy material, by the decaying foliage thereby promoted, falling down and being so much deposited on the land.

All these materials, during the state of decay, undergo different changes in their constituent principles or parts; the water which they contain being decomposed, pure air or oxygen is absorbed, heat disengaged, and new compositions of the aerial and saline kinds formed; by which means a number of matters are prepared and fitted for the use and support of vegetable life, which could not have been supplied in any other way, as well as rendered much more extensively applicable in this intention than they could otherwise possibly have been.

It is advised, that in order to promote the formation and production of vegetable earth or mould, recourse should be had not only to such substances as accelerate the putrefactive process, but also to such as have a tendency to increase the solubility of the vegetable earth or mould of the land itself: and that the first of these purposes may be promoted and attained by the application of such substances and materials as have been found useful in changing vegetable matters into the state of mudilage, such as the carbonate of lime, or effete lime, marle, chalk, and calcareous matters in general, and likewise some earthy saline substances, as the refuse of salt manufactories, and others of that kind. That the latter of such intentions is to be attempted by the use of different substances and matters that are of an alkaline nature; such as the ashes produced by the burning of various green vegetable materials, the urine of animals, the liquor of dung-hills and pits, night-soil, and many other such animalized matters and substances. There are many other ways, too, in which vegetable earth or mould may be made and rendered more abundant in land; such as the frequent growth of those kinds of crops that cover the ground in a close full manner, so as to produce a confined state of the air, as already suggested; the consuming upon, or turning down into the ground, full, rich, and succulent green crops, by which much vegetable matter is brought into a state of decay; and

by the causing of the destruction and evacuation of insects of various sorts, which are predominant in land, by the use and application of such substances and matters as have the power of effecting these different purposes and intentions.

It must be noticed, however, that it has been remarked by the writer of the work on the "Connection of Agriculture with Chemistry," that too large a proportion of vegetable matter in land, particularly where it is exposed to be much acted upon by the oxygen principle of the atmosphere, is liable to render the ground too loose and open in its nature for the growth of most sorts of crops of the grain kind; winter corns being, especially from the sudden alternations of frost and thaw, frequently thrown out of such lands, and almost wholly destroyed. In cases of this nature, great advantage may, it is said, be derived from the use of different matters of the saline kind, and lime in its saturated state, as by such means the vegetable parts of the land will be brought to their most proper and productive state, in so far as the growth of crops is concerned.

It has been conceived too by the same writer, that the absorption of the oxygen principle from the surrounding atmosphere, or what is termed the process of oxygenation, is the principal cause of the retention of vegetable matter on the surface of the earth, in deep peaty lands as well as others, but especially in such as have been long in a state of tillage, or under the plough. This process having the power, it is supposed, of rendering the vegetable matter less destructible, scarcely any of it being carried away in a state of dissolution by rains, or water in other ways, an accumulation takes place, which, under other circumstances, could not have happened. The indestructible state of vegetable matters under these circumstances, and their constant accretion, may, it is thought, be referred to the insoluble compounds produced by the action of pure air on such inflammable substances. The insolubility, to a certain degree, of this system adopted by nature, is undoubtedly, it is supposed, to be preferred to one more completely soluble; for it is evident, it is said, that if putrefaction or oxygenation had possessed the power of rendering all the vegetable matter, by a speedy process, soluble in water, two pernicious consequences must have followed: the rains would have washed down such extracts, and soluble matters, as fast as formed, into the rivers and springs, contaminating the waters, and rendering them unfit for the existence of fishes, or for the use of terrestrial animals. The sea in process of time would thereby receive all the vegetable and animal produce of the dry land, and the earth would ultimately become barren, consisting alone of the simple earths, without any admixture of vegetable matter; consequently there could be no accumulation of this substance on the surface, as is the case to an immense degree at present. As such, there cannot, it is conceived, be a doubt, but that the present incomplete process of putrefaction, oxygenation, or solution of organic bodies, has been established by the great Creator of all things for wise and benevolent purposes; especially when it shall be understood, that the apparent imperfections of this, to a certain degree, insoluble system, are, as they respect agriculture and vegetation, to be remedied, when necessary, by the ingenuity and industry of man. It is consequently supposed that the vegetable matters which exist in lands, from their admitting different degrees of this process, and, of course, becoming more or less insoluble, have different powers in forwarding the growth and support of plants. Where the exposure to these causes has been long, they are generally more insoluble in their nature than where the contrary has been the case. See OXYGENATION.

Upon the whole, vegetable earth or mould should be accumulated

mulated in grafs lands as much as poffible ; but where grain-crops are to be raifed, a proper mixture of other earths is neceffary, to give them ftability, and prevent their being thrown out of the ground.

VEGETABLE Fly, in *Natural Hiftory*, an infect found in the ifland of Dominica, and (excepting that it has no wings) re-fembling the drone in fize and colour. In the month of May this infect buries itfelf in the earth, and begins to vegetate. By the latter end of July the tree is arrived at its full growth, and refembles a coral branch ; being about three inches high, and bearing feveral little pods, which dropping off become worms, and afterwards flies, like the Englifh caterpillar. Dr. Hill, in his account of this production, to whole examination it was fubmitted, obferves, that the *cicada* is common in Martinique, and in its nymphs ftate, in which the old authors called it *tettigometra* ; it buries itfelf under dead leaves to wait its change ; but when the feafon is unfavourable, many perifh : and that the feeds of the *clavaria fobolifera*, which is a fungus producing foboles or shoots from its fides, and growing in putrid animal bodies, find a proper bed on this dead infect, and grow. This, he fays, is the fact ; though the untaught inhabitants fuppofe a fly to vegetate, although there exifts a Spanifh drawing of the plant's growing into a trifoliate tree ; and it has been figured with the creature flying with this tree upon its back. Phil. Tranf. vol. liii. p. 270, &c.

VEGETABLE Oil. See OIL.

VEGETATION, in *Vegetable Phyfiology*. See GERMINATION, CIRCULATION of Sap, SPIRAL Veffels, LEAF, &c.

VEGETATION, as it relates to *Agriculture and Gardening*, is of confiderable importance, by explaining the nature and means by which plants and crops receive nourifhment and fupport, and are the beft promoted in their different growths. In refpect to grain, feeds, and fets, it feems evident, from the experimental enquiries of Mr. Gough and others, that during the act or procefs of their germination or infant vegetation, they draw the oxygene principle from the furrrounding atmo-fphere, part of which is retained, and the remainder thrown off, charged with a portion of carbon ; and that, in this procefs or operation, the fubftances of the feed-lobes, or other parts that anfwer the fame purpofe, of courfe undergo a confiderable change, an additional proportion of the fame principle entering into their compofition, while a portion of their carbon is difipated and deftroyed : that by this alteration in the proportion of their conftituent principles and parts, the faccharine fermentation is induced to take place, and fugar is formed, as demonftrated in the operation of malting grain : and that the fugar and carbonic acid, from their being more foluble in water than in the oxyd of farinaceous matter, eafily combine with the moifture in the capillary veffels of the feed or other fubftances, and find a ready paffage to the germ ; the vegetative principle being thus brought into action by a ftimulus fited to the particular nature of it : and that by the decomposition of the feed-lobes, or other parts, a nutritious fluid being thus formed and diftributed through the infant plant, its organs are excited to exert their peculiar fpecific actions in decomposing the nourifhment conveyed to them, and in forming new oxyds from the elementary principles of it, in order to the increafe and evolution of the veffels and fibres.

As it is in this manner that the firft ftage of germination or vegetation is fuppofed to commence, it would appear that in fuch feeds and fets, in order to their undergoing thefe different changes the moft readily, and in the moft perfect manner, on which, probably, healthy growth may materially depend, they fhould not only be properly deposite

in the earth or foil, but, in the cafe of grain and feeds, be fo well ripened and filled with farinaceous or mealy matter, and poffefs fuch a degree of moifture, as may difpofe them to undergo fuch changes in a fuitably fpeedy manner ; while, at the fame time, a due fupply of proper nutritious matter is afforded for the perfect germination and early growth of the infant vegetables or plants. They fhould not confequently be put fo deep in the ground as to be too much excluded from the action of the air, or be fown or fet when in too dry a condition from the ftate of the feafon or other caufes, but be constantly fuffered to have as much of the agency and influence of fuch forwarding powers as may be neceffary for the perfect vegetation and growth of the plants or crops.

Others conclude on the grounds, and for the reafons that are ftated below, that two of the airs of which the atmo-fphere is compounded, are abfolutely neceffary to the nourifhment and proper growth of vegetables ; thofe of vital air or oxygen, and mephitic air or azote. It is found from different trials, that plants placed in vital or oxygene air grow larger, become more powerful, and are greener than thofe put in that of the atmofpheric kind. That if the feeds of the kidney-bean and the pea be put into earth of the filiceous kind, and be fprinkled with water mixed with a fmall portion of the oxygenated muriatic acid, in which oxygen the moft abounds and the moft loofely adheres, they germinate much fooner than if fprinkled with pure water : but that if feeds be immerfed in diluted muriatic acid, they become black and rugous, and never germinate. That in no kind of air deprived of oxygen do plants vegetate ; for if they be placed in azotic or mephitic air, in carbonic or fixed air, they become flaccid and drooping, it is faid, by the heat of the fun, and gradually die away. And that in nitrous air, plants become inactive in a few hours. It would appear from this, it is thought, that the portion of vital or oxygene air imparts a natural ftimulus, which is highly neceffary to excite the fibres and fustain the living power and ftrength of the veffels of plants ; and that, laftly, this air, with the peculiar acidifiable bafes, generates the various acids which are found in plants or vegetables.

As the gluten of the fibres of vegetables confifts of carbon, chemically combined with azote, it follows, it is fuppofed, that the azotic air is abforbed or taken up by the plants ; and that it is by this means that vegetables increafe fo rapidly in rich foils, cemeteries, and other places where animal and vegetable matters putrefy and decay in large quantities in or on the ground.

Carbonic air too difolved in water is abfolutely neceffary to the vegetation of plants in order to provide their carbonic principle, which is a conftituent part of the fibres, oil, mucilage, and other vegetable principles.

It is fuggelted, that plants appear to derive their caloric or matter of heat from the furrrounding atmofpheric air. Hence it is that the fhades of trees are fo cool ; and that nothing is more healthy for almoft all plants in their vegetation and growth, than mild tepid fhowers, by which they obtain water together with this principle. That, laftly, feeds do not vegetate in the cold, and many plants die in it. Heat too is evidently of much benefit in vegetation, as giving the natural colour to the foliage, flowers, and fruits of plants, caufing or promoting the flow and circulation of the fap-juice, increafing the faccharine matter, and promoting the flavour of moft forts of fruit.

Light too contributes to the life and healthy growth of plants ; for thofe which vegetate in atmofpheric air deprived of its light, as in the night and dark places, become pale and weak ; but in the day-time, ftrong and coloured.

VEGETATION.

The rays of light, likewise, appear to contribute to stimulate plants, with the various gases or vapours they absorb and take up from the air.

Pure air has also been found by many to be essential to the production of perfect feeds, pulse, grain, and fruit, and that by its action upon or being taken up by the soil, it has very powerful and beneficial effects in promoting vegetation and the perfect growth of plants and crops.

Thus water, air, and these other matters, appear to have a very great share in the vegetation and nourishment of vegetables, but especially the two former. The first has been considered as indispensably necessary to the process, and as supplying the principal materials of vegetable juices. It is unquestionably the chief medium through which the various nutritious matter derived from the soil, is conveyed to the plants which grow upon it. But it has been supposed more favourable to the vegetation and growth of grass plants or crops than those of the grain kind; as crops of grasses may be continually produced by watering, while with those of grain it has been found to be wholly impossible. It is found, however, that soft water, such as that of rivers, rain, or which has been exposed to the action of the sun for some time, is more favourable to vegetation, than such as is hard, as that of springs, or which is impregnated with metallic substances and other such matters. The author of *Phytologia* considers the first three things necessary to the infant vegetation and growth of plants to be heat, water, and air, as furnishing the general cause of fluidity, the menstruum in which nutriment is conveyed, and the principle of excitability so perpetually necessary to all organic life.

However, besides these different matters, other agents are necessary, after the plants have been formed and evolved, to the perfect vegetation and growth of the crops, as those of earth or other such matters, which are not only useful and essential for the purpose of holding and supporting the plants in a steady and erect manner, but also for containing and conveying, at least, some portion of the food on which they live, as derived from the atmosphere or other sources, and for the regular ramification and extension of their fibrous roots, in order that it may be more certainly provided and supplied. They are beneficial too in receiving, retaining, and distributing moisture to them, as well as in receiving, reflecting, and dispersing the heat of the sun, dews, and exhalations of different kinds, by which their growth and perfection are greatly promoted. For though some plants of the aquatic kind grow in water, most of them have their roots in earth. Even marine plants, although they grow upon bare rocks or stones, are well known to be fixed to them, and that they derive their food from the seawater in or near which they exist. It has been contended by some, that plants are actually nourished by earth alone, but numerous experiments shew the opinion to be erroneous, and that it is perhaps only the medium of their existence. It is well ascertained that they are capable of acquiring a great accession of weight, without almost any loss of weight of the earth in which they have been planted.

The aid and assistance of dead organized materials are, likewise, requisite in the process of vegetation and the growth of crops, as it would seem to be a part of the beautiful and orderly arrangement of Nature, that nothing should have life in vain, and that the destruction of one plant or animal should furnish food for others: consequently, that however useful air, water, light, heat, and earth may be to the growth of plants and crops, it is, if not certain, at least questionable, it is thought, whether they could ever come to perfection without the help of matter that had been for-

merly in an organized state. The richest soils, it is well known, are full of dead animal and vegetable matter, and there is no soil that will not produce plants or crops if a sufficient quantity of dead animal or vegetable substance be added to it. Under this denomination are comprehended all those manures which are found so useful in cultivation, more especially those to which some authors give the name of *muclaginous*, *enriching*, or *nutritious*. These substances and materials are greatly beneficial, by correcting the tenacity of stiff soils or lands, and the over-porosity of light ones, by producing a fermentation in them, and by affording nutritive matter to the roots of vegetables, as well as by retaining moisture in dry and expelling it in wet lands. Saline substances have been supposed too of much importance in vegetation by some, but they do not appear essential to the growth of any sort of plants except the marine; and there are many productive soils in which little or no saline matter can be discovered. Such matters may, however, be of use to vegetation, though not essential to it. That of common salt may operate upon plants as it does upon the human body, by assisting to digest the food, without furnishing nutriment itself. It is of use, mixed with dung, as an assistant to putrefaction, and it may act in the same way in promoting vegetation. It is serviceable too by attracting moisture, destroying vermin in the soil, and decaying and reducing the roots of any plants it may first meet with, thus furnishing nourishment to the succeeding ones.

It is found likewise, that the culture of the earth is essentially necessary for the vegetation and growth of plants and crops to perfection, the health and vigour of both the roots and branches being thereby greatly increased. By dividing and reducing the particles of soils, the roots of the plants and crops put into them can more easily and readily penetrate and spread out in them, as well as suck in more expeditiously the nourishment which they contain. By proper and effectual culture too, such weeds or useless plants as are apt to rise, are extirpated and destroyed, whilst stirring the earth admits air and moisture more fully to the soils, and to those plants and crops the feeds or sets of which have been sown or put in them. It is evident likewise, that young trees thrive and succeed much better, if the soils in which they are planted have been previously ploughed in so deep a manner, as readily to admit their roots and suckers. Even after they are planted, it is supposed to be of great service to have potatoes and other such roots cultivated among the young trees in the plantations with a view to kill weeds, and loosen the soil for the free admission of air and water. And the practice seems to be generally well received, and to have much effect in promoting vegetation in most sorts of vegetable.

The management of the farmer and gardener should, of course, aid and assist these views and intentions in every way as much as possible, in raising and producing plants and crops of different kinds; as by the suitable cultivation of the ground, the proper application of manure or other substances of that sort to it, the preservation of the moisture of it by different modes of cropping, and by every other practicable method in their power; as by such means the perfect vegetation and growth of them may be the best promoted and assisted. See *FALLOWING Land*, *PULVERIZATION*, *SEED*, &c.

It may be observed, that the substances or matters in land which have hitherto been found injurious to vegetation, are chiefly those of the metallic, sulphureous, aluminous, and astringent kinds. It has been noticed, that where mines of iron, lead, or copper, are near the surface, no plants will grow to perfection, as is well ascertained to be the case in different

different mining districts. Schistus too, in which there is generally a great deal of iron and alum, is found so unfavourable to vegetation, that any considerable quantity of it would destroy the fertility of the richest sorts of land. The noxious, corroding, and weakening effects of such substances on the tender roots of vegetables being such in some cases as to cause their decay, dissolution, and destruction. Frequent stirring, or the exposure of new surfaces of land to the action of the air, and the use of lime, chalk, or other dissolving matters, will, it is supposed, correct the injurious qualities of this substance, and promote the vegetation and growth of plants and crops in such states of land. The astringent principle or acidity in peat is often so great and so noxious to vegetation, that until any quality of that nature which may exist be subdued, though that sort of land be a perfect mass of vegetable matter, nothing but heath and other such miserable plants are capable of growing in it. Vegetation is consequently in such cases only to be assisted by breaking the parts of the land well down, and the application of earthy and other matters to it, so as to wholly destroy its astringent property, and in fact change its nature. See SOIL.

It may be noticed too, that the vegetation or growth of plants and crops is frequently much injured and impeded by the various sorts of vermin with which the earth as well as the air abounds. Those which inhabit the earth, it has been supposed, may be destroyed and got quit of by the use of saline matters, lime, and other different substances, operations, and arts, as are seen under their several proper heads. See GRUB, MOLE, SLUG, WORM, VERMIN, &c. also TURNIP.

But in regard to the myriads of those of the insect kind with which the air abounds, it is more difficult and uncertain to propose or point out any remedy or means of prevention that may be effectual. It is not ascertained that the smell of any plant, in its natural growing state, is destructive of insects; but there are several plants which are, when dried and reduced to powder, or when burnt near to certain insects, destructive of them, as those of tobacco, hemlock, henbane, rue, wormwood, and others. Sometimes, however, vermin of this sort are occasioned by the weakness and unhealthy growth of the plants, and the poverty of the soil of the land where they grow; the best remedies in such cases are, of course, those of more perfect tillage and cultivation, so as to render them strong and healthy in their vegetation.

VEGETATION, Artificial. Many of the processes and operations in chemistry afford productions, whether of salts or metals, or of whatever other substances, which very much resemble plants of one kind or other, whence they have been called *metallic* vegetation. But though many have been hence induced to believe, that these productions were formed in the manner of vegetables, there is not the least ground for such an opinion from reason or experiment.

M. Homberg, who has treated very accurately of the several kinds of these chemical vegetations, divides them into three different classes.

Those of the first class are such as consist of a pure massy metal, without the mixture of any foreign matter whatever. Those of the second class are composed of a dissolved metal, which, though it has concreted afterwards, yet retains a part of the menstruum in it; and the third class contains those which have no metal in them, but are merely composed of salts, oils, or earths, or of combinations of these.

All the productions of the first kind are made without the admixture of any liquor, and are merely owing to the

force of fire. These are of a firm and solid texture, and may be taken out of the vessels in which they were made, without danger of breaking them. On the other hand, the vegetations of the second kind are all formed in a fluid, and are all so brittle, that they are not to be touched without breaking. Of the third kind, some are formed, or will subsist at least, in the dry air; others are very tender, and are formed only in fluids, the very stirring about of which destroys them. See ARBOR.

VEGETATION of Salts, a name given by M. Petit of the Academy of Paris, to the concretions which salts form, after solution in water, when set in the air to evaporate.

These concretions always appear round the surface of the liquor, affixed to the sides of the vessel, or arising above its top, and are very different in the different salts, and in most of them very beautiful.

One of the most ready and most beautiful of all the saline vegetations, is that formed by a solution of the salts in the caput mortuum of aquafortis with common water. If a pint of water be put to half a pound of this caput mortuum, and the whole boiled together, that the salts may be dissolved, and the liquor afterwards filtrated, and exposed in an earthen vessel, there will be formed, in about eight and forty hours, vegetations wholly like those from the mixture of spirit of nitre and oil of tar, except that those from the caput mortuum are more ramified and more beautiful. When the solution is exposed in a glass vessel, they form themselves on the surface into very beautiful figures of trees, shrubs, and bushes; and this not only on the surface, but on both the inside and outside of the glass. These can be compared to no known concretion, except to the vegetations of iron, described by M. Lemery; they differ indeed in nothing from these, but that the vegetations of the metal are of a brownish colour, whereas those of the salt are white.

This impregnation succeeds best in dry weather, for in a moist season the vegetations form themselves more slowly, and are much less beautiful. Glass vessels are also essential to the vegetations being formed in their greatest beauty; they are never nearly so beautiful in earthen ones; and even in the former, the vegetations succeed much better in some sort of glass than in others. The caput mortuum of aquafortis also is very different, from the different distillations; and all of it does not succeed alike in this vegetation of the salt. That which looks lightest, and of the reddest colour, seems the best for this purpose. An impregnation of this caput mortuum in red-wine produces no vegetations, but only forms a crust with small eminences on the sides of the vessel; and saltpetre, dissolved in the impregnation of this caput mortuum in water, produces a much more beautiful vegetation than that of saltpetre alone; but at the same time much less beautiful than that of the impregnation alone. Salt-water, dissolved in the same impregnation, sometimes will produce beautiful vegetations, but sometimes only a rough crust. Common rough saltpetre forms no vegetations, but only crusts over the vessel; as is the case with the solutions of many of the metals in different acid menstrua. And the same is the case in regard to many salts from which it might be natural to expect concretions of this kind. *Memoirs Acad. Par. 1722.*

VEGETIUS, FLAVIUS RENATUS, in *Biography*, lived in the reign of the emperor Valentinian, to whom he dedicated his treatise "De Re Militari." Although he was probably a military man, his Latin style was pure, considering the age in which he lived. The best editions of his work are the Variorum, Leyd. 1644, and Vesal. 1670. Turpin's Commentary was printed in French, Paris 1783, in 2 vols. 4to.

A work on the veterinary art, by a writer of the same name, is printed with the "Scriptores Rei Rusticæ." Moreri. Gen. Biog.

VEGETO-ANIMAL MATTER, in *Agriculture*, a term formerly applied to one of the principal constituent parts of the farina, meal, or flour of some vegetable seeds. It is found in the greatest proportion in grain, especially that of the wheat kind, existing in a state of mechanical union or mixture with mucilage or starch. On cautiously washing wheaten flour in the form of paste, in a kneading manner, under a small stream of water, until the whole of the starchy matter be removed, this substance or material is found in an elastic, ductile, tenacious state, but incapable of being dissolved in it. It has none or scarcely any taste, readily draws out and contracts, and is of a whitish-grey colour. When fully drawn out, it extends to the length of about twenty times its diameter before it breaks, and appears as if composed of fibres placed beside each other, according to the direction in which it has been drawn. If the force ceases, it recovers its original form by its elasticity; when dry, it is semi-transparent, and somewhat resembles glue in its colour and appearance. If it be drawn out thin when first obtained, it may be dried by exposure to the air, and in that state has a polished surface, somewhat resembling that of animal membranes. If it be exposed to warmth and moisture while wet, it putrefies like an animal substance; it crackles, swells, and burns, exactly in the manner of a feather or piece of horn. By distillation it affords, like animal substances, alkaline water, concrete volatile alkali, and an empyreumatic oil. Its coal is very difficultly incinerated, and does not afford fixed alkali. From these facts, it is said to be obvious, that it is a substance totally different from all the others known to exist in vegetables, except albumen, which has lately been discovered in some of them, and in many of its characters resembles the fibrous part of the blood. It does not appear to exist in any considerable quantity in other farinaceous substances, such as rye, barley, buck-wheat, rice, and others of the same kind. M. Berthollet, however, thinks that it contains phosphoric salt like animal matters, and that this is the reason of the difficulty with which it is incinerated; and the younger Rouille found a glutinous substance in the fecula of plants analogous to that of wheat. It is now commonly called gluten, and said to become of a brown colour by exposure to the air, to be very slightly soluble in water, and to differ from albumen in being infinitely less soluble in that fluid. When burnt, it affords similar products to that substance, and probably differs very little from it in composition. It is found in a great number of plants. Proust is said to have discovered it in acorns, chestnuts, horse-chestnuts, apples, quinces, barley, rye, peas, and beans; and likewise in the leaves of rue, cabbages, cresses, hemlock, borage, saffron, in the berries of the elder, and in the grape. It appears, it is said, to be one of the most nutritive of the vegetable substances; and that wheat seems to owe its superiority to other grain, from the circumstance of its containing it in larger quantities.

In the work on the "Connection of Agriculture with Chemistry," it is said that different kinds of grain contain mucilage or starch, and this substance in different proportions, and that the same sort of grain contains them in different quantities, according to the climate, season, and soil. But that good wheat generally contains two-fifths of animalized matter, and three-fifths of starch. And that good and well-raised bread depends on flour containing a due admixture of these two substances. Hence, it is thought, by mixing the flour of different sorts of wheat, better bread

may at times be produced than from one sort only. Extensive benefits, too, may arise to the processes of brewing, distilling, and making of vinegar, by a mixture of the different sorts of grain; and to that of distilling, a further advantage would be derived by a mixture of different roots with the grain, such as potatoes, parsnips, carrots, and many others, if prepared in a proper manner.

VEGETO-MINERAL WATER of Goulard, in *Medicine*. See *Water of LEAD*.

VEGGIANI, in *Geography*, a town of the island of Corfica; 12 miles W. of Bonifacio.

VEGI, or **UGI**, the names given by the Arabian physicians to the acorus. These writers seem not to have been acquainted with the plant itself in its growing state, but only to have known that part of it which was used in medicine in their time; but the Greeks described the plant in some sort.

VEGIA, in *Geography*, a town of Africa; 45 miles W. of Tunis.

VEGIANO, a town of Naples, in Basilicata; 12 miles S. of Potenza.

VEGIO, **MAFFEO**, in *Biography*, was born at Lodi in 1406, and studied at Milan and Pavia, manifesting in the former place an attachment to poetry, and in the latter directing his attention to civil jurisprudence. He obtained some honorary and lucrative appointments under the popes Martin V., Eugenius IV. and Nicholas V. Highly respected and esteemed for his genius and learning, as well as for the sanctity of his life, he died in 1458. As a Latin poet, he composed with facility, but without being distinguished for elegance or purity. He began, in his early age, with profane poetry, composing, among other works, an additional book to Virgil's *Æneid*; but after he entered into the priesthood, he confined himself to sacred subjects. The best of his works in this class, highly commended by Dupin, was his treatise "De Educatione Liberorum et eorum claris moribus." His prose style is accounted elegant and polished for his time. Moreri. Gen. Biog.

VEGLENSKOI, in *Geography*, a town of Russia, in the province of Ustiug, on the Vim; 72 miles N.N.E. of Yarensk.

VEGLIA, an island in the gulf of Venice, near the coast of Dalmatia, about 30 miles in length, from 6 to 14 broad, and 90 in circumference, anciently called *Curiæa* and *Fulfinio*. In the decline of the Greek empire, it obtained the name of *Becla*, of which the present is a corruption. It is situated in the innermost part of the gulf of Quarnera, and separated from the continent by a small canal only. There are many harbours, but unfit for the reception of large vessels, on account of the storms by which they are agitated. Its soil is mountainous and rocky, towards the north sterile, but very fertile to the south, and the vallies are extremely fruitful. The greater part is covered with woods, which occasion a considerable trade in fire-wood. Agriculture is not so much attended to here as the culture of the vine, which produces excellent wine. The culture of silk is insignificant: the breeding of horses is more important. The breeding of sheep and goats is likewise considerable. The quarries produce a red spotted marble, not unlike that of Verona, which is much known by the name of *Mandolato of Venice*. This isle is inhabited by 17,000 souls. N. lat. 45° 16'. E. long. 14° 42'.

VEGLIA, a sea-port town, situated on the S.W. coast of the island so called, surrounded with walls and defended by a castle, in which the governor resides. It is the see of a bishop, suffragan of Zara, and contains about 3600 inhabitants. N. lat. 45° 11'. E. long. 14° 38'.—Also, a town of Naples, in the province of Otranto; 15 miles S. of Brindisi.

VEGLIANA, a town of France, in the department of the Po, near the Little Doria, where the French obtained a victory over the Piedmontese and Spaniards, in the year 1630; 11 miles N. of Turin.

VEGLIONELLA, a town of Naples, in Basilicata; 20 miles S.S.W. of Turfi.

VEGRE, a river of France, which runs into the Eure, near Yvry.

VEHAILEK, a town of Arabia, in the province of Nedsjed; 70 miles S.W. of Jamama.

VEHICLE, VEHICULUM, in its literal sense, signifies somewhat that carries, or bears a thing along. See CARRIAGE, WAGGON, WHEEL, &c.

Thus, in *Anatomy*, the serum is said to be the vehicle that conveys the globules of the blood.

In *Pharmacy*, any liquid serving to dilute another with, or to administer it in, more agreeable to a patient, is called a vehicle.

In *Painting*, vehicles denote certain fluids, which are added to colours, in order to give them an unctuous consistence while used, that they may be laid on and spread properly, adhere to the grounds on which they are laid, acquire a proper degree of tenacity when dry, and defend them from being injured by accidents. The principal vehicles hitherto used are oils, water, spirit of wine, and turpentine. But as water and spirit of wine want the unctuous consistence necessary for spreading the colours, and dry away totally without leaving any glutinous substance to bind and fix such of the pigments as are of an earthy or incohering texture; gums, size, sugar, and other such viscid substances have been superadded to supply their defects, and render them of a due consistence and body.

VEHNE, or VEENE, in *Geography*, a river which rises in the bishopric of Munster, and joins the Solte, near Stickhausen.

VEIA. See VEGLIA.

VEICAMA, a town of Spain, in the province of Guipuscoa; 12 miles from Tolosa.

VEIENTANA GEMMA, in *Natural History*, the name of a gem described by Pliny, and said to be found in Italy; he says it was black, but surrounded with a circle of white: it was probably a stone of the camea kind.

VEJER, in *Geography*, a town of Spain, in the province of Seville, near the Straits of Gibraltar; 9 miles S. of Medina Sidonia.

VEII, in *Ancient Geography*, a town of Italy, in Etruria, S. of the Falerii, but nearer the Tiber and Rome. This was a very ancient town, and very considerable on account of the wealth and the valour of its inhabitants. Its original name was Veja, which was also, among the Osci, the name of one of those carriages in which they resided before they had houses. Its vicinity to Rome was one principal cause of its misfortunes; for the jealousy and envy of that city were excited by its opulence and prosperity. From the time of Romulus, the inhabitants of these rival towns contended. At length Veii was taken by Camillus, after a siege of ten years, in the year of Rome 356 or 357. The booty was very considerable; and part of it was lodged in the temple of the Pythian Apollo. It is a sufficient evidence of the eligible situation of Veii, that after the capture of Rome by the Gauls, it was a subject of deliberation whether this town should not be made the capital of the republic.

VEIL, VELUM, a piece of stuff, serving to hide or prevent the sight of any thing.

In this sense, we read of a large veil, or curtain, in the temple of Jerusalem, miraculously rent at the passion of our

Saviour. In the Roman churches, in time of Lent, they have veils, or curtains, over the altar, crucifix, images of the faints, &c.

VEIL is also used for a large piece of crape, worn on the head by nuns, as the badge of their profession. Whence, to *take the veil*, signifies to commence religious.

The novices wear white veils; and those who have made the vows, black ones.

The prelate before whom the vows are made, blesses the veil, and gives it to the religious.

VEIL, in *Botany*, see CALYPTRA. These terms are now exclusively appropriated to the membranous covering of the germen in MUSCI and HEPATICÆ, through the summit of which impregnation takes place, and which therefore must be considered as a peculiar organ, partly perhaps, but not exactly, analogous to a corolla. It is elevated with the ripening capsule in *Musci*, but splits irregularly, to let the fruit pass, in *Hepaticæ*. The reader is requested to correct two important errors of the press in the 8th column of the article MUSCI: line 18th, for *sinks*, read *spring*; line 60th, for *sexual*, read *asexual*.

VEIL, CHARLES MARIE DE, in *Biography*, the son of a Jew at Metz, and a profelyte to the Roman Catholic religion by Bossuet, became a monk of the Augustine order, and entered among the canons-regular of St. Genevieve. Pursuing his theological studies at Angers, he took the degree of doctor in theology, and taught in the public schools. In 1679 he visited England, and abjuring Popery, conformed to the English church. He had previously distinguished himself by his scriptural researches, and published Latin commentaries on the gospels of St. Matthew and St. Mark, on Joel, and the Canticles. During his stay in England he addressed a letter to Mr. Boyle, the design of which was to prove, against Father Simon, that the Scripture is the only rule of faith. In London he reprinted his commentary on the Canticles, giving a literal explanation of that book; and he also published commentaries on the twelve minor prophets, and on the Acts of the Apostles. At this time he styled himself a presbyter of the English church, but in consequence of marrying the daughter of a Baptist, he became connected with persons of that persuasion, and preached among them in the year 1685. His death is supposed to have happened about the close of the century.

The brother of the preceding, LOUIS DE COMPEIGNE DE VEIL, was also a converted Jew, and distinguished for his knowledge of Hebrew literature. He was interpreter of Oriental languages to the king of France, when he accompanied his brother to England, and joined in communion with the English church. The principal works he published were "The Jewish Catechism of Abraham Jagel;" a Latin translation, with notes, of "Maimonides de Sacrificiis," and also of Abarbanel's "Exordium in Leviticum." Moreri. Gen. Biog.

VEILLANE, in *Geography*. See VEGLIANA.

VEILLY, or VESLEY, a town of France, in the department of the Aisne, on the Aisne; 9 miles E. of Soissons.

VEIN, in *Anatomy*, the name of those vessels which convey back to the heart the blood carried out from it by the arteries. All the details relating to the structure of these tubes, to their arrangement in the body, and to their office in the circulating system, are considered in the articles HEART and CIRCULATION.

The veins are naturally arranged in three divisions; viz. 1st, the general venous system, commencing from the capillaries all over the body, and pouring the black blood into the heart by three large trunks: 2dly, the pulmonary veins, which

VEIN.

which are concerned only in the minor circulation: and 3dly, the system of the vena portarum, in which the blood that has circulated through the organs of digestion is conveyed to the liver, and distributed through the substance of that organ. The umbilical venous system of the fœtus, with its ramifications in the placenta, its trunk in the umbilical chord, and its subsequent course and distribution in the liver, is not included under either of these divisions. It belongs to the fetal state of existence, and is described under EMBRYO.

On the subject of the pulmonary veins, we have nothing to add here to what is stated in the articles LUNG, CIRCULATION, and HEART: the vena portarum is described under LIVER; and the peculiarities of arrangement, belonging to the veins of any organs, are noticed in the account of those organs: so that the present article will include simply a description of the situation and course of the veins of the general system. These we shall trace, according to the course of the blood in them, from the branches to the trunks; as, on the same principle, the arteries have been traced from the trunks to the branches.

The veins of the general system may be arranged in three divisions, according to the great trunks which terminate in the right auricle; viz. the cardiac veins, those belonging to the superior, and those to the inferior vena cava.

I. The *veins of the heart* do not all end in one trunk: besides one large vein, there are some smaller. The great coronary vein of the heart (*grande veine cardiaque postérieure*) runs in the groove between the left auricle and ventricle; and opens on the left of, and below the fossa ovalis and valvula Eustachii, in the right auricle. A middle coronary vein runs on the inferior flat surface of the heart, between the two ventricles, to open by a common orifice with the former, or close to it. At this opening into the auricle, a valve is placed, differing considerably in size and appearance; sometimes semilunar and broad, covering the whole aperture, at other times smaller and hardly distinguishable; sometimes perforated or reticulated. See HEART.

Some smaller veins open by one or more trunks in the anterior part of the right auricle. See the plates of Senac, sur la Structure du Cœur, &c. on these veins.

II. The *superior vena cava* receives the veins of the head, neck, thorax, and upper extremities.

The superficial veins of the head and face end for the most part in two trunks, an anterior and a posterior.

The anterior facial vein (frontal or angular) commences on the forehead, runs along the inner angle of the eye, and then pursues its course obliquely along the face from the corner of the eye to the basis of the jawbone, which it passes at the same point with the external maxillary artery. It joins, behind the angle of the jaw, the trunk of the posterior vein. This anterior facial vein, which is a large and very constant trunk, receives a vast number of venous ramifications from all parts of the forehead and face, which are covered by one universal venous net-work or plexus. (See two excellent plates by Walter, *Observat. Anat.* 1775.) The following are enumerated as the vessels which open into it: 1, *venæ frontales*; 2, *v. supra orbitalis*; 3, 4, *v. dorsalis nasi*, superior and inferior; 5, *palpebralis inferior interna*; 6, 7, *alaris nasi*, superior and inferior; 8, *palpebralis inferior externa*; 9, 10, *labiales superiores*; 11, 12, two from the zygomatici and levator labii superioris; 13, *ramus profundus venæ facialis internæ*, formed by the junction of, a. *vena ophthalmica facialis*, which, communicating by its opposite end with the cavernous sinus, receives branches from some parts in the orbit; b. *nasalis posterior interna*; c. *alveolaris superior*; d. veins of the buccinator, &c.;

14, *labialis media*; 15, 16, *vena labii inferioris*, superior and inferior; 17, 18, *buccalis*, superior and inferior; 19, 20, two, three, or four *venæ massetericæ*; 21, *submentalis*; 22, *glandulosa*.

The posterior facial vein is much larger than the anterior; it arises on the side of the head by branches accompanying the ramifications of the temporal artery, descends in front of the ear, through the parotid gland, behind the angle of the jaw, and unites with the former. It receives several deep temporal veins; the maxillaris inferior; several pterygoid veins: these join its deep-seated trunk. The superficial trunk is joined by three superficial temporal branches; articularis anterior and posterior; auriculares anteriores and profunda; transversalis faciei; auricularis posterior; several parotid veins.

The common trunk, formed by the union of the anterior and posterior facial veins, behind the angle of the jaw, terminates in the internal jugular near the point, at which the common carotid divides into the external and internal branches. It also anastomoses with the external jugular: this trunk receives the superior thyroid vein.

Veins of the Brain.—They possess no valves: their coats are much thinner than those of other veins; their capacity very much exceeds that of the arteries. Their greatest and most distinguishing peculiarity consists in the circumstance, that they do not accompany the arteries, either in their great or smaller branches. Their trunks are collected in the pia mater, and run either in the interval of the convolutions, or over the convexities of the latter. They pour their blood into receptacles formed in the dura mater, and called sinuses; and in this respect again they differ from all other veins. The sinuses are composed, externally, of the dura mater, which holds the place of the external coat of other veins; internally, of a smooth thin membrane, corresponding to the internal membrane of the veins, and continuous with it. The cerebral veins open in large numbers into these sinuses, of various sizes, from that of a crow's-quill to a writing quill; and they enter, for the most part, very obliquely, and with an obliquity contrary to the direction of the blood in the sinus.

These receptacles, being formed in the dura mater, which is attached to the bone, are fixed in their situations. They are generally of a triangular figure: the interior is lined by a smooth membrane, but, in many instances, it presents small transverse fibrous bridges going from side to side. They receive not only all the cerebral veins, but also those of the dura mater and the ophthalmic.

There are four large sinuses, of which the others appear to be subordinate dependencies; they are the superior longitudinal, the two lateral, and the fourth sinus.

The superior longitudinal sinus (*falciformis superior*) begins near the crista galli, where it is small; it runs from before backwards to the internal occipital tuberosity, along the middle line of the cranium, occupying the superior or convex edge of the falx, and increasing to the size of the little finger. A vertical section of it, from side to side, is exactly triangular; the base of the triangle being upwards, and corresponding to the excavation in the bone, the sides of the triangle being lateral, or turned towards the hemispheres, inclined towards each other, and united below so as to form the apex, which is downwards. Several fibrous bridges cross its cavity, which contains a greater or smaller number of the granular bodies called *glandulæ Pacchioni*. Numerous small veins enter the sinus from the cranium, and others from the dura mater; through the parietal foramina it receives veins from the integuments: blood may be expressed from these, when they have been lacerated by detaching

taching the skull-cap. But the principal veins it receives come from the superior or convex surface of the hemispheres. These are spread irregularly over the convexities, advance from the sides towards the middle, uniting into larger and larger trunks, and open in considerable numbers on each side of the sinus: they receive the veins from the opposed flat surfaces of the hemispheres. The anterior branches are the smallest; the middle and posterior much larger. They are directed at their termination obliquely from behind forwards, and sometimes pass for half an inch, in the substance of the coats, before they open.

The two lateral sinuses, right and left (*sinus transversii*), are produced by the division of the superior longitudinal at the internal occipital protuberance. They are usually of equal size, but sometimes differ in this respect, the right being often larger. They proceed along the internal transverse ridge of the occiput, at the posterior attachment of the tentorium, as far as the commencement of the petrous portion of the temporal bone, when they descend along the internal surface of the mastoid portion of that bone to the foramen lacerum in basi cranii, through which they quit the skull, taking the name of the internal jugular veins. These sinuses are as large as the termination of the superior longitudinal; and are generally uniform on the internal surface. The cavity is triangular, where it occupies the posterior attachment of the tentorium: the base of the triangle being turned backwards, and corresponding to the skull, and the two sides being inclined towards each other, and joining at an acute angle in the tentorium. Where it lies in the mastoid portion, it consists of a layer of membrane lining the bony channel, and another passing directly over it.

The lateral sinus receives veins from the back of the cerebrum and cerebellum, and some meningeal veins; large branches from the integuments of the skull through the mastoid foramina, and from the muscles of the neck through the posterior condyloid holes; veins from the cavity of the tympanum, according to Soemmerring; the superior and inferior petrous sinuses; and the occipital sinuses.

At the under or concave edge of the falx, there is found the inferior longitudinal sinus (*falciformis inferior*). This is very small, just admitting a probe, and it opens behind into the following: it may rather be regarded as a vein than a sinus.

The fourth sinus (*perpendicularis*, *torcular Herophili*, *sinus droit*) is placed at the junction of the falx and tentorium, has a triangular figure, the basis being formed by the tentorium, and the sides by two oblique layers of the falx, and exhibits internally several prominent fibrous fasciculi. In size it is about equal to a goose-quill. It receives in front the small vein called the inferior longitudinal sinus, and a large vein, called *vena magna Galeni*, which brings back the blood from the choroid plexuses and interior of the ventricles: it also receives, at its under surface, the superior veins of the cerebellum. It opens behind into the bifurcation of the superior longitudinal sinus; sometimes having a double termination.

The superior petrous sinus runs along the sharp ridge of the petrous portion, at the attachment of the tentorium, and opens into the lateral, just where that begins to descend from the tentorium. Besides some small meningeal veins, it has some from the anterior lobe of the cerebrum, and from the cerebellum.

The inferior petrous sinus is larger than the preceding, and runs in the junction of the basilar process of the occipital bone and the petrous portion of the temporal. Its anterior end joins the cavernous sinus, while the posterior opens into the lateral sinus, just before it enters the foramen

lacerum. The right and left are united by one or more transverse communications on the basilar process. This transverse communication unites the two inferior petrous sinuses just where they communicate with the cavernous: it is placed at the anterior end of the basilar process, is broad, and is described by Bichat to contain the same kind of cellular substance as the cavernous sinus.

The cavernous is the most complicated in its structure, and altogether the most remarkable of the cerebral sinuses. It occupies the side of the sphenoid bone, reaching behind to the fissure which separates the end of the petrous portion from the sphenoid, and in front to the foramen lacerum: above, to the summits of the clinoid processes, and below, to the openings through which the nerves of the fifth pair pass. The dura mater, in this situation, is divided into two layers, one of which adheres to the bone, as in other situations, and forms the internal side of the sinus; the other, which is much thicker, forms its external side, and is part of the internal surface of the cranial cavity. In this latter layer the nerves of the third, fourth, and fifth pairs are placed, contained in sheaths of the membrane. The interval of the two layers is occupied by a soft kind of filamentous cellular substance, through which the nerve of the sixth pair and the internal carotid artery pass. The ophthalmic vein, returning the blood from the orbit, opens into this sinus, which receives also meningeal veins, and communicates with the veins on the side of the basis cranii. It opens behind into the inferior petrous sinus. The right and left cavernous sinuses are said to communicate sometimes with each other under the pituitary gland.

The circular sinus is a small one occupying the superior aperture of the sella Turcica, and describing a circular course round the edge of the pituitary gland. It communicates on each side with the cavernous; and it receives veins from the dura mater and the pituitary gland. The anterior or posterior semicircle, or even the whole sinus, is sometimes wanting.

Occipital Sinuses.—These are very small; they begin at the sides of the foramen magnum, run backwards and upwards, and open into the lateral sinuses close to their origin. Anterior occipital sinuses are described, communicating with the inferior petrosal and the cavernous, and opening into the lateral near its exit from the head: they are not constant.

For representations of the veins and sinuses of the brain, see Haller, *Icon. Anat. fascic. 1*; Vicq d'Azyr, *Traité d'Anat. et Physiol. avec des pl. color. pl. 33. 35. 36.* Santorini, *Tab. Posthum. 3.*

The meningeal veins, or veins of the dura mater, receiving innumerable ramifications from the substance of the cranium, form trunks, which accompany the arteries, and often on each side, being lodged with them in bony channels of the skull: these veins open into the sinuses, particularly towards the basis of the skull, and they are said to communicate with the pterygoid veins.

Veins of the Eye.—(See Walter, *Epistola Anatomica de Venis Oculi.*)—The *vena ophthalmica cerebialis* begins about the internal canthus, communicating with the *ophthalmica facialis*, goes outwards and downwards behind the globe, and ends in the cavernous sinus. The following veins enter it; *viz.* *vena nasalis*, *ethmoidalis anterior*, *infraorbitalis*, *ciliaris interna*, *ciliaris superior*, *lacrymalis*, *ciliaris posterior*, *ciliares longæ*, *ethmoidea posterior*, *centralis retinae*. The arrangement and distribution of these vessels in the eye are described under *EYE*.

There are free communications between the external and internal veins of the head, in various situations, which have been already noticed; *viz.* at the parietal, the mastoid, and the

VEIN.

the posterior condyloid foramina. The veins of the orbit also constitute a communication between these two sets of veins, as they are connected on one side with the facial vessels, and on the other with the cavernous sinus.

It appears from the preceding description, that all the sinuses end, either mediately or immediately, in the right and left lateral, and consequently that all the blood conveyed to the brain is returned by these vessels. Having passed the foramen lacerum, the tube is called the internal jugular vein; it swells out into a dilatation received into the fossa jugularis of the temporal bone, descends perpendicularly along the neck, in company with, and on the outside of the internal carotid first, and afterwards of the common carotid artery, and of the par vagum, with which parts it is enclosed in a common cellular sheath. Just behind the anterior extremity of the first rib it ends, by joining at a right angle the subclavian vein. The internal jugular is a very large vein; when distended in the living subject, or by injection after death, it is nearly as large as the thumb. It receives the following veins; *viz.* the pharyngeal, the lingual, the common trunk formed by the union of the anterior and posterior facial, the superior and middle thyroid.

The external or superficial jugular vein is formed by two or three principal trunks, and by smaller branches, which form a kind of venous plexus on the side of the neck, covered by the skin and by the latissimus colli. These trunks are the occipitalis superficialis, which commences, in company with the occipital artery, from the integuments of the back of the head, and receives branches from the muscles of the neck; transversa colli, which accompanies the artery of the same name: deep-seated veins of the cervical muscles; subcutaneous veins towards the front of the neck; and smaller twigs from the sterno-mastoideus and lymphatic glands. The trunk terminates at the angle of union of the internal jugular and subclavian, or in the subclavian itself.

For the veins of the neck, see Walter's plates in the *Observat. Anat.* already quoted.

Veins of the Upper Extremities.—The arteries are every where accompanied by corresponding veins, which lie close to them, and are generally double, one on each side. These it is not necessary to describe. In addition to these, which may be called the deep-seated, there is a cutaneous set of veins in the fingers, fore-arm, and arm, forming large trunks placed merely under the skin, not accompanied by any arteries. Both the deep-seated and cutaneous veins end in a single large trunk, the axillary, which accompanies the artery of the same name.

The superficial veins of the fore-arm lie between the skin and the fascia, and form a venous net-work, composed of larger and smaller branches, over the whole limb. There is great variety in the size and arrangement of the trunks, which, however, are regular and constant in the arm. The digital veins run into trunks at the backs of the fingers, completely covering them after successful injection; they form a plexus (*dorsalis manus*) on the back of the hand, from which a large trunk (*cubitalis interna*, or *ulnaris superficialis*) or two, with smaller ramifications, run in the course of the ulna to the elbow. It passes over the tendon of the biceps, and assumes the name of basilic vein; ascends along the arm, on the inner edge of that muscle, in company with the brachial vessels, and enters the axilla, where it ends in the axillary vein.

A large vein on the back of the hand, arising from the little finger, was called by the ancients *salvatella*.

A venous plexus arises from the thumb, of which the largest branch is sometimes called *cephalica pollicis*: this

plexus, containing one or two larger trunks, (*radialis externa*, or *cephalica minor*,) is continued along the radial side of the fore-arm to the bend of the elbow, where it divides into two branches; the largest, under the name of median vein, passes obliquely in front of the joint to join the basilic vein; the other is called the cephalic, (*cephalica major*,) ascends on the outer edge of the biceps, runs in the cellular interval between the pectoralis major and deltoid to the edge of the clavicle, then dips under the bone, and ends in the axillary vein.

There is considerable variety in the median vein, which is sometimes merely an oblique communication between the basilic and cephalic: in other instances, a large branch comes from the middle of the fore-arm, (*mediana communis*,) and divides at the elbow into two trunks, which separate like the branches of the letter V, and join, one the basilic, and one the cephalic. These branches are then called *vena mediana basilica*, and *mediana cephalica*. There is always a large communication at the elbow, between this median vein and the radial and ulnar veins.

The axillary trunk, in which all the veins of the upper extremity end, is placed in front of its corresponding artery, on the side and anterior part of the chest; passes in front of the anterior scalenus muscle, then taking the name of subclavian, and ends at the sternal extremity of the first rib, by joining the internal jugular at a right angle. In this angle the thoracic duct ends behind, on the left side; and the minor trunk in front, on the right side.

For representations of the veins of the upper extremity, see Camper, *Demonstrationes Anatomico-Pathologicae*, lib. i. *Klint de Nervis Brachii*.

The axillary trunk receives the superior and inferior thoracic veins, the external and internal scapular, the *dorsalis thoracica*, the vertebral, and the superior intercostal vein.

The trunk of the latter accompanies its corresponding artery in the transverse processes of the cervical vertebræ, commencing about the foramen magnum, and receiving numerous branches, of which the most remarkable are from a large plexus of veins lying close on the vertebræ before and behind, and connected with the transversa colli, the occipital, and the internal jugular veins, from the sinuses of the medulla spinalis in the neck, (*circuli venosi cervicales medullæ spinalis*), and communicating with the cerebral veins, at the foramen magnum. The vertebral and superior intercostal veins end in that part of the trunk called subclavian.

The right superior intercostal is sometimes deficient; that is, the veins of the two or three superior intercostal intervals, instead of uniting into a separate trunk, join the *vena azygos*. The left is always a considerable vein, formed by the veins belonging to the five or six superior intervals, which join into a trunk ascending on the left side of the vertebral column, receiving the left bronchial vein, and some other small branches.

The subclavian vein, having received the internal jugular, descends on the right side almost perpendicularly, and on the right of the *arteria innominata*, receives the internal mammary vein, and very soon receives the left subclavian at a right angle. It now takes the name of superior or descending *vena cava*, continues its course in the same direction, receives the *vena azygos* from behind, and after a farther perpendicular descent of about an inch, having penetrated the pericardium, terminates in the right auricle.

The left subclavian vein crosses the chest, immediately behind the upper edge of the first bone of the sternum, and in front of the trachea and primary branches of the

aortic arch, proceeding transversely from left to right, and joining the right subclavian above the pericardium, as already described. It receives in this course the left internal mammary, the mediastinal, thymic, superior pericardiac, and inferior thyroid veins.

The internal mammary vein accompanies the artery. The thymic veins are connected with the mediastinal, pericardiac, &c. They end either in the subclavian, internal mammary, bronchial, superior intercostal, or thyroid.

The superior and posterior pericardiac veins generally end in the subclavian; but they may terminate in the bronchial or internal mammary. The vein accompanying the left phrenic nerve ends in the bronchial; on the right side, in the internal mammary.

The vena azygos returns the blood from the parietes of the chest, except in so far as the superior intercostal veins are concerned, which, as we have already described, join the subclavian. This vein connects the superior and inferior veins of the body: for its inferior ramifications anastomose with the lumbar or other abdominal veins. Hence, where the inferior cava has been obstructed, the blood has found its way through the vena azygos into the superior.

The minute origins of the vena azygos on the right side of the body are connected with the vena cava, the lumbar, or the renal veins. The trunk, at this part small, enters the chest, either with the aorta, or through an interval in the right crus of the diaphragm. It ascends on the right side of the vertebral column, in front of the right intercostal arteries, covered by the pleura, with the trunk of the aorta on its left, and the thoracic duct in the cellular substance between it and that artery, receiving the intercostal veins, and increasing in size. About the third dorsal vertebra it quits the spine, passing forwards over the right bronchus and pulmonary artery, receiving the right bronchial and some œsophageal veins, and of a considerable size, and opens into the back of the superior vena cava.

The intercostal veins, which it receives in its course, accompany the arteries of the same name, and return the blood from the intercostal muscles, and those of the back, from the medulla spinalis, from the vertebræ, pleura, integuments, &c.

About the seventh or eighth rib, the vena azygos receives a large branch from the left side, called hemi-azyga. This begins by roots, which communicate with the abdominal veins, from a trunk entering the chest through the diaphragm, ascending on the left side of the chest, receiving four, five, or more left inferior intercostal veins, and then crossing to the right side, to join the trunk. Sometimes the hemi-azyga joins the common trunk by two or three branches; sometimes it is not formed, and the left intercostals proceed straight to the right side. See Wrisberg, *Observat. Anat. de Vena azyga duplici, aliisque hujus venæ varietatibus*. Goetting. 1778.

III. *The inferior Vena Cava*.—The veins of the lower extremities, of the pelvis, and the abdomen, terminate in this trunk.

The veins of the lower, like those of the upper extremity, consist of a deep-seated set accompanying the arteries, and therefore not requiring a separate description; and a superficial order, covered only by the skin, and intervening between it and the fascia. The femoral vein is the common channel for the blood of both these systems of veins.

The superficial veins of the leg compose two principal trunks, called saphenæ: there is indeed, as in the upper limb, a plexus covering nearly the whole of the foot and leg, of which the different branches every where communicate.

The saphena externa or minor arises from the venous

plexus of the sole and back of the foot towards the outer edge; it runs below and behind the outer ankle, then rises over the calf, and having frequently communicated with the deep-seated veins, terminates in the trunk of the popliteal.

The saphena externa or major is made up by the veins coming from the backs of the toes, and from the inner side of the sole, which form a considerable trunk, ascending in front of the internal malleolus, on the inside of the leg, knee, and thigh, communicating frequently with the deep-seated veins, and ending in the trunk of the femoral, about an inch below the crural arch. Just before its termination, it receives some veins from the external organs of generation (*puvicæ externæ*); and a considerable trunk, which descends from the integuments of the abdomen.

The femoral vein passes under the crural arch, on the outside of the corresponding artery, and continues in company with the artery, under the name of the external iliac, along the side of the psoas magnus, until it meets with and joins the internal iliac or hypogastric vein from the pelvis, at the sacro-iliac symphysis, or the point where the common iliac artery bifurcates into its external and internal branches. Immediately above the crural arch, the external iliac receives the epigastric and circumflex iliac veins.

The internal iliac or hypogastric vein is made up by the union of venous trunks, corresponding to the various arteries which are given off from the internal iliac artery. These veins accompany their respective arteries; but they are remarkable for forming thick and intricate plexuses, which surround the prostate, vesiculæ seminales, neck, and fundus of the bladder, urethra and vagina, and rectum.

A large vein runs along the back of the penis, in its middle, between the two arteriæ dorsales, and returns the blood from the glans, corpus spongiosum, bulb, and corpora cavernosa. It passes under the arch of the pubes, and divides into a right and left branch, which run into the plexus about the prostate and vesiculæ feminales.

The superficial veins of the penis and scrotum find their way under the arch of the pubes, communicating with the internal pudic vessels, and end in the plexuses about the neck of the bladder.

They are united on the outside with branches of the spermatic vein, and of the femoral. The prostate and vesiculæ seminales, the lateral and inferior parts of the bladder, are covered by numerous ramifications of a dense plexus, from which the trunks of the vesical veins convey the blood to the hypogastric.

The veins in the labia are numerous, and communicate frequently: these and the veins of the clitoris pass under the arch of the pubes; the front of the vagina and urethra are covered by a thick plexus, which is the common termination of the external and internal pudic vessels. These plexuses envelope the sides of the vagina, the anterior, lateral, and inferior parts of the bladder, and end in the vesical veins.

The external hemorrhoidal veins end in the pudendal; the middle occupying a space of three or four inches, and united with the plexuses already mentioned, join the hypogastric. These latter then are interposed between the internal hemorrhoidal, which joins the vena portarum, and the external, from which the hemorrhoidal flux proceeds.

Large veins proceed from the vagina and uterus to the internal iliac: there are also the lateral sacral veins, corresponding in number to the sacral foramina, out of which they proceed, and united with the middle sacral vein. The other vessels contributing to the hypogastric vein are, the obturatrix, ischiatic, pudenda communis, glutea, ileo lumbaris.

The primary or common iliacs, formed by the junction,

VEIN.

at nearly right angles, of the externa and internal, are very considerable venous trunks, differing slightly on the right and left sides of the body. The right is much the shortest, and proceeds obliquely behind, and rather above its corresponding artery. The left, placed behind and below the left common iliac artery, proceeds obliquely upwards and towards the right, across the front and upper part of the sacrum; then goes between the fifth lumbar vertebra and the right common iliac artery, to join its corresponding vein, at an acute but open angle, on the right side of the vertebral column, at the interval between the fourth and fifth lumbar vertebrae; forming by this union the great trunk of the inferior or ascending vena cava.

One or two lumbar veins sometimes join the common iliac. The sacra media, a small vein, terminates, either at the angle of union, or in the left common iliac.

The inferior vena cava lies at its origin, close to the aorta, on its right, and on the right side of the vertebral column: it ascends in the same relative position, first connected to the spine, then to the right crus of the diaphragm, but more and more distant from the aorta, as it rises higher in the body. It leaves the vertebral column towards the upper part of the abdomen, and enters a deep fissure in the posterior or thick edge of the liver, which covers two-thirds, and sometimes the whole vein. From the loins upwards the size of the trunk is considerably increased: it will easily admit a large thumb. Quitting the liver, it penetrates the tendon of the diaphragm (see DIAPHRAGM), and immediately opens into the right auricle of the heart. (See HEART.) In its passage it receives the following veins.

1. The sacra media has been already mentioned.
2. The lumbar veins correspond to the arteries of the same name, and return the blood from the parts supplied by those vessels. They form about four trunks on each side, which end in the lateral and posterior part of the inferior cava.
3. The spermatic veins. They come from the testicles in the male subject, from the uterus and ovaria in the female; receive various branches from the ureter (uretericæ), fat of the kidney (adiposæ), &c. and communicate with veins in the mesentery and mesocolon; form first a considerable plexus, with several trunks communicating together, and afterwards a single vein, which ends in the front of the vena cava on the right side, and in the renal vein on the left.
4. Renal or emulgent veins. Of these large trunks, the right is much shorter than the left, on account of the relative position of the vena cava and the kidneys. The latter crosses the vertebral column in front of the aorta. There are rarely more than one on each side.
5. Capsular veins. These often end in the renal, particularly on the left side, otherwise they terminate in the cava.
6. Hepatic veins. They are numerous, and of different sizes. Usually there are from three to five large ones, and several smaller. They return the blood of the vena portarum and that of the hepatic artery.

7. Inferior diaphragmatic veins; accompanying the arteries, and ending either in the cava, or in an hepatic vein. Soemmerring states that some diaphragmatic veins join the vena portarum.

Besides the works to which we have referred in the course of this article, for plates illustrating particular veins, we may refer in general to the Fasciculi of Haller, to the plates of the veins in Loder's collection, and to Mayer's Anatomische Beschreibung der Blutgefäße des menschlichen Körpers; mit kupfern, 1788, 8vo. See also Walter Angiologisches Handbuch, 1779. Soemmerring, De Corporis Humani Fabrica, t. 5. Bichat's Anatomie Descriptive, t. 4.

VEINS, Diseases of the. Veins (says Mr. Hodgson) are liable to all those morbid changes which are common to soft parts in general; but the membranous lining of these vessels is peculiarly susceptible of inflammation. When a vein is wounded, the inflammation, which is the effect of the injury, sometimes extends along the lining of the vessel into the principal venous trunks, and, in some instances, even to the membrane which lines the cavities of the heart. This inflammation sometimes produces an effusion of coagulating lymph, by which the opposite sides of the vein are united so as to obliterate the tube. In this manner, a great extent of the vessel is occasionally converted into a solid cord. In some instances, the secretion of pus into the cavity of the vessel is the consequence of inflammation of the membranous lining of veins: under these circumstances, the matter is either mixed with the circulating blood, or the inflammation, having produced adhesion of the sides of the vessel at certain intervals, boundaries are formed to the collections of pus, which in this manner form a chain of abscesses in the course of the vessel.

When the inflammation of veins is not very extensive, its symptoms are the same as those of local inflammation in general; but when the inflammation extends into the principal venous trunks, and pus is secreted into the vessel, it is accompanied with a high degree of constitutional irritation, and with symptoms which bear a striking resemblance to those of typhus fever. See Hodgson's Treatise on the Diseases of Arteries and Veins, p. 511, 512.

In the first volume of the Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge, Mr. Hunter has published an extremely interesting paper on the subject of inflammation of veins, and he has particularly adverted to that common case, an inflamed arm after bleeding. By some, he observes, this complaint has been imputed to the wounding of a tendon; by some, to the injury of a nerve; and by others it has been ascribed to a bad constitution.

Mr. Hunter expresses his doubts of the accuracy of these opinions, and he remarks, that the manner in which these fore arms come on, plainly proves that they arise from the wound not healing by the first intention; for, in most cases, the external wound first festers or inflames, and then suppurates or ulcerates, the cavity of the vein becoming subsequently impervious. In some instances, this suppuration is only superficial, the vein and parts below having united. In other examples, the skin appears to be united, but not close to the vein, so that a small abscess forms between the vessel and the integuments. This bursts and discharges a thin watery fluid, and no further mischief happens. When, however, this imperfection of union is continued on to the cavity of the vein, this vessel inflames both upwards and downwards, frequently to a considerable extent, and the surrounding parts join in the inflammation.

We find, says Mr. Hunter, all these variations in different cases. Sometimes the disease goes no further than an inflammation near the orifice of the vein, and the case often ends in resolution. At other times, the inflammation is carried further, but suppuration is prevented by the adhesive inflammation taking place in the affected portion of the vein, and, in such cases, the veins may be plainly felt, like hard cords, after the surrounding tumefaction has subsided. But this salutary effect is not always produced, and suppuration in the vein is the consequence, but often in so limited a degree, that only a small abscess forms in the cavity of the vein, near the puncture. The confinement of the matter in this part of the vein, arises from adhesions in the vessel, a little above and below the orifice. But, in many cases, adhesions

adhesions do not occur, and then the inflammation and suppuration are not confined to the vicinity of the wound. On the contrary, an abscess is frequently produced, occupying a considerable length of the vein in both directions; and, says Mr. Hunter, we often have more than one abscess; nay, sometimes there is a series of them, generally in the direction towards the heart; but not always in this course; for, occasionally, these abscesses are observed between the orifice in the vein and the extreme part of the limb.

In consequence of a wound in the foot, Mr. Hunter saw the vena saphena inflamed all up the leg and thigh, nearly as high as the groin; and he was obliged to open a chain of abscesses, which reached nearly the whole course of the vessel.

In cases in which the inflammation had been violent, and in which the opportunity of examination was afforded, Mr. Hunter found the inflammation at some distance from this violence in the adhesive state; in some places, the sides of the vein were adhering; and, in others, the inner surface of the veins was covered with coagulable lymph. When different abscesses had formed, he always found, that the spaces of the vein between them had united by the adhesive inflammation, and it is this union which circumscribes such abscesses.

In examining the arm of a man who died at St. George's hospital, Mr. Hunter found the veins, both above and below the orifice, united in many places by the adhesive inflammation. He also found in many parts of the veins the commencement of suppuration, without ulceration having actually begun; while, in several other places, ulceration had occurred, and destroyed the surface of the vessel next the skin, a circumscribed abscess being produced. The vein near the axilla was in a state of suppuration, and as no adhesions were formed beyond the part affected, Mr. Hunter conceived that the matter had passed freely into the circulation, and most probably been the occasion of the man's decease.

When larger abscesses had come on than those arising from the ulceration of the wound of the lancet, Mr. Hunter always found that the vein was afterwards obliterated, having united and healed up as any other cavity does, so that the patient could never be bled in the same vein again.

Inflammation of a vein is a common effect after bleeding horses, which is to be ascribed to the careless and rough manner of closing the puncture with a pin. Mr. Hunter has seen the jugular veins of horses inflamed through their whole course, the swelling extending to all the side of the head, and the inflammation reaching even to the chest. In these cases there is always an abscess formed at the wound, and often several along the vein, as in the human subject; and whenever the complaint is carried as far as this stage, the vein is rendered for ever afterwards impervious. Many horses die of this disease; but what is the particular circumstance which occasions their death, Mr. Hunter was not able to determine. It may (says he) either be that the inflammation extends itself to the heart, or that the matter secreted from the inside of the vein passes along that tube in considerable quantity to the heart, and mixes with the blood.

Although the operation of venesection, which is the most frequent cause of this complaint, is to appearance trifling, yet, as it is often of very serious consequence, both to the life of the patient and the character of the surgeon, the operator should use the utmost care to prevent an evil of such magnitude. He should be particularly attentive to the mode of closing the wound and binding up the arm. This is to be done by bringing the two sides of the wound together,

in order that they may unite by the first intention. To accomplish this, let the surgeon, with the thumb of that hand which holds the arm, push the skin towards the orifice, while he draws it on the other side to the same point with the compress, which is then to be immediately applied. The compress should be broad, so as to keep the skin better together; and thick, in order that the compression may be more certain. Mr. Hunter preferred a compress of linen, or lint, to sticking-plaster. He very properly thought, that the blood which dried over the orifice was a more natural and effectual bond of union than any other application. This conclusion, he observes, is drawn from practice; and he had seen more fore arms, in consequence of bleeding, where the puncture had been dressed with plasters, than under other circumstances.

When inflammation takes place beyond the orifice, the surgeon should endeavour to promote adhesion of the inflamed sides of the vessel by means of compression. If it be suspected that suppuration has happened, the pressure should be applied just above the suppuration, with a view of producing an obliteration of the vessel in that situation. (See *Trans. of a Society for the Improvement of Med. and Chir. Knowledge*, vol. i. p. 18, &c.) As Mr. Hodgson observes, the treatment of the inflammation, when only the punctured vein is affected, should be the same as that of local inflammation in general; namely, the application of leeches, the use of evaporating washes, purgatives, and low diet. Although the constitutional irritation, which takes place in extensive inflammation of veins, is attended with more debility than usually accompanies acute inflammation, yet the case can hardly be relieved without recourse to copious bleedings, and the usual antiphlogistic remedies.

For additional information on the foregoing subject, we refer to Mr. Hodgson's excellent Treatise on the Diseases of Arteries and Veins, a publication which reflects the highest credit on its intelligent author. Some other affections of the veins are noticed in distinct articles of this Cyclopædia. See CIRSOCELE, HEMORRHOIDS, VARICOCELE, VARICOSE Veins, VARIX, &c.

VEINS, *Method of opening*, for the purpose of taking away blood. See BLEEDING.

VEIN, in *Botany and Vegetable Physiology*, *vena*, is a term used for all those assemblages of tubes, through which the sap of a plant is transmitted along the leaves, and by some of which also the secreted fluids must be returned into the bark and wood, for the increase of both. Hence Hedwig, for the sake of precision, has invented the term *ductorum fasciculus*, a cluster of ducts, for the ribs of the foliage in Mosses; but we see no improvement in this phraseology. The larger, primary, or more direct, assemblages of vessels have obtained the name of ribs, *costæ*, or nerves, *nervi*; but the limits between these and veins are not always very certain. Large transverse veins, as well as the great longitudinal ones, are often called ribs or nerves, especially if they send off finer and more complex ramifications, interbranching with each other like net-work, to which the name of veins is evidently more suitable. We could wish to apply the term *costa* to the great central rib, and *nervi* to the lateral ones, whether longitudinal or transverse, but this has not been adopted with any regularity. See COSTA and LEAF.

Veins are also found copiously in the *petals* of flowers, and are exactly analogous to the veins, ribs, or nerves of leaves, except being generally more pellucid and homogeneous. When the petals undergo any changes of colour, in their progressive stages of growth, the veins partake remarkably of such changes, and mostly in the first instance. Ribs, rather

VEIN.

rather than veins, are most apparent in the *calyx* of many plants.

VEINS, *Metallic* and *Mineral*, in *Geology*, are fissures intersecting rocks or strata, filled more or less completely with mineral or metallic matter, different from the substance of the rock. When veins are seen on the surface intersecting or traversing a mountain, they have been supposed to resemble the veins of animals; but the resemblance is only superficial, for veins are not tubular, except in a few instances; but their thickness is small, compared with their length and depth.

Metallic veins are the principal repositories of most of the metals, except iron and manganese, which occur more frequently and abundantly in beds than in veins. The thickness of metallic veins varies from a few inches to several feet or yards: the same vein varies also in thickness in different parts of its course, sometimes contracting to a narrow string of ore, and then expanding again to the width of several yards. The depth to which they descend is unknown, for we believe no instance has occurred of a considerable vein being worked out in depth, though it may sink too deep to render the operation of the miner profitable; or it may branch off in a number of strings, which are too much intermixed with the rock to be worked to advantage. In cases where the metallic ores have disappeared at considerable depths, the veins are still continued, though they are filled exclusively with the mineral matter or vein-stone which accompanied the ore in the upper part of the rock. Some veins appear to grow wider, and others to contract as they descend. The direction of veins downwards inclines more or less from the perpendicular; but they sometimes run for a certain distance parallel with the dip of the beds or strata in a mountain, and then strike down through the lower beds.

The length of metallic veins has rarely, if ever, been accurately determined; they have frequently been traced several miles, but their further progress has been concealed by the intervention of valleys, rivers, or accumulations of sand and alluvial deposits. Some of the metallic veins in South America have been traced to the distance of eighty miles. Large veins generally take a nearly direct line through a country, except where they are turned aside by cross veins, or what are called in Cornwall *cross courses*: it is also remarkable, that the metalliferous veins in England generally run nearly east and west, and the cross courses north and south. To what cause this is owing we are perfectly ignorant. Large metalliferous veins frequently send off smaller veins, or strings of ore, from their sides, which penetrate the rock to a considerable distance on each side of the large vein. Veins are seldom entirely filled with ore, but sometimes it extends in a compact mass from one side to the other. More frequently, the ore is intermixed with mineral matter called vein-stone, *matrix* or *gangue*: this, according to the rock which it intersects, will be either calcareous spar, fluor spar, barytes or quartz. The vein-stone and the ore are frequently arranged over each other, lining the sides of the vein with alternate layers of metallic and mineral matter, and filling up the whole vein. In the mines of Cornwall, the ores of copper and tin commonly occur in detached masses, which are called *bunches* of ore; and the other parts of the vein, being unproductive, are called *deads*.

The vein is generally separated from the rock which it intersects by a thin layer of mineral matter distinct from the vein, and from the rock itself, and also by a thin lining of clay. Sometimes there are large cavities in veins called *druses*, which are generally lined with crystals. In other instances the vein divides, inclosing a piece of rock, which is called the *rider*; but it is observed, that the inclosed mass,

or rider, differs in its quality from that of the rock through which the vein passes.

The superficial part of a vein generally contains the ore in a decomposing state; and it frequently happens that the ores in the upper and lower part of the vein are different: thus in Cornwall, blende, or the sulphuret of zinc, often occupies the uppermost part of the vein, to which succeeds tin-stone, and at a greater depth, copper pyrites. See ZINC, TIN-STONE, and COPPER.

When Mr. Pryce wrote his "*Mineralogia Cornubiensis*," the mines of Cornwall had not been worked to a great depth, for he says the richest state of a mine for copper was from eighty to one hundred yards deep, and for tin, from forty to one hundred and twenty yards. This account by no means corresponds with the present state of the Cornish mines. The Dolcooth copper-mine, near Redruth, is worked to the depth of four hundred and fifty-six yards, and is very productive at that depth.

Veins generally decline from the perpendicular, and descend into the earth obliquely. The sides, or, as they are called, the walls or cheeks of the vein, are differently denominated, the upper side being called the *hanging-side*, the *up-cheek*, or *hanger*; and the under side, the *hanging-side*, the *down-cheek*, or the *ledger*. The veins we have been describing are called *rake* veins in some parts of England, and in Cornwall, they are denominated *lodes*; which see. These metalliferous veins have commonly the same direction, or nearly so, in the same district, and the veins which cross them are generally unproductive, or contain metallic ores of a different kind. They are called *cross courses*, or north and south veins.

Metalliferous rake-veins intersect most of the mountains called primary, such as granite, gneiss, and mica-slate. (See GRANITE, &c.) But they are more abundant in slate-rocks than in rocks of granite or porphyry. (See GRANITE, SLATE, and PORPHYRY.) They also intersect the rocks of transition and mountain lime-stone, which rest upon slate, or alternate with it; but they rarely rise into the secondary strata which contains coal. This fact seems to prove that veins were formed prior to the deposition of the upper secondary strata. When a metallic vein in its descent passes through different kinds of rock, it is frequently observed that the products of the vein vary in each bed; and when it passes through regularly stratified beds of the same rock, there are particular strata in which the veins are always found most productive, and these in the north of England are called *bearing measures*. If the nature of the rock seems to have produced a change in the quality of the ore, it is no less remarkable that the rock itself is also frequently changed or decomposed in the immediate vicinity of a vein. This change is more apparent in some rocks than in others, particularly in granite, sienite, gneiss, mica-slate, argillaceous schistus or slate, and porphyry. In such instances, according to Werner, it is only one of the component parts of the rock that is decomposed, either the felspar, the hornblende, or the mica, but never the quartz. This change sometimes extends to a considerable distance on each side of the vein, even to a fathom or more; it extends farther in some places than in others, and is most general in those parts where the vein contains sulphur. Sometimes this change in the rock may be perceived so far, that it serves as a guide to the miner; and in following a sterile vein, when he comes to a place where the rock is decomposed, he concludes that the metallic ore will soon be found. In Cornwall, the felspar is frequently changed in the vicinity of a vein, and tin-stone is sometimes disseminated through the rock to some distance on each side of it.

The cross courses or veins which intersect the metalliferous veins, frequently occasion a considerable derangement in the position of metalliferous veins, and, what is still more remarkable, occasion a change in the quantity or quality of their contents. When a vein is cut through by another, either in its line of bearing along a country, or crosses it by declining in a different direction, the vein which is cut through is supposed to be of more ancient formation than the vein which crosses and cuts through it; but it may be doubted, from various circumstances, whether many of these veins were not formed at the same time with the rock itself, or were fissures passing through the rock in different directions, into which the various metallic substances were secreted, during its consolidation. To form a more distinct idea of the structure of a vein and its intersection by cross courses, we refer to *Plate IV. Geology. Fig. 4.* *a a* represent a rake-vein descending obliquely; *b b*, the rock; *c, c*, the walls or cheeks of the vein; *d*, an interposing piece of rock, called the rider; *e, e, e*, the division of the vein into numerous small veins or strings of ore. If the space at *d*, which is supposed to be filled with rock, were empty, or filled with water, it would constitute what is called a druse; and it is in these cavities or druses that all the most beautiful and regular crystallizations of the mine occur. *Fig. 5.* represents the section of a rock containing a metallic vein cut through, and displaced by cross courses or veins of another metal; *a a a* is a vein which appears to have been once continuous, and contains tin; *b, b, b*, represent different veins of copper, which cut through the former, and have upheaved the lower part, and brought them nearer the surface. In *Plate II. Geology, fig. 10.* represents the ground plan or horizontal section of a plot of ground traversed by a vein and a cross course; *E. W.* represent the east and west sides of the ground. It is in this direction the vein *a a* passes, but it is cut through by the cross vein *b b*, which has carried the western side of the vein and the ground along with it considerably to the north of its original position. Such a fracture and removal of the vein can only be conceived to have taken place by a lateral or horizontal motion of a portion of the ground. Such a motion has been frequently observed during violent earthquakes. For though the ground is heaved upwards, the greater resistance which certain parts offer to this motion must occasion a lateral pressure on other parts of the earth's surface, and to such a pressure we must also refer the remarkable contortions of the coal strata near Valenciennes. See *Plate II. fig. 9.*

Metallic veins frequently occasion a displacement of the strata when they pass through regularly stratified rocks; and it is observed, that when this displacement is considerable, so as to bring a bed of lime-stone on the same level with a bed of sand-stone or shale, the vein is never so productive as when the opposite sides or walls of the vein are in the same kind of rock. See *Plate II. Geology, fig. 8.* where the different strata *a, b, c, d, e, f, g*, represent different strata on each side of a vein or fault. If *d, d*, are supposed to represent parts of a bed of lime-stone broken by the vein, and *g g* a bed of sand-stone below the lime-stone, but brought on the same level with it by the upheaving of the strata,—in that part of the vein where the lime-stone, *d*, and the sand-stone, *g*, form the walls opposite to each other, the vein will be unproductive, though in other parts of the district, when the vein passes through the same bed of lime-stone, on each side of it, at the same level, it will be remarkably productive. These facts may be commonly observed in the mining districts of the western parts of Northumberland and Durham, where the strata consist of different beds of mountain lime-stone,

sand-stone, and shale. See STRATA, under which article the succession of the different beds is enumerated.

As cross veins generally displace and injure the quality of veins, on the contrary, when east and west veins in a district meet, by a slight variation in their direction or dip, the part where they join is frequently very rich in ore; and where a number of metallic veins cross each other at the same place, they frequently produce a large irregular conical mass of ore of vast extent, from which the different veins diverge, like radii from a common centre. The main shaft of such a vein, which Mr. Williams, in his Mineral Kingdom, calls an *accumulated vein*, "resembles," he says, "the inside of a glass-house; and the vast capacity of this vein is frequently filled with a rich body of metallic ore, often imbedded in soft mineral soils; but the veins and branches which join and diverge resemble rake-veins, or perpendicular mineral fissures. When the ore is worked out of an accumulated vein, it exhibits a frightful gulf, sometimes fifty or sixty feet wide below, and is often worked down to a great depth from the surface." A number of these accumulated veins have been worked at Pike-Law, in the county of Durham. Cross courses sometimes contain ore to a small distance from their junction with metallic veins, and in other situations they become so rich as to be worked with advantage. The Botallack mine, on the sea-coast near St. Just, in Cornwall, offers a striking illustration of this, though we believe its structure has not been generally known or understood. The vein which is worked is a north and south vein, varying in width from nine to twelve feet, and extending under the sea. The vein-stone is quartz, with a small quantity of fluor spar. It is found to contain ore of copper and tin only in those parts where the east and west veins enter it, and for thirty or forty fathoms on each side of the junction. This mine produces the richest ore of copper in Cornwall, the grey sulphuret yielding twenty *per cent.* of this metal. It is deserving notice, that the metalliferous veins which enter this lode on the east side and render it productive, have never been found on the west side, so that they appear to terminate in it. The rock near the great north and south vein is a soft killas or slate, but beyond this it is a very indurated flinty slate. This vein may properly be considered as a cross course, rendered rich in ore in various parts by a number of small veins which fall into it, like brooks into a large river where they are lost. The situation of this mine is truly remarkable, at the foot of a precipitous cliff that overhangs the Atlantic ocean. If ever a spot seemed to bid defiance to the efforts of the miner, it was this. At the very commencement of his labours, he was required to lower an immense steam-engine down a precipice of more than two hundred feet, with a view of extending his operations under the bed of the sea, where the workings are at present continued for seventy fathoms in length and sixty-five fathoms in depth. In these caverns of darkness, many human beings for a small pittance, and that even of an uncertain amount, are constantly digging for ore, regardless of the horrors which surround them, and of the roar of the Atlantic ocean, whose boisterous waves are incessantly rolling over their heads. In some places the sea actually penetrates through; and it is worthy of observation, that the water is deprived of a great portion of its salts; but whether this arises from filtration, or whether some portion of the fresh water from the land percolated through subterranean fissures in the rocks, we could not ascertain when we visited this singular mine. If the filtration be more abundant after heavy rains, it would prove the intermixture of rain-water. The thin cross courses filled with clay called *flucan*, heave the east and west veins, and also hold up the water. The vein which is rich

VEIN.

in ore on one side of the flucan, will be poor on the other side. This fact, which we believe has not been sufficiently noticed, is well deserving attention, and would indicate that the presence of water affected the contents of veins.

Some veins contain little diversity in the nature of their contents, being filled principally with one kind of ore or vein-stone. Other veins contain a great variety of minerals, without any apparent regularity of arrangement: there are also numerous veins which have a regular structure, the different minerals being arranged in parallel layers, coating each other: the same succession of different minerals occur on each side and meet in the middle, filling up the vein, or sometimes leaving an empty space between. Thus calcareous spar, fluor spar, barytic spar, lead-ore, blende, and grey copper-ore, form different layers over each other in the same succession on each side of the vein. In the Botallack mine, before described, copper-ore is frequently found lining each side of the vein, and this is covered by tin; but in other parts of the mine the tin covers the walls, and is succeeded by copper.

Irregular Veins.—Besides rake-veins, which may be considered as regular, there are other veins which present a great variety of structure, and are called *bellies*, *pipes*, &c. according to their form. If a rake-vein be regarded as a tubular mass of mineral matter intersecting mountains; if this vein become irregular, and have its sides closed, or, as the miners call, *twitched in*, it forms what they denominate a pipe-vein, or mass of ore and vein-stone sometimes of a tubular shape, descending to a considerable distance like a pipe. In other instances, the sides are closed in both above and below, as well as on the sides, inclosing what the miners call a *belly*, or mass of ore of considerable magnitude. Sometimes a small rib of ore is continued through that part of the rock where the sides of the vein are twitched in, until the vein expands again and produces another mass of ore. In some instances there is no ore between, a rib of vein-stone or rider of clay being carried through the narrow part or *twitch* of the vein, but many of these twitches contain neither ore, clay, nor rider. In such cases, it becomes exceedingly difficult to follow the vein through the rock, to where it opens out again.

The veins in general do not close suddenly, but the sides gradually approach each other, and the ore terminates in the form of a wedge at the *twitch*.

These contractions or twitches are of various lengths, and no miner can tell, when the vein is so squeezed in, how many fathoms he must pass through before it opens again, unless the same twitch has before been cut through above or below the part where he is working. The intervening space between two masses of ore is called a *bar*, and sometimes extends ten, twenty, or even a hundred fathoms or more; and when it is cut through, the ore makes its appearance, and begins gradually to widen and form another mass or belly. When one of these bellies of ore proves pure and solid, it generally happens that all the contiguous bellies prove so in the same vein. According to Mr. Forster, instances have been known of eight hundred *bings* of ore being raised by six miners from one of these bellies in the space of nine weeks.

When the matrix in these large bellies of ore is soft, the ore is generally found in a globular form, more or less irregularly imbedded in the soft materials, and these globular masses of ore are of various dimensions. It is no uncommon thing to find the soft openings in this kind of vein swell to an enormous width, so as to make it difficult to find the real sides of the vein. Working these veins is the most difficult part of mining, as there is no proceeding a foot

without advancing timbers as far as they go, in the form of a passage in a house, composed of two side-posts, a lintel and a sole. The miners stand within this square frame, where they work and erect more timber as they proceed. It frequently happens that the ore is so plentiful and rich in this kind of metallic repository, as abundantly to compensate for all the labour and expence.

Flat Veins and Beds.—When a vein runs parallel with the strata, it is called a flat vein. If the strata are soft, and the metallic matter is widely distributed, such veins do not differ from beds, being regular beds or strata impregnated with metallic matter. When flat veins run between hard strata, they are also liable to contractions, or *twitches*, and again expand, forming *pipes* or tubular masses of ore, which extend in an inclined position, having the same dip as the strata. Flat veins may be distinguished from beds by this character; proper flat veins appear to be openings between the strata which have been filled with metallic matter from a rake-vein, or are at least connected with it, as they seldom are productive of ore, except in the vicinity of the vein; whereas beds are regular strata, having the same elevations and depressions as the other strata in a mountain, but containing metallic matter more or less abundantly scattered through them. Iron ores and ores of manganese frequently occur in beds, forming regular parts or layers of the mountain. Other metallic ores, which occur less frequently and abundantly in beds, are, we believe, for the most part veins which have taken the course of the softer beds and distributed their contents through them. It is well known, that when a vein descends through strata of different kinds of rock, it grows wider in the soft strata, and contracts in the harder beds of rock.

The metalliferous beds in Cumberland appear, in many instances, to be soft beds, rendered productive of ore by a number of small veins running through them. There are few metallic beds in England, except in that county. Manganese occurs in beds in red sand-stone in the vicinity of Exeter, but the metallic matter decreases as the beds dip from the surface. Metallic beds, in primary countries, occur most frequently among the schistose mountains, composed of gneiss, mica-slate, and slate. (See Rock.) It is observed, that the ores and minerals which occur in beds are seldom crystallized, as these beds contain few druses or cavities to admit the formation of crystals. The minerals in beds are accompanied with garnet, actinolite, and hornblende, which never occur in rake-veins. See GARNET, &c.

Stock-work.—When a rock is crossed and penetrated by a great number of small veins in every direction, the whole mass is worked as an ore, and is called by the Germans a *stock-work*, or *werke*, the rock being afterwards separated from the ore by pounding and washing, in the same manner as the vein-stone is cleared from the ore in other mines. When the ore is diffused in particles through the rock, such rocks are also worked for the ore when it exists in sufficient quantity. In some instances, masses of ore of great magnitude are found imbedded in rocks, without any apparent connection with veins, which masses must have been formed at the same time with the rock itself.

Rocks and strata are sometimes penetrated by metallic salts or oxyds, diffused through the mass in the same manner as we frequently observe strata of sand-stone abounding with the red oxyd of iron. Where the metals are valuable, such impregnated rocks or strata are sometimes worked as ores. At Alderley Edge, a hill near Macclesfield, in Cheshire, the sand-stone, which is in some parts a kind of breccia, is impregnated with the black oxyd of cobalt, with the carbonate and oxyd of copper, and with particles of sulphuret
and

and carbonate of lead, and has formerly been worked for the lead and copper, and more recently for the cobalt. Mr. Williams, in his "Natural History of the Mineral Kingdom," describes a singular stratum of stone near Loffmouth, in the shire of Moray, of about eight feet thick, which is composed of several species of hard and fine stones of various beautiful colours. "This stratum is a kind of pudding-stone, in the composition of which there is blended about an eighth part of good blue lead-ore or galena.

"This curious bed of stone is nearly horizontal, but dips away with an easy slope towards the north of the Moray Frith. The lead is found in larger and smaller grains and flowers, blended through the whole body and composition of the stone, in the same manner as the small masses of agates and coloured crystals, and other species of stone, are found blended through the whole body of the stratum."

Where metallic ore is thus intermixed with fragments of rock forming a conglomerate or breccia, it may probably be referred to the same kind of metallic repository as stream-works, (see *STREAM-Works*,) in which particles and masses of ore are intermixed with loose pebbles and sand, forming beds at the bottom of valleys, or on the sea-shore, the metallic matter, as well as the pebbles, being derived from the disintegration of rocks containing metallic veins; but in the instance cited by Mr. Williams, the parts have become united, forming a solid stratum.

The manner in which metallic veins were filled with ore has greatly divided the opinions of geologists. George Agricola, a Saxon, who died in 1555, appears to have been the first writer who had any distinct knowledge of the structure of metallic veins, which he published in a work entitled "De Rê Metallica," and another work entitled "Bermanus." His theory of veins is in some respects similar to that of Werner, which has lately excited much attention. According to Agricola, the rents or fissures which are filled with metallic matter were partly formed at the same time with the rocks themselves, and partly afterwards, by the waters penetrating the softer parts; so that where there has been a larger quantity of water, or where the substance of the rock has been much softened, there the largest fissures occur. With respect to the earths and stones found in veins, he conceives the former to have been detached from the rocks and carried into the veins by water; the latter he considers as arising from the earthy matter, hardened partly by change of temperature and partly by a lapidific juice. Minerals and metals he regards as being deposited from a solution in water, containing the earthy parts intimately mixed and combined with it in certain proportions. The solution of these mineral substances he conceives to have been greatly promoted by heat, on the abstraction of which they assumed their present solid form; the precious metals being the result of a more pure and perfect solution.

Becher, in his "Physica-Subterranea," published in 1669, ascribes the formation of metals and minerals to certain subterranean vapours which arise from the bowels of the earth, and penetrating the substance of veins, produce a peculiar change in the earthy or stony matter they meet with. He regards the earth as a hollow body, filled with clay, water, sulphureous and bituminous substances, from which arise certain exhalations that form the metals. The celebrated German physician Stahl, considers veins, as well as the substances they contain, to have been formed at the same time with the earth itself, and of course as being contemporaneous with the rocks they intersect; but he is disposed to attribute some effect to the action of air and other causes.

Henkel, in his "Pyritologia," has given an ingenious theory of the formation of metallic veins, which has been adopted,

with certain modifications, by some later geologists: he attributes the formation of ores to a peculiar exhalation produced and engendered by fermentation, supposed by him to take place in the interior of rocks. The basis of each ore and mineral he supposes to exist in the substance of the rock, and by a peculiar process of nature it is matured and converted into the metal. He does not venture to ascertain the nature of these bases, but in one passage he treats of subtle earths, in another of mercurial, arsenical, and sulphureous parts. These three last he probably considered as constituent parts, and the metals as compounds. Air, water, and fire, are substances, according to this mineralogist, of which Nature avails herself in the formation of metals. He also supposes certain kinds of earths and stones to exist, which serve as the matrix for others, and which are indispensably necessary in the formation of minerals.

Zimmerman, the pupil of Henkel, is the first mineralogist who considers veins to have been formed by a transformation of the substance of the rock. Minerals, he says, are undoubtedly formed in the rock; but daily experience shews that the rock is not of itself capable of forming a metal, for were the mineralizing principle capable of converting it into a metal, we should find whole mountains which had undergone this change. But this change is only met with in certain directions, where the part of a rock, being thus transformed, constitutes veins. These veins, when they have not suffered an entire change, or when they do not contain perfect metals, are still of a different nature from the rest of the rock. An attentive examination will shew that they are of a decomposed and friable nature, appearing to have a tendency to return to this natural earthy state, from which we may conclude that these veins were originally the same as the rock, but that their texture had been altered and decomposed by some particular saline substance, which penetrated the rents and fissures, and had rendered them fit to be transformed into minerals.

Before noticing the theory of Von Opperl, which has since been adopted by Werner, we shall state the opinions of those geologists who, with Henkel and Zimmerman, suppose that veins have been filled by local causes which may still continue to operate; whereas Von Opperl and Werner conceive that they were formed by a general cause, the operation of which ceased before the present state of the globe. Lehman, in his treatise on the matrices of metals, published in 1753, says, "the veins which we find in mines appear to be only the branches and shoots of an immense trunk, which is placed at a prodigious depth in the bowels of the earth, but in consequence of its great depth we have not been able to reach the trunk. The large veins are its principal branches, and the inferior ones the twigs. What I have said," he adds, "will not appear incredible, when we consider that the bowels of the earth are, according to every observation, the workhouse where Nature carries on the manufacture of the metals; that, from the beginning of the world, she has been working at, and elaborating their primitive particles; that these particles issue forth, in the form of vapours and exhalations, to the surface of the globe through rents, in the same manner as the sap rises and circulates through vegetables by means of the vessels and fibres of which they are composed."

The latter part of the theory of Lehman, which supposes that changes are now taking place in the interior of the globe, by which metallic ores are still forming, has been supported by many geologists, who have had opportunities of extensive observation. Mr. Von Trebra, sub-director of mines in Saxony, in his work entitled "Observations on the Interior of Mountains," advances a theory nearly similar to that of Zimmerman, and agreeing in part with Lehman.

From the third letter of that work we make the following extract.

“ In explaining the phenomena which are observable in the interior of mountains (it must however be remembered, that I do not include such as are evidently of volcanic origin), I do not avail myself of those great causes which, by their magnitude, the suddenness of their action, and by their effects, produce sudden changes which take place under our eyes, such as subterranean fires, earthquakes, and the like. I refer these phenomena to natural causes, which, though less evident and slower in their operation, are no less certain of producing a radical transformation. Of this kind are putrefaction and fermentation. It is of little consequence by what name we distinguish this peculiar action exerted by Nature in the mineral kingdom; it consists in an intestine motion in the central parts of the globe, and appears to be produced by water combined with heat in different degrees of intensity. I observe such changes still going on, and can conceive them to continue so long as the same series of operations exist in nature. I am persuaded that there is constantly going on in our mountains a variety of transformations, compositions and decompositions, which not only take place at present, but will continue to the end of time.

“ Fermentation, if I may be allowed to call by that name this quality which acts by insensible degrees, produces the most perfect transformations in the bowels of the earth; fermentation I say may, according to my theory, alter the entire mass of a mountain; it may convert granite into gneiss, as this last only differs from the former in its structure, which is slaty or schistose; gneiss indeed has no other distinctive character than its structure, namely, the regularity and parallelism of its beds, and in some places a decomposed felspar approaching to clay. This fermentation may also convert greywacke into an argillaceous schist, which last may again by induration become jasper, when this process is either diminished or stopped. By it, also, quartz may be converted into clay, calcareous substances into quartz, and the whole mass of a mountain into inflammable or saline matter, or even into ores, metals, or semimetals. To it I ascribe the power of producing, preserving, and continuing to form the different beds and mineral repositories, which are found both in primitive and Sætz mountains: finally, the effects which the waters produce in filtering from above to below, and which in their passage through the different rocks may undergo some peculiar modification, appear to me the principal cause why this fermentation may act with more force in one part of the same mountain than in another.”

Patrin, a celebrated French mineralogist, considers the changes taking place in the mineral kingdom, as effected by a process somewhat similar to secretion in the animal and vegetable kingdoms, and ascribes a kind of mineral life to the earth itself, differing perhaps as much from vegetable life as the latter differs from that of animals. According to this theory, each kind of mineral substance is capable of converting masses of mineral matter into its own peculiar nature, as animals convert their aliment into flesh and blood. Whatever may be thought of this theory, we believe that those who are most practically conversant with the various phenomena and transmutations that occur in mines, will readily admit that many changes are taking place, which cannot be explained on any known chemical or mechanical principles, and which bear a strong resemblance in their effects to the process of secretion. Nor can it, even in the present state of chemical science, appear improbable that the different earths and metals may be converted into each other by natural processes. The different beds of rock intersected by metallic veins, are themselves metallic substances combined with oxygen; or, in

other words, all the rocks and strata which form the earthy parts of the globe, consist of oxygen combined with metallic bases; and as these metallic bases may perhaps be compounded of the same elementary parts united in different proportions, the transmutation of one earth or metal into another, may be effected by a simple change in the arrangement of the elementary molecules.

The theory of veins proposed by Von Oppel, and in part supported and extended by Werner, supposes veins to have been fissures originally formed by the desiccation of mountains, and the shrinking in of the mass. These fissures, being open at the top, were afterwards filled with their contents by metallic solutions poured in from above. Mountains, according to Werner, have been formed by a successive accumulation of different beds and layers, placed or heaped over one another. “ The substance of these beds was at first wet, and possessed little solidity; so that when the accumulation of matter had attained a certain height, the mass of the mountain yielded to its weight, and must consequently have sunk and cracked. As the waters which assisted in supporting the mass began to retire, and lower their former level, these masses then lost their support, and yielded to the action of their weight, opening, and falling to the side where the least resistance was opposed. The shrinking of the mass of a mountain produced by desiccation, and still more the fractures by earthquakes, and other similar causes, may also have contributed to the formation of fissures.

“ The same precipitation, which in the humid way formed the strata and beds of rock, furnished and produced the *substance of veins*. This took place when the solution, from which the precipitation was formed, covered the existing rents, which were as yet wholly or partially empty, and open in the upper part. Veins, whether considered as rents, or as the substance constituting the vein, have been produced at very different times; and the antiquity or relative age of each can be easily determined.”

Such, in Werner's own words, are the great outlines of his theory, a theory which we conceive to be decidedly opposed by all the most striking appearances existing in the mineral kingdom, and equally opposed to the simplest known and acknowledged laws of nature. If metallic veins were once open fissures, filled by precipitations from a solution that covered the whole globe, with the highest mountains in which metallic veins are found; it is obvious that these metallic precipitations would be most considerable in the lower parts of the surface, in valleys and plains, where the fluid must have been much deeper than on the summits and sides of mountains. We ought, therefore, to find thick beds of metallic matter covering and incrusting the low and level parts of the globe; but nothing is more rare than to find beds of metallic matter in low plains. Where beds of metallic matter exist, it is always in comparatively high countries, abounding in veins; and it is much more probable that the beds and veins were formed by local causes, and not from a solvent covering the whole globe. The metallic parts of this metalliferous ocean must have possessed the greatest specific gravity, and instead of floating on the top of the fluid, to be deposited in the fissures of lofty mountains, it would have descended by the laws of gravity, forming crusts of different degrees of thickness from the bottom to the top, increasing downward. The reverse of this is the fact. It is principally in alpine districts, and at enormous heights, that metallic matter is accumulated in the greatest abundance. It is in the heights of the Cordilleras of Peru that the productive mines of Potosi are situated: it is in the same chain of mountains, more

than 14,000 feet above the level of the sea, that the prodigious mass of mercurial ores is found at Guanaca Velica, where, in the space of two centuries, more than 15,000 quintals of this metal have been procured.

But the facts most opposed to the theory of Werner are those which we have stated, namely, that when a metallic vein passes through different strata, the mineral substances it contains generally vary in each stratum, either in kind or quality. Sometimes an entire change takes place, as from tin to copper or lead; in other instances, the vein will contain the same kind of ore in the different strata, but it will be invariably richer or poorer in some of the strata than in others, and there will be certain strata in which scarcely any ore occurs. Very frequently where the same kind of metallic matter is contained in the vein, it will be mineralized or combined with different substances, as the vein passes through different beds: thus we find a metallic sulphuret more prevalent in one part, and a metallic salt or oxyd in another part of the vein.

In Derbyshire, where the veins of lead pass through different beds of mountain lime-stone, which alternates with beds of basaltic amygdaloid, provincially called toad-stone, it is found that the vein scarcely ever contains lead as it passes through the toad-stone, where it is always much narrower, and in some places appears to be entirely cut off by it; but on sinking into the under beds of lime-stone, the vein is found again, and is as productive as in the upper beds. Where the vein can be traced through the toad-stone, it contains calcareous spar, and sometimes a few particles of lead-ore. If veins had been filled from above by metallic solutions, it is impossible to conceive that the nature of the rock could change the quality of the ore; much less could the ore disappear in one stratum, and appear again in a stratum below it. Professor Jameson, in a paper published in the Memoirs of the Wernerian Society, has attempted to explain the difficulty presented by the interruption of the veins in Derbyshire, on the supposition that the different beds of lime-stone and toad-stone, together with the metallic veins, were contemporaneous, and that the toad-stone cut through the veins at the period of their formation. On this hypothesis, Mr. Bakewell, in his Introduction to Geology, remarks: "The existence of different organic remains in the upper and lower beds of the mountain lime-stone in Derbyshire, precludes the possibility of these beds having been all formed at the same time. The zoophytes in the lower beds of rock could not be living and co-existent with the shell-fish in the upper, nor with the vegetables, the remains of which are occasionally found in the sand-stone that covers the whole, and into which the veins sometimes shoot. Cuvier has well observed, that the existence of different organic remains in the upper and lower strata offers inconceivable proofs that they were formed in succession over each other." In point of fact also, the veins are not always cut off by the toad-stone; but they are never productive of ore, where they pass through it, except in very small particles.

These facts are not less opposed to the igneous theory of metallic veins than to that of Werner. If metallic veins had been filled with their contents by the operation of subterranean fire, which cracked the surface, and injected the metallic matter in a state of fusion, it is impossible to conceive that the nature of the rock, through which the veins pass, could have produced any material change in the quality of the ore. Metallic ores may, in some instances, have been formed slowly by exhalations from subterranean fires; as specular iron-ore, and even gold, has been found in the craters of volcanoes; and the phenomena, presented by the

lava which destroyed Torre del Grecco in 1794, indicate the manner in which such ores are formed. The lava had buried entire houses for more than twelve months, at the latter end of which time it had considerably cooled; and when the houses were opened, pieces of iron were found converted into a state of black, red, and magnetic oxyds, having the hollow parts and interstices filled with a brownish-red transparent oxyd of iron, and with specular iron-ore. In the articles made of iron, which had undergone this change, the external form was scarcely altered, which evinces that the crystals had been produced by sublimation. Copper articles were changed into crystallized red oxyd of copper, and red oxyd with green and blue carbonate. From the absence of metallic sulphurets, it is inferred that the lava contained little, if any, sulphur. These changes shew that metallic matter may be sublimed and converted into the state of ore by subterranean heat, at a much lower degree of temperature than has been supposed.

There is a circumstance on which those who contend for the aqueous formation of metallic veins have laid much stress. In some instances, rounded pieces of stone, apparently resembling water-worn pebbles, have been found in mines at a considerable depth; but as many veins contain hollow spaces, through which water is continually running, the formation of pebbles might admit of a satisfactory explanation, without supposing that these pebbles had fallen in from above. The pebbles which we have seen of this kind, from the mines in Cornwall, are all of a chlorite schistus, and the form oblate, presenting the appearance which may frequently be observed in rocks of the same kind. It is in all probability an original formation, and not a breccia from pre-existing rocks.

There is another circumstance which appears to have escaped the attention of geologists. The water in the mines of Cornwall, particularly in the vicinity of copper veins, has a temperature considerably above that of the natural temperature of the earth: it is said to be at 70° Fahrenheit; and the working miners, from its sensible warmth, can predict with certainty the vicinity of a copper vein. The increase of temperature, if any, in the vicinity of tin veins is less sensible.

From hence, as well as from various appearances in mines, we are led to infer that there are certain chemical changes now going on in the interior of the earth; and it is from a more enlarged acquaintance with these phenomena, that we can alone expect to obtain a satisfactory theory of the formation of metallic veins.

The following is a summary account of the rocks and situations in which metallic ores are generally found.

Platina, and the recently discovered metals, palladium, rhodium, osmium, and iridium, have not been hitherto found in veins, but in the sands of rivers. The four latter metals are found as alloys in the grains of platina. See PLATINA, PALLADIUM, &c.

Gold and silver are found in veins, and disseminated in primary and transition rocks, in porphyry, sienite, and the lower sand-stone. Gold has been occasionally discovered in coal, and is very abundantly disseminated in the sands of some rivers. See GOLD and SILVER.

Mercury is found in slate, in lime-stone, and in secondary strata. See MERCURY.

Copper occurs in veins and beds in primary and transition rocks, in porphyry and sienite, and occasionally in sand-stone. Masses of native copper, of large size, are found on the surface of the ground, in the interior of North America. See COPPER.

Lead and zinc occur in veins, and disseminated in primary and

VEIN.

and transition rocks, except trap and serpentine, in the lower secondary strata, and in porphyry and sienite. See LEAD and ZINC.

Antimony occurs in veins in primary and transition mountains, except trap and serpentine.

Bismuth, cobalt, and nickel, occur in primary and transition mountains, except lime-stone, trap, and serpentine. Cobalt and nickel also occur in transition mountains, and in sand-stone. See BISMUTH, &c.

Arsenic occurs in veins, either as a sulphuret or mineralizer of other metals, in primary and transition mountains, and in porphyry. See ARSENIC.

Tellurium occurs in veins in porphyry, combined with gold. See TELLURIUM *Mines*.

Manganese occurs in beds and veins in primary and transition mountains, and in beds, and disseminated in red sand-stone. See MANGANESE.

Molybdena, tungsten, and titanium, occur in granite, gneiss, mica-slate, and argillaceous schistus. These metals, with chromium and cerium, are very rare, and can only be reduced to the metallic state with great difficulty. See MOLYBDENA, &c.

Mineral veins differ from metallic veins, being destitute of ores, and filled with the same substances which compose entire rocks, or with earthy minerals.

Quartz veins (see QUARTZ) resemble in their structure and position many metallic veins; and it not unfrequently happens that a vein, which contains metallic ore in one part, intermixed with quartz and other vein-stones, will, in another part, be entirely filled with quartz. Quartz veins intersect almost all primary and transition rocks, but are particularly abundant in rocks of argillaceous schistus and greywacke. (See ROCK.) The quartz in veins is most frequently white, and nearly opaque; and being much harder than the rocks which it intersects, it remains on the summits of mountains, after the surface of the rock is decomposed, until it is carried down by diluvial currents into the beds of rivers, where it becomes rounded by attrition, and is transported to distant districts. Most of the white quartz pebbles in England have probably been formed from the quartz veins of decomposed rocks, as no quartz of a similar kind exists as a rock in any part of England or Wales; but the same mineral abounds in veins.

Granite, argillaceous schist or slate, porphyry, greenstone, pitch-stone, basalt, and various other rocks, frequently form veins in mountains of the same kind with themselves, or in different rocks. Where a vein of one kind of rock intersects a rock of a similar kind, the substance of the vein generally differs from that of the rock in texture, colour, and other characters. The granite in veins, which passes through granitic rocks, will generally be coarser or finer grained than the rock which it passes through, and have the constituent parts differently mixed. The followers of Werner assert, that veins which contain rock substances have been filled from above by matter poured into the fissures, and that the granite in veins is of a secondary formation. They further maintain, that the lower rocks, which they consider as the older, never rise into the upper rocks in the form of veins. In opposition to this opinion, it has been discovered that veins of granite, in Cornwall, may be distinctly seen rising into the schist or killas which covers the granite rocks in many parts of that county, particularly at St. Michael's mount, east of Penzance, and at Mousehole, two miles west of that town. Where the junction of the granite and schist is exposed by the action of the sea, veins of the former rock may be traced, at low water, running in a zigzag form for many yards into schist, gradually

growing narrower, and terminating in small branches and strings. One circumstance we observed in these granite veins at Mousehole, which may deserve notice: the same vein which penetrated the schist, when it entered the granite, was different in texture from the granite rock, though it had the same constituent parts; it might be distinctly traced for a considerable distance into the granite. The granite also, in the vicinity of the schist, was smaller grained than the general body of the rock; and the schist, where in junction with the granite rock or granite veins, was changed to a kind of very fine-grained gneiss. These facts seem to indicate that both the granite and the schist, to a considerable distance from their junction, had been in a softened state at the same time, and that their consolidation was contemporaneous. Similar appearances, with an intermixture of veins of schist in granite, are presented at Glentilt, and other parts of Scotland. Veins of granite, porphyry, or schist, never penetrate the upper secondary strata; but veins of basalt and trap (see TRAP) have been found in every kind of rock, even penetrating chalk. These veins are sometimes of vast extent and width, and frequently occasion great dislocations and derangements in the stratified rocks, particularly in the coal strata, where they have been most observed; hence they are called faults. (See FAULT and STRATA.) The dislocation of the strata by a vein of this kind is represented in *Plate II. Geology, fig. 8*, where the different strata, *c, d, e, f, g*, on the left-hand side, are separated from the corresponding strata on the right, and considerably elevated.

As the veins of trap or basalt are nearly vertical, and often several yards in width, and the substance with which they are filled being frequently harder than the strata which they intersect, these veins remain when the surface is decomposed to a considerable depth, rising like a wall or fence, which, in the language of North Britain, is synonymous with *dyke*; hence such veins have been called *dykes*, or *whin-dykes*, the term whin-stone being used to denote basaltic rocks. (See WHIN-STONE.) Basaltic veins, or whin-dykes, vary in width from a few inches to several yards, and are sometimes more than one hundred yards wide. They often extend many miles in length; in other instances they terminate at shorter distances, forming irregular wedge-shaped masses. When basaltic dykes are of considerable width, the basalt is intersected by fissures; and sometimes the central parts and sometimes the sides are harder or softer than the other; and in some parts the basalt graduates into a dark ferruginous clay. Masses of basalt from the dyke are frequently found wedged in between the strata, extending to some distance; and where basaltic dykes intersect coal strata, the coal in the immediate vicinity of the dyke has frequently the appearance of being charred. At Corkfield-fell, in the county of Durham, the coal strata are cut through by a basaltic vein or whin-dyke, which is about seventeen yards wide. Where it comes in contact with the coal, the latter substance, for several feet, is converted into a pulverulent state, like foot. At a greater distance from the basalt, the coal is reduced to a coke or cinder, which burns without smoke, and with a clear durable heat. At the distance of fifty feet from the basalt, the coal is found in the state of common mineral coal. The roof over the coal is lined with bright crystals of sulphur, probably sublimed by heat from the pyrites common to coal. In these appearances we recognize every circumstance which might be expected from the agency of heat, but which would be extremely difficult to reconcile with the aqueous formation of basalt. We have seen similar appearances near basaltic dykes in Northumberland. The vein, or dyke, of basalt

at Cockfield-fell, is part of the longest dyke which has been traced in England, or perhaps in any other country. According to the description of it in Mr. Bakewell's Introduction to Geology, "it extends from the western side of Durham in an eastward direction, to Bewick in Yorkshire, crossing the river Tees at this place, and proceeding in the same direction through the Cleveland hills, in the East Riding of Yorkshire, to the sea-coast between Scarborough and Whitby. It rises to the surface, and is quarried, in many parts of its course, for stone to repair the roads. It crosses the turnpike near the seven mile-stone from Whitby to Pukering, where there is a quarry sunk in it. The vein, or dyke, is here about ten yards wide; the stone is a dark greyish-brown basalt, and is the principal material for mending the roads in the district called Cleveland. The extent of this dyke has been traced in a direct line about seventy miles. In its course it intersects the metalliferous lime-stone of Durham, the coal district, and the aluminous schistus. The circumstances attending this and other extensive dykes, which have not hitherto been regarded by geologists, completely invalidate," says Mr. Bakewell, "the theory, that these dykes were originally open fissures, formed by the drying or shrinking in of the rocks. As the different rock formations through which it passes contain different organic remains, they must have been formed in succession at different periods, and the metalliferous lime, with the lower strata, must have been consolidated long before the upper strata were deposited; and the causes which might dispose the upper strata to shrink and open, cannot be supposed to act on the lower rocks. It is also remarkable, that the width of this vein is more than twenty yards in the lower rocks on the west; but in the upper rocks it is not more than ten yards. The dyke must have been filled with its contents at the time of its formation, otherwise it would contain fragments of the rocks which it intersects. As it passes through the limestone, it has rendered it more crystalline in its vicinity, and the effects in charring the coal, before described, point to subterranean fire as the original cause of its formation, and as the source whence the basalt that fills it was supplied. The close resemblance between the basalt and compact lava, add probability to the opinion that this great dyke was originally formed by an expansive force operating from below, which opened a chasm in the surface of the earth, and ejected the contents in a state of fusion. A volcanic dyke was formed on the western side of Vesuvius, June 12, 1794, two thousand three hundred and seventy-five feet in length, and two hundred and thirty-seven feet in breadth, through which lava rose to the surface. This lava, when cooled, formed a wall of stone intersecting the former beds of lava, and constituting a real dyke. The stone has a dark-grey colour, and is in some parts so compact as to resemble horn-stone." See VOLCANO.

The effects of basaltic veins on the contiguous parts of the strata of sand-stone which they intersect, are no less remarkable. In some instances, the sand-stone appears very considerably indurated, and converted into a substance resembling horn-stone.

It is observed by Mr. Allan, Transactions of the Royal Society of Edinburgh, vol. vii. that the sand-stone which is thus indurated, contains calcareous earth, which appears to have promoted its semi-vitrification; but where the sand-stone remains unchanged in the vicinity of a dyke, the calcareous earth is wanting. Sir G. Mackenzie observed basaltic dykes in Iceland, the walls or sides of which were lined with a glassy substance resembling obsidian. These effects offer further illustration of the igneous origin of

basaltic veins. A very interesting account of the effect produced by basaltic veins on the different beds of rock at the Giants' Causeway, and on other parts of the same range on the north coast of Antrim, is given in the third volume of the Transactions of the Geological Society.

Various beds of columnar basalt, argillaceous lime-stone, and chalk, are intersected by perpendicular dykes or veins of basalt. The chalk in the vicinity often undergoes a remarkable change, extending eight or ten feet from the wall on each side, and thence gradually decreases. The part nearest the basalt is converted into a dark-brown crystalline lime-stone, like coarse-grained primitive lime-stone. The next strata is that of finer-grained primitive lime-stone, or faccharine lime-stone; then fine-grained arenaceous lime-stone. A compact variety, having a porcelain aspect, and a blueish-grey colour, next succeeds; this, towards the outer edge, becomes gradually white, and insensibly graduates into unaltered chalk. The flints in the altered chalk assume a greyish-yellow colour. The altered chalk is highly phosphorescent when subjected to heat. In other parts of the range, the argillaceous beds of lias appear converted into horn-stone by contact with the basalt, and contain in that state the imbedded fossils peculiar to the lias stratum. (See STRATA.) The basalt in some of the veins is columnar; but the columns lie horizontally. It has been conjectured, with some probability, that this has been caused by its passing from a state of igneous fluidity, and the refrigeration commencing from the sides. From the same cause, in the beds of columnar basalt in that range, (see GIANTS' Causeway,) the columns are perpendicular, the cooling commencing from the top and the bottom of each bed. The marine organic remains in the strata over the basalt, prove that the whole were formed under the sea. In some instances, basaltic veins appear to have been opened, and the intervening space filled with debris from the upper strata; and there are basaltic dykes in Northumberland, in which the basalt being divided into irregular masses, the interstices are filled with iron-clay, and contain impressions of ferns, like those in the coal strata which these dykes or veins intersect. On the whole, no country in the world which has yet been examined presents so many interesting appearances of basaltic veins as the northern parts of Great Britain and Ireland, nor are they any where exposed to the eye of the observer with so much distinctness as on many parts of the sea-coast, where the ocean has bared the surface, and exposed the most magnificent and instructive sections of entire mountains, penetrated by these veins to the height of many hundred feet. The veins may often be seen extending from the mountains into the sea, rising up like enormous walls, which serve as monuments of the ravages of the ocean upon the coast. The great hardness of the substance which fills the veins has prevented their destruction by the waves that have broken down and removed the mountain masses in which these veins were once imbedded.

Messrs. Lewis and Clarke, the American travellers, describe extensive walls of dark columnar stone ranging through the interior of North America: these walls were undoubtedly dykes or veins of columnar basalt, remaining where the surface of the ground had been washed away. There are also instances where the substance of basaltic veins has been softer than the surrounding rock, and is washed out wherever the rock is exposed, forming deep fissures, with perpendicular walls of rocks on each side. Such appearances are not uncommon on the sea-coast in various parts of Scotland. For an account of basaltic rocks, see TRAP.

VEIN is also applied to the streaks, or waves, of divers colours appearing on several sorts of woods, stones, &c.

as if they were really painted; and which the painters frequently imitate in painting waincots, &c.

Marble is generally full of such veins.

Lapis lazuli has veins like gold. Ovid, speaking of the metamorphosis of men into stones, says—"Quæ modo vena fuit, sub eodem nomine manfit."

Veins, in stones, are often a defect, proceeding usually from an inequality in their consistence, as to hard and soft: which makes the stone crack, and shiver in those parts.

VEJOURS, or VIEWERS, *Vifores*, in *Law*, are persons sent, by the court, to take a view of any place in question, for the better decision of the right.

It is also used for those sent to view such as esjoin themselves *de malo lecti*, whether, in truth, they be such as that they cannot appear, or whether they counterfeit.

VEIRAS, in *Geography*, a town of Portugal, in Alentejo; 15 miles N.N.E. of Estremos.

VEIRY, a town of France, in the department of the lake of Lemán: 9 miles E. of Seiffel.

VEISENBERG, a town of Russia, in the government of Revel, on the coast of the gulf of Finland; 56 miles E. of Revel. N. lat. 59° 22'. E. long. 26° 14'.

VEISENSHTEIN, a town of Russia, in the government of Revel; 32 miles S.E. of Revel.

VEIT, *St.*, a town of Germany, in the circle of Bavaria, and archbishopric of Salzburg, near the Salza; 28 miles S. of Salzburg.—Also, a sea-port town of Istria, called also *Fiume*, situated near the gulf of Venice, on a narrow plain, which yields good grapes, figs, and other fruits. The harbour is formed by the Fiumara. For the convenience of exportation and importation, the emperor Charles VI. caused an highway to be made from this place to Carlstadt, in Croatia. A sugar-house has also been founded here. *St. Veit* is exempt from taxes and contributions; 3 miles S.E. of Trieste. N. lat. 45° 46'. E. long. 14° 42'.—Also, a town of Germany, sometimes called *St. Weit*, in the duchy of Stiria; 3 miles S.E. of Pettau.—Also, a town of Germany, in the duchy of Carinthia, situated on the river Glan; 8 miles N. of Clagenfurt.—Also, a town of Germany, in the archduchy of Austria; 5 miles W. of Vienna.—Also, a town of Germany, in the archduchy of Austria; 11 miles W.S.W. of Freustadt.

VEITA, a small island in the Mediterranean, near the east coast of Tunis. N. lat. 35° 1'. E. long. 11° 12'.

VEITH, *St.* See *St. Veith*.

VEITSBERG, a town of Saxony, in the circle of Neustadt; 3 miles N.E. of Weyda.

VEITSHOCHHEIM, a town of the duchy of Wurzburg, on the Mayne; 20 miles S.W. of Schweinfurt.

VEL, in *Ancient Geography*, a town in the interior of Africa, and one of those which were subjugated by Cornelius Balbus. Pliny.

VELA, in *Geography*, a rocky shoal in the Spanish Main. N. lat. 15° 16'. W. long. 75°.

VELA, *Cape de la*, a cape on the N. coast of South America. N. lat. 11° 50'. W. long. 71° 46'.

VELABORI, in *Ancient Geography*, a people who inhabited the territory on the western coast of Hibernia, S. of the Gangani. Ptolemy.

VELACH, in *Geography*, a town of the duchy of Carinthia, at the union of the Campach and Moll; 11 miles N.N.W. of Saxenburg.

VELAGA, in *Botany*, *Gærtn. v. 1. 245. t. 133*, a name of Adanson's, adopted by Gærtner, and belonging to the genus now called *PTEROSPERMUM*; see that article, under which it should be cited as a synonym.

VELAINE, in *Geography*, a town of France, in the department of the Meurte; 6 miles E.N.E. of Nancy.

VELAM, a town of Hindoostan, in the country of the Nays; 34 miles E. of Calicut.

VELAMEN, is used, by some *Surgeons*, for the bag, skin, or bladder, of an imposthume, or swelling.

VELAMENTUM BOMBYCINUM, a name which some anatomists give to the velvet membrane, or inner skin of the intestines.

VELANGOODY, in *Geography*, a town of Hindoostan, in Marawar; 7 miles W. of Truman.

VELANI, in *Botany* and the *Arts*, sometimes called *Valonia*, a name given by the modern Greeks to the acorns of a species of oak, (see *QUERCUS Ægilops*, and *QUERCUS Infectoria*.) denominated the "Velanida." The tree grows on the western coast of Natolia, in the islands of the Archipelago, in those of Corfu and Cephalonia, and throughout all Greece. For an account of the galls of this oak, we refer to the article *GALLS*. The Orientals take care to gather the galls at the precise time which experience has proved to be most favourable, or in which the excrescence has acquired its full size and weight. For this purpose, they visit the hills and mountains that are covered with oaks. The first galls that are picked up are laid apart; these are known in the East under the name of "Yerli," and distinguished in trade by the terms of "black galls" and "green galls." Those which have escaped the first searches, and which are gathered a little later, called "white galls," are of a very inferior quality. The galls of the environs of Mosul and Tocat, and in general those which come from the eastern part of Turkey, are less esteemed than those of the environs of Aleppo, Smyrna, Magnesia, Karahissar, Diarbekir, and the whole interior of Natolia. The former are sold at Smyrna and at Aleppo two or three piasres less *per* quintal than the others. The inhabitants neglect to gather the acorns, which serve as food for the wild boars and goats; the latter contribute very much to render the oak small and stunted, by devouring, with its fruit, a part of its foliage and young boughs.

The diplopepis which produces these galls has a body of a fawn-colour, with the antennæ dark, and the upper part of the abdomen of a shining brown. It is sometimes found, under its latter form, in the inside of the galls which are not yet pierced. On the same oak are found other galls in great numbers, which the inhabitants neglect to gather, because they are not fit for dyeing.

The velani, or valonia, is gathered in the autumn, and dried under sheds, which protect it from rain, and is in a proper state for shipping about the beginning of March: that which is gathered on the mountains is preferred to that of the valleys. There is also a difference with respect to its age or size; the small and young is taken from the trees before it has attained its full growth, and is reckoned better than the large, or that which remains till it is full grown. Those of the best quality are usually sent to England, and the inferior to Ancona and Trieste. This gall is used for dyeing and tanning, and in Turkey a considerable quantity is consumed for the latter purpose.

The quantity shipped annually from the different Turkish ports may be calculated at from 4000 to 5000 tons. It is sent to several places in Europe; particularly London, Liverpool, Leghorn, Trieste, Ancona, and Genoa. The nut, or kernel, of the valonia is not reckoned of any value, and is sometimes picked out to save freight and charges. The loss in weight thus occasioned, together with garbling, (that is, freeing it from dirt, stones, &c.) is from 10 to 25 *per cent.*, according to the quality of the article, and the expence

expenſe is from 30s. to 40s. *per* ton. The cup which contains the nut or kernel conſtitutes the value of the valonia. It has been uſed in this country many years by the dyers, and has lately been introduced into the tanneries as a ſubſtitute for oak-bark, and the quantity uſed in this way has been very conſiderable. The quantity imported into London and Liverpool for the years 1811, 1812, 1813, amounted to above 1200 tons *per annum* on an average. This was at a time when oak-bark was ſcarce and dear; but when the price of bark is low, the conſumption of velani is leſs extenſive; for the leather manufactured with oak-bark is preferred to that prepared with velani, chiefly on account of its colour, as the quality of the leather is reckoned to be equal, if not ſuperior, to that which is tanned with bark. We may here obſerve, that the great diſtance from which valonia, or velani, is brought, and the heavy duty it pays, compared with oak-bark, diſcourage its uſe; but if the duty ſhould be taken off, it is probable that the conſumption would be greatly increaſed.

VELANIDA, in *Botany*. See QUERCUS, n. 68.

VELARIUS, in *Antiquity*, an officer in the court of the Roman emperors, being a kind of uſher, whoſe poſt was behind the curtain, *vela*, in the prince's apartment; as that of the chancellors, *cancelli*, was at the entry of the baluſtrade, and that of the *oſtarii* at the door.

The velarii had a ſuperior, of the ſame denomination, who commanded them; as we find in two inſcriptions, quoted by Salmalius in his notes on Vopiuſcus, and by a third in Gruter.

VELASCO, DON ANTONIO PALOMINO, in *Biography*, was a Spaniſh painter and hiſtorian of the artiſts of his country. He was a native of Valencia, where he flouriſhed about 1700. He was painter to Philip V., and painted many pictures for the churches and convents of Valencia, Salamanca, and Grenada, but is much better known to us as an author. He publiſhed an elaborate treatiſe on the art of painting, in two folio volumes, in which he notices 250 painters and ſculptors who had flouriſhed in Spain previous to the concluſion of the reign of Philip IV. Of this work, there was an abridgment publiſhed in London in 1742, entitled "Las Vidas de los Pintores y Statuarios eminentes Eſpanoles," of which there is an Engliſh tranſlation.

VELASCO, in *Geography*, a town of North America, in the province of Mexico.

VELASQUEZ DE SILVA, DON DIEGO, in *Biography*, the moſt diſtinguiſhed painter of the Spaniſh ſchool, was born at Seville in 1594. His parentage was noble, being of a family originally of Portugal, which had eſtabliſhed itſelf in Andaluſia. Though confined in fortune, they gave him a liberal education, and, as he had evinced much inclination for drawing, placed him with Franeſco de Herrera, the elder; but he afterwards became the diſciple of F. Pacheco, an artiſt of very conſiderable ability, and a ſcholar, then reſiding at Seville. With him Velasquez ſtudied attentively, and his talents diſplayed themſelves in a variety of imitations of natural objects, particularly of peaſantry in their peculiar habits and occupations. Of theſe we have now a ſpecimen in England, which had at all times been eſteemed as a maſter exhibition of his early acquirements, and celebrated under the appellation of the "Water Carrier." It was ſtationed in the new palace at Madrid, but was removed from thence by Joſeph Bonaparte, and was found, with a great number of other pictures, in the imperial carriage taken at the battle of Vittoria. It is now in the poſſeſſion of the duke of Wellington, among the numerous other trophies of that great man's fame. Still, however, it is conſidered by his grace as the property of the Spaniſh crown. Velasquez continued attached to this particular application of

his art, conſcious of his ſuperiority, and declining to extend his views to a more elevated claſs of ſubjects, till at length the ſight of ſome pictures by Guido and Caravaggio, which Pacheco had received from Italy, excited his emulation, and he then turned his thoughts to hiſtory and portraiture. After he had been five years with Pacheco, that maſter beſtowed upon him the hand of his daughter in marriage, and he continued ſtill to praſtiſe his art under the guidance of that able inſtructor. In 1622, Velasquez left Seville, to viſit the metropolis of Spain and the Eſcurial, and there his talents recommended him to the notice of the count De Olivarez, the favourite miniſter of Philip IV., who patronized and befriended him; taking him into his own palace to dwell. Soon after he introduced him to the king, who immediately ordered him to paint his portrait. From the completion of this picture, which was upon a grand ſcale in armour, and on horſeback, the reputation of Velasquez was eſtabliſhed above all his contemporaries, and his patron was ordered to inform him, that from that time the royal perſon would be intruſted to no other painter but himſelf. He received the royal permiſſion to make a public exhibition of it, when it was loudly applauded by all about the court, and held up to public eſtimation by laudatory verſes in its honour from the poets.

After this ſucceſsful commencement of his public career, he was employed to paint the portraits of the infants Don Carlos and Don Fernando; and that of the miniſter, his patron, mounted, like his royal maſter, on a noble Andaluſian charger, richly caparifoned. He now, therefore, began to enjoy the bleſſings of fortune, as well as thoſe of fame. He was appointed principal painter to the king, with a liberal ſalary, beſides receiving munificent remuneration for his pictures, and being buſily occupied in portraits.

He now alſo, in emulation of other Spaniſh painters, determined to undertake a work upon a more extended ſcale than he had before done, and took for his ſubject the expulſion of the Moors from Spain by Philip III. But, if we may judge by the deſcription given of the picture, it does not appear to have poſſeſſed much intereſting matter of a high hiſtoric quality; however, he gained great reputation from the ſkill with which he executed it. The compoſition repreſented the king armed, and in the act of commanding a party of ſoldiers, who are eſcorting a group of Moors of different ſexes and ages to the ſea-ſhore for embarkation. On the other ſide is perſonified the kingdom of Spain, as a maſtetic matron, with a ſtately edifice. This picture, as appears by an inſcription upon it, was painted in 1627, and it was no ſooner completed than he again experienced the munificence of his ſovereign, who made him one of his chamberlains, and allowed him an additional ſtipend.

It was at this time that Rubens viſited Madrid. He formed an intimacy with Velasquez, and firſt inſpired him with a deſire to viſit Italy; and he obtained from his royal patron every advantageous means of going there, with recommending letters to render his residence in Rome and Venice as uſeful and agreeable to him as poſſible.

He embarked at Barcelona in 1629, and firſt landed at Venice, where he was received and entertained by the Spaniſh ambaffador. In this delightful birth-place of colouring, the works of its great maſter Titian, in the palace of St. Marc, excited his warmeſt admiration, and he made ſeveral copies of them: and no one ever more thoroughly imbibed the principles upon which they are conſtructed. But perhaps it is of Tintoretto that Velasquez is more the imitator, than of Titian. His freedom of pencil appears to have been more congenial with the taſte of the Spaniard, than the ſober and more correſt hand of the former. After remaining at Ve-

nice a few months, he went to Rome, where he was most graciously received by the cardinal Barberini, nephew to Urban VIII., who procured for him apartments in the Vatican, and access at all times to the works of Raffaele and M. Angelo. During his residence at Rome, he painted his celebrated history of Joseph's coat brought to Jacob; and also another very able work, of Apollo informing Vulcan of the infidelity of Venus; in which he had an opportunity of displaying his power of handling, and his admirable skill in colouring. Vulcan is at his forge, the light and shadow proceeding from which are most skilfully conducted: the strong and muscular forms of the Cyclops gracefully contrasted with the pure form of the Apollo; and the whole composition arranged with infinite judgment. Both these pictures were sent to Spain, and honoured by having distinguished places assigned to them in the palace of the king.

On his return home he went to Naples, and there painted the portrait of Donna Maria of Austria, queen of Ferdinand III. After about the lapse of a year and a half, he arrived at Madrid, and found his favour with his royal master undiminished. He was again lodged in the royal palace, and the king kept a key of his painting room, that he might have free access to him without ceremony; and this he frequently indulged himself with, as his great predecessor, Charles V., had done with Titian. And so strong were the resemblances in his pictures, that it is said the king, going into his room one day, expressed some surprize, that a nobleman, to whom he had given a commission which required his absence from Madrid, had not departed, imagining that he saw him in the room, when it was in reality only his portrait.

In 1638, Velasquez painted his most celebrated picture of our Saviour on the Cross, for the convent of St. Placido, at Madrid; and about the same time, that of the general Pescara receiving the keys of a Flemish citadel from the governor of the place. The management of all the different characters, the officers, &c. and the effect of the fortification, &c. of the town and landscape in the back-ground, is altogether eulogized by Mengs as the chief-d'œuvre of Velasquez.

Though his patron d'Olivarez fell into disgrace in 1643, yet Velasquez maintained his interest at the court; and in 1648, was commissioned by the king on a particular embassy to pope Innocent X., and at the same time was empowered to purchase for his majesty the finest works of art, both of sculpture and painting, which he could procure in Italy. On this occasion he embarked at Malaga, and having landed at Genoa, passed through Milan and Padua to Venice, where he was well pleased to renew acquaintance with the great masters of art, whom he had before beheld with so much admiration. He afterwards visited Bologna; and on his arrival at Rome, was received with great favour and distinction by the pope; and in the unengaged moments of his more serious business, he painted a very fine portrait of his holiness, of which there is a capital exemplar at Luton, the seat of the marquis of Bute, which has every character of originality. For this painting, the pope gave him a gold medal and chain; and the academicians of St. Luke elected him of their body.

After a lapse of nearly three years, Velasquez took his departure from Genoa, in a vessel freighted with a magnificent collection of pictures, statues, busts, &c. which he had collected, and on his arrival was most graciously received by the king, and honoured with further marks of his royal favour and bounty; among which the order of Santiago was not the least, as being confined to persons of the highest rank, or the most eminent abilities. He thus lived,

in honour and riches, till 1660, when the ruthless hand of death put an end to his labours and enjoyments. He was buried with great funeral pomp in the church of San Juan.

VELATODURUM, or **VELATUDURUM**, in *Ancient Geography*, a place on the route from Befançon to Epamandodurum or Mandura.

VELAUNI, a people of the Maritime Alps near the sea, E. of the Nerufii.

VELAUR, in *Geography*, a river of Hindooftan, which rises near Attore, in the Mysore country, and runs into the bay of Bengal, near Portonovo.

VELAY, before the revolution, a country of France, in Languedoc, situated to the W. of the Vivarais, and the E. of Auvergne. It is mountainous, but fertile: Le Puyen Velay was the capital. It now constitutes the department of the Upper Loire.

VELAZGHERD, a town of Persia, in the province of Kerman; 54 miles N.E. of Gomron. N. lat. 28° 10'. E. long. 56° 34'.

VELBERG, a town of Germany, in the territory of the imperial town of Hall; 7 miles E. of Hall.

VELBERT, a town of the duchy of Berg; 5 miles N.N.E. of Medman.

VELBURG, a town of Bavaria, in the principality of Neuburg; 12 miles N. of Dietfurt. N. lat. 49° 10'. E. long. 11° 28'.

VELCERA, in *Ancient Geography*, a town on the coast of Illyria, between the mouth of the river Cœneus and the town of Senia. Ptolemy.

VELDEN, in *Geography*, a town of Bavaria; 6 miles S.S.W. of Landshut.—Also, a town of Germany, in the territory of Nuremberg, on the Pregnitz; 21 miles N.E. of Nuremberg. N. lat. 49° 37'. E. long. 11° 31'.

VELDÉNTZ, a town of France, in the department of the Sarre, formerly capital of a county, in the circle of the Upper Rhine, united with the palatinate; the environs are celebrated for an excellent Moselle wine; 17 miles E.N.E. of Treves. N. lat. 49° 55'. E. long. 6° 58'.

VELEGIA, in *Ancient Geography*, a town of Africa, in Libya Interior, situated on the banks of the river Niger, N. of it. Ptolemy.

VELEIA, a town of Hispania Citerior.—Also, a town of Italy, S. of Placentia, in Gallia Cispadana: now in ruins.

VELEN, in *Geography*, a town of Germany, in the bishopric of Munster; 22 miles W. of Munster.

VELETRI, a town of the Popedom, in the Campagna di Roma. This was a very ancient town, and considerable in the time of the first Roman kings. It was taken by Ancus Martius, fourth king of the Romans, and retaken by the Volscians, under the command of Coriolanus. The Romans took it again some time after, and, removing the inhabitants, filled it with a Roman colony. It is the see of a bishop, united with Ostia, who is called the bishop of Ostia, but his residence is at Veletri; 28 miles N.N.W. of Terracina. N. lat. 41° 42'. E. long. 12° 50'.

VELEZ, a town of South America, in New Grenada; 100 miles from Santa Fé de Bogota. N. lat. 5° 50'. W. long. 73° 16'.

VELEZ de Gomera. See GOMERA.

VELEZ Malaga, a sea-port town of Spain, in the province of Grenada, near the coast of the Mediterranean. The chief article of trade is raisins. In 1487, this town was taken from the Moors by Ferdinand, king of Castile and Arragon; 13 miles E. of Malaga. N. lat. 36° 47'. W. long. 4° 18'.

VELEZ *el Rubio*, a town of Spain, in the province of Granada, near the Guadalentin. This town was, in the time of the Moors, a strong place, and furnished with a garrison; 14 miles S. of Huéca.

VELEZAR, a river of Spain, formed by the union of the little rivers Burcia and Sil, on the confines of Leon, which, after receiving several other small streams, unites with the Minho, a little above Orense.

VELEZIA, in *Botany*, was so named by Linnæus, at the recommendation of his pupil Læfing, in honour of Dr. Christoval Velez, examiner, first physician, and demonstrator of botany, at Madrid, who shewed Læfing his manuscript *Flora* of the environs of that capital, which we do not find to have ever been published.—Linn. Gen. 176. Schreb. 174. Willd. Sp. Pl. v. 1. 1329. Mart. Mill. Dict. v. 4. Sm. Prodr. Fl. Græc. Sibth. v. 1. 283. Ait. Hort. Kew. v. 2. 109. Juss. 302. Lamarck Illustr. t. 186. Gærtnd. t. 129.—Class and order, *Decandria Digynia*. (Pentandria, or Hexandria, Digynia, Linn.) Nat. Ord. *Caryophylleæ*.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, long and slender, with five angles, five intermediate furrows, and five pointed, erect, small teeth, permanent, without any appendages at the base. *Cor.* Petals five; claws linear, erect, very narrow, the length of the calyx; limbs spreading, oblong-wedged-shaped, cloven or toothed, hairy at the base, much shorter than the claws. *Stam.* Filaments ten, capillary, about the length of the calyx, inserted into the receptacle; anthers roundish, incumbent. *Pist.* Germen superior, cylindrical, short; styles two, thread-shaped, hardly so long as the stamens; stigmas simple. *Peric.* Capsule cylindrical, slender, of one valve and one cell, opening with four teeth at the summit. *Seeds* numerous, oblong, alternate, imbricated downwards, concave in front, convex at the back, inserted in a simple row, by the dorsal scar, into a thread-shaped, unconnected receptacle.

Eff. Ch. Calyx of one leaf, nearly cylindrical, furrowed, naked. Petals five, with very long claws; limb bearded at the base. Capsule superior, cylindrical, of one cell. Seeds imbricated.

A small genus of slender campion-like plants, with numerous little pink flowers, nearly related to *SAPONARIA*, (see that article,) and certainly to be placed next to it in the artificial, as well as natural, system. Linnæus knew but one species. We have a new one found by Dr. Sibthorp in Asia Minor.

1. *V. rigida*. Rigid Velezia. Linn. Sp. Pl. 474. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 390, unpubl. (Knawel majus, foliis caryophylleis; Buxb. Cent. 2. 41. t. 47. *Lychnis minima rigida* Cherleri; Bauh. Hist. v. 3. 352. *L. corniculata minor*; Bocc. Mus. 50. t. 43. Barrel. Ic. t. 1018, and probably t. 1017.)—Calyx thread-shaped, downy. Petals cloven.—Native of the south of France, Italy, Crete and Cyprus, flowering in summer. A hardy inconspicuous annual, sometimes introduced, for the sake of curiosity, into our botanic gardens. *Root* long and thread-shaped, tough. *Stems* several, diffuse, hairy, zigzag, about a span long, leafy, many-flowered. *Leaves* linear, awl-shaped, sessile, opposite at each joint of the stem, a little downy or hairy, hardly an inch long. *Flowers* axillary, solitary, sessile. *Calyx* extremely slender, and of uniform thickness, near an inch long, striated. *Limb* of the *corolla* spreading scarcely a quarter of an inch, pink, with a deep crimson angular mark on each *petal*, forming a central star. Five of the *stamens* longer than the rest. *Capsule* slender, smooth, semi-pellucid. *Seeds* black.

2. *V. quadridentata*. Four-toothed Velezia. Sm. Prodr. Fl. Græc. Sibth. n. 954. Fl. Græc. t. 391, unpubl.—Calyx club-shaped, smooth. Petals with four teeth.—Gathered by Dr. Sibthorp in Asia Minor, and, if we are not mistaken, in the isle of Patmos. This has the precise habit of the foregoing, but is rather larger, and quite smooth. The *flowers* are stalked. *Calyx* angular, swelling upwards. *Limb* of the *corolla* marked like *V. rigida*, with a central star; but each *petal* has four strong teeth, or acute lobes, instead of being only simply cloven. Each *claw* is crowned, in both species, with a transverse row of white hairs. *Stamens* in the present all of equal length. *Capsule* rather stouter, shorter, and less accurately cylindrical, than the former.

We have no doubt of this genus being equally distinct from *SAPONARIA* and *GYPSOPHILA*, (see those articles,) though the first species betrays most affinity to the former, the second to the latter. An ovate, even *calyx*, and oblong *capsule*, are proper to *Saponaria*; a bell-shaped angular *calyx*, and almost globular *capsule*, to *Gypsophila*. *Velezia* is perhaps more naturally akin to *DIANTHUS*, but wants the scales at the bottom of the *calyx*.

VELHAS, in *Geography*, a river of Brazil, which runs into the Parana.

VELIA, or HELIA, in *Ancient Geography*, a town of Italy, in Lucania, westward, on a small gulf of the same name, formed by the small stream Heles, from the Greek *Helia*, signifying a marsh.—Also, a town of Hispania Citerior, belonging to the Caristi. Ptolemy.

VELICALA, in *Geography*, a town of California, near the coast of the Pacific ocean. N. lat. 20° 35'. W. long. 115° 50'.

VELIDIA, a town of Morocco, on the coast of the Atlantic; 25 miles S.W. of Mazagan.

VELIKA, a town of Morlachia; 25 miles S.E. of Segna.—Also, a river of Croatia, which runs into the Save, near Craliova Velika.—Also, a river of Russia, which runs into the Viatka, 10 miles N.E. of Orlov, in the government of Viatka.—Also, a river of Russia, which runs into the Tchudskoi lake, near Pskov.

VELIKIE LUKI, a town of Russia, in the government of Pskov, on the Lovat; 124 miles S.E. of Pskov. N. lat. 56° 28'. E. long. 30° 14'.

VELIKOI, a small island of Russia, in the White sea. N. lat. 66° 45'. E. long. 32° 20'.

VELILLA, a town of Spain, in the province of Aragon. The author of the "Continuation of Mariana's History of Spain," speaks of a bell in this town of great celebrity, which rung sometimes without the help of man; and that a particular description of its wonders was printed at Madrid in 1657.

VELINO, a mountain of Naples, in Abruzzo Ultra; 12 miles S. of Aquila. This is one of the Apennines, and probably the highest of them. Its summit, 8397 feet above the Mediterranean, is covered with snow in June; about 46 geographical miles N.W. of Rome.—Also, a river of the Popedom, which runs into the Nera, about four miles from Terni, in the duchy of Spoleto.

VELINUS, (VELINO,) in *Ancient Geography*, a small river in the country of the Sabines, in the northern part: its sources were about twenty miles from Reate, towards the E., in mountains abounding with water. It passed southward, by a place called Vacunis, afterwards by Interoceca, where it turned towards the W., to the plain on which was situated Cutilie. Changing its direction towards the N.W., it entered an immense plain, in which were high mountains, and formed a large lake. These stagnant

flagrant sulphureous waters were found very inconvenient. M. Curius pierced a mountain and made a canal to the Velinus, so that its waters had a free passage to the sea, by a valley, which Cicero compared to the valley of Tempé. The inhabitants of Reate found here abundance of roses, whence they called it *Rosea*. The Velinus discharged itself into the Nar near Interamna.—Also, one of the seven mountains of Rome.

VELIOPASSES, *Velocassis* of Cæsar, *Vellocassis* of Pliny, and *Veneliocassii* of Ptolemy, were a people joined by Cæsar to the Caleti, and others among the Belgæ, separated by the Seine from the Celtæ. But in the division of Gaul by Augustus, the Veliocasses, as well as the Caleti, are placed in the Lyonnese, and they are referred to in that province by Ptolemy and Pliny. Their capital, Rotomagus, became the metropolis of the second Lyonnese, when the Lyonnese of Augustus was divided into two provinces.

VELISCUM, a place of Africa, in Mauritania Cæsariensis, upon the route from Rufocurrum to Celama, between Sufasar and Taranamusa Castra. Anton. Itin.

VELITES, in the *Roman Army*, one of the four kinds of foot soldiers that composed a legion, who were armed lightly with swords, bows and arrows, slings, and javelins.

For defensive armour they had only a small target, and a helmet or head-piece.

These were commonly young men of mean condition, and took their name à *volando*, or à *velocitate*, from their swiftness and expedition: and they were designed for skirmishing with the enemy before a battle, and pursuing them after a defeat.

They seem not to have been divided into any distinct bodies or companies, but to have hovered in loose order before the army.

The other classes of the Roman infantry were the *hastati*, *principes*, and *triarii*. In the day of battle, the hastati were placed in the first line, the principes in the second, and the triarii in the third. The Velites formed small flying parties both in front and rear. See BATTLE.

VELITIS, in the *Natural History of the Ancients*, the name of a peculiar sort of sand used in the manufacture of glass; for which purpose they always chose such as was found washed clean on the banks of rivers; and this they therefore called glass-sand, or *velitis*, or *hyalitis*.

VELITRÆ, or VELETRI, in *Ancient Geography*, a town of Italy, in Latium, in the country of the Volscians. It was at some distance from the Appian way, S.E. of Alba, and became considerable under the Romans. It had an amphitheatre, of which no trace now remains. Two roads led to Velitræ; one to the W. detached itself from the Appian way, the other to the E. communicated with the Latin way. See VELETRI.

VELIZ, in *Geography*, a town of Russia, in the government of Polotsk; 88 miles E. of Polotsk. N. lat. 55° 20'. E. long. 31° 4'.

VELL, in *Rural Economy*, a term applied in some districts to the bag or stomach of the calf, which is used in making running or runnet; or to the prepared stomachs of the animals or rennet for curdling the milk in cheese-making, which are often called *vells*. In some dairies, instead of making the rennet ready some time previous to its being used, a small piece, proportioned to the quantity of milk to be coagulated, is cut from the vell the over-night, and put into half a pint of water, or whey, to infuse until the morning. In this case, the vells are to be supposed to be equal in goodness; and it is probable, that the virtue may not be so fully extracted as by a longer infusion. It is suggested too as not improbable, but that the strength

of the rennet might be ascertained by means of experiment, by the application of alkaline salt, and by such means be rendered more certain in its use. See DAIRYING.

VELLA, in *Botany*, an old Latin name, used by Galen, and supposed to belong to the Water-cress. De Theis traces it from *Velar*, *Veler*, or *Belar*, Celtic appellations of some plant or plants of the cress kind; and the first of which Pliny gives as synonymous with *Erysimum*. Linnæus, finding the word unoccupied in modern botany, adopted it for a genus of the same family and qualities as the ancient *Vella*.—Linn. Hort. Cliff. 329. Gen. 331. Schreb. 435. Willd. Sp. Pl. v. 3. 422. Brown in Ait. Hort. Kew. v. 4. 79. Sm. Fl. Brit. 675. Prodr. Fl. Græc. Sibth. v. 2. 4. Juss. 241. Lamarck Illustr. t. 555. Gærtn. t. 141.—Class and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siliquosæ*, Linn. *Crucifera*, Juss.

Gen. Ch. *Cal.* Perianth inferior, cylindrical, erect, of four linear, obtuse, closely converging, deciduous leaves. *Cor.* cruciform, of four obovate spreading petals, whose claws are the length of the calyx. *Stam.* Filaments fix, as long as the calyx, the two opposite ones rather shorter; anthers simple. *Pist.* Germen superior, ovate; style greatly dilated, bordered, leafy, ovate; stigma obtuse. *Peric.* Pouch orbicular, tumid, entire, of two cells, crowned with the permanent, ovate, erect, rigid style, which is a continuation of the membranous partition. *Seeds* several, roundish; "their cotyledons folded;" *Brown*.

Obf. *V. Pseudo-cytifus* has the four larger filaments destitute of anthers, and combined together in pairs. *Linnaeus*.

Ess. Ch. Pouch tumid, crowned with the leafy ovate style. Cotyledons folded. Calyx closed.

1. *V. annua*. Annual Cress-rocket. Linn. Sp. Pl. 895. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1442. (Nasturtium sylvestre valentinum; Clus. Hist. v. 2. 130. Bauh. Hist. v. 2. 920. Eruca nasturtio cognata tenuifolia; Ger. Em. 247, good.)—Leaves pinnatifid. Pouches pendulous.—Native of sandy fields in England, Spain and Greece. With us it is a very rare plant, scarcely ever observed but on Salisbury Plain, about Stonehenge, where it was first gathered by Mr. Isaac Lawson, in Ray's time, and has occasionally been seen since, flowering in June. The root is fibrous, small and annual. *Seed-leaves* permanent for some time, inversely heart-shaped, smooth. *Herb* variable as to luxuriance, erect; its stem about twelve or fifteen inches high, alternately branched, bushy, leafy, rough with deflexed bristles. *Leaves* alternate, doubly pinnatifid, roughish, with narrow blunt segments. *Spikes* terminal, many-flowered. *Calyx* purplish. *Petals* entire, sulphur-coloured, with purple veins. *Pouch* turned downwards as it ripens, about the size of a hemp-seed, rough, crowned with the smooth, spatulate, enlarged style, twice its own length. *Seeds* roundish, three or four in each cell.

2. *V. Pseudo-cytifus*. Shrubby Cress-rocket. Linn. Sp. Pl. 895. Willd. n. 2. Ait. n. 2. Cavan. Ic. v. 1. 32. t. 42. (Cytifis facie Alysson fruticans quorundam; Lob. Ic. v. 2. 49. Cytifus adulterinus, five Alysson fruticans; Ger. Em. 1306.)—Leaves undivided, obovate, fringed. Pouches erect.—Native of the neighbourhood of Aranjuez in Spain, flowering in May. Sometimes kept for curiosity as a hardy greenhouse plant, but not remarkable for beauty. The stem is shrubby, branched, roughish, two feet high. *Leaves* alternate, rather fleshy, entire, rough, scarcely an inch long, tapering down into a short footstalk, and generally accompanied by two smaller leaves. *Flowers* in long spikes, yellow, with pale veins. Permanent style broad,

nearly orbicular, scarcely longer than the *pouch*. Cavanilles says he found all the *anthers* perfect, though Linnæus is correct in his description of the combined *filaments*.

VELLA, or *Verra*, in *Geography*, a river of the Ligurian republic, which runs into the Magra, three miles above Sarzana.

VELLACHERY, a town of Hindoostan, in the Carnatic; 10 miles S.E. of Madura.

VELLADY, a town of Hindoostan, in Myfore; 14 miles S. of Damicotta.

VELLAS, a town of the island of Ceylon; 44 miles W.N.W. of Candi. N. lat. $7^{\circ} 45'$. E. long. $81^{\circ} 16'$.

VELLATOOR, a town of Hindoostan, in Myfore; 5 miles E. of Coimbatore.

VELLECHYPALEAM, a town of Hindoostan, in Myfore; 13 miles N. of Coimbatore.

VELLEIA, in *Botany*, received its name from the author of the present article, in honour of his highly valued friend Col. Thomas Velley, F.L.S., author of a descriptive work on the Submarine Plants of Britain, with coloured plates, in folio, consisting of only one fasciculus. This amiable and accomplished botanist was unfortunately killed by accident, a few years since, in the town of Reading, as he was travelling between Bath and London.—Sm. Tr. of Linn. Soc. v. 4. 217. Brown Prodr. Nov. Holl. v. 1. 580. Labillard. Nov. Holl. v. 1. 54. (Euthales; Brown Prodr. Nov. Holl. v. 1. 579. Ait. Hort. Kew. v. 1. 363.)—Class and order, *Pentandria Monogynia*. Nat. Ord. *Camparaceæ*, Linn. *Campanulaceæ*, Juss. *Goodenovicæ*, Brown.

Gen. Ch. *Cal.* Perianth inferior, unequal, either of three or five roundish leaves, or of one leaf in five segments, the upper division largest, permanent. *Cor.* of one petal, irregular; tube rather longer than the calyx, split longitudinally at the back, almost to the base, more or less tumid, or spurred, underneath; limb in five rather unequal, spreading, bordered, broad-keeled segments, almost two-lipped. *Stam.* Filaments five, thread-shaped, shorter than the tube, inserted into its membranous base, alternate with the segments of the limb; anthers erect, oblong, unconnected, of two cells, bursting lengthwise. *Pist.* Germen superior, turbinate; style angular, rather longer than the stamens; stigma thick, obtuse, encompassed with a membranous, cup-shaped, abrupt integument. *Peric.* Capsule of one cell and four rigid valves. *Seeds* several, orbicular, compressed, roughish, imbricated on both sides of a central receptacle, shorter than the valves.

Eff. Ch. Calyx inferior, three or five-cleft, unequal. Corolla tubular, five-cleft, two-lipped; tube cloven at the back. Capsule of four valves and one cell. Seeds imbricated, orbicular, compressed.

Obs. Mr. Brown's *Euthales* is so strictly united in habit and character, except the *calyx*, with our *Velleia*, that we cannot but consider it as of the same natural genus. Our learned friend, from whom we always scruple to differ, has discovered some acknowledged *Velleia* with five leaves to the *calyx*, instead of three, originally attributed to it. Here then is an approach toward the five-cleft, though single-leaved, *calyx* of *Euthales*. Linnæus has declared, Phil. Bot. sect. 170, "*Raro observatur genus in quo pars aliqua fructificationis non aberrat.*" The *calyx* appears to be the part in *Velleia* which runs wild, if we may so translate it, and strikingly confirms the above maxim. We may extend this observation to the whole order of Mr. Brown's *Goodenovicæ*, in which even the situation of the *calyx*, whether superior or inferior, is not uniform; which circumstance must lead us to mistrust other differences in the same part, when not supported by other characters.

Without attention to such principles as these, we may almost, as Linnæus says, make as many genera as species of plants.

SECT. 1. *Calyx* of one leaf, in five segments. EUTHALES. Brown.

1. *V. trinervis*. Three-ribbed *Velleia*. Labill. Nov. Holl. v. 1. 54. t. 77. (*Euthales trinervis*; Brown Prodr. Nov. Holl. v. 1. 580. *Goodenia tenella*; Andr. Repof. t. 466. Curt. Mag. t. 1137.)—Calyx tubular, of one leaf, in five acute segments. Leaves downy.—Native of the fourth coast of New Holland. Sent to Kew garden in 1803, by Mr. Peter Good. A perennial greenhouse herb, flowering most part of the year. The root is fibrous. Stem none. Leaves all radical, numerous, downy, more or less acute, tapering at the base; sometimes entire; sometimes toothed, or partly runcinate. Flower-stalks numerous, a span high, nearly erect, forked, with a pair of opposite lanceolate bractæas at each division. Flowers stalked, erect, yellow; keel of each segment green underneath; two upper ones marked in front with a dark brown spot; all emarginate; tube white, enclosing the stamens and style. The flowers seem variable in size. We should hardly, without Mr. Brown's authority, have supposed all the above synonyms to belong to the same species.

SECT. 2. *Calyx* of five leaves. Corolla with a spur at the base, which is permanent. MENCERAS (a section of *Velleia*). Brown.

2. *V. paradoxa*. Blunt-toothed Spurred *Velleia*. Br. n. 1.—"Downy. Leaves bluntly toothed."—Native of New South Wales, Van Diemen's island, and the fourth coast of New Holland. Brown.

3. *V. arguta*. Sharp-toothed Spurred *Velleia*. Br. n. 2.—"Smooth. Leaves sharply toothed."—Gathered by Mr. Brown, on the fourth coast of New Holland.

SECT. 3. *Calyx* of three leaves. Corolla a little gibbous, on one side, at the base. True VELLEIÆ. Brown.

4. *V. lyrata*. Lyrate *Velleia*. Br. n. 3.—Smooth. Bractæas distinct. Leaves lyrate, or sharply toothed at the base. Calyx-leaves roundish-ovate.—Native of Port Jackson, New South Wales. This is our original species of the genus. The leaves, all radical, much resemble those of *Crepis tectorum*. Stalks a span high, rigid, once or twice forked; one branch at each fork being sometimes wanting. Bractæas ovato-lanceolate, acute, entire, separate at the base, with a small internal tuft of hairs. Flowers yellow, on short partial stalks. Calyx-leaves quite distinct, acute, nearly entire, a quarter of an inch long, downy within; the upper one rather broadest, and almost orbicular.

5. *V. spatulata*. Spatulate *Velleia*. Br. n. 4.—"Smooth. Bractæas distinct. Leaves spatulate, almost without teeth; quite entire at the base; with axillary tufts of hairs."—Observed by Mr. Brown near Port Jackson, as well as in the tropical part of New Holland.

6. *V. pubescens*. Downy *Velleia*. Br. n. 5.—"Downy. Bractæas distinct. Leaves toothed. Calyx-leaves oblong-ovate, acute."—Native of the tropical part of New Holland. Brown.

7. *V. perfoliata*. Perfoliate *Velleia*. Br. n. 6.—"Smooth. Bractæas very large, combined, roundish, toothed."—Found by Mr. Alexander Gordon, in the neighbourhood of Port Jackson, but seen by Mr. Brown in a dried state only.

The whole genus is stemless, and we believe the flowers are all yellow.—None but the first species has hitherto made its appearance in the European gardens, though some of them might possibly prove hardy annuals, if not perennial with us.

VELLEIACIUM, in *Ancient Geography*, a town of Italy, in the midst of the hills of Gallia Cispadana, according to Pliny.

VELLEITY, **VELLEITAS**, in the *School Philosophy*, is usually defined a languid, cold, and remiss will.

Others say, it implies an impotency of obtaining what we require. Others will have it, a slight desire for something, which a person does not esteem much, or is too indolent to seek; as *Catus amat piscem, sed non vult tangere lympham*.

VELLEIUS, in *Biography*. See **PATERCULUS**.

VELLEKAT, in *Geography*, rocks in the East Indian sea, about 15 miles E. from the island of Myfol. S. lat. $2^{\circ} 1'$. E. long. $131^{\circ} 2'$.

VELLEPEKONDA, a town of Hindooftan, in Golconda; 15 miles S. of Warangole.

VELLIA, in *Ornithology*, a name used by some authors for the *lanius minor*, or *lanius tertius* of Aldrovand, called in England the *flusber*.

VELLIAM, in *Geography*, a town of Hindooftan, in Coimbatore; 16 miles S.E. of Erroad.

VELLICA, in *Ancient Geography*, a town of Hispania, in the territory of the Tarragonese. Ptolemy.

VELLICATION, among *Physicians*, the act of twitching or stimulating. The word is more particularly applied to a sort of sudden convulsions that happen to the fibres of the muscles.

VELLICULA. See **FORFICULA**.

VELLIN, in *Geography*, a town of Pomerania; 4 miles N.N.E. of Polnow.

VELLING, in *Agriculture*, a term applied to the operation or process of ploughing or cutting up and taking off the turf or upper surface of sward land, in order to its being burnt, or for other purposes. It is usually performed nearly in the same manner as baulking or wrest-baulking, except that instead of being turned over, the furrow-slice is, in some cases, cut with its turf upwards; and the work in this process is in effect the same thing; but as the outer point of the wing of the share in the plough is turned upwards, there is less necessity for holding it an oblique position. The plough too in executing this operation, is always turned to the right upon the head-land, which is contrary to that which is practised in skirting, the slice or furrow being turned towards the ploughed instead of the unploughed land. In velling, the plough is thrown so far into the land from the line of draught, as to enable the ploughman to carry with ease about twice as much land as is displaced by the ploughed slice, which is pared very thin and even, and on the land side not cut so deep as in the operation of skirting, but gradually lifted and turned neatly on its green side upon the baulk, left on the right-hand or furrow side of the plough. This manner of ploughing, in contradistinction to splitting, is called, in some districts, gathering of the land; and the day-work five or six roods. See **SPLITTING**.

In cases where the furrow-slice is not turned, it is in some places drawn out with small hooks, by the labour of women and boys, or harrowed, and then raked together in heaps, and burned. This is a mode of velling which is commonly adopted in cases where there is not time to permit the turf or sod to rot, as is the case in other methods of practice. See **PARING and Burning**, and **TURNING to Rot**.

VELLO, in *Geography*, a town of Italy, in the Veronese; 10 miles N. of Verona.

VELLON, in *Commerce*, a kind of money, in which accounts are kept in many parts of Spain. The real vellon

is the most general money of account: it consists of $8\frac{1}{2}$ quartos, 17 ochavos, or 34 maravedis vellon. Madrid, and all Castile, with most of the adjacent provinces, and also Bilboa, Malaga, and Galicia, keep accounts in reals and maravedis vellon. See **MARAVEDI** and **REAL**.

VELLOUL, in *Geography*, a town of Hindooftan, in Guzerat, on the coast; 9 miles W.N.W. of Puttan Sumnaut.

VELLUM. See **VELOM**.

VELLUM, in *Geography*, a town of Hindooftan, in the Carnatic; 5 miles S.W. of Tanjore. N. lat. $10^{\circ} 43'$. E. long. $79^{\circ} 7'$.

VELLY, **PAUL-FRANCIS**, in *Biography*, was born near Fismes, in Champagne, in 1711. Quitting the society of Jesuits after having belonged to it for about eleven years, he devoted himself to historical researches. His chief work was his "Histoire de France," in 8 vols., written in an easy and correct style, and possessing the character of candour and truth. He is charged, however, with too often attacking the privileges of the clergy, and with having borrowed freely from Voltaire's Essay on General History, and with having been misled in some instances by adopting his sentiments. This history, which he terminated with Charles le Bel, was continued to the 16th volume by Villaret. He also published a translation of Swift's "History of John Bull." He was virtuous and amiable, and of a very cheerful disposition. His death happened in 1759.

VELMES, in *Geography*, a town of France, in the department of the Dordogne; 15 miles S.W. of Mucidan.

VELOCE, Ital., in *Music*, swift; *Velocissimo*, superl. very swift.

VELOCITY, in *Mechanics*, *swiftness*; that affection of motion, by which a moveable is disposed to run over a certain space in a certain time.

It is also called *celerity*, and is always proportional to the space moved.

Huygens, Leibnitz, Bernouilli, Wolfius, and the foreign mathematicians hold, that the momenta, or forces, of falling bodies, at the end of their falls, are as the squares of their velocities into the quantity of matter: the English mathematicians, on the contrary, maintain them to be as the velocities themselves into the quantity of matter. See **MOTION**.

Velocity is conceived either as *absolute* or *relative*: the velocity we have hitherto considered is *simple* or *absolute*, with respect to a certain space moved in a certain time. *Relative* or *respective* velocity, is that with which two distant bodies approach each other, and come to meet in a longer or less time; whether only one of them moves towards the other at rest, or whether they both move; which may happen two ways, either by two bodies naturally approaching each other in the same right line, or by two bodies moving the same way in the same line, only the foremost slower than the other: for, by this means, this will overtake that; and as they come to meet in a greater or less time, the relative velocity will be greater or less. Thus, if two bodies come nearer each other by two feet in one second of time, their respective velocity is double that of two others, which only approach one foot in the same time.

Velocity is also *uniform* or *equal*, when a moving body passes through equal spaces in equal times; or *unequal*, when in equal times it passes through unequal spaces; in which case it is either *accelerated* or *retarded*; and this acceleration, or retardation, may also be equal or unequal. See **ACCELERATION** and **MOTION**.

In the doctrine of fluxions, it is usual to consider the velocity with which magnitudes flow, or are generated. Thus the velocity with which a line flows, is the same as that of the point which is supposed to describe or generate the line. The velocity with which a surface flows, is the same as the velocity of a given right line, that, by moving parallel to itself, is supposed to generate a rectangle, always equal to the surface. The velocity with which a solid flows may be measured by the velocity of a given plane surface, that, by moving parallel to itself, is supposed to generate an erect prism, or cylinder, always equal to the solid. The velocity with which an angle flows, is measured by the velocity of a point, supposed to describe the arc of a given circle, which subtends the angle, and measures it. See *Macl.* Fluxions, book i. chap. 1.

All these velocities are measured at any term of the time of the motion, by the spaces which would be described in a given point of time, by these points, lines, or surfaces, with their motions continued uniformly from that term.

The velocity with which a quantity flows at any term of the time, while it is supposed to be generated, is called its fluxion. See *FLUXION*.

VELOCITIES of Bodies moving in Curves. According to Galileo's system of the fall of heavy bodies, which is now admitted by all philosophers, the velocities of a body falling vertically are, each moment of its fall, as the roots of the heights from whence it has fallen; reckoning from the beginning of the fall. Hence that author inferred, that if a body fall along an inclined plane, the velocities it has, at the different times, will be in the same ratio; for since its velocity is altogether owing to its fall, (and it only falls as much as there is perpendicular height in the inclined plane,) the velocity should be measured by that height as if it were vertical. See *Inclined PLANE*.

The same principle, likewise, led him to conclude, that if a body fall through two contiguous inclined planes, making an angle between them, much like a stick when broken, the velocity would be regulated after the same manner, by the vertical height of the two planes taken together; for it is only this height that it falls; and from its fall it has all its velocity.

This conclusion was universally admitted till the year 1693, when M. Varignon demonstrated it to be false. From his demonstration it should seem to follow, that the velocities of a body falling along the cavity of a curve, for instance, of a cycloid, ought not to be as the roots of the heights, since a curve is only a series of an infinity of infinitely little contiguous planes, inclined towards one another; so that Galileo's proposition would seem to fail in this case too; and yet it holds good, only with some restriction.

All this mixture of truth and error, so near akin to each other, shewed that they had not got hold of the first principle; M. Varignon, therefore, undertook to clear what related to the velocities of falling bodies, and to set the whole matter in a new light. He still supposes Galileo's first system, that the velocities, at the different times of a vertical fall, are as the roots of the corresponding heights. The great principle he makes use of to attain his end, is that of compound motion.

If a body fall along two contiguous inclined planes, making an obtuse angle, or a kind of concavity between them; M. Varignon shews, from the composition of those motions, that the body, as it meets the second plane, loses somewhat of its velocity, and, of consequence, that it is not the same at the end of the fall, as it would be, had it fallen through the first plane prolonged; so that the proportion of

the roots of the heights asserted by Galileo does not here obtain.

The reason of this loss of velocity is, that the motion, which was parallel to the first plane, becomes oblique to the second, since they make an angle: this motion, which is oblique to the second plane, being conceived as compounded, that part perpendicular to the plane is lost, by the opposition thereof, and part of the velocity along with it; consequently, the less of the perpendicular there is in the oblique motion, or, which is the same thing, the less the two planes are from being one, *i. e.* the more obtuse the angle is, the less velocity does the body lose.

Now all the infinitely little, contiguous, inclined planes of which a curve consists, making infinitely obtuse angles among themselves; a body falling along the concavity of a curve, the loss of velocity it undergoes each instant is infinitely little; but a finite portion of any curve, how little soever, consisting of an infinity of infinitely little planes, a body moving through it loses an infinite number of infinitely little parts of its velocity; and an infinity of infinitely little parts makes an infinity of a higher order, *i. e.* an infinity of infinitely little parts makes a finite magnitude, if they be of the first order or kind; and an infinitely little quantity of the first order, if they be of the second, and so *in infinitum*. Therefore, if the losses of velocity of a body, falling along a curve, be of the first order, they will amount to a finite quantity in any finite part of the curve, &c.

The nature of every curve is abundantly determined by the ratio of the ordinates to the correspondent portions of the axis; and the essence of curves in general may be conceived as consisting in this ratio, which is variable in a thousand ways. Now this same ratio will be, likewise, that of two simple velocities, by whose concurrence a body will describe any curve; and, of consequence, the essence of all curves, in the general, is the same thing as the concurrence or combination of all the forces, which, taken two by two, may move the same body. Thus we have a most simple and general equation of all possible curves, and of all possible velocities.

By means of this equation, as soon as the two simple velocities of a body are known, the curve resulting from them is immediately determined. It is observable that, according to this equation, a uniform velocity, and a velocity that always varies according to the roots of the heights, produce a parabola, independent of the angle made by the two projectile forces that give the velocities; and, consequently, a cannon-ball, shot either horizontally or obliquely to the horizon, must always describe a parabola. The best mathematicians, hitherto, had laboured much to prove, that oblique projections formed parabolas as well as horizontal ones.

To have some measure of velocity, the space is to be divided into as many equal parts as the time is conceived to be divided into; for the quantity of space corresponding to that division of time, is the measure of the velocity. For an instance: suppose the moveable A passes through a space of 80 feet in 40 seconds of time: dividing 80 by 40, the quotient 2 shews the velocity of the moveable to be such, as that it passes over an interval of two feet in one second; the velocity, therefore, is rightly expressed by $\frac{80}{40}$; that is, by 2. Suppose, again, another moveable B, which in 30 seconds of time travels 90 feet; the index of the celerity will be 3. Wherefore, since in each case the measure of the space is a foot, which is supposed every where of the same length, and the measure of time a second, which is conceived every where of the same duration; the

VELOCITY.

the indices of the velocities 2 and 3 are homogeneal, and therefore the velocity of A is to the velocity of B, a 2 to 3.

Hence, if the space be = s , and the time = t , the velocity may be expressed by $\frac{s}{t}$; the space being in a ratio of

the time and the velocity. See MOTION.

VELOCITY, *Circular*. See CIRCULAR.

VELOCITY, *Initial*, in *Gunnery*, denotes the velocity with which military projectiles issue from the piece by which they are discharged. This is now known to be much more considerable than was formerly apprehended. For the method of estimating it, and the result of a variety of experiments by Mr. Robins, Dr. Hutton, &c. see GUN, GUNNERY, PROJECTILE, and RESISTANCE.

We shall here add, that Mr. Thompson (Count Rumford) has lately published the result of a variety of experiments upon gunpowder, and also an account of a new method of determining the velocities of all kinds of military projectiles. From the equality of action and re-action, it appears, says Mr. Thompson, that the momentum of a gun must be precisely equal to the momentum of its charge; or that the weight of the gun, multiplied into the velocity of its recoil, is just equal to the weight of the bullet and of the powder (or the elastic fluid that is generated from it) multiplied into their respective velocities: for every particle of matter, whether solid or fluid, that issues out of the mouth of a piece, must be impelled by the action of some power, which power must re-act with equal force against the bottom of the bore.

It is easy to determine the velocity of the recoil in any given case, by suspending the gun in a horizontal position by two pendulous rods, and measuring the arc of its ascent by means of a ribbon, according to the method which Mr. Thompson has described, and this will give the momentum of the gun, its weight being known, and consequently the momentum of its charge.

But in order to determine the velocity of the bullet from the recoil, it will be necessary to find how much the weight and velocity of the elastic fluid contribute to it. That part of the recoil which arises from the expansion of this fluid is always very nearly the same, whether the powder is fired alone, or whether the charge is made to impel one or more bullets, as Mr. Thompson has determined by various experiments.

If, therefore, a gun, suspended according to the method proposed, is fired with any given charge of powder, but without any bullet or wad, and the recoil is observed; and if the same piece is afterwards fired with the same quantity of powder, and a bullet of a known weight; the excess of the velocity in the latter case above that in the former, will be proportional to the velocity of the bullet; for the difference of these velocities, multiplied into the weight of the gun, will be equal to the weight of the bullet multiplied into its velocity.

Accordingly, if W is put for the weight of the gun; U , for the velocity of its recoil, when it is fired with any given charge of powder, without any bullet; V , for the velocity of the recoil when the same charge is made to impel a bullet; B , for the weight of the bullet, and v for its velocity; we

shall have $v = \frac{V - U \times W}{B}$. Let $B = 580$ grains, $W =$

336,000 grains; and, therefore, $B : W :: 580 : 336,000$;

i. e. :: 1 : 579.31 nearly, and $V - U$ is found by experiment to be equal to 1.8522; and, consequently, $v = 1.8522 \times 579.31 = 1073$ feet in a second; which is very near 1083 feet in a second, the mean of the velocities determined by the pendulum after the manner of Mr. Robins.

But the theorem will be rendered more simple by putting c for the chord of the recoil in English inches, when the piece is fired with powder only, and C for the chord when a bullet is discharged by the same charge; and then $C - c$ will be as $V - U$; and consequently, as $\frac{V - U \times W}{B}$,

which measures the velocity of the bullet, the ratio of W to B remaining the same.

Supposing, therefore, $C - c = 1$ inch, and the velocity of the bullet to be computed from that chord; the velocity in any other case, in which $C - c$ is greater or less than one inch, will be found by multiplying the difference of the chords C and c by the velocity that answers to a difference of one inch. Or the velocity of the bullet, expressed in feet per second, may in all cases be found by multiplying the difference of the chords C and c by 118.35; the weight of the barrel, the length of the suspending rods, and the weight of the bullet, remaining the same, whatever be the charge of powder or its strength.

According to this rule, Mr. Thompson has computed by several experiments the velocities of bullets from the recoil, and compared them with the velocities obtained by the pendulum. The result, making the necessary allowances for the difference in the conclusions arising from these two methods, leads Mr. Thompson to infer, that there is the greatest probability that the velocities of bullets may in all cases be determined by the recoil with great accuracy; and if this method succeeds with musquet-bullets, it may also be applied as well to cannon-balls and bomb-shells of the largest dimensions: he apprehends also, that it will be much preferable to any other method hitherto known, not only as it may be applied indifferently to all kinds of military projectiles, with little trouble or expence, but also because by this method the velocities with which bullets are actually projected are determined; whereas, by the pendulum, their velocities can only be ascertained at some distance from the gun, after they have lost a part of their initial velocities by the resistance of the air through which they are obliged to pass to arrive at the pendulum.

Those who advert to what has been delivered under the article GUNNERY, will find that, according to Mr. Robins's theory, farther confirmed by Dr. Hutton's experiments, when bullets of the same diameter, but different weights, are discharged from the same piece by the same quantity of powder, their velocities should be in the subduplicate ratio of their weights.

But this theory, says Mr. Thompson, is founded upon a supposition, that the action of the elastic fluid, generated from the gunpowder, is always the same in every given part of the bore when the charge is the same, whatever may be the weight of the bullet; and as no allowance is made for the expenditure of force required to put the fluid itself in motion, or for the loss of it by the vent, he concludes that the theory is defective. And from a variety of experiments, made with a view of ascertaining this point, he infers, that the ratio of the velocities of bullets to their weights is different from that which Mr. Robins's theory supposes; and from other experiments he finds, that the velocities computed, according to the reciprocal sub-triplicate ratio of the weights, agree much better with the conclusions deduced

duced from those experiments, than those computed upon Mr. Robins's principles; though, in this mode of computation, the difference between the actual and computed velocities was in some of the experiments inconsiderable. But as the powder itself is heavy, it may be considered as a weight put in motion along with the bullet; and if the density of the generated fluid be supposed always uniform from the bullet to the breech, the velocity of the centre of gravity of the powder, or of the elastic fluid, and the gross matter generated from it, will be just half as great as the velocity of the bullet; putting, therefore, P to denote the weight of the powder, B the weight of the bullet, and v its initial velocity; then $Bv + \frac{1}{2}Pv = B + \frac{1}{2}P \times v$ will express the momentum of the charge at the instant when the bullet quits the bore. Instead, therefore, of ascertaining the relation of the velocities to the weights of the bullets, α e proposes to add half the weight of the powder to the weight of the bullet, and to compute the velocities from the reciprocal sub-triplicate ratio of the quantity $B + \frac{1}{2}P$: and the result of several experiments shews an agreement between the actual and computed velocities that is very remarkable.

We shall only add, that Mr. Thompson disputes the justness of Mr. Robins's conclusion with respect to the force of gunpowder, which makes it 1000 times greater than the mean pressure of the atmosphere; whereas, from the result of one of his experiments, its force appears to be at least 1308 times greater than the mean pressure of the atmosphere. Phil. Transf. vol. lxxi. part ii. p. 229—321.

VELOCITY, *Measure of*. See MEASURE.

VELOCITY of Light, Sound, Wind, &c. See LIGHT, SOUND, WIND, &c.

VELOM, or VELLUM, is a kind of parchment (which see), that is finer, even, and more white than the common parchment.

The word is formed from the French *velin*, of the Latin *vitulinus*, belonging to a calf. See ABORTIVE.

For regulations relating to makers of vellum, and duty on the same, see LEATHER.

VELORE, in *Geography*, a town of Hindoostan, in the Carnatic; 14 miles W. of Arcot. N. lat. $12^{\circ} 54'$. E. long. $79^{\circ} 15'$.

VELOSO, a town of Portugal, in the province of Beira; 14 miles S. of St. Joao da Pefqueira.

VELPE, a river of Brabant, which joins the Demer, at Halen.

VELPI, in *Ancient Geography*, mountains of the Cyrenaica, on the confines of Africa Propria. These mountains were inhabited by the Macatute, according to Ptolemy.

VELSER, or WELSER, MARK, in *Biography*, was born at Augsburg, of an ancient and opulent family, in 1558, and educated at Rome under the celebrated Muret. Upon his return to his native city he practised at the bar, and became a senator in 1592, and having attained the highest rank in the government of the city, he was regarded as its chief ornament; nor was he less distinguished as the promoter of literature and science. He died in 1614, at the age of 56. The principal of his works, which were numerous, are "Rerum Augustanarum Vindelicarum Lib. VIII." Venet. 1594, and "Rerum Boicarum Libri V." Aug. Vind. 1602. He was a principal contributor to Gruter's Collection of Inscriptions, and he aided many others in their publications. A collection of his writings was published in a folio volume at Nuremberg, in 1682. Bayle. Gen. Biog.

VELT, or VELTE, in *Commerce*, a measure for brandy

in several parts of France. At Bourdeaux, brandy is contained in casks of 50 velts, more or less; but it is sold by the barrique of 32 velts, or about 60 English gallons: 5 velts proof of Bourdeaux make 4 velts proof, by which it is sold in London. At Cognac, it is sold by the 27 velts; and 11 velts proof of Cognac make 10 velts proof, by which it is sold in London. At Rochelle, brandy from this place, Cognac, Isle de Rhé, and the river Charente, is in casks of 3 barriques, containing in all 75 or 90 velts, and is sold by the 27 velts: 16 velts = about 31 English gallons. At Bourdeaux, 1.64 barrique = 100 English gallons, and each barrique measures 14,033 cubic inches: 52.74 velts = 100 English gallons, and each velt = 438 cubic inches. At Cognac, 51.68 velts = 100 English gallons, and each velt measures 447 cubic inches. At Nantes, 67.34 velts = 100 English gallons, and each velt measures 343 cubic inches. At Rochelle, 2.17 wine barriques = 100 English gallons, and each barrique measures 10,636 cubic inches; and 51.79 brandy velts = 100 English gallons, and each velt measures 446 cubic inches.

VELTÆ, in *Ancient Geography*, a people of European Sarmatia, in a part of the Venedic gulf.

VELTHAUSEN, in *Geography*, a town of Germany, in the county of Bentheim; 2 miles N.N.E. of Nienhuus.

VELTHEIMIA, in *Botany*, received its name from professor Gleditsch, in the Berlin Transactions for 1769, in compliment to a German nobleman, Augustus Ferdinand von Veltheim, author of several mineralogical works, and reported to have been also a lover and patron of botany.—Willd. Sp. Pl. v. 2. 181. Ait. Hort. Kew. v. 2. 289. Poiret in Lam. Dict. v. 8. 448.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronaria*, Linn. *Asphodeli*, Juss.

Gen. Ch. Cal. none. Cor. of one petal, tubular, nearly cylindrical; limb regular, in six very short, broad, almost equal, segments. Stam. Filaments six, thread-shaped, inserted into the tube and not projecting beyond it; anthers ovate, cloven at the base. Pist. Germen superior, roundish; style thread-shaped, declining; stigma simple, acute. Peric. Capsule membranous, somewhat pellucid, three-lobed, three-celled, each lobe extended into a compressed rounded wing. Seeds mostly solitary, obovate, rather compressed.

Eff. Ch. Corolla tubular, with six teeth. Stamens inserted into the tube. Capsule membranous, with three wings, and three cells, with solitary seeds.

Obs. This genus, confounded by Linnæus with his ALETIS, is well separated therefrom, as well as from TRITOMA, (see those articles,) both on account of their habits and characters. The genuine *Aletis* has a funnel-shaped corrugated corolla, into the base of whose segments the stamens are inserted; and many seeds in each cell of the capsule. *Tritoma* is distinguished by its long stamens, inserted into the receptacle, and projecting far out of the flower.

1. *V. viridifolia*. Waved-leaved Veltheimia. Willd. n. 1. Ait. n. 1. Jacq. Hort. Schoenbr. v. 1. 41. t. 78. (*V. capensis*; Redout. Liliac. t. 193. *Aletis capensis*; Linn. Sp. Pl. 456. Curt. Mag. t. 501.)—Leaves lanceolate, obtuse, with wavy plaits. Teeth of the corolla rounded, erect.—Native of the Cape of Good Hope, from whence its bulbs are said to have been first imported into this country in 1768, by the late Mr. Malcolm. The plant is now frequent in most good greenhouses, flowering copiously in the winter and spring, yet it is not easily increased, either by root or by seed. The bulb is ovate, larger than a hen's egg. Leaves numerous, all radical, spreading, smooth, a span long,

long, entire, broadly undulated; of a deep grass-green above; pale and glaucous beneath. *Stalk* solitary, erect, straight, naked, eighteen or twenty inches high, elegantly spotted and streaked with blood-red or purple, bearing a long, dense, ovate *cluster*, of pendulous inodorous *flowers*, each accompanied by an awlshaped pink *bractea*, much longer than its *stalk*. The *corolla* is of a waxy pink, or glaucous rose-colour, pale yellow, or greenish, about the extremity; its length about an inch and a half. *Capsules* nearly the same length, of a tender bladdery texture, pale and pellucid, so as to shew the black *seeds* within.

2. *V. glauca*. Glaucous-leaved Veltheimia. Willd. n. 2. Ait. n. 2. Curt. Mag. t. 1091. Jacq. Hort. Schoenbr. v. 1. 40. t. 77. (*Aletris glauca*; Ait. ed. 1. v. 1. 463.)—Leaves lanceolate, glaucous, tipped with a small point; somewhat crisped at the margin. Teeth of the corolla spreading.—Native likewise of the Cape of Good Hope, from whence it was brought to Kew garden by George Wynch, esq. in 1781, being among the many new species of plants, chiefly from that country or from America, for the knowledge of which the botanical world is indebted to the late Mr. Aiton, and his learned coadjutors, in the first edition of the *Hortus Kewensis*. The number of such is greatly increased in the second edition, principally from New Holland and the East Indies. No work of the kind has furnished so many. The plant before us differs from the preceding in having a more oblong pointed *bulb*; much straighter and more erect *leaves*, glaucous on both sides, whose marginal undulations are slight and very small. The *flowers* are smaller, paler, and less showy; their marginal segments more expanded. This is much more rare than *V. viridifolia*, being more difficult of culture and less handsome. It flowers from January to April. For the two other species referred to this genus by Willdenow, *Uvaria* and *pumila*, see TRITOMA.

VELTZEN, or ULZEN, in *Geography*, a town of Westphalia, in the principality of Luneburg; 20 miles E. of Lucko.

VELVALEG, a town of Grand Bucharia; 5 miles S. of Arhenk.

VELUCA, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Arevaci. Ptolemy.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being very strong and close.

The word is formed of the French *velours*, which signifies the same, and which comes from *velu*, a thing covered with hair.

The knap or shag, called also the *velveting*, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow channelled ruler, or needle, or wire; and which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp.

The principal and best manufactories of velvet are in France and Italy, particularly at Venice, Milan, Florence, Genoa, and Lucca; there are others in Holland, set up by the French refugees, of which that at Haerlem is the most considerable.

Velvets are now made to great perfection at Manchester and other parts of England.

There are some brought from China, but they are the worst of all.

There are velvets of various kinds, as *plain*, that is, uniform and smooth, without either figures or stripes:—*figured*, that is, adorned and worked with divers figures, though the

ground be the same with the figures; that is, the whole surface velveted:—*ramage*, or *branched*, representing long stalks, branches, &c. on a fatten ground, which is sometimes of the same colour with the velvet, but more usually of a different one. Sometimes, instead of fatten, they make the ground of gold and silver, whence the denominations of *velvets with gold grounds*, &c.:—*uncut*, that in which the threads that make the velveting, have been ranged over the channelled ruler, or wire, but not cut there:—*striped*, that in which there are stripes of divers colours running along the warp; whether those stripes be partly velvet and partly fatten, or all velveted:—*cut*, that in which the ground is a kind of taffety, or gros de Tours, and the figures velvet.

Velvets are likewise distinguished, with regard to their different degrees of strength and goodness, into velvet of four threads, three threads, two threads, and a thread and a half: the first are those where there are eight threads of shag, or velveting, to each tooth of the reed; the second have only six, and the rest four.

In general, all velvets, both worked and cut, shorn and flowered, are to have their warp and shag of organzine, spun and twisted, or thrown in the mill, and their woof of silk well boiled, &c. They are all of the same breadth.

VELUM, in *Ecclesiastical Writers*, the same with what is otherwise called *brandeum*.

VELUM *Quadragesimale*, a veil or piece of hangings, anciently drawn before the altar in Lent, as a token of mourning and sorrow.

VELUM, in *Anatomy*, a part in the brain. See BRAIN.

VELUM *Palati*, or *Pendulum*, the soft palate. See DEGLUTITION.

VERNANIA, called *Viana* by Ptolemy, in *Ancient Geography*, a place of Rhætia, upon the route from Pannonia in the Gauls, in passing by Sopianæ, between Campodunum and Brigantia. Itin. Anton.

VERMETSTOSTE, or WEMMELSTOSTE, in *Geography*, a town of Denmark, on the E. coast of the island of Zealand; 6 miles S.W. of Heding.

VERPESUM, in *Ancient Geography*, a town of Italy, in Latium. Ptolemy.

VERNA, in *Geography*, a town of Naples, in Calabria Ultra; 9 miles N.W. of Squillace.

VERNA, in *Mythology*. See VINA.

VERNA, *Vein*, in *Anatomy*. See VEIN.

VENABULUM, in *Antiquity*, a long kind of spear, used in hunting wild beasts.

VENÆ LACTEÆ, in *Anatomy*, the absorbing vessels, so called because they were supposed to be veins. See LACTEA *Vasa*.

VENÆ *Lymphaticæ*. See LYMPHATICS.

VENAFRO, in *Geography*, a town of Naples, in Lavora, the see of a bishop, suffragan of Capua; 14 miles N. of Sezza. N. lat. 41° 30'. E. long. 13° 58'.

VENAFRUM, (VENAFRO,) in *Ancient Geography*, a town of Italy, in Campania, northwards, towards the Samnium, which became a Roman colony. It was famous for its olives and oils.

VENAÏSSIN, *Comtat de*, *County of Venaissin*, in *Geography*, a country of France, bounded on the N. by the department of the Drôme, on the E. by the department of the Lower Alps, on the S. by the department of the Mouths of the Rhone, and on the W. by the Rhone, which separates it from the department of the Gard, about 12 leagues in length, and 7 in breadth. It takes its name from Venafque, the Vendanica or Vendasca of the ancients, and was possessed, after the 11th century, by the counts of Touloufe,

Toulouse, but reassumed again in the 13th century, and held by count Raymond the elder. The popes laid claim to the sovereignty of this country from the time of count Raymond de St. Gilles, although it is certain that the emperors, as kings of Arles, had exercised that power. In the year 1234, the emperor Frederick II. transferred the imperial rights of the county of Venaissin to Raymond the younger. And the pope found himself compelled to relinquish them to him. From the descendants of Raymond, it came to Philip the Bold, king of France, who in the year 1273, restored it to pope Gregory X. as a fief of the see of Rome, and it has been governed under the popes, by officers called rectores. The soil is fertile, the climate mild, and the air pure; the productions are corn, olives, silk, saffron, and excellent wine. Carpentras was the capital. This country now belongs to France, and forms part of the department of the Vaucluse, being formally ceded by the pope on the 19th of February 1797.

VENAL, or VENOUS, among *Anatomists*, something that bears relation to a vein.

The extremities of the cava and pulmonary veins, where they enter the auricles of the heart, are called *venous sinuses*. See VEIN.

VENAL, formed from *venalis, to be sold*, is also used for something bought with money, or procured by bribes.

Thus we say, venal bards; courtizans and flatterers are venal; even justice, in Turkey, is venal, and must be bought of the bashaws.

In England, there are several offices in the revenue, policy, &c. venal; but this venality of offices is no where so considerable as they were in France, where all offices of judicature were bought of the king, and only municipal officers are elected. Offices in England are venal only by a kind of connivance; in France it was a thing solemn and authorized. The venality was first introduced by Louis XII. who, to clear those immense debts contracted by his predecessor for Charles VIII. without burdening his people with new taxes, bethought himself to sell the offices of finance; and, in reality, he made a vast sum by it; but he forbade, by an edict in 1508, the sale of offices of judicature. Francis I. made an advantage of the same expedient to get money, and sold his posts, not excepting the offices of judicature, openly: under this king, it was only accounted a kind of loan; but that loan was no more than a name to disguise a real sale. However, it is said, that the sale of offices of judicature was established by edicts of Charles IX. and that military offices were sold under the reign of Henry III.

The parliament, not being able to relish the venality of offices, always made the buyer take an oath that he did not buy his post, either directly or indirectly; but there was a tacit exception made, of monies lent the king for being put into them. At length the parliament, finding its oppositions were in vain, and that the traffick of offices was publicly authorized, abolished the oath in 1597.

VENAMALI, in *Mythology*. See VANAMALI.

VENANA, in *Botany*, an unexplained name.—Lamarck Illustr. "v. 2. 59." t. 131. Dict. (by Poiret), v. 8. 450.—Class and order, *Pentandria Monogynia*. Nat. Ord. undetermined.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cup-shaped, short, with five rounded marginal lobes. *Cor.* Petals five, regular, obovate, rounded, spreading, thrice the length of the calyx. *Stam.* Filaments five, awl-shaped, dilated at the base, the length of the petals; anthers oval, versatile, incumbent. *Pist.* Germen superior, ovate; style short and thick; stigma obtuse, nearly triangular. *Recept.*

befet with numerous bristles, about half as long as the stamens, surrounding the pistil. *Peric.* and *seeds* unknown.

Ess. Ch. Petals five, rounded. Calyx inferior, with five notches. Stigma obtuse, slightly triangular. Receptacle bristly.

1. *V. madagascariensis*.—Native of Madagascar, as its uncouth specific name denotes, where it was found by Commerçon. The stem is arborescent, with alternate, cylindrical, smooth branches. Leaves simple, alternate, stalked, obovate, obtuse, entire, smooth, an inch or two long, with one rib and many fine transverse veins. Clusters terminal, their partial stalks alternate, an inch or two in length, compressed, gradually, though slightly, dilated upwards, smooth, each bearing a little terminal head, of eight or ten small sessile flowers.

VENANGO, in *Geography*. See FORT Franklin.

VENANGO, a county of Pennsylvania, containing eight townships, with 3060 inhabitants. Fort Franklin is the chief place.—Also, a township of Pennsylvania, in Crawford county, containing 434 inhabitants: the county contains 6178.—Also, a township of Pennsylvania, in Butler county, containing 377 inhabitants.

VENANT, St. See St. *Venant*.

VENANTIUS HONORIUS FORTUNATUS, in *Biography*, a Christian poet of the sixth century, was born near Trivigi, in Italy, studied at Ravenna, and became eminently skilful in grammar, rhetoric, and poetry. Superstitiously conceiving that he had obtained relief in a disorder of his eyes at the intercession of St. Martin, he wrote the history of that saint in verse. At Poitiers he was ordained priest about the year 1565, and afterwards elected bishop of that church. He is supposed to have died about the beginning of the seventh century, and an annual festival is kept at Poitiers in honour of his memory.

His works are mostly written in verse. His writings are chiefly the lives of saints. Father Brower, a Jesuit, published his works in one vol. 4to. 1616, and they were also published by M. A. Luchii, at Rome, in 2 vols. 4to. 1786–87. His poems have found a place in the *Corpus Poetarum of Mattaire*. *Nouv. Dict. Hist. Gen. Biog.*

VENASCA, or VENASQUE, or *Benasca*, in *Geography*, a town of Spain, in Aragon, on the river Eßora, in a valley to which it gives name, on the frontiers of France; 45 miles N. of Balbastro.

VENASII, in *Ancient Geography*, a people of Asia, in Cappadocia. Strabo.

VENASQUE, in *Geography*, a town of France, in the department of the Vaucluse, formerly the capital of the Venaissin, on the Nasque; 14 miles E.N.E. of Avignon.

VENCATIGHERRY, a town of Hindoostan, in Mysore; taken in 1791 by the British, under captain Read; 51 miles E. of Bangalore. N. lat. 12° 57'. E. long. 78° 38'.—Also, a town of Hindoostan, in the Carnatic; 23 miles S.W. of Nellore. N. lat. 14°. E. long. 79° 6'.

VENCATRAM, a town of Hindoostan, in Mysore; 25 miles E. of Rydroog.

VENCE, a town of France, in the department of the Var. Before the revolution, the see of a bishop, suffragan of Embrun; 6 miles N.E. of Grasse.

VENCU, in *Botany*, the Chinese name for an excellent fruit found in that country, which the Portuguese call *jamboa*, and the Dutch *pompebinos*. It grows on prickly trees, like the limon-tree, only larger. Its flowers are white, exactly the same in shape with those of the limon, and have an exceeding sweet smell: a very fragrant water is distilled from them. The fruit itself far exceeds the
citron

citron in bulk, being in size equal to, and sometimes exceeding a man's head; the rind is like that of the golden rennet; the pulp is of a reddish colour, and its taste partakes of sweet and acid, resembling that of grapes not fully ripe. A liquor is pressed from it, as in Europe from apples, pears, &c. It will keep for a whole year.

VENDEE, in *Law*, the person to whom any thing is sold, in contradistinction to vendor, or the seller.

VENDÉE, in *Geography*, a river of France, which rises about eight miles N.N.E. from Fontenai-le-Comté, and runs into the Sevre Niortoise, about a mile E. of Marans.

VENDÉE, one of the nine departments of the western region of France, formerly Lower Poitou, lying between Charente and Lower Loire, in N. lat. $46^{\circ} 30'$; bounded on the N. by the departments of the Lower Loire and Mayne and Loire, on the E. by the department of the Two Sevres, on the S. by that of the Lower Charente, and on the S.W. and W. by the sea. Its territorial extent is $7242\frac{1}{2}$ kilometres, or 373 square leagues, and the number of its inhabitants is 270,271. It is divided into 3 circles or districts, 29 cantons, and 324 communes. The three circles are, Sables d'Olonne, including 87,653 inhabitants; Montaigne, 65,943; and Fontenai-le-Peuple, 116,675. According to Hassenfratz, its extent in French leagues is 24 in length, and 21 in breadth; its circles are 6, its cantons 58, and its population 305,610. Its capital is Fontenay. Its contributions, in the eleventh year of the French era, were 2,438,463 fr.; and its expences for administration, judiciary, and for public instruction, were 201,615 fr. 33 cents. This department, watered by many copious streams, is one of the most fertile in France. It is divided by nature into the thicket, the marsh, and the plain. The first, so called on account of the great quantity of wood that covers it, includes nearly five-ninths of the whole territory. Its soil is of various qualities, yielding grain, wine, and excellent pastures. The second, lying on the W. and S. coasts, formerly covered by the sea, is impregnated with saline substances. Nevertheless it is fertile, producing plentiful crops of grain, flax, hemp, and pastures. The third is a fertile and well-cultivated strip of land, inclosed between the thicket and the S. border of the department.

Bouin, an island containing about three square leagues, participates in all the qualities of the marsh. It was separated, not many years ago, from the main land by a narrow channel, which has now almost disappeared. *Noirmontier* (which see) is a fertile island containing about three square leagues, opposite to the N. extremity of the department. It has a port capable of receiving vessels of fifty or sixty tons. But downs of fine sand, near its N.W. coast, are frequently raised by the wind, and driven into the interior part of the island. *Ile Dieu* is a very small island, covered with a thin bed of vegetable soil, mixed with sand, and not productive.

VENDELIA, in *Ancient Geography*, a town of Hispania Citerior, belonging to the Antrigones. Ptolemy.

VENDELÓS, in *Geography*, a town of the island of Ceylon; 64 miles N.E. of Candi.

VENDEN, a mountain of the Tyrolese; 14 miles N.N.E. of Brixen.

VENDEN, a town of Russia, in the government of Riga, on the Aa. In the year 1577, Magnus, duke of Holstein, was brought to this town by Ivan Vassilievitch II. czar of Russia, to be made king of Livonia; but the new monarch was prevailed upon by his subjects, ever averse to the Russian yoke, to form a secret alliance with the king of Poland, and to counteract the czar's progress in Livonia. Ivan, soon apprized of this negociation, laid immediate siege to Venden, with so numerous an army, that the inhabitants, finding all

opposition ineffectual, proposed to capitulate. Magnus himself carried the terms of capitulation, and advancing to supplicate the incensed monarch, threw himself at his feet, and interceded for the town. The czar, spurning at him with his foot, and striking him in the face, loaded him with reproaches for his ingratitude, and ordered him to prison; then entering the town, his troops committed every species of horror and devastation. Many of the principal inhabitants, retiring into the citadel, determined to defend it to the last extremity; but soon perceiving all resistance to be fruitless, and expecting no quarter, they calmly assembled, received the sacrament, and then destroyed themselves, by blowing up the citadel; 36 miles N.E. of Riga. N. lat. $57^{\circ} 12'$. E. long. $25^{\circ} 14'$.

VENDENTIS, in *Ancient Geography*, a town of Upper Mœsia, at a distance from the Danube. Ptolemy.

VENDEVIL, in *Geography*, a town of France, in the department of the Aisne; 8 miles S. of St. Quintin.

VENDITIONI EXPONAS, in *Law*, is a judicial writ, directed to the sheriff, commanding him to sell goods, which he has formerly, by commandment, taken into his hands, for the satisfying of a judgment given in the king's court.

VENDITOR REGIS, the king's saleman, or person who exposed to sale goods or chattels seized or distrained to answer any debt to the king. This office was granted by king Edward I. to Philip de Lardimer, in the county of York, "Ita quod ipse, vel certus suus attorney, ibit ad mandatum vicecomitis de loco in locum infra com. præd. fumptibus suis, ad venditiones faciendas, & capiat de unaquaque venditione pro feodo suo xxxii. den.;" but the office was seized into the king's hands for the abuse thereof, anno 2 Ed. II.

VENDOEUVRES, in *Geography*, a town of France, in the department of the Aube; 11 miles W. of Bar-sur-Aube.

VENDOME, a town of France, and principal place of a district, in the department of the Loir and Cher, on the Loir. Before the revolution, it gave name to a county in Beauce, called Vendomois; $7\frac{1}{2}$ posts N.E. of Tours. N. lat. $47^{\circ} 48'$. E. long. $1^{\circ} 8'$.

VENDRE le Port, a small sea-port town of France, in the department of the Eastern Pyrenees; 12 miles S.S.E. of Perpignan.

VENDRELL, a town of Spain, in the province of Catalonia; 25 miles W.S.W. of Barcelona.

VENDRESSE, a town of France, in the department of the Ardennes; 9 miles S. of Charleville.

VENDUE, denotes an auction or public sale.

VENDUM, in *Ancient Geography*, the name of one of the four towns possessed by the Japodes, in the country that extended itself from the Pannonians to the Adriatic sea. Strabo.

VENECA, a town of Asia, in the interior of Media. Ptolemy.

VENEDI, a people originally of Sarmatia, who occupied the whole coast of the Venedic gulf, and who passed from thence into Germania with the Slavi, where they inhabited the territory abandoned by the Germans. Ptolemy. Jornandes says that these people, before this migration, had been vanquished and subjugated by Hermanicus, king of the Goths.

VENEDICI MONTES, mountains of European Sarmatia. Ptolemy.

VENEDICUS SINUS, a port of the Baltic sea, in which were found the mouths of the Turuntua, Chefinus, Rubo, and Chronus. Ptolemy.

VENEDITOVA, in *Geography*, a town of Russia, in the

the government of Irkutsk, on the Amur; 8 miles E.N.E. of Nertchinsk.

VENEERING, **VANEERING**, or *Fineering*, a kind of marquetry, or inlaying, by which several thin slices, or leaves of fine wood, of different kinds, are applied and fastened on a ground of some common wood.

There are two kinds of inlaying; the one, which is the more ordinary, goes no farther than the making of compartments of different woods; the other requires much more art, and represents flowers, birds, and the like figures.

The first kind is what we properly call veneering; the latter we have already described under **MARQUETRY**.

The wood intended for veneering is first sawed out into slices, or leaves, about a line thick: in order to saw them, the blocks or planks are placed upright, in a kind of sawing-press; the description of which may be seen under the article **PRESS**.

These slices are afterwards cut into slips, and fashioned divers ways, according to the design proposed; then the joints being carefully adjusted, and the pieces brought down to their proper thickness, with several planes for the purpose, they are glued down on a ground, or block of dry wood, with good strong English glue.

The pieces thus joined and glued, the work, if small, is put in a press; if large, it is laid on the bench, covered with a board, and pressed down with poles, or pieces of wood; one end of which reaches to the ceiling of the room, and the other bears on the boards.

When the glue is quite dry, they take it out of the press and finish it, first with little planes, then with divers scrapers, some of which resemble rasps, which take off dents, &c. left by the planes.

When sufficiently scraped, the work is polished with the skin of a sea-dog, wax, and a brush and polisher of shave-grass: which is the last operation.

VENELI, or **VENELLI**, in *Ancient Geography*, a people who inhabited the maritime part of Lyonnese Gaul, and whose capital was the town of Crociatonum. Ptolemy.

VENELLIS. See *VICIS & venellis mundandis*.

VENENUM COCCI, a term used by many of the ancients for the purple tinge, which the kermes berry, as it is usually called (see **KERMES**), gave to linen, or other things.

The word *venenum* being generally understood to express poison, it has been supposed by many, that the kermes was esteemed poisonous, or that there were two sorts of this drug; the one a harmless medicine, the other poisonous. But there is no warrant for this in any of the old writers, and the whole seems indeed but a mistake about the sense of the word *venenum*, which we find by many passages of the best authors, signified a stain, as well as a poison.

The ancients called the vestments dyed scarlet with the kermes indifferently, by the names of *flammae* or *venenate*. Servius tells us, that in certain sacred ceremonies, it was necessary that the priest should be clothed in a scarlet robe; and he uses the word *venenato* to express it in some places, and *flammeo* in others.

VENER, one of the many names by which the chemists call mercury.

VENERE, **CAPE**, or *Capo di Venere*, in *Geography*, a cape on the coast of Genoa. N. lat. 44° 4'. E. long. 9° 40'.

VENEREA CONCHA, in *Natural History*, the name of a very large and elegant genus of shells, more usually called *porcellanae*. See **PORCELAIN Shell**.

VENEREAL, something belonging to Venus.

A venereal person is one addicted to venery, or venereal pleasures. Venereal medicines are called *aphrodisiacs*, *provocatives*, &c.

VENEREAL Virus, in *Surgery*. Of all the maladies which afflict human nature, none has excited greater controversy than that to which we now refer. Fortunately, however, it is likely in the end to prove a means of inducing an accuracy in description, a closeness of reasoning, and legitimacy of induction, for which we have in vain looked in the healing art. A diseased taint, as it was called, was supposed to be every where present, to remain for ever with a person once infected, and to descend to his posterity. Even Astruc, who detected some of the laws of this poison, assimilates it to a Pandora's box, and describes the supposed changes it has undergone at different periods of the world, as similar to the revolutions of empires; thus eluding the most important question in his whole dissertation by a poetical image, and by an illustration of the immutable laws of nature, taken from the vicissitudes of human institutions. Yet even Astruc was rational compared with some of his successors. He at least described the primary symptoms with accuracy: in the others, he seems puzzled by an attempt to reconcile contradictory opinions, and we ought to add, by a want of confidence in his own observation: this however can only be said of primary symptoms. On secondary symptoms, he was as much at a loss as every honest man before and since his time; and his only error was in attempting to account for these difficulties, instead of acknowledging his incapacity to do so. Boerhaave did not scruple to consider himself a Tyro in this disease, after all Europe had pronounced him qualified to be a teacher in the whole science of medicine. Sydenham, with every other writer of any celebrity, will be found either admitting his ignorance, evading the question, or solving it in an unsatisfactory manner.

After all we have already said, (see **MORBID Poison**, and **LUES Venerea**.) it might seem unnecessary to return to the subject, were it not, that even in so short a time since the publication of those articles, new facts have occurred; and we shall shew in this, as in most inquiries into nature, every new discovery proves not only a confirmation, but in some measure an illustration of what Mr. Hunter taught us. We might add, as a farther apology, that his manner of conducting this single inquiry by the facts he produced, now universally admitted, by the caution with which he drew his inferences, and the legitimate inductions which necessarily followed, affords, if not the first, the most perfect model of this mode of reasoning to be met with in the whole science of pathology.

The first consideration was to establish the true character of the venereal ulcer, or *chancre*. For want of this, every ulcer found in suspicious parts was considered the effect of that morbid poison; and from this unhappy error, the firmest constitutions were often destroyed by repeated salivations to cure diseases, which, if not the effect of, were exasperated by mercury. During his life-time, Mr. Hunter had the happiness to see some little remission of this cruel practice. But unfortunately, when he could be no longer consulted in person, another error arose, namely, that all such ulcers as yielded to this remedy were venereal. Hence arose a practice the most truly empirical, that of prescribing for a disease by its supposed name, and judging of its reality by the effect of our remedy. In vain was it argued from his writings, that the cure by the same remedy was no proof of the identity of diseases, and that even this proof, if sufficient, was rarely present: for that those ulcers which had not the true venereal character, yielded to mercury with a readiness very different from that constitutional effect which was necessary for the cure of the true venereal chancre.

Dr. Adams has since shewn, (see his **Morbid Poisons**,) that

VENEREAL VIRUS.

all these ulcers, excepting the venereal, were well known to Celsus, who describes with much accuracy in his chapter *de obscenarum partium vitiiis* all those ulcers on the genitals which are mentioned by writers since the appearance of syphilis as varieties of or anomalies in the venereal character. Yet it is hardly credible, that almost to this day there are writers who will conceive that local diseases, different in character in all their stages, in their mode of spreading and healing, and requiring different modes of treatment, must still be the same; who, while they admit that the venereal disease is of comparatively recent origin, will still confound it with appearances most accurately described more than twelve centuries past.

Mr. Hunter, with that accuracy which distinguishes all his remarks, began by fixing the character of the disease, and even shewing, that from the laws of the economy, as ascertained in all other local diseases, such must be the character of an ulcer arising from some external cause, and for the cure of which animal economy had made no provision.

First: In every local irritation, he shewed that a secretion of some fluid would take place, by which the irritating subject might be removed. The venereal matter, therefore, irritating a solid part, induces ulceration, that the part may rid itself of this irritating cause. But from the nature of a morbid poison, the effect of that irritation is to produce a local action, by which a substance is secreted similar to that which induced the irritation. In some cases, as in small-pox, as soon as this effect is produced it ceases, and the parts heal as readily as after any other loss of substance; but such is not the case with an ulcer from venereal poison. When this is once set up, its action continues until some substance induces a more powerful irritation, and thus supercedes the venereal.

Secondly: When the curative process of a sore from any cause is interrupted, it must spread, or a new action must be set up. This new action, in common ulcers, is the formation of thick, or, as they are usually called, callous edges, after which the ulcer remains stationary. This was well remarked by Celsus, who gives this process the name of *vetustas*, describing the thickened lips, and remarking, that whilst they continue, no applications to the ulcer are of any use.

Thirdly: The peculiarity which distinguishes the venereal ulcer from all others is, that the incapacity in the part to alter the diseased action, produces the same effect as in parts where there is any other impediment to healing; namely, the thickened edge and base. But though the attempt at healing is given up, still the irritation continues from the constant presence of the virus, and consequently the ulceration also, in order to rid the part of the cause of such irritation. Hence we have what is not to be met with in any other ulcer, namely, a continued ulceration, attended with or accompanied by a hard edge and base. This is the only true primary venereal ulcer, and the only ulcer or *vitiium* not described by Celsus in the chapter before alluded to.

The next question was, in what manner a disease incurable of itself was always relieved by mercury. For this a thousand whimsical causes were assigned, the most common of which was, that *mercury was its antidote*. This no one could doubt, but did such an expression do more than assign a word where we were looking for an action? At length Mr. Hunter shewed, that this also was perfectly consistent with what had been before observed; namely, if the venereal ulcer is the effect of an action arising from the irritation of a specific substance, the cure must be effected by the use of another substance, the effect of whose irritation

would be greater than the irritation excited by venereal matter; and the manner in which the disease always yields to the remedy, confirms the doctrine. For no quantity of this antidote, as it is called, will produce any effect on a venereal ulcer, unless an excitement is induced greater than the venereal: that is, if the chancre is recent, a very slight mercurial irritation will be sufficient to alter its action; if more inveterate, the mercurial irritation must be excited proportionally higher, and be longer continued.

It may at first seem that we have gained little, inasmuch as we have now a more severe disease than before. But it will readily occur, that the parts themselves are capable of forming venereal matter, which is the cause of the first irritation, and which will continue till the action excited by that irritation is superceded. But the parts are not capable of forming mercury, by which the second irritation is induced; we might therefore expect, as actually happens, that when the use of mercury is discontinued, the action excited by it would gradually cease also, and the parts be restored to their original or healthy action.

But other difficulties remained. After the ulceration of the genitals was perfectly healed, it sometimes happened, at uncertain periods, that the throat, the skin, or the bones, or all of them, would shew diseased actions, which, though very different from those on the genitals, were equally incurable without the remedy; and which, from their uniformity in so many subjects, whether during the primary symptoms, or after they were healed, evidently arose from the same cause. The ignorance of former practitioners induced them to suspect that these symptoms of confirmed pox, as they were called, arose from an insufficient use of the remedy when the chancre was healed. Yet it was impossible they should be ignorant, that in many instances in which but comparatively little mercury had been used, none of these symptoms on distant parts of the body had occurred; and in others in which the mercury had been used to a very great excess, the patient had been a second or a third time affected, though always in different parts, and with local complaints, different from primary ulcers, yet arising from a similar cause. Besides, if the disease occurred from the want of a sufficient use of mercury, how did it happen that the parts first affected should remain sound, and parts not previously shewing any diseased action, should now become in a state of open ulceration?

To account for this, Mr. Hunter shewed, that though it is now well ascertained, that mercury will with certainty cure every form of the venereal disease which we can detect; it does not follow that it will cure it before such an action has commenced, as evinces itself by some alteration in the texture of the part; in other words, that it will supercede the venereal action by its higher irritation; but in order to do this, the venereal action must have commenced. But it is urged, that doubtless the venereal action has commenced before we can trace it by our senses, and that therefore mercury ought in this state to supercede it, and to prevent its arriving at open ulceration. In answer to that, Mr. Hunter produces his facts, and shews that when the action has appeared, it invariably yields to mercury, and never appears again from the same source of infection in the same order of parts. He taught us also what is now universally admitted, that in the skin and throat it is always curable by a much slighter course of mercury, than was necessary for curing the primary chancre. Consequently, if mercury could prevent the venereal action in these secondary parts, the first course would prove sufficient for that purpose. But the concurrent testimony of all the best writers goes to prove, that none of them knew when to expect nor how to

VENEREAL VIRUS.

prevent the appearance of the disease in more distant parts of the body, after it had been cured in the parts first affected; yet all knew how to cure it when it appeared in those distant parts. Boerhaave fancied he had discovered the cause of these difficulties, by comparing the solid texture of the bones with the more yielding condition of the softer parts. Both he and Dr. Swan were sensible how easy it was to cure the disease when it occurred in the skin and throat; but, as honest men, they were forced to confess their incapacity to prevent it, or even after they had cured it in those parts, to prevent its re-appearance in the bones, though in them also they could cure it with equal certainty after the diseased action had commenced.

An accurate attention to all these events induced Mr. Hunter to construct a series of experiments, by which he might ascertain the laws which govern the actions excited by this poison, and thus meet all the difficulties of former writers. His first object was to fix the precise character of the chancre, or primary venereal ulcer. Having done this, he watched, by every possible means, those cases in which secondary symptoms occurred, and was convinced that it did not depend on any causes which could with certainty be controlled. This he urged was not different from many other morbid poisons. In inoculating for small-pox, no one can ascertain whether the patient will have pustules beyond the spot inoculated. Had he lived to witness the effect of cow-pox, he would have found a still more striking analogy. It is well known that secondary vesicles from cow-pox, that is, a cutaneous eruption usually fourteen days after inoculation, and some few days after the inoculated part has scabbed, will sometimes appear at distant parts of the body; but we have no means of ascertaining under what circumstances these secondary eruptions occur, nor of preventing them, nor of producing them.

The conclusions drawn by Mr. Hunter were, first, that from every local action arising from a morbid poison, absorption takes place; secondly, that the absorbed virus circulates with the blood, and is ejected at some of the emunctories, probably the skin; thirdly, that for the most part it passes without contaminating any part in its passage; but that sometimes the throat, or the skin, or the bone, or all three are contaminated. In these cases the parts thus contaminated take on the diseased action at certain periods, according to the nature of their structure, and the property of the morbid poison; for it is well known that few, if any, morbid poisons produce their effect, till a certain period after their application. The small-pox effluvia are received usually from ten to fourteen days, before the disease shews itself; and the effect then commences on the face several days before the lower extremities exhibit any pustules. Under inoculation, the pustules on distant parts of the body appear at periods later than on the inoculated parts. But though every morbid poison requires a certain period between its application and the effect produced, and though this period is different in different morbid poisons, yet there is a medium in each; and Mr. Hunter ascertained, that the medium for the appearance of the secondary symptoms of syphilis is usually on the skin or throat, six weeks after the cessation of the irritation excited by the mercurial course which cured the primary disease or chancre: that the appearance on the bones is usually three months after the same event; and that if the patient remains well longer than those periods after the healing of the chancre, he may for the most part consider himself free from any further danger from that source of infection. It must be admitted, that these periods are not always precise; but the same may be said of the small-pox, cow-pox, and other morbid poisons;

and when we consider that the medium in one instance is from ten to fourteen days, and in the other from six weeks to three months, it must follow that the variations in each are not greater than their comparative medium would lead us to expect.

From these facts Mr. Hunter improved the practice in this disease so much, that we are often led to believe the disease itself to be milder than heretofore. But the truth is, that we now have some method in directing our treatment, which till his time could hardly be said to be the case. It was known, indeed, that mercury would prove a cure; but neither was the character of the disease accurately ascertained, nor the laws by which it yielded to the remedy, nor to which the secondary symptoms were imputable. Hence mercury was indiscriminately applied to all ulcers on those parts, and many were greatly exasperated by it: and as in the true disease secondary symptoms sometimes occurred, the patient was overwhelmed with a disgusting and deleterious remedy, to prevent what could not be prevented, though it rarely occurred; and when it did occur, was readily cured. But the mode of treatment was far from being the only advantage of Mr. Hunter's discovery. By ascertaining the laws of the disease, he relieved the practitioner from every embarrassment, when secondary symptoms occurred; and the patient from the perpetual dread of an evil, from which it was supposed neither he nor his offspring were ever secure.

It is not to be wondered if the obscurity of Mr. Hunter's mode of writing on a subject familiar to himself, but new to every reader, for a long time precluded the world from the benefit they have since derived from his discoveries. For this benefit we are indebted to Dr. Adams, and perhaps to those writers who attempted to controvert the doctrine itself. The latter were very numerous, and, as often happens, few were acquainted with the subject they opposed. Dr. Adams explained the difficulties principally by shewing the errors of his master's antagonists, and at this time we believe the doctrine is universally admitted by all those who take the trouble to study it. That is, that the antidotal property of mercury consists in the high irritation it excites; that no ulcer on the genitals is syphilitic, unless it continues to spread with a hard edge and base; that it is useless to give mercury in order to prevent the secondary symptoms of the disease, either in the skin or bones, though that remedy will always cure them, if they should appear; and that if these secondary symptoms do not appear before a certain period after the primary ones, there is no reason to apprehend their appearing at all, unless the patient exposes himself again to the same cause. Such is the general doctrine of Mr. Hunter, divested of certain expressions, by which *action* is with more technical precision distinguished from *disposition*. As this language is not necessary we have not introduced it, but refer such of our readers as wish to be acquainted with the precise terms of the discoverer, to the article *Lues Venerea*.

Dr. Adams has carried one of Mr. Hunter's opinions somewhat further than the inventor. Mr. Hunter had observed, that after the venereal action of the primary ulcer was superseded by the mercurial irritation, *new flesh* would sometimes arise, but that it rarely happened that such new flesh would regularly cicatrize or heal. His commentator shewed that this was not peculiar to this disease, but extends to all morbid poisons; that in the small-pox and cow-pox it produces the pitting from the first, and indentation from the second; and that in all other morbid poisons where there is a loss of substance, that loss is never restored by the common

means of incarnation, called granulations. That if such an attempt is ever made it produces a fungus, called by Mr. Hunter *new flesh*, which will not heal, and which requires the application of caustic before any attempt at skinning will commence. After this application, Mr. H. remarks the readiness with which the whole will *skin over*. In this language, the surgical reader will observe the caution with which Mr. Hunter avoids the common terms of *granulation* and *cicatrization*, by substituting for the first *new flesh*, which will not heal, and for the second, *skinning*, which rapidly takes place over the whole sore, whereas it is well known that cicatrization is the most tedious part of the healing process in all other ulcers. In this manner the writer of this article conceives we are to reconcile ourselves to that remark on the granulating property of chancre mentioned under the article *LUES Venerea*; which see. See also *MORBID Poisons*.

VENERIA, or **APHRODISIUM**, *Faradese*, in *Ancient Geography*, a town of Africa, situated on the sea-coast, N.N.W. of Adrumetum. Ptolemy.

VENERIE, LA, in *Geography*, a town of France, in the department of the Po, which took its name from a royal palace built by Emanuel II. duke of Savoy, for a hunting seat: in this town are carried on manufactures of wool and silk. The palace was magnificent, and the adjacent country abounds with game; 3 miles N.N.W. of Turin.

VENERIS Ænadis Templum, in *Ancient Geography*, the name of a temple built by the Trojans in honour of Venus, when they landed on the coast of Epirus, and took possession of the peninsula called Leucas. Dion. Halic. This temple was on the promontory of Actium.

VENERIS Arsinoes Fanum, a temple of Egypt, on the promontory Zephyrium, between Canopus and Alexandria. Strabo.

VENERIS Aureæ Campus, a territory of Egypt, in that of Memphis. Diod. Sic.

VENERIS Insula, an island of the Arabic gulf, on the coast of Egypt. Pliny.

VENERIS Lacus, a lake situated, according to Pliny, at Hierapolis in Syria. It was a marsh, near a temple of Juno, according to Lucian.

VENERIS Mons, a mountain of Spain, S. of the Tagus, and near the country of the Carpetani, according to Appian.

VENERIS Portus, a port of Gallia Narbonensis, on the Mediterranean sea, between the promontories of the Pyrenees, and N. of Cervaria. This port was famous for a temple of Venus.—Also, a port of Italy, in Liguria, on the confines of Etruria, between Segesta and Portus Delphini. Anton. Itin.—Also, a port of Egypt, upon the Arabic gulf. It was anciently named “Myos Hormus,” or “Muris Statio;” also called “Magnus Portus,” and afterwards “Veneris Portus,” according to Ptolemy, who says that it was near the promontory Drepanum.

VENERIS Æstrum, the *stimulus* or *incentive* of *venery*, is an appellation given, by some anatomists, to the clitoris.

VENERIS Æstrum is also used, by others, for the transport of love, or the utmost ecstacy of desire or enjoyment in coition.

Some are of opinion, that infectious women are the most apt to communicate the poison when they are thus excited with desire; whereas, with indifference, they may admit the same intercourse, without giving the infection.

VENERIS Ens. See **ENS**.

VENERIQUE, in *Geography*, a town of France, in the department of the Upper Garonne; 10 miles S. of Toulouse.

VENERY is used for the act of copulation, or coition, of the two sexes.

It takes its name from Venus, the supposed deity of the passion of love.

VENERY also denotes the art or exercise of hunting wild beasts; which are also called *beasts of venery*, and *beasts of the forest*.

Such are the hare, hart, hind, boar, and wolf. See **BEAST, GAME, and HUNTING**.

VENESECTION, in *Surgery*, the operation of opening a vein, for the purpose of taking away blood for the relief of diseases. See **BLEEDING**.

VENESS, in *Geography*, a cape on the S.E. coast of the island of Eday. N. lat. 59° 1'. W. long. 2° 38'.

VENETA BOLUS, a fine red earth used in painting, and called in the colour-shops *Venetian red*. See **RED**.

It is improperly denominated a bole, being a genuine species of red ochre. It is of a fine bright, and not very deep red, approaching, in some degree, to the colour of minium, or red-lead, and is moderately heavy, and of an even and smooth texture, yet very friable, and of a dusty surface: it adheres firmly to the tongue, is very smooth, and soft to the touch, easily crumbles to pieces between the fingers, and very much stains the skin in handling. It has a slight astringent taste, effervesces considerably with aquafortis, and in water immediately breaks into a fine powder.

It is dug in Carinthia, and sent from Venice into all parts of the world, being an excellent colour, and very cheap; our colourmen, however, find too many ways of adulterating it. Hill and Da-Costa.

VENETI, in *Ancient Geography*, a people of Italy, in Venetia, of Celtic origin. According to some historians they were the descendants of a colony of Trojans, who came to establish themselves here on the ruin of their own country; but Herodotus says that they were an Illyric nation.—Also, a people of Gallia Celtica, in Armorica, who inhabited the peninsula above the Namneti, according to Cæsar (De Bel. Gall. lib. iii. c. 8.) who ascribes to them the glory of being the most powerful of all the people who inhabited this coast, and who availed themselves of their shipping, and of the science and practice of navigation. Ptolemy calls their capital Dariorigum. Cæsar denominates their territory Venetia, although the Veneti, who inhabited that promontory of Gaul which is now called Brittany, excelled, as Cæsar says, all the nations on the continent in their knowledge of maritime affairs, and in the number and strength of their ships; yet, when they were preparing to fight a decisive battle against the Romans by sea, they asked and obtained auxiliaries from Britain; which they certainly would not have done, if the Britons could have assisted them only with a few wicker-boats, covered with skins. It is therefore probable, that the people of Britain had ships much of the same form and construction with those of their friends and allies the Veneti, with which they joined their fleet on that occasion. These ships of the Veneti are described by Cæsar as very large, lofty, and strong, built entirely of thick planks of oak, and so solid, that the beaks of the Roman ships could make no impression upon them. The combined fleets of the Veneti and Britons, in the famous sea-fight off the coast of Armorica, now Brittany, against the Romans, consisted of two hundred and twenty of these large and strong ships, which were almost all destroyed in that unfortunate engagement; by which the naval power both of Gaul and Britain was entirely ruined. This great disaster is believed, by some of the best of our antiquaries and historians, to have been the

reason that the Britons never attempted to make any opposition to Cæsar by sea, when the very year after it he invaded their country.

VENETIA, a country of Italy, which commenced E. of Gaul, near the lake Benacus, and the river Mincius, which flowed from it. Its boundaries to the N.E. were not very distinctly ascertained. Its principal rivers, beside the Po, were the Athesis, the Medoacus Major, and the Plavis. It was very fertile in pasture, and furnished excellent horses. The people were denominated Veneti or Heneti. Their principal towns were Hadria, Ateste, Patavium, Verona, Vicentia, Altinum, Tarvisium, &c. See **VENICE**.

VENETICÆ INSULÆ, or *Venetorum Insula*, comprehended, under this denomination, a great number of islands situated on the western coast of Gallia Celtica or Lyonnensis. This general appellation included Bellise, Houat, Hedic, Groa or Grouais, now Quiberon. These islands occupied that part of the sea which was opposite to the continent inhabited by the *Veneti*; which see.

VENETICO, in *Geography*, a small island in the Mediterranean, near the coast of the Morea. N. lat. $26^{\circ} 41'$. E. long. $25^{\circ} 53'$.—Also, a small island in the Grecian Archipelago, near the S. coast of the island of Scio.

VENETORI, a town of Walachia; 24 miles W. of Bucharest.

VENETUS LACUS, in *Ancient Geography*, the name of one of those two lakes, which the Rhine formed near its source in the Alps. The lake now called Boden-see, or more commonly the lake of Constance, is called "Brigantinus" by Pliny, and "Brigantia" by Ammianus Marcellinus. Strabo assigns to it 300 stadia of length, and 200 of breadth. Its name Boden-see is derived from a place called Bodman, situated at the extremity of the lake opposite to which is Bregentz, whence the appellations Brigantia and Brigantinus.

VENEV, in *Geography*, a town of Ruffia, in the government of Tula, on the Oser; 40 miles N.N.E. of Tula. N. lat. $54^{\circ} 20'$. E. long. $38^{\circ} 14'$.

VENEW. See **VENUE**.

VENEZIANO, ANTONIO, in *Biography*. Of this early painter the birth-place is not exactly known, as he is by one author supposed to have been a Venetian, and by another a Florentine. His principal works are at Pisa and Florence, and in the Ducal palace at Venice. He certainly improved upon the style of those painters who preceded him, if we except Giotto; his manner was less formal, and he is said to have painted well in fresco, and to have carried the management of it to a considerable degree of perfection. He died in 1384, at the age of 74.

VENEZIANO, DOMENICO, was born at Venice in 1420, and was a disciple of Antonio da Messina, after he had, as Vafari relates, learned the secret of oil painting from J. V. Eyck; and to him Messina communicated his secret. He painted several pictures at Loretto and Perugia, and afterwards settled at Florence; where the novelty of his manner, and the ability with which he executed it, acquired for him considerable renown. Unfortunately for him, he formed an intimacy with Andrea Castagno, an eminent Tuscan painter, and taught him the management of oil colours; when his treacherous friend conceived the horrible design of assassinating him, that he might remain sole possessor of the secret, and effected his detestable purpose in 1476, when Domenico had attained his 56th year.

VENEZIANU, ANTONI, a Sicilian poet, was born in 1543, at Monreale, and acquired great celebrity in science

and polite literature, so that it was fashionable to cultivate acquaintance with him; and amongst those who fought this honour was Tasso. In 1578 he was taken, on a voyage to Rome, by an Algerine corsair, but redeemed; on his return to his native country, he was imprisoned under a suspicion of being the author of some writing against the viceroy of Sicily, and being confined at Palermo, he was destroyed in the castle by the explosion of a powder-magazine in August 1593. His writings consist chiefly of sonnets and lyric poems in the Sicilian dialect; and some of his compositions in pure Italian were printed at Palermo in 1572. A large collection of his Sicilian poems exists in MS. Gen. Biog.

VENEZUELA, in *Geography*, a province of the eastern part of Terra Firma, or of Spanish America, included within the jurisdiction of the captain-generalship of Caraccas, which is not only the capital of this province, but the metropolis of the captain-generalship, the seat of the royal audience and of the intendency, whose authority extends over the provinces of Venezuela, Maracaibo, Varinas, Cumana, Guiana, and the island of Margareta; extending from N. lat. 12° to the equator, and from 62° to 75° long. W. from the meridian of Paris. The name of Venezuela, which is in Spanish a diminutive of Venice, was given to this province on account of some Indian villages, which the first conquerors found on the lakes of Maracaibo. Others have erroneously ascribed the origin of this name to the following circumstance; viz. that Alphonso Ojeda, having landed here in 1499, caused some huts to be constructed upon poles, in order to elevate them above the stagnant water which covered the plain; but though it is true that Ojeda, in 1499, visited the eastern shore of Terra Firma, he never thought of erecting any huts over its stagnant waters. The chief place of the province of Venezuela has never been nearly on a level with the water. Caraccas is at least sixty toises above the level of the sea, and has no other water besides that of three brooks which pass rapidly through it, and of a small river which bounds it on the south. The first settlement of the Spaniards on the borders of the lake of Maracaibo took place in 1527. The population of Venezuela, including Varinas, consisted, in 1801, of 500,000 persons; that of the government of Maracaibo, of 100,000; of Cumana, 80,000; of Spanish Guiana, 34,000; and of the isle of Margareta, 14,000; making a total, according to the statement of Depons, of 728,000. The population of Caraccas, in 1802, is stated at from 41,000 to 42,000, consisting of whites, slaves, freed persons, and very few Indians; the first class forming nearly a fourth of the whole, the slaves a third, the Indians a twentieth, and the freed persons the rest. All the whites are either planters, merchants, military men, priests, monks, or persons employed in the administration of justice or finance. In this population, the whites are computed at two-tenths, the slaves at three, the descendants of freed-men at four, and the Indians compose the remainder. A late writer, professing himself a "South American," in his "Outline of the Revolution in Spanish America," (1817), says, that in the town of Caraccas alone there were 45,000 inhabitants; and the whole population of Venezuela, including the several provinces, above enumerated, amounted in 1811 to more than 800,000. The soil of Venezuela is fertile, and yields, with prodigal liberality (says Depons), all the productions which are to be met with in the West India islands, besides many others which they do not possess. If a man labour, he must grow rich; and if he vegetate merely in indolence and sloth, he has only to stoop, in order to gather from the soil more than sufficient to satisfy the wants of nature. The cacao of this province is abundant and excellent. It likewise furnishes

VENEZUELA.

nishes Indian corn, indigo, tobacco, cotton, sugar and coffee. Its vanilla, produced from a creeping plant, which, like the wild vine and ivy, entwines round the trees, is obtained in great plenty. Wild cochineal is also the product of this country, and with due cultivation, it might be made to furnish a variety of woods, barks, and plants for the dyer; and also gums, resins of balsam and medicinal oils: its sarsaparilla is said to exceed the consumption of the whole of Europe; saffras and liquorice abound; squills are plentiful; so are likewise storax, cassia, aloes, &c. The horned cattle, affording the article of exportation (hides), the horses, mules, sheep, and deer, are here very numerous. It abounds in all kinds of game, and its rivers and lakes supply plenty of fish.

In order to give a brief account of the revolution that has lately taken place in this province, and in other parts of Spanish America, we shall trace the origin and progress of the Spanish establishments in this part of the world. Terra Firma was discovered by Christopher Columbus in 1498, in his third voyage from Spain to America. After having discovered the gulf of Paria, he coasted along Terra Firma as far west as the Testigo islands, from which point he sailed with a fair wind to St. Domingo. Ojeda obtained permission from the Spanish government to pursue the discovery; and having arrived at the territory of Maracapna, in the year 1499, he followed the coast as far as Cape de la Vela, entering several ports in order to collect more minute information. From Cape de la Vela he sailed for St. Domingo, according to Oviedo and Robertson; but according to Charlevoix, he returned before that to Maracapna, a village upon the coast of Cumana, and there had a brig built. Not long after, the account which Columbus had given to the Spanish government attracted to Terra Firma another vessel from Spain, whose real object was commerce, but which concealed its design under a permission from the king to prosecute the discovery of the country. This vessel, commanded by Christopher Guerra, touched on the coast of Paria, at Margareta, Cubagua and Cumanagola, now called Barcelona. In these places, in exchange for trinkets, he obtained a great quantity of pearls, gold, Brazil wood, &c. of which he formed a very rich cargo. Guerra pursued his course along the coast to the westward, and landed only at Coro, where he found, to his great astonishment, some Indians, as much disposed to take away from him whatever he had got, as those on the eastern coast had been to give them to him. He had too much to lose to run the risk of a war, by which neither glory nor emolument was to be acquired. He, therefore, wisely took the resolution of returning to Spain, in order to place his riches out of the reach of danger.

The report of his arrival and fortune spread over the whole kingdom, and immediately from every part expeditions were fitted out for Terra Firma. At the same time, Charles V. gave permission to make slaves of the Indians who should impede or embarrass the conquest; a grant so much the more deplorable to humanity, as it strongly excited the avarice of those in whose breasts money usurped the place of every other consideration. It is easy to imagine, that upon those coasts, where pillage had nothing to fear either from the vigilance of the magistrate, or the sword of justice, there must have been established a nefarious commerce which had no other object than insatiable avarice, no other result but rapacity, tyranny, and ferocity. The crimes committed by that swarm of robbers, who contended with one another for superiority in feats of plunder, were so great and so numerous, that the cries of the victims reached the audience of St. Domingo, who are entitled to our applause for having immediately taken measures to make it appear to the inha-

bitants of the new world, whom they wished to lead rather than to drive into obedience, that the enormities of that scum of the Spanish nation were not properly chargeable on the nation itself. The audience sent thither, in quality of commissary and governor, a man of very great merit, named John Ampues, who arrived on the Coriana coast in 1527, with sixty men. His mildness, affability, and knowledge soon gained the confidence of the cacique of the Coriana nation; and a solemn treaty confirmed the union and alliance which they formed, and the cacique took the oath of allegiance and vassalage to the Spanish monarch. On the 26th of July, 1527, Ampues laid the foundation of Coro. Thus the province of Venezuela had the pleasing prospect of arriving, without commotion, to a degree of prosperity which would crown the happiness of its inhabitants. However, the commercial house of the Welfers, established at Augsburg, being considerably in advance to Charles V., the emperor submitted to the demand which they made of granting to them, under the title of an hereditary fief of the crown, the province of Venezuela, from Cape de la Vela as far as Maracapna, with the right of extending indefinitely towards the south. But the province having suffered much from the monopoly and tyranny of the agents of the Welfers, the treaty with them was rescinded, and the emperor appointed as governor the licentiate John Peres de Tolosa, who, according to Oviedo, had likewise the title of captain-general. This new reform produced a favourable change in the system and mode of conquest; and it was an established point, that instead of committing devastation, the conquerors should form settlements; and instead of plundering, respect property. Laws, which had been enacted in 1526, 1540, 1542, 1550, and 1552, were put into execution. These laws declare the Indians to be free, not even excepting those who should be taken prisoners in the act of bearing arms. As soon as an Indian nation was subjected to the Spaniards, a convenient site was chosen on which to build a town, for the better security of the conquest. One hundred Spaniards formed the population of the new city, to which a cabildo was attached. They afterwards divided the city in portions among the new inhabitants, according to their rank and merit; and after having made an enumeration of the Indians, they shared them among the Spaniards, who thus acquired over them a right, not of property, but of superintendance. This is what is called "repartimientos de Indios," the dividing of the Indians. This measure was followed by more fixed regulations, under the name of "encomiendas;" the effect of which was to place under the immediate superintendance and authority of a Spaniard, exemplary for his morals, the Indians who lived within a limited extent of ground, corresponding to that of the communes in France. In return for these attentions, the Indians were to pay the commissioned superintendants of the encomiendas, who were called encomenderos, a yearly tribute in labour, fruits, or money. When this tribute was once paid, the Indians were exempted from every other personal service. It appears that, according to the solemn and special contract entered into between the kings of Spain and the discoverers, conquerors, and settlers in Spanish America, politically divided by the Spanish government, and comprehending the viceroalties of New Spain or Mexico, Santa Fé de Bogota or New Grenada, Peru, Buenos Ayres, or the provinces of Rio de la Plata, and the captain-generalships of Guatemala, Venezuela, and Chili; these last were to remain lords of the country, on the basis of feudal vassalage, under the names of "encomenderos." Such, however, was the inhuman conduct of the first of these towards the natives, that Charles V. and his successors were under the necessity

of gradually abolishing many of their privileges, and the "encomiendas" fell at length, in most of the provinces, to the crown; and certain inferior privileges were then granted to the settlers, in lieu of those originally possessed, with the titles of marquis, count, &c. Spanish America was from that time considered as a kingdom, independent in itself, yet united to Spain, as being both under the government of one king. The incorporation of this country to the crown of Castile was decreed by Charles V. in Barcelona, September 14, 1519, and confirmed by Donna Juana, Philip II. and Charles II. Accordingly, in the opening of the royal decree published in the year 1524, for the nomination of a supreme council for the Indies, the term kingdom is expressly used, and its use admits, that the inhabitants had a natural right to hold the appointments of profit and honour in the country. The energetic remonstrances of Montefino, Cordova, Las Casas, and others, to the court of Spain, against the arbitrary measures of the conquerors and settlers, gave rise to the establishment of the Council of the Indies. (See *COUNCIL of the Indies*.) Whilst the legislative power of the kingdom of the Indies rested in this council and the king, the executive power belonged to the viceroys and captain-general. The viceroys were also invested with *royal power*, that is, they were authorized by a special commission to act with plenitude of power in extraordinary and delicate emergencies.

From the most exact calculations, it is concluded that the continental part of Spanish America contains thirteen millions of inhabitants; part of which population is employed in agriculture, particularly in Venezuela, Guatimala, Guayaquil, Chili, Carthagená, &c.; and many in the care of cattle, especially in the provinces of Rio de la Plata and part of Venezuela; while the inhabitants of several provinces of Mexico, Peru, and New Grenada, are almost wholly employed in working the mines. The Indians and Negroes have retained, in a great measure, their primitive customs; the Creoles have received theirs from the Spaniards. The Catholic religion being that of Spanish America, the church government and ecclesiastical dignities are the same as in the mother-country. The inquisition was also established in the new continent: all access to the Spanish settlements was not merely closed against foreigners, but even the inhabitants of the different provinces were prohibited from intercourse with one another. Commerce was exclusively carried on with Spain, and was almost entirely in the hands of Spaniards; about the end of the last century, however, some special licences were obtained from the viceroys and captains-general to trade with the Antilles, when communication with the mother-country was very difficult; and in 1797 the court of Madrid was obliged to allow some of the ports of Terra Firma to be opened for the advantage of commerce. Urged by similar motives, Cisneros, the viceroy of the provinces of Rio de la Plata in 1809, opened the ports of Buenos Ayres, that a free trade might be carried on with the nations in alliance with Spain.

The court of Madrid long maintained its power in the new continent, by a small number of Spanish troops, as the Creoles were cordially attached to the mother-country, and the Indians unable to free themselves; but about the middle of the last century, a plan of conspiracy was formed in Caraccas, with a view of destroying the company of Guipuscoa, to which the privilege had been granted of exclusively trading with Venezuela. The design was discovered, and the head of the conspiracy condemned to death. (See *CARACCAS and GUIPUSCOA*.) The oppressions of the repartimientos, and other grievances, gave rise also to the insurrection which took place in Peru in 1780. By the system of

the repartimientos, the Indians were obliged to receive their necessary supplies of goods, hardware, and mules from the corregidores (officers named by the king), at the prices they fixed, and on the credit they thought proper to give. In 1781, some reforms and additional taxes were introduced in New Grenada, in the province of Socorro, one of the most populous of the viceroyalty; but the province openly declared against these changes, and having assembled near 17,000 men, marched against Santa Fé de Bogota, exclaiming, "Long live the king, but death to our bad governors."

Some few Creoles and Spaniards, well acquainted with the principles laid down by the French politicians in the early period of the French revolution, and with those of the writers who preceded that period, formed a plan for revolution in Caraccas in 1797. They treated the Spanish government with contempt, and trusted to the protection of the English, in consequence of Mr. Pitt's well-known plan of giving independence to Terra Firma. The conspiracy was discovered, and the ostensible leaders made their escape; but one of them was afterwards apprehended and hanged. Sir Thomas Picton, governor of Trinidad, issued at this time a proclamation, in which he says, towards encouraging the inhabitants (of the continent near to Trinidad) to resist the oppressive authority of their government; "I have little more to say, than that they may be certain, that whenever they are in that disposition, they may receive all the succours to be expected from His Britannic Majesty, be it with forces, or with arms and ammunition to any extent; with the assurance, that the views of His Britannic Majesty go no further than to secure to them their independence, without pretending to any sovereignty over their country, nor even to interfere in the privileges of the people, nor in their political, civil, or religious rights." To assist the revolutionary party in Spanish America, the English cabinet is said to have paid the expedition of Miranda to Venezuela in 1806, and to have sent that of Whitelocke to Buenos Ayres in 1807, both of which failed. It is certain that the inhabitants of Spanish America have been long discontented, and that they have complained of various grievances to the court of Madrid. This court, however, knew how to answer petitions without redressing grievances. But Napoleon Bonaparte, when he became in fact master of the Peninsula, and possessor of the wealth of America by the influence he had in this court, having invaded the kingdom and seized the royal family of Spain, loosened those bonds which united the new to the old world, and gave rise to a revolution which, from the wide extent of the country in which it is seated, its character, and its consequences, is unparalleled in the annals of history. When Bonaparte had not only invaded the kingdom, but seized king Ferdinand, and assemblies under the denomination of "juntas" were established in various provinces of Spain, each assuming in its respective district the supreme authority, the Spanish Americans were perplexed and dubious as to the conduct which they ought to pursue. The moment for freedom seemed at length to present itself, after they had been wearied and exhausted by a series of sufferings for three centuries. However, Spanish America was still attached to the mother-country: and when it was announced at Caraccas, in July 1808, that Joseph Bonaparte had taken possession of the Spanish throne, the city was immediately in arms: 10,000 of its inhabitants surrounded the residence of the captain-general, and demanded the proclamation of Ferdinand VII. as their king: which he promised to do next day. But such was their ardour, that they proclaimed him that evening by heralds in form, throughout the city, and placed his portrait, illuminated, in the gallery of

VENEZUELA.

of the town-house. Some months after this wonderful display of attachment to the mother-country and its sovereign, many respectable families of Caracas concurred in presenting a petition to the captain-general, Casas, for permission to elect a junta similar to those in Spain. The petitioners indeed were arrested; but after a confinement of very few days they were released. About the end of July, 1808, Liniers, viceroy of Buenos Ayres, received intelligence of the events that had occurred in the Peninsula; and in a proclamation addressed to the people, he exhorted them, in the name of Bonaparte, to remain quiet. Xavier Elio, the governor of Monte-Video, accused him of disloyalty, and thus separated the country under his command from its allegiance to him, by forming a junta resembling those of Spain.

The news of the general insurrection in Spain reached Mexico on the 29th of July, 1808; and a junta was immediately established. La Paz, which was the capital of one of the districts under the dominion of the audiencia of Charcas, considering Spain too feeble to free herself from the power of the French, wished to provide for its own security; and, in the beginning of the year 1809, formed a government for itself, composed of many respectable persons, which was styled "junta intuitiva." The viceroy of Buenos Ayres sent an army to oppose this motion; and Goyeneche marched, by order of the viceroy of Peru, against La Paz, who succeeding, ordered numbers of the patriots to be ignominiously and cruelly executed. Quito, nevertheless, capital of the audience bearing its name, established a separate government, August 10th, 1809. But the viceroy of Santa Fé de Bogota hastened to destroy the junta of Quito by force of arms; and Abascal, the viceroy of Peru, did the same. The defenders of the junta were obliged to yield to superiority of force, receiving a promise from the Spanish president of Quito, that past events should be forgotten. But regardless of this promise, many patriots, amounting to more than 300, were murdered in cold blood. In 1810, the junta of Caracas commemorated the fate of these victims with funeral honours equally magnificent and solemn. Upon the dispersion of the central junta in Spain, and an illegal election of a regency, the inhabitants of Caracas resolved to try to obtain by force what reasonable representation had failed to gain for them. The municipal body, in conjunction with many persons named by the voice of the people, assumed the reins of government, and the appellation of "junta suprema." The acts of the junta were published in the name of king Ferdinand VII. The establishment of the junta of Buenos Ayres was effected with more tranquillity than that of Caracas. A junta was formed at Chili in September; and disaffection, occasioned in Mexico by violent measures, produced an insurrection, September 16th, 1810, in the town of Doleras, near Guanajuato; which insurrection soon extended through the whole country.

When the council of regency received intelligence of the proceedings at Caracas, by which the inhabitants declared themselves independent of the mother-country, and determined upon forming a governing junta to exercise this supposed independent authority, it resolved to adopt vigorous measures for preventing the progress of this evil; and, for this purpose, consulted the council of Spain and the Indies. Accordingly the regency declared the province of Caracas in a state of rigorous blockade. The measures now adopted evinced the prevalent spirit that actuated the Spanish Americans, though the different provinces were not acting in concert with each other. War seemed to be the wish of the merchants of Cadiz, and of the cortes that had been assembled by the regency; and various methods were used

to excite and encourage it. Its long continuance, and the savage manner in which it is prosecuted, evince the irreconcilable animosity of the contending parties. "The Spaniards fight for reconquering their once possessed territories, and the Spanish Americans to obtain independence: the first are cruel in the hour of triumph, and with adversity their enmity increases; the latter are courageous in attack, and, when defeated, ready to place confidence in their leaders, and to rally under their banners. The first possess great military skill; the latter, superiority of number. Both have uniformly shewn a firmness and decision in action suited to the high objects they have in view, and to the great obstacles they have to overcome. In these contests, the blood of thousands has already inundated an extent of country of more than 1600 leagues, which comprise the Spanish settlements in the new continent; and as if the mortality in the field of battle were not sufficient, numbers are daily murdered in cold blood."—"The Spanish chiefs and rulers, it is said, gave the first example of violating capitulations, of shooting prisoners, and of refusing all means of accommodation, in the cruel war carried on in the new continent, by the authority of the cortes of Spain, and by Ferdinand VII. The old Spaniards of either world must be altogether unable to find an excuse, or even a palliation, for their want of humanity, and breaches of faith, since the beginning of the revolution. The cruelty of the Spanish chiefs, and tokens of approbation on the part of the regency and cortes, have exasperated the newly-formed governments in Spanish America, and given strength to their decisions. At first the revolutionary spirit was confined to very few persons, but it soon spread through the whole continent. This sufficiently appears in the spirit and language of the act of independence published by the congress of Venezuela, July the 5th, 1811. Similar declarations to those of the congress of Venezuela were made in Mexico, and in Carthagena, Socorro, Tunja, Pamplona, Antioquia, and the other provinces, which composed the confederation of New Grenada, and more lately by the congress of Buenos Ayres."

When king Ferdinand, in his decree of the 4th of June, 1814, announced to the South Americans his return to his country, he ordered that they should lay down their arms; and this order was enforced by an army of 10,000 men, equipped at Cadiz, and placed under the command of Morillo. This army appeared on the coast of Venezuela in April, 1815. All hopes of reconciliation were now abandoned, and a revolt in Spanish America against Ferdinand VII. may be dated from this period. From Campano general Morillo proceeded to Margareta, and from thence to Caracas; and in the following August he besieged Carthagena. Although dissensions had occurred between Bolivar and Castello, both commanders of the South American forces, and lessened the means of defence which Carthagena possessed, the inhabitants, nevertheless, supported by nearly 2000 regular troops, prepared for a vigorous resistance. But provisions failed, and more than 3000 persons died of famine. On the 5th of December, 1815, the governor and garrison of Carthagena evacuated the place, and on the following morning the king's troops entered. General Morillo, thus possessed of Carthagena, was enabled to conquer New Grenada. He entered Santa Fé de Bogota in June, 1816, and remained there till November. More than 600 persons of those who composed the congress and provincial governments, as well as the chiefs of the independent army, were shot, hanged, or exiled; and the prisons were full of others waiting their fate.

The first decree of the junta suprema of Caracas, formed

April 19th, 1810, contained orders to arrest the captain-general, and the members of the audiencia, who were sent to the United States of America: it was decreed that the alcabala, or duty on selling any commodity, should be abolished, the tribute paid by the Indians, and the slave-trade; that freedom of commerce, agriculture, &c. should be established; and that these political changes should be made public, and communicated to the English government. Juntas were formed for similar purposes in different provinces. The regency of Spain was incensed, and it declared all the ports attached to the new government to be in a state of blockade; and orders were given for reducing Venezuela to its former subjection. When these orders proved ineffectual, spies and emissaries of every description were sent to all parts of Venezuela, for the purpose of effecting a counter-revolution. General Miranda reached the shores of Caraccas in the end of 1810, notwithstanding the instructions given by the junta suprema for opposing the return of the general to his native country, with a view of evincing the moderate plan of conduct which the junta had adopted towards Spain. A general congress met, and the plan of a confederation, as the best sort of government for Venezuela, was formed and adopted. Miranda, however, opposed it, and his conduct gave offence. In April, 1811, the congress nominated three persons, who were to constitute the executive power, which was very limited. Although several persons were secretly desirous of reunion with the mother-country, they durst not avow it, so earnest were the inhabitants of Caraccas for independence. The anniversary of the revolution, on the 19th of April, was kept with great rejoicings. A most alarming conspiracy was just ready to break out in June, 1811, but it was discovered and defeated. In the midst of the prosperity of Venezuela, it was visited, March 26th, 1812, by a most tremendous earthquake, which destroyed nearly 20,000 persons. The towns of Caraccas, La Guayra, Mayquetia, Merida, and San Felipe, were totally demolished; and Barquisimeto, Valencia, La Victoria, and others, suffered very considerably. At this crisis, general Miranda had the command of the army, and general Monteverde commanded the royalists. Caraccas at length fell under the power of the royalists; the republican army was disbanded; and Miranda, with many others, proceeded to La Guayra, intending there to embark for Carthagena. But Miranda was betrayed, and he, with nearly 1000 patriots, were thrown into dungeons at La Guayra and Puerto Cabello. In consequence of this disaster, Cumana and Barcelona acknowledged the authority of Monteverde; and other similar events occurring, the Spanish government resumed its authority in Venezuela. Vengeance filled the mind of Monteverde. The Spaniards thought, by destroying the inhabitants of Venezuela, the first province which had shaken off their yoke, to punish in them the insurrection of the whole southern continent. Every royalist became a public accuser; every prison was filled with patriots; and almost the whole population were under confinement. This conduct of the royalists, instead of conciliating, excited the hatred of the inhabitants; and the courage of those who were attached to the cause of independence revived. The province of Cumana first opposed the oppression of Monteverde; and here he was twice defeated. Don Simon Bolivar, one of the most distinguished natives of Caraccas, obtained from the congress of New Grenada near 600 men; and with these he felt confident that he should be able to conquer the enemies of his country. Bolivar, after a variety of prosperous adventures, was rapidly advancing towards Caraccas, where the inhabitants waited for him, as their

deliverer. A junta was assembled, and it was proposed to make proposals of capitulation to Bolivar. The general accepted the offered treaty, and granted leave to any person, who was desirous of it, to emigrate from Venezuela, and to withdraw his property. The articles of the treaty, though they were extremely liberal, were disapproved by the captain-general Monteverde, because it was derogatory to the dignity of the Spanish nation to treat with insurgents. Bolivar made his triumphant entry into the city of Caraccas, amidst the congratulations of the inhabitants, on the 4th of August, 1813. The dungeons of La Guayra were thrown open, and those who had survived a year's confinement were restored to their country and friends; while the people, shouting with joy, blessed their deliverer, at the sight of every individual who rushed from the prisons. In the midst of this popular ferment, none of the Spaniards were insulted. The provinces which formed the republic of Venezuela were again in the power of the patriots; but Monteverde obstinately persisted in refusing to treat with Bolivar. In the mean while, Monteverde received from Spain a reinforcement of about 1200 Spanish troops; and thinking himself warranted to act offensively, he attacked the republicans, but was completely defeated. Almost all the Spaniards were killed or taken prisoners, and Monteverde himself was severely wounded. After this defeat, Bolivar laid siege to Puerto Cabello both by sea and land. But the royalists retiring into the fortrefs, determined not to surrender. Bolivar, in invading Venezuela under the protection of the congress of New Grenada, had received orders to reinstate the republican congress; but this he did not think it advisable to do. Bolivar, however, having given an account of his intentions and operations, in the invasion of Venezuela, to an assembly that had been convened of persons of all ranks, resigned the supreme authority which he held. But the governor of Caraccas proposed, and his proposal was agreed to, that Bolivar, denominated the "Libertador de Venezuela," should be invested with dictatorial authority, till the reunion of the provinces of Venezuela to those of New Grenada, under the same representative form of government. The Spaniards, not being able to subdue Venezuela, determined to destroy it. Accordingly the slaves were to be raised in rebellion against their masters. The number of slaves in Venezuela amounted to 70,000; and one of the most formidable emissaries for this purpose was Boves, over whom Bolivar obtained a signal victory at La Vittoria. After gaining several other considerable advantages over the royalists, Bolivar considered himself as secure in the possession of Venezuela; and turned his attention to Coro and Los Llanos, whither the enemy had fled. But as the three divisions of the republican army were separated many leagues from each other, Bolivar was attacked by Boves on a plain called La Puerta, nearly 50 leagues from Caraccas, and, after many hours fighting, compelled to abandon the field to Boves. Other disasters also occurred, and from this time confusion reigned among the patriots, and there was no longer any army for the protection of Caraccas. Success no longer attended Bolivar; his former good fortune had forsaken him; and even the commander of his flotilla, which protected the coast, refused to obey his orders. Despairing of the independence of his country, he and a few of his chosen officers, who were willing to partake his ill fortune, embarked for Carthagena. From Carthagena he proceeded to the town of Tunja, where the congress of New Grenada was sitting; and he was commissioned by the congress to compel by force the city of Santa Fé de Bogota to acknowledge its authority. In this he succeeded; after which he was sent with 3000

men to reduce to allegiance the province of Santa Marta. Carthagena was to contribute troops and guns; but it was prevailed upon to refuse the demanded supply, under pretence of Bolivar's ambitious views, and his sanguinary career in Venezuela. Bolivar marched against Carthagena; but intelligence having been received of the expedition from Spain having reached this city, Bolivar gave up his plan, quitted the army, and his troops united to those of Carthagena to defend that city. The royalists entered Carthagena about four months after the siege had begun; but in the mean while, Bolivar, who had gone to Jamaica, proposed to assist Carthagena by landing an expedition on her shores. The capture of Carthagena prevented the execution of his plan, and he again turned his attention to Venezuela. Stimulated by the hopes of once flattering prospects, Bolivar planned an expedition for assisting the efforts of the patriots of Margareta; and joining Borion, an affluent native of Curaçoa, assembled the emigrants from Venezuela, and part of the garrison which had evacuated Carthagena. Borion was appointed commander of the maritime forces, which were to be employed on this occasion. Sailing from Aux Cayes at the end of March, 1816, they landed in the beginning of May at La Margarita. From Margarita Bolivar failed for Carapano, about five leagues west of the town of Cumana, of which he dispossessed the royalists; and having armed many of the corps of guerillas, who had advanced to join him, they failed for Ocumara. When he landed at Ocumara, he issued a proclamation, giving liberty to the slaves. This proclamation, dated July 6th, 1816, does honour to his judgment and feelings. "Your tyrants," says he, "shall be destroyed or expelled, and you shall be restored to your rights, your country, and peace."—"No Spaniard shall be put to death, unless in battle. No American shall suffer the least injury for having joined the king's party, or for having committed acts of hostility against his fellow-citizens."—"That unhappy portion of our brethren, which has groaned under the miseries of slavery, is now set free. Nature, justice, and policy, demand the emancipation of the slaves: henceforward there shall be only one class of people in Venezuela—all shall be citizens."

Bolivar, who after the defeat at Ocumara had returned to Aux Cayes, brought new reinforcements to Margarita, where he landed in December, 1816. There he published a proclamation, convoking the representatives of Venezuela to a general congress; and went afterwards to Barcelona, where he organized a provisional government. In this place he repulsed the royalists under Real and Morales, in February or March, with great loss. Although the patriots lost the town of Barcelona on the 7th of April this year (1817), and the royalist forces in Venezuela received an addition of 1600 men from Spain in May last, it is now (August) reported, that Bolivar has succeeded in completely establishing the republic of Venezuela.—Travels in South America, by Depons, in 2 vols. 1807. Outline of the Revolution in Spanish America, by a South American, 1817.

VENEZUELA. See CORO.

VENGAMBOOR, a town of Hindoostan, in Myfore; 17 miles S.E. of Erroad.

VENGAPALEAM, a town of Hindoostan, in Myfore; 11 miles N.N.W. of Daraporum.

VENGOLINA, in Ornithology, an African bird, which seems not to have been described by any of the ornithologists. According to the Hon. Daines Barrington's account, it is of the *finch* tribe, and about the same size with our aberdavine, or fiskin; the colours are grey and white, and the cock hath a bright yellow spot upon the rump; it is a very

familiar bird, and sings better than any of those which are not European, except the American mocking-bird. Phil. Transf. vol. lxxiii. part ii. p. 254.

VENHUYSEN, in Geography, a town of Holland; 4 miles S.W. of Enckhuysen.

VENIA, among our *Ancient Writers*, denotes a kneeling, or low prostration, to the ground; used by penitents. See GENUFLEXION.

Walsingham, p. 196. "Rege interim prostrato in longa venia. Per venias, centum verrunt barbis pavementum."

VENIAL, a term in the Romish *Theology*, applied to slight sins, and such as easily obtain pardon.

In confessing to the priest, people are not obliged to accuse themselves of all their venial sins. The thing that gives the greatest embarrass to the Romish casuists is, to distinguish between venial and mortal sins. See POPERY.

The reformed reject this distinction of venial and mortal sins; and maintain, that all sins, how grievous soever, are venial; and all sins, how slight soever, may be mortal: and the reason they urge is, that all sins, though of their own nature mortal, yet become venial, or pardonable, by virtue of our Saviour's passion, to all such as fulfil the conditions on which it is offered in the Gospel. To which the Romanists answer, that the chief of these conditions is confession.

VENICE, in Geography, a city of Italy, and for a long time the capital of a republic. This city makes a very grand appearance at a distance, as seeming, from its being built on a multitude of islands, to float on the sea; or rather, with its stately buildings and steeples, as it were, rising out of it. The number of these islands is uncertain: some reckoning 60, others 72, and others again making them amount to 138. The Laguna, or marshy lake, which lies between the city and the continent, and is five Italian miles in breadth, is too shallow for large ships; but, by the attention of the republic, was prevented from becoming part of the continent, and from being ever frozen so as to bear an army. Towards the sea, the access to the city is also difficult; but the safe and navigable parts are indicated by piles; which, at the approach of an enemy's fleet, can be cut away. Besides, as a considerable number of galleys and men of war could be fitted out very expeditiously for sea from the docks, which contained vast quantities of naval stores, the city was strong without fortifications. The fish, caught even at the very doors of the houses, might be reputed a good preservative against famine. The return of the sea is sometimes later here than every sixth hour, and it generally rises between four and five feet, keeping the water between the islands of the city in continual motion. Some of the canals being very narrow, the mud is not so effectually carried off as to prevent ill smells in hot weather. The great canal, which winds through the city, and divides it into two parts, is 1300 paces long. The best way of going up and down the city is in gondolas, which, indeed, strike the eye with a mournful appearance, being all lined either with black cloth or serge, or painted black. Over the several canals are laid four hundred and fifty (some say upwards of five hundred) bridges, great and small, and the better part of them stone: the highest and longest is the Rialto. (See BRIDGE.) The city may, indeed, every where be traversed on foot; but the streets are very narrow, and the free-stone pavement very slippery in wet weather. The many small bridges, with their steps, are also not a little troublesome. The whole city is said to be six Italian miles in circumference; and to make the tour of it in a gondola, takes up somewhat more than two hours. Venice contains seventy parish-churches, besides others, fifty-four convents

of monks, twenty-six nunneries, seventeen rich hospitals, eighteen oratories, forty religious fraternities with their chapels, and fifty-three squares. The buildings, indeed, are all of stone; but the greater part mean, without beauty or elegance. St. Mark's square, it is true, is very fine, and so are the several stately marble palaces that border upon the grand canal, though most of them are of Gothic architecture. In the churches and convents, the most admirable parts are the paintings; and indeed Venice, highly renowned for fine paintings, is said, in this very respect, to have surpassed even Rome itself. Venice, from the fertility of its neighbourhood, and the facility of carriage, enjoys a constant plenty. The spring-water being very indifferent, almost every house has a cistern, into which the rain-water is conveyed from the roof, and clarified by being filtrated through sand. Water is also brought from the river Brenta, and preserved in cisterns. Among the diversions of Venice, the carnival is accounted the chief: it usually begins the second day of Christmas, and continues till Shrove-Tuesday; consisting chiefly of masquerades and *ridottos*: St. Mark's place is the general rendezvous. Other diversions are plays and operas. The trade in cloth, especially scarlet, silk goods, and looking-glasses, is still very considerable. Here also gold and silver stuffs are manufactured; which, although not so beautiful as those of France, have a very good sale in the Levant. The brocatellas, a kind of stuff like brocade, made of coarse silk, are much used for carpets. Venice is divided into six parts, called *Sestieri di Sestiera*. S. Marco contains the piazza di S. Marco, with the adjacent buildings. This square, the pride of the city, forms a right angle, the shortest side of which, two hundred and forty paces long, and seventy-five broad, reaches along the ducal palace. The ducal palace, towards the water-side and St. Mark's place, is entirely Gothic; but on the side of the small canal, and in the court, of modern architecture, and mostly of marble. It not only served for the residence of the doge, but also for the meeting of the council. The finest ornaments of the council-chamber and other apartments, are the paintings of famous ancient masters. In one side of the palace, towards the canal, Rio di palazzo, were dark prisons, strongly secured with iron grates. The lower gallery, or arched walk, on the side of St. Mark's square, together with the opposite hall, is called Broglio. Here, at a certain hour of the day, the nobles took their walks, and at this time no Venetian of an inferior rank must be seen on it; though a foreigner, as supposed unacquainted with the custom, is not desired to quit the place. Between these two buildings and the piazza were two pillars of Oriental granite, on one of which stood St. Mark's lion in brass, and on the other a marble statue of St. Theodore. Between these is the place for the public execution of malefactors, through which no nobleman is ever seen to pass. A galley, completely rigged and armed, lay close to the Broglio, for the defence of the ducal palace on any sudden emergency. Contiguous to the north part of the doge's palace is St. Mark's church, also styled the doge's chapel. Its materials justify it to be called magnificent, being, both on the out and inside, covered with fine marble; but the architecture is entirely Gothic. The best part of it consists of the Mosaic paintings, and the four brass horses, formerly gilt, standing over the great door, and said to have been brought here from Constantinople. In the church treasury is kept a very famous manuscript of the gospel of St. Mark, pretended to be autographical; but the dampness of the place where it lies has spoiled it to such a degree, that no part of it is any longer legible, and it is not so much as certain whether it be written in Latin or Greek. In the *Sestiera di Castello* is the arsenal or dock,

two Italian miles and a half in circuit, walled and moated in, with twelve towers along its walls; and within the inclosure a great variety of buildings, in which every thing requisite for a land or sea armament is kept in readiness; with shops, store-houses, and basons and slips for ship-building, &c. Within it lie the men of war, frigates, galleys, and other vessels, with the Bucentauro, which is also laid up here. In the *Sestiera di Canale Regio* is the theatre, and in this quarter the Jews live, to the amount of fifteen hundred, who must wear a scrap of red cloth in their hats, by way of distinction from Christians. *Sestiera di S. Pavolo* contains the exchange, the bank, &c. On the invasion of Italy, in the fifth century, by the Huns, under their king Attila, and the general desolation that every where appeared, great numbers of the people who lived near the Adriatic took shelter in those islands where now stands the famous city of Venice; and which islands, about the year 421, particularly Rialto, had, in some measure, been built upon by the Paduans, for the advantage of commerce. (See VENETIA.) Here having settled their small places or states, they were at first governed by consuls; afterwards by tribunes; and formed a kind of republic, the council of which was represented by the persons of these magistrates. These islands became still better inhabited on the succeeding incursions of the Goths and Longobardi into Italy; multitudes from Rome and other large cities repairing thither, so that this state became soon able to make some head against these bold invaders. At length the chiefs of the islands and the Longobardi came to an agreement, by which the former were to remain unmolested. This was the commencement of the city and state of Venice. About the beginning of the eighth, or end of the seventh century, the former government of these islands was abolished, and an unlimited power conferred on Paulucio Anafesto, with the title of duke. Under this sovereignty the state greatly increased, till the people, justly becoming weary of the ills of domestic despotism, chose, in the year 1171, another duke, but curtailed his power, by assigning him a council of 240 persons, composed of commons as well as nobles. Duke Ziani sided with pope Alexander III. against the emperor Frederick, and obtained over him such a signal victory at sea, that the pope presented him with a ring, which he was to drop into the Adriatic, as a sign of his marriage with, and perpetual sovereignty over it. The Venetians, who had already extended their dominion into Istria, Dalmatia, Syria, Lombardy, and other places, made a very considerable acquisition in the beginning of the thirteenth century, by possessing themselves of the principal islands in the Archipelago and Mediterranean, particularly that of Candia. From this time they alone carried on, at an immense profit, the trade for East India goods, which they imported from Alexandria, in Egypt, to which place they were brought across the Red sea, and by the way of Suez. Under duke Marino Morosino was introduced the form of electing the doge; and it was at this juncture that jealousy and envy fomented the war with Genoa, which, after continuing 130 years, was at last put an end to by a treaty, in 1381. During this war, duke Peter Grandonigo, in the year 1296, ordained that the nobility alone should be capable of sitting in the grand council. Thus the government became aristocratical. In the 14th century, the Venetians extended their possessions in Lombardy; and, in 1473, the last king of Cyprus appointed the state of Venice his heir. Towards the end of the 15th century, the Venetian commerce, and consequently power, began to decline, when the Portuguese discovered a route by sea to the East Indies, which opened the trade to all nations. In the 16th century, the pope, the emperor, France, and Spain, joining in a league against them, they

VENICE.

were dispossessed of all their towns and places in the kingdom of Naples, the ecclesiastical state, and the Milanese. They received another severe blow from the Turks, who drove them out of the island of Cyprus. In the 17th century a sharp contest arose between the state, the clergy, and the pope, in which, however, they had the advantage. They were also long engaged in troublesome wars with the Turks, losing Candia, and gaining part of Dalmatia, and all Morea; but the greater part of these have been lost in succeeding wars. Thus the republic of Venice continued upwards of 1300 years, amidst many foreign wars and intestine commotions. Its grandeur was chiefly owing to trade and liberty; and since the decline of the former, its strength and consequence must have suffered a considerable diminution. The power was lodged in the hands of the nobility, said to be near 2000, including those whom public employments in the provinces obliged to reside out of Venice. On the birth of a nobleman's son, his name was entered in the golden book, otherwise he forfeited his nobility. Every noble was, indeed, a member of the senate; and on this account it was a received maxim, that they all were equal in dignity. But the difference, notwithstanding, between the interest and authority of families, was very considerable. To the first class belonged the ancient houses, whose ancestors chose the first duke, and who, from thence, were called "Le Case Eletterali;" and on them, preferably to others, were conferred the higher offices. Next follow eight houses, almost as ancient. The second class had its origin from the Serrar del Consiglio; duke Grandonigo having passed a law that the council should perpetually consist of the families which then composed it, and some others which he ennobled. This produced a second class of nobility, who, accordingly, were then registered in the golden book. It consisted of upwards of eighty families, and some of great wealth and reputation. With these were also included families raised to nobility after the Genoese war, on account of their large contributions towards carrying it on with vigour. The third and last class was composed of the Cittadini, or citizens, whose nobility was purchased for 100,000 Venetian ducats, a resource of the republic for raising money in necessitous times. Crowned heads, German and other princes, have not thought it any degradation to be made nobles of Venice. The habit of the nobility, whilst at Venice, was a black furred gown, reaching to their heels, with a belt about three inches broad, and plated with silver. Instead of hats they had long caps. The head of the republic was the doge, or duke, who, on the demise of the former, was chosen in a peculiar manner, by forty-one nobles, selected for this purpose by a process which it is needless to describe. These forty-one electors were confirmed by the grand council; and, being shut up in a chamber of the ducal palace, there remained till they had chosen a new doge. To the due and legal election of a doge, it was required, that out of the forty-one he should have twenty-nine votes. His election was followed by a kind of coronation; the ducal cap being placed with great ceremony on his head. This was performed at his public entrance into St. Mark's church. His yearly income was 12,000 Venetian ducats. He was subject to a variety of restrictions; and he was under the inspection and controul of the council of ten, who kept a watchful eye over his whole administration, and, at any time, could come and search his most private apartments. In general, his authority, essentially considered, was no greater than that of a private person, unless he could influence the whole council. On his death a formal inquiry was made, whether he had abused his power; whether, from a care of his own concerns, he neglected those of the pub-

lic; whether he lived agreeably to his dignity, &c. If found guilty of any thing alleged to his charge, his heirs were fined in proportion to the nature of the crime. On Ascension-day, the doge, or, in case of illness, the vice-doge, performed the annual frivolous ceremony of marrying the Adriatic sea. (See DOGE.) In the grand council, all nobles of the age of twenty-five years might take their place, though some younger found means to obtain admittance. The senate, or *pregadi*, were a committee of the grand council, by whom they were also chosen. This senate had the management of the most secret and important state affairs, as the making alliances and peace, declaring war, sending ambassadors, coining money, filling up offices, imposing taxes, &c. Next was the collegium, in which all public instruments directed to the state and doge were read, audiences given to foreign ministers, and other matters of importance transacted. The procurators of St. Mark had not only the inspection of the church of St. Mark, its library, and the records of the republic, but likewise managed all affairs relating to the poor, together with wills, guardianships, redemption of Christian slaves, and bringing over-rigid creditors to a reasonable composition. Their number never exceeded nine: their office was of great authority, and during life; and out of them the doge was generally chosen. Titular or extraordinary procurators of St. Mark were more numerous; the republic gladly selling these titles in a public scarcity of money. Il consiglio di dieci was a high penal court, which consisted of ten counsellors, the doge, who was president, and his six consiglieri. The established religion was the Roman Catholic; but Greeks, Armenians, and Jews, were allowed the public exercise of their worship, and Protestants, observing privacy, remained unmolested. The patriarch of Venice, the chief ecclesiastic of the republic, was chosen by the senate; and though confirmed by the pope, must, in all other respects, be independent of the papal chair. The territories of the republic were under governors chosen out of the nobility, changed at the expiration of a certain term of years. The annual revenue of the republic was computed at 8,200,000 ducats, and was under the direction of three *governatori dell' Entrate*. In war-time, both the nobles and the other subjects, even the doge, contributed, proportionably to their incomes, towards defraying the public expences. The states of Italy subject to the Venetians were the Dogado, the Paduan, the Polesine di Rovigo, the Veronese, the Vicentin, the Bressan, the Bergamasco, the Cremasco, the Trevigiano, the Feltrin, the Bellunese, the Cadornin, great part of Friuli and Istria; to these may be added a part of Dalmatia, the islands of Corfu, Zante, Cephalonia, and some others. The number of inhabitants in the city of Venice was estimated at 160,000, and, of the whole state, at 2,500,000. In the year 1797, in consequence of some partialities which the Venetians shewed to Austria, the French attacked and made themselves masters of the city. By the peace of Luneville, Venice with its dominions was given to Austria; but by the peace of Presburg transferred to the new kingdom of Italy. In December 1807, prince Eugene Napoleon was created prince of Venice by the emperor Napoleon.

Venice has always been renowned for its cultivation of the fine arts, and for giving birth to great professors, particularly in painting, architecture, and music. At the head of the first, Titian, Paul Veronese, and Tintoret; of the second, Palladio and Scamozzi; and of the third, Zarlino, Lotti, Marcello, and Galuppi; names that can never be heard without pleasure by the votaries of those arts. Printing, too, has been carried on at Venice with great spirit ever since the year 1459, when it was established there by

Nicholas Jansen; and in the beginning of the next century, pursued by the Aldi with more accuracy than in any other part of Europe.

But Venice has long manifested its attachment to music by the establishment of its conservatorios, or musical schools, of which it has four; the Ospidale della Pietà, the Mendicanti, the Incurabile, and the Ospidaleto a S. Giovanni e Paolo; at each of which there is a performance every Saturday and Sunday evening, as well as on great festivals. The performers at them all, both vocal and instrumental, are females: the organs, violins, flutes, violoncellos, and even French horns and double-basses, are supplied by these females. See CONSERVATORIO.

Though the composers of the Venetian school are, in general, good contrapuntists, yet their chief characteristics are delicacy of taste and fertility of invention; but many circumstances concur to render the music of Venice better, and more general, than elsewhere. The Venetians have few amusements but what the theatres afford; walking, riding, and all field-sports, are denied them. This in some degree accounts for music being so much, and in so costly a manner, cultivated; the number too of theatres, in all which the gondoliers have admission gratis, may account for the superior manner in which they sing, compared with people of the same class elsewhere. And in the private families, into which the girls of the conservatorios marry, it is natural to suppose that good taste and a love for music are introduced.

Venice, in 1639, was the first city in Italy that opened public theatres for the performance of operas; and in less than a century from that period, 658 musical dramas were brought on the several stages of that city, the chief part of which were produced by natives of the Venetian state. In the last century, not only the poetry and music of the lyric theatre were greatly superior to those of preceding times, but the performers; for at Venice all the great vocal talents to which the opera had given birth, were more constantly summoned, patronised, and cherished, than in any other city of Europe.

Accounts are kept at Venice in lire of 20 soldi or marchetti; and each foldo is divided into 12 denari di lira. They are also kept in ducats of 24 grossi; and the grosso is divided into 12 grossetti, or denari di ducato. A ducato of account is worth $6\frac{1}{2}$ lire, or 124 marchetti. The gold coins of the old republic are zecchini, or sequins, with halves and quarters. The sequin is commonly reckoned at 22 lire, but its agio fluctuates, and in the year 1805 it was 37 *per cent*. The silver coins are the scudo Veneto, or della croce, of 12 lire 8 soldi, and halves and quarters in proportion; the ducato, or giustina, of 11 lire; the ducato effettivo of 8 lire, with halves and quarters; and base silver pieces of 30 soldi, called lirazze, and of 20, 15, 10, and 5 soldi. There are pieces of 10 lire, which were coined in 1796. The copper coins are soldi and half soldi, or bagattini.

When Venice became subject to Austria, in 1797, a base silver money was introduced, called moneta provinciale, which, in 1802, was declared to be out of currency; and a new coinage took place, consisting of pieces of $1\frac{1}{2}$, 1, and $\frac{1}{2}$ lira, or, in Austrian money, of 18, 12, and 6 creutzers, which contained only a fourth of fine silver, but they were heavier than the former coinage. This money was called "moneta di nuovo stampo." The Austrian government also introduced copper pieces of 6 and 3 creutzers, or 10 and 5 soldi, and pieces of 2 and 1 soldi. All the above-mentioned monies and coins are now valued in "moneta piccola," which is the effective currency of Venice.

The bank of Venice was instituted in 1587; its original capital being five millions of ducats. The owners received no

interest for their money, but could draw it out on demand or transfer it in payment, like the banks of Amsterdam, Hamburg, and other banks of deposit. Bills of exchange were mostly paid in banco, and also wholesale bargains of merchandize above 300 ducats. The bank received no money but sequins and silver ducats. The bank of Venice was in high credit and prosperity from its first institution to the year 1797, when the French seized upon the city, and ceded it to Austria; from this period it declined. In 1805 Venice was incorporated with the kingdom of Italy; and in 1808, the bank was totally discontinued.

According to the rate of coinage at Venice, $68\frac{3}{4}$ sequins are to contain a Venetian mark of fine gold, with a very small, but uncertain, quantity of alloy. No remedy was allowed at the mint of Venice, either in the weight or fineness of its coins. The Venetian sequin, weighing nearly 54 English grains, is therefore worth 9s. 6d. sterling. The silver ducat weighs $351\frac{1}{2}$ English grains, and is 9 oz. $18\frac{1}{2}$ dwts. fine, which gives its value at $40\frac{1}{2}$ d. sterling; hence the ducat of account of $6\frac{1}{2}$ lire piccola is worth $31\frac{1}{2}$ d. nearly, and the lira about 5d. sterling; or, more exactly, 1l. sterling = 47 lire 8 soldi piccoli. But taking the value of the lira from the coinage introduced by the Austrian government, it will be found worth about $4\frac{1}{4}$ d.; and 1l. sterling = 56 lire $9\frac{1}{2}$ soldi piccoli.

Venice has two different weights for merchandize, *viz.* peso grosso, or large weight; and peso sottile, or small weight: the pound of the former is divided into 12 oz. and 192 carats, in all 2304 carats; and the pound of the latter into 12 oz. and 144 carats, in all 1728 carats. The pound peso grosso weighs 19 oz. peso sottile; hence 12 lbs. peso grosso = 19 lbs. peso sottile; and 18 lbs. peso grosso, or $28\frac{1}{2}$ peso sottile = 19 lbs. avoirdupois. A carica is 400 lbs. peso sottile. The ounce for weighing silk and thread is divided into six faggi or fazi, and these into halves, quarters, &c. Oil is sold either by weight or measure: a miglajo weight contains 40 miri, each 25 lbs., in all 1000 lbs. peso grosso. A miglajo measure should contain 1210 lbs., or 40 miri, each $30\frac{1}{4}$ lbs. peso grosso: such a miro answers to about $4\frac{1}{4}$ English gallons. The amphora, a wine measure, contains 4 bigoncio; a bigoncia, 4 quartari, 16 secchie, or 256 lbs. peso grosso; but a bigoncia of brandy is only 14 secchie.

Two sorts of long measure are used at Venice, both of which are called the braccio; that for woollens is $26\frac{3}{8}$ English inches, and that for silks is $24\frac{5}{8}$ English inches. The Venetian foot is 154 French lines, or $13\frac{2}{3}$ English inches; hence 36 Venetian feet = 41 English feet.

Venice exchanges with London 50 lire piccola, more or less, for 1l. sterling, at three months' date. The usance for bills drawn from London is three months after date. Bills are allowed six days grace, after which they must be either paid or protested. Protests are made by the fanti or clerks of the commercial college, who enter all the bills they have protested in a book, to which every merchant has free access. Thus many bills, which would otherwise be returned, are accepted and paid for the honour of the drawer or indorser. This practice is likewise useful in giving early notice of approaching insolvency. (Kelly's Un. Cambist.) Venice is situated 216 miles N. of Rome. N. lat. $45^{\circ} 28'$. E. long. $12^{\circ} 18'$.

VENICE, *Gulf of*. See ADRIATIC.

VENICIUM, in *Ancient Geography*, a town in the interior of the isle of Corsica, according to Ptolemy.

VENICNII, a people who inhabited the western coast of Hibernia. Ptol.

VENICNIUM PROMONTORIUM, a promontory on the northern coast of Hibernia. Ptol.

VENICONTES, a people of Britain, S. of the Caledonii to the W. whose town was Orrea. Ptol.

VENIERO, DOMENICO, in *Biography*, an Italian poet, was born of a noble family at Venice in 1517; and after receiving a good education, and being introduced to the friendship of Bembo, and having been thus led into the way of advancement to honourable and lucrative stations, he lost the use of his limbs at the age of thirty-two, and was confined to his chamber for life. In this condition he sought solace from poetry and the conversation of his learned friends, who in great numbers resorted to his house. These meetings laid the foundation of the celebrated Venetian academy, of which Veniero was the principal ornament. Notwithstanding the pain which he experienced, his poems are distinguished by liveliness of imagery and force of expression. He died in 1582, at the age of sixty-five. His poems were first printed in the collections of Dolce and Ruccelli; and they were edited at Bergamo in 1751 and 1753, with those of his nephews, Maffeo and Luigi Veniero, the former of whom was archbishop of Corfu. Their father Lorenzo was also a poet. Gen. Biog.

VENIRE FACIAS, in *Law*, is a judicial writ, lying where two parties plead, and come to issue; directed to the sheriff, to cause twelve men, of the same neighbourhood, to meet to try the same, and recognize the truth upon the issue taken.

Afterwards a compulsive process is awarded against the jurors, called *habeas corpora juratorum*, or *distringas*, that they may appear upon the day appointed. See JURY.

VENIRE *Facias* is also the name of a writ, which is the proper process in an indictment for any petty misdemeanor, or on a penal statute, and which is in the nature of a summons, to cause the party to appear. And if by the return to such *venire* it appears, that the party hath lands in the county by which he may be distrained, then a *distrains infinite* shall be issued from time to time till he appears. But if the sheriff returns that he hath no lands in his bailiwick, then, upon his non-appearance, a writ of *capias* shall issue; and if he cannot be taken upon the first *capias*, a second and a third shall issue, called an *alias*, and a *pluries capias*.

VENIRE *Facias tot Matronas*. See VENTRE *Inspiciendo*.

VENISON, VENAISON; the flesh of beasts of game, or of animals to be caught in the way of game, *i. e.* by hunting, &c, as deer, hare, &c.

The word is French, *venaison*; formed of the Latin *venatio*, hunting.

The old huntsmen have determined, that every beast of the forest, that is food for man, is venison. In many parts of the world the bears are as regularly hunted as the hare and buck, &c. are with us, and there are called venison; but with us, at present, the word venison seems limited to the flesh of the hart, the hind, the buck, the doe, and the other creatures of that kind.

Some have extended the signification of the word to the beasts of the forest which were chased as game, and afforded the diversion of hunting, whether their flesh were eaten or not; thus, in some places, the wolf and the fox are reckoned among the venison beasts.

VENIUS, or VAN-VEEN, OTHO, in *Biography*, was of a distinguished family in Holland, and was born at Leyden in 1556. He received an excellent education from his parents, and though his progress in literature was unusual, yet he was permitted to pursue his desire of becoming a painter. He received lessons in design from Isaac Nicholas, but is more indebted to John Van Winghen. The war in the Low Countries drove him to Liege at the age of fifteen, and there he continued to prosecute his studies in literature

and the arts. He acquired the favour of cardinal Grosbeck, at that time prince bishop of Liege, who, desirous of his advancement, advised him to visit Rome, and furnished him with letters of recommendation to cardinal Marduccio, then in that city. On his arrival there he was kindly received and entertained by his eminence, and he became a disciple of Fred. Zucharo, by whose instructions, and his own industry in studying the beautiful works of antiquity with which he was surrounded, he acquired a very great degree of correctness in design, and a more elevated taste than his countrymen usually exhibited in their works.

Having devoted seven years to his studies in Italy, he visited Germany, where he staid some time, and received a flattering invitation to remain in the court of the emperor; but his desire to revisit his native country prevailed, and he declined this honourable proposal. As he passed through Munich and Cologne, he was employed by the duke of Bavaria and the elector; and on his arrival at Brussels, the governor, Alexander Farnese, appointed him his principal engineer and painter, and sat to him for his portrait.

After the death of his patron he established himself at Antwerp, where he was much engaged in painting historical works for the churches, &c. and gained a great reputation; which has not been diminished by his having had for his disciple so renowned an artist as Rubens.

When the archduke Albert was appointed governor of the Netherlands, Otho Venius made the designs for the triumphal arches erected on his entrance, with which the archduke was so much gratified, that he invited him to Brussels, and appointed him his principal painter, and master of the mint, which situations he occupied till his death in 1634, at the age of 78.

Otho Venius did not confine himself to painting, he wrote and published several works adorned with prints, chiefly engraved by his brother, Gilbert Venius, from his designs. Among them are, a translation of part of Tacitus; Horace's Emblems, with notes and observations; the Life of Thomas Aquinas; and the Emblems of Love, divine and profane.

VENIZY, in *Geography*, a town of France, in the department of the Yonne; 3 miles N. of St. Florentin.

VENLO, a town of France, in the department of the Lower Meuse, late the duchy of Guelderland, situated on the E. side of the Meuse, takes its name from the two Flemish words *Veenen* and *Loo*, which signify a low meadow. Before the year 1343, it was only a small town, when Renaud II. duke of Gueldres, fortified it, and gave it the title and privileges of a city. It has only one parish-church, which is dedicated to St. John. After several changes of possessors, it was ceded, in 1715, to the States-General by the barrier treaty. In this town was made the first trial of bombs, about 1588; and they were first used by Alexander Farnese, duke of Parma, at the siege of Watchendonck, not long after. In 1794, it was taken by the French; 12 miles N.N.E. of Ruremond. N. lat. 51° 27'. E. long. 6° 2'.

VENNO, a town of the republic of Lucca; 5 miles S.S.W. of Lucca.

VENOE, a small Danish island, in the gulf of Lymford. N. lat. 56° 34'. E. long. 8° 38'.

VENOM, VENENUM. See POISON.

The terms *venom* and *poison* only differ from each other in this, that the latter is more frequently used where the noxious matter is taken inwardly, as in foods, drinks, &c.; and the former, where it is applied outwardly, as in stings and bites of serpents, scorpions, vipers, spiders, &c.

The pike is said to have a venomous tooth. All venomous beasts, in the general, have that quality in a greater degree, when

when bred in mountains and dry places, than when in wet and marshy places; and the southern more than the northern; those hungry and enraged, more than others; and all of them in summer more than winter. See VIPER.

VENONIS, in *Ancient Geography*, a town of Britain, in the 9th Iter of Antonine, situated between Ratis or Leicester, at the distance of 12 miles from it, and Bannavantium near Daventry; supposed to be the present Cleycester.

VENOSA, CARLO GESUALDO, *Prince of*, in *Biography*, a Neapolitan nobleman, whose fame has been extended by his musical productions more than by his high rank, though this rank will be found reciprocally to have added lustre to the compositions, was nephew to cardinal Alfonso Gesualdo, archbishop of Naples, and had his title from the place which gave birth to Horace, the Venusium of the ancients. Pomponius Nenna, a voluminous and celebrated composer of madrigals, had the honour to instruct him in music. His productions consist of six sets of madrigals for five voices, and one for six. The principal editor of his works was Simone Molinaro, maestro di capella at Genoa, who, in 1585, published the first five books in separate parts; and, in 1613, the same madrigals, with the addition of a sixth book, in score.

The numerous editions of these madrigals in different parts of Europe, and the eulogies bestowed on the author by persons who rank high in literature, as well as music, made us extremely curious to see and examine them. Gerard Vossius, Bianconi, Bap. Doni, Taffoni, and many others, speak of him as the greatest composer of modern times; as one who, quitting the beaten track of other musicians, had discovered new melodies, new measures, new harmonies, and new modulation; so that singers, and players on instruments, despising all other music, were only pleased with that of this prince.

Taffoni tells us, that James I. king of Scotland, had not only composed sacred music, but invented a new species of plaintive melody, different from all others; "in which he has been imitated by the prince of Venosa, who, in our times, has embellished music with many admirable inventions."

This passage in Taffoni, which has so often been cited by Scots writers, seems to imply, not only that James, king of Scotland, had invented a new species of melody, but that his melody had been imitated by the prince of Venosa; at least, this is the sense in which the passage has been understood by the natives of Scotland, and indeed by ourselves, till, on finding no kind of similarity between the national tunes of North Britain and the melodies of the prince of Venosa, we examined the passage anew, with more attention; when it appeared to us as if Taffoni's words did not imply that the prince of Venosa had *adopted* or *imitated* the melodies of king James; but that these princely dilettanti were *equally* cultivators and inventors of music. See DAVID RIZZIO, *SCOTS Tunes*, and OSSIAN.

The Neapolitan prince seems to merit as little praise on account of the expression of words, for which he has been celebrated by Doni, as for his counterpoint; for the syllables are constantly made long or short, just as it best suited his melody; and in the repetition of words, we frequently see the same syllable long in one bar, and short in another, or the contrary; by which it is manifest that their just accentuation was never thought of.

The remarks of Taffoni certainly must have been hazarded either from conjecture or report; as is but too frequently practised by men of letters, when they become musical critics, without either industry or science sufficient to verify their assertions.

The prince of Venosa was perpetually straining at new expression and modulation, but seldom succeeded to the satisfaction of posterity, however dazzled his contemporaries may have been by his rank, and the character he bore among the learned, who so frequently get their musical information from tradition, that whether they praise or censure, it is usually *sans connoissance de cause*.

Dilettanti usually decide in the same summary way, with an additional prejudice in favour of their own little knowledge, and a disposition to censure whatever they are unable to acquire, be it science or execution.

Cicero has long since said, that "it is not with philosophy and science, as with other arts; for what can a man say of geometry or music, who has never studied them? He must either hold his tongue, or talk nonsense."

With respect to the *excellencies* which have been so liberally bestowed on this author, who died in 1614, they are all disputable, and such as, by a careful examination of his works, he seemed by no means entitled to. They have lately been said to consist in "fine *contrivance*, *original harmony*, and the *sweetest modulation conceivable*." As to *contrivance*, it must be owned that much has been attempted by this prince; but he is so far from being happy in this particular, that his points of imitation are generally unmanageable, and brought in so indiscriminately on concords and discords, and on accented and unaccented parts of a bar, that, when performed, there is more confusion in the general effect than in the music of any other composer of madrigals with whose works we are acquainted.

His *original harmony*, after scoring a great part of his madrigals, particularly those that have been the most celebrated, is difficult to discover; for had there been any warrantable combinations of sounds that Palestrina, Luca Marenzio, and many of his predecessors, had not used before him, in figuring the bases, they would have appeared. And as to his *modulation*, it is so far from being the *sweetest conceivable*, that, to us, it seems forced, affected, and disgusting.

We have bestowed more remarks on this prince of musicians, and more time in the examination of his works, than perhaps they now deserve, in order to furnish our readers with what seems, to our comprehension, a truer idea of their worth, than that which partiality and ignorance have hitherto given. A score of one of his madrigals in the 3d vol. of Burney's *Gen. Hist. of Mus.* p. 223. will justify our censures of the musical productions of this tuneful prince.

VENOSA, in *Geography*, a town of Naples, in Basilicata, the see of a bishop, suffragan of Matera. It contains seven churches, and as many convents. In the 9th century, Venosa was taken by the Saracens, and in 1528 by the French; 9 miles N.N.W. of Acerenza. N. lat. 40° 58'. E. long. 15° 48'.

VENOSA Arteria. See ARTERIA Venosa.

VENOSTA, in *Geography*, a valley of the Tyrolese, on the banks of the Adige; 20 miles S. of Glurentz.

VENOSUM FOLIUM, in *Botany* and *Vegetable Physiology*, a veiny leaf. See LEAF and VEIN.

VENOUS, VENOSUS. See VENAL.

VENT, in *Geography*, a river of England, in the county of Cumberland, which runs into the South Tyne.

VENT, formed from *ventus*, *wind*, *vent-hole*, or *spicacle*, a little aperture left in the tubes or pipes of fountains, to facilitate the air's escape; or, on occasion, to give them air; as in frosty weather, &c. for want of which they are apt to burst.

A Vent, taken in this sense, is properly the end of a pipe, placed

placed erect, and reaching above the ground; usually soldered to the turns, or elbows, of pipes. The vents of large pipes are to be as high as the superficies of the reservoir, unless there be a valve in them.

VENT is also used for a little hole, pierced in vessels of wine, beer, &c. that are on tap; and which admits air enough to make the liquor run, but not so much as to corrupt and spoil it.

VENT, again, is applied to the covers in wind-furnaces, by which the air enters, which serves them for bellows; and which are stopped with registers, or slices, according to the degree of heat required: as in the furnaces of glass-houses, assayers, &c.

VENT is also used for a pipe of lead, or other matter; one end of which opens into the cell of a necessary-house, and the other reaches to the roof of the house, to give room for the corrupt fetid air to exhale.

There are also vents, or apertures, made in the walls which sustain terraces, to furnish air, and give a passage for the waters.

This kind of vent the Italians, and we from them, call a *barbacane*.

VENT, in *Gunnery*. See *TOUCH-Hole*.

The common method of placing the vent is within about a quarter of an inch from the bottom of the chamber or bore. Some, however, have thought, that if the vent was to come out at the middle of the charge, the powder would be inflamed in less time than in any other case; but Mr. Muller, by firing mortars with two vents, one at the bottom and the other in the middle, and so contrived that one was shut whilst the other served to fire, found always the range of the shell greater when the lower vent was used, than when the powder was fired by the middle one. *Artillery*, p. 83.

Mr. Thompson (Count Rumford) has lately made a number of experiments, in order to determine the best position of the vent; from the result of which it appears, that the effect of placing the vent in different positions with respect to the bottom of the chamber, is different in different charges; but the difference in the force exerted by the powder, which arose from the particular position of the vent, was in all cases so inconsiderable, as to afford occasion for concluding, that any given charge of powder exerts nearly the same force, whatever is the position of the vent. He infers, upon the whole, that in the formation of fire-arms no regard need be had to any supposed advantages that gunsmiths and others have proposed to derive from particular situations for the vent; such as diminishing the recoil, increasing the force of the charge, &c.; but the vent may be indifferently in any part of the chamber where it will best answer upon other accounts; and he thinks there is little doubt but the same thing will hold good in great guns, and all kinds of heavy artillery. Workmen in general agree, that the vent in fire-arms should be as low or far back as possible, in order, as they conceive, to lessen the recoil: accordingly some make the bottom of the chamber flat, and bring the vent out even with the end of the breech-pin; others make the vent slanting through the breech-pin, in such a manner as to enter the bore just in its axis; others again make the bottom of the chamber conical; and there are those who make a little cylindrical cavity in the breech-pin, of about two-tenths of an inch in diameter, and near half an inch in length, coinciding with the axis of the bore, and bring out the vent even with the bottom of this little cavity.

The objection to the first method is, that the vent is apt to be stopped up by the foul matter that adheres to the

piece after firing, and which is apt to accumulate, especially in damp weather. The same inconvenience in a greater degree attends the other methods, with the addition of another, arising from the increased length of the vent; for the vent being longer, is not only more liable to be obstructed, but it takes a longer time for the flame to pass through it into the chamber; in consequence of which the piece is slower in going off, or, as sportsmen term it, is apt to hang fire. Mr. Thompson proposes, that the bottom of the bore should be in form of a hemisphere; and that the vent should be brought out directly through the side of the barrel, in a line perpendicular to its axis, and pointing to the centre of the hemispheric concavity of the chamber. In this case the vent would be the shortest possible; it would be the least liable to be obstructed, and the piece would be more easily cleaned. Similar advantages, he apprehends, would be gained by making the bottom of the bore and vent of the great guns in the same manner. *Phil. Trans.* vol. lxxi. part ii. p. 272, &c.

From a variety of experiments made by order of the king of Prussia in 1765 and 1766, it appears, that the concave chamber produced the greatest ranges, and that the bottom of the chamber is the best place for the vent.

VENT-*Afragal*, is that part of a gun or howitz which determines the vent-field.

VENT-*Field*, is the part of a gun or howitz between the breech-mouldings and the afragal.

VENT, *Port*. See *PORT-VENT*.

VENTA, in *Ancient Geography*, a name given to several British towns, of which our antiquaries have given different etymologies. Mr. Baxter's conjecture may be allowed to be most probable, who supposes that it is derived from *wend*, or *went*, which signifies head or chief. For it is observable, that all the towns which were named Venta, were the capitals or chief towns of the nations or people to whom they belonged.

VENTA *Belgarum*, a town of Britain, placed in the seventh Iter or route of Antonine, from Regnum or Chichester to London, between Clausentum or Old Southampton, and Calleva Atrebatum or Silchester; and situated at the present Winchester, as our antiquaries agree. It was the capital of the Belgæ.

VENTA *Icenorum*, a town of Britain, placed at the head of the ninth Iter or route of Antonine, 128 miles from London. This town was probably the capital of the Icenii, or ancient inhabitants of Norfolk, Suffolk, Cambridgeshire, and Huntingdonshire; and it is generally supposed by our antiquaries to have been situated at Caister, upon the river Yare, about three miles from Norwich, which is thought to have arisen out of the ruins of this ancient city. Here have been found some faint vestiges of this ancient capital of the Icenii.

VENTA *Silurum*, a British town, placed in the fourteenth Iter or route of Antonine, from Isca or Caerleon, to Calleva or Silchester. This was a considerable town of the Silures, between Isca and Abona. It is our Caerwent. See *SILURES*.

VENTA *Cibay, La*, in *Geography*, a town of Spain, in Guipuscoa; 6 miles from Trevigno.

VENTA *de Cruz*, a sea-port town of America, on the isthmus of Darien, on the river Chagre, where the merchandise from Panama is put on board barks to be conveyed to Porto Bello; 20 miles N. of Panama. N. lat. 9° 26'.

VENTA *Quemada*, a town of Spain, in the province of Jaen; 42 miles N. of Jaen.

VENTA *de en Medio*, a town of Peru; 20 miles N. of Ouro.

VENTA *Sierra*, mountains of South America, in the province of Venezuela.

VENTALDA, a town of Sweden, in the province of Smaland; 34 miles S.E. of Jonkiöping.

VENTAROLI, a name given in Sicily, &c. to grottoes formed under their houses, from which issues a constant extreme cold wind, and at times with impetuosity, and a noise like water dashing upon rocks. These are shut up with doors like cellars, and made use of as such, as also to keep provisions fresh, and to cool liquors. At Cefi, in the Roman state, there are many such ventaroli; and the inhabitants of that town, by means of leaden pipes, conduct the fresh air from these into the rooms of their houses, so that by turning a cock they can cool them to any degree. Some who have refined still more upon this luxury, by smaller pipes, bring cold air under the dining table, so as to cool the bottle of liquor upon it. On mount Ætna and Vesuvius, and in the island of Ischia, there are many caverns of this kind. Phil. Transf. vol. lxx. part i. p. 73.

VENTENATIA, in *Botany*, was so named by M. Palissot-Beauvois, in honour of the late M. E. P. Ventenat, member of the National Institute, a distinguished French botanist, who was formerly an ecclesiastic, and, if we mistake not, of some religious order; but he took advantage of the revolution to free himself from such unnatural and immoral shackles, in order to fulfil the duties of a man and a Christian. He has distinguished himself by the publication of a *Tableau du Regne Végétal, selon la Méthode de Jussieu*, in 4 vols. 8vo.; as well as the magnificent *Jardin de la Malmaison*, with coloured plates, in large folio; and the uncoloured *Jardin de Cels*, and *Choix de Plantes*; the latter having been soon cut short by his death. The writer of this article had dedicated to the name of M. Ventenat, a New Holland genus, (see *STYLIDIUM*,) which now yields to the prior right of the genus before us.—Palissot Beauv. Fl. d'Oware et de Benin, fasc. 2. De Theis 479. Poiret in Lamarck Dict. v. 8. 450.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Tiliaceæ* Juss.?

Gen. Ch. Cal. Perianth inferior, in three deep, equal, oblong, obtuse, concave, coriaceous, deciduous segments. Cor. Petals numerous (eleven or twelve), spatulate, spreading, strongly veined; rounded at the extremity; contracted into a claw at the base. Stam. Filaments numerous, thread-shaped, erect, unequal, much shorter than the petals, inserted, like them, into the receptacle; anthers Pist. Germen superior, oval; style thread-shaped, undivided, longer than the stamens; stigma thick, obscurely five-lobed. Peric. Berry oval-oblong, of five cells, furrowed longitudinally, terminating in a kind of mammillary point. Seeds numerous in each cell.

Ess. Ch. Petals numerous. Calyx in three deep deciduous segments. Berry superior, of five cells, with many seeds.

Obf. M. Palissot Beauvois remarks, that this genus is obviously referrible to Jussieu's 13th class, (Poiret by mistake says the 3d), but its order in that class is not so easily determined. Dissections of the ripe seed are wanting to ascertain this point. The fruit nearly accords with Jussieu's *Aurantia*, but the structure of the flower, and the want of pellucid dots in the leaves, exclude it from that order. The want of stipulas prevents its perfect agreement with the *Tiliaceæ*, and M. Beauvois considers this genus as probably making one of a new order, confounded by Jussieu with his *Tiliaceæ*.

1. *V. glauca*. Glauous Ventenatia. Palissot Beauv. Fl. d'Oware et de Benin, 29. t. 17. Poiret n. 1.—Native of elevated, airy, open situations, near Agathon, on the coast

of Africa. A *shrub*, with alternate, round, smooth branches. Leaves alternate, stalked, very large, elliptic-oblong, entire, tipped with a long acute point; rounded at the base; smooth on both sides; covered on the under surface with a kind of glaucous viscosity, which when dry becomes almost powdery. Stipulas none. Flowers lateral, towards the extremity of each branch, solitary, stalked, alternate, sometimes opposite to the leaves; their stalks half the length of the leaves, cylindrical. Calyx short, smooth. Corolla large, of a fine crimson, beautifully veined. Poiret.

VENTER, in *Anatomy*, the abdomen; called also minus venter. See ABDOMEN.

VENTER is also used for the womb, or uterus, of women. And hence the writ *de ventre inspiciendo*.

Hence, also, in the civil law, we say, *partus sequitur ventrem*, the child follows the belly; meaning, that its condition is either free or servile, according to that of its mother.

They also say, to appoint a curator for the belly, with regard to posthumous children, yet in the mother's womb. With regard to princes, the venter, or belly, has been sometimes crowned in form.

VENTER is also used, in speaking of a partition of the effects of a father and mother, among children born, or accruing, from different marriages.

This partition is so ordered, as that a single child of one marriage, or venter, takes as much as several of another marriage, or venter; in order to which, the estate is divided into so many parts as there have been venters, or marriages.

VENTER, or *Belly*, of a muscle. See BELLY of a Muscle.

VENTER *Draconis*, *Dragon's Belly*, in *Astronomy*. See *DRAGON'S BELLY*. See also DRAGON, in *Astronomy*.

VENTER *Equi*, *Horse's Belly*, among *Chemists*, denotes horse-dung, or a dunghill, on which are inclosed certain vessels for particular operations, to be performed by means of the gentle heat of it.

VENTES *les Grandes*, in *Geography*, a town of France, in the department of the Lower Seine; 9 miles N.W. of Neufchâtel.

VENTHIE, LA, a town of France, in the department of the Straits of Calais; 9 miles N.E. of Bethune.

VENTIA, in *Ancient Geography*, or *Venetsium Civitas*, a town situated in the Maritime Alps. Dion Cassius, speaking of an expedition, dated in the year of Rome 693, against the Allobroges, who had revolted, mentions a town under this name, at a small distance from the Isere. According to some circumstances pertaining to this expedition, there is reason to believe that it is Vinet, between Moirène, or Tullin and St. Marcellin, at some distance from the right bank of the Isere.

VENTIDUCTS, in *Building*, are spiracles, or subterraneous places, where fresh cool winds, being kept, are made to communicate by means of tubes, funnels, or vaults, with the chambers, or other apartments of a house, to cool them in sultry weather.

These are much in use in Italy, where they are called *ventidotti*. Among the French they are denominated *prisons des vents*, and *palais d'Eole*. See VENTAROLI.

VENTILAGO, in *Botany*, so called by Gærtner, because the appendage to the seed-vessel was thought to bear some resemblance to a winnow or flapper, *ventilabrum*. It does not answer to the common idea of a fan, being neither plaited, nor much dilated upwards.—Gærtner. v. 1. 223. t. 49. Willd. Sp. Pl. v. 1. 1106. Roxb. Coromand. v. 1. 55. Mart. Mill. Dict. v. 4. Poiret in Lamarck Dict. v. 8. 452.

—Class

—Class and order, *Pentandria Monogynia*. Nat. Ord. *Dumose*, Linn. *Rhamnii*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cup-shaped, with five equal, triangular, deciduous, marginal segments. *Cor.* Petals five, spatulate, inserted into the rim of the calyx, alternate with its segments, and rather longer. *Stam.* Filaments five, awl-shaped, opposite to the petals, the length of the calyx; anthers of two round lobes. *Pist.* Germen superior, invested below with the tube of the calyx, nearly globose; style short, cloven half way down; stigmas two, divaricated, acute. *Peric.* Capsule globular, of one cell, and two valves; splitting at the base; crowned at the summit with an elliptic-oblong, flat, coriaceous, ribbed wing, many times longer than the capsule. *Seed* solitary, globose.

Ess. Ch. Calyx cup-shaped, with five deciduous segments. Petals five, opposite to the stamens. Capsule of one cell, crowned by an elongated wing. Seed solitary.

Obs. Gærtner did not see the capsule in a sufficiently advanced state to discover that it has really two valves, which separate at the base, continuing connected at the apex by their long coriaceous wing, in which the most remarkable character of the genus consists. The flowers are occasionally dioecious, from the imperfection of one or other organ of impregnation.

1. *V. maderaspatana*. Yerra Chirtaly of the Telingas. Willd. n. 1. Roxb. Coromand. v. 1. 55. t. 76. (*Funis viminalis*; Rumph. Amboin. v. 5. 3. t. 2.)—Native of forests and uncultivated places, among the mountains of Hindoostan and Ceylon, and of rocky thickets on the shores of Amboyna, flowering in the cold season. The stem is woody, climbing to a great extent, with long, round, pliant, tough, leafy, often downy, branches. Leaves alternate, on short stalks, ovate, bluntish, two or three inches long, coriaceous, more or less obscurely crenate, seldom quite entire, smooth or minutely downy, furnished with one midrib, and many transverse ones, connected by extremely fine parallel veins. Flowers very numerous, small, greenish-white, in large, terminal, compound panicles, their scent highly offensive, resembling *Sterculia foetida*. Wing of the capsule entire, greenish-yellow, slightly downy, above an inch in length. — Willdenow, according to Poiret, has distinguished two species of this genus, in the new Transactions of the Berlin Society; one having entire and smooth, the other crenate and downy, leaves. But we are persuaded, from an examination of wild specimens from Roxburgh and Koenig, that these characters are variable.

VENTILATION of Mines, comprises the various modes by which impure air is removed, and a current of atmospheric air propelled through the subterranean openings and passages of mines. The health, the safety, and lives of a very large and industrious class of the community depend on the regular ventilation of mines; yet the application of the principles on which this should be undertaken has been but imperfectly understood, and it is but very recently that the subject has engaged the attention of men of science. Since the constitution of the atmosphere was ascertained, (see ATMOSPHERE,) it is well known that the one-fifth part of it, or the oxygen gas, is essentially necessary to support the processes of respiration or combustion, by which it undergoes a chemical change, and is converted into carbonic acid gas, a gas destructive of animal life, and in which flame is instantly extinguished. It is also as well known, that the remaining four parts of the atmosphere, or the azote, are equally destructive of life, and incapable of supporting flame: hence the necessity of ventilation, or a regular supply of fresh air, in all confined situations, where

men are to labour or exist, is very easily explained. Besides the destruction of oxygen gas by respiration or combustion, which takes place in confined apartments above ground, there are other causes that render the air impure in almost all subterranean passages or mines, through which there is not a regular current of wind constantly passing. The causes by which the air in mines is rendered impure, or destructive of animal life, are of three kinds. First, the respiration of men and horses in the mine, and the combustion of the lamps, &c; secondly, the production and evolution of carbonic acid gas in the beds or strata in which the mine is situated; and thirdly, the production of carburetted hydrogen or inflammable gas. For the properties of these gases, see GAS. The two former sources of impurity are much less destructive of life than the latter, the inflammable gas or *fire-damp* of the miners: when this becomes mixed to a certain degree with the air of the mine, it explodes with great violence on the approach of a lamp or candle, and occasions the most fatal accidents, destroying all the vital air in the mine, and burning or suffocating the workmen. By explosions of this nature, it was estimated that not less than six hundred persons perished during the years 1813 and 1814, in the coal-mines on the rivers Tyne and Wear, in Northumberland and Durham; and the destruction of human life in other coal districts has been perhaps equally great, in proportion to their extent. In the ventilation of mines, where the air is impure from respiration, combustion, or the evolution of carbonic acid gas, called by the miners *choak-damp*, the object of the miner is simply to introduce a current of fresh air through the works; but besides the difficulties to be overcome in effecting this, where the works are extensive, the miner who has to combat with the fire-damp must guard against the greater evil of an explosion, to which he is almost constantly exposed.

In the working of metallic mines, the veins being generally nearly vertical, the currents of water, or the natural passages, aided by the varied temperature of the mine, are frequently sufficient to insure the circulation of air; and these mines are very rarely affected by the production of the fire or choak damp. It is principally where a shaft or well is sunk, or a horizontal passage or gallery is made, that any means of artificial ventilation are necessary. The most obvious remedy, and that which is most frequently resorted to, is opening a communication with some other part of the mine, or with the surface; and when this is done, the ventilation is found to be perfect by the rushing of the currents, which often takes place with considerable force, from the different degrees of temperature in the lower and upper air, and these currents change their direction as the temperatures above and below alternate. The great objection to this mode is the expence with which it is commonly attended wherever the gallery is at a great depth, and the intervening rock of a very hard kind, and where a shaft is merely wanted to supply air, and not for the passage of the water. To avoid this, the shaft or level is sometimes divided into two distinct parts, communicating near the part intended to be ventilated, so that a current may be produced in opposite directions on each side of the partition; and this is often effectual to a certain extent. It has, however, its limits at no very great distance, and the current is but a feeble one, from the nearly equal temperature of the air on each side of the partition.

The other mode employed is to force air down tubes with a large pair of bellows worked by the hand, or by boxes or cylinders of various forms placed on the surface, with a large opening against the wind, and a smaller one communicating with the air-pipes by a cylinder and piston working

working in it, and when driven by a sufficient force, this has great power.

Mr. John Taylor, in the Transactions of the Society of Arts for 1810, has described a method of effecting this process more easily, by attaching an air-pump of a very simple construction to a small fall of water. The engine discharges more than two hundred gallons of air in a minute, and a stream of water supplied by an inch and a half bore falling twelve feet is sufficient to keep it regularly working. This method may be introduced with great advantage into narrow passages or wells, but would be obviously inadequate to ventilate the immense excavations in coal-mines, except it were directed only to some confined part of the works. In metalliferous mines, the generation of the fire-damp is much less frequent than in coal-mines, and the extent and position of the excavations make the ventilation of the latter a labour of much greater difficulty. The most valuable beds of coal in England, with the exception of Staffordshire, are from two to nine feet in thickness, and they rarely incline more than about fifteen or twenty degrees from the horizontal level, and are frequently nearly flat. Each pit has two shafts or wells, called the *downcast pit* and the *upcast pit*. The excavations or passages in the coal, which communicate from one pit to the other, are frequently not less than forty miles or more in length, through which circuitous route the air has to take its course, though the distance from the downcast to the upcast shaft, in a right line, may not be more than a few hundred yards or feet, or even much nearer. And here we cannot but observe, that as the means to force the air through a route of such extent must be very complicated, and as a failure or accident to a part might destroy the whole ventilation, we conceive that much too large a surface is frequently worked from two shafts, in order to avoid the expence of additional shafts for several detached workings of a smaller extent. By this, the risk of the workmen is greatly increased, to save expence to the owners of the coal. In the year 1813, some gentlemen in the north of England, impressed by the dreadful catastrophes which had recently taken place, very laudably established a society, with a view to inquire into the causes of these calamities, and the possible means of prevention. They entitled themselves "A Society for preventing Accidents in Coal-Mines." Mr. John Buddle, an eminent coal-viewer in Northumberland, addressed a letter to the president, which was published by the society in 1815. In this letter he details the various methods which had been employed for the prevention of accidents by fire, which, he says, "consist in a mechanical application of the atmospheric air to the removal or sweeping away of the inflammable gas, as it is generated in the workings of collieries, or as it issues from the fissures which the workings intersect in their progress." He details the various methods by which this is effected: these are explained by a number of figures and sections, without which they could not be rendered intelligible to the reader. We shall endeavour to give an idea of the principle on which the various modes of ventilating mines depend, by stating one of the simplest forms in which they can act. If two wells or shafts were sunk at a given distance, say fifty yards from each other, and a horizontal passage were cut from the bottom of one well to the other, so soon as the communication were made, there would be a tendency in the air to descend one shaft and ascend the other, whenever the temperature of the external air varied from that of the air below. The currents of air in natural caverns, that are open at each extremity, proceed from the same cause. In certain states of the atmosphere, should the current not be sufficient, or should a quantity of impure air

be generated in the passage, the circulation may be increased by kindling a fire at the top or at the bottom of one of the wells, to rarefy the air and cause it to ascend more rapidly. Or the air may be forced down the other well, by causing a stream of water to fall into it. Also by means of vanes, or by an air-pump attached to a steam-engine, the circulation may be easily increased according to the will of the engineer, and the facilities which may be presented for carrying away the water, &c. Thus little difficulty could arise in a case of simple ventilation of this kind; but if from the horizontal passage which runs from one shaft to the other, we make a number of passages on each side at right angles with it, as is done in coal-mines, the current of air which passes through it will not enter these lateral passages, or occasion any circulation in them. In order, therefore, to make the air pass through the whole series, another passage must be opened, connecting the further extremities of the lateral passages with each other: the first passage must then be closed, and the air which descends conducted along the lateral passages, up one and down the other, taking a circuitous route through the whole, until it arrives at the up-cast shaft, which it ascends. To conduct the air in this manner, a number of trap-doors and stops are necessary, in order to prevent the mixture of the air from the different passages, which would entirely destroy the ventilation. See *Plate IV. Geology, fig. 8.* which represents part of the workings of a coal-mine; the shaded part is the bed of coal, in which the workings are carried along the different passages, from the pit or shaft *a*, to the pit or shaft at *b*. The current of air is represented by darts and dotted lines. The stops and trap-doors, which close to prevent the passage of the air, and confine the currents to a particular course, are represented by double lines and cross lines, as at *t t*. This figure represents the improved system of ventilation, by which the current of air sweeps every part of the workings. By tracing the darts and dotted lines, it will be seen that the current of air from the downcast pit *a*, first passes along the main passage to *A*, and the adjoining passage *M B*, to which it has access through lateral passages, called *walls*, 1, 2, 3, 4: its further progress in every direction is closed, except at 5, where it enters the passage *C*, from which it has access to the passage *D*, through the openings 6, 7, 8, 9: at *E*, the currents unite in one stream, and enter an advanced part of the workings, called the *head-ways*, ventilating the passages *F* and *G*, being forced into them by partitions called *brattices*, placed at *X X*, round which the air must pass in its progress to *H*.

Where the current of air divides and sweeps along two passages at the same time, and unites again as above-described, it is called *double coursing*; but where it runs down one passage and up another, as may be seen in its further progress from *H* on the south side, to *H* on the north side of the mine, it is called *single coursing*.

The remaining part of the ventilation back to the passage *K K*, is in double courses, along which it is forced by the stoppings at *s, s, s, s*, and the other stoppings *r, r, r, r*, until it ascends the upcast shaft at *b*. Under this system, says Mr. Buddle, *if the stoppings, &c. be all in order*, and the passages kept sufficiently open for the current of air to circulate freely, there can be no partial stagnations in the workings,—no accumulation of inflammable gas. For in the event of a large discharge of gas, from what is called a blower, commencing at any place, as at *M, N, P, Q*, its stream is immediately carried off by the circulating current of atmospheric air, and so diluted that it cannot explode, unless indeed the discharge of inflammable air should be so copious as to mix with the current up to the *firing point*, or to that degree

VENTILATION.

degree in which it would inflame by access to a lighted candle or to fire.

This improved system of ventilation by double courses was introduced into the collieries on the Tyne and Wear about the year 1760, and has ever since continued in general use; but it is found inadequate to the intended purpose in the following cases.

1. When sudden discharges of inflammable gas mix with and raise the whole circulating mass of air to the firing point.

2. When the wind is south-east, and the weather wet or hazy, and the barometer sinks below twenty-nine inches.

In this case the atmospheric current, which under the most favourable state of the air is merely sufficient to sweep the noxious effluvia from some mines, gets so contaminated by the discharge of inflammable gas, and the slowness of its own progress, as to be exceedingly unsafe, and generally inaccessible with candles.

3. When inflammable air fills a part of the mine between the workmen and the upcast shaft.

4. When the gas is ignited by lightning, as it ascends the upcast shaft.

The presence of inflammable gas from the slightest mixture, through all its gradations to the first firing point, is readily discoverable by an experienced collier, and he judges very correctly of the degree of inflammability and danger which threaten the safety of the mine, by observing attentively the appearance of the spire upon the top of his candle. The common pit-candles vary in size, but those generally used are forty-five to the pound; the wick is of cotton, and the candle made of ox or sheep tallow: but clean ox-tallow is best.

The mode of trying the candle, as it is called, to ascertain the mixture of inflammable gas, is as follows.

In the first place, the liquid fat is wiped off, the wick snuffed close, and carefully cleansed of red embers, so that the flames may burn as purely as possible. The candle, being thus prepared, is held between the fingers and thumb of the one hand, and the palm of the other is placed between the eye of the observer and the flame, so that nothing but the fire and the flame can be seen, as it gradually towers over the upper margin of the hand. The observation is generally commenced near the floor of the mine, and the light and hand are gently raised upwards, till the true state of the circulating current be ascertained. The first indication of the presence of inflammable air, is a slight tinge of blue or a blueish-grey colour shooting up from the top of the spire to the candle, and terminating in a fine extended point. The spire increases in size, and receives a deeper tinge of blue as it rises through an increased proportion of inflammable gas, till it reaches the firing point; but the experienced collier knows accurately enough all the gradations of show (as it is called) upon the candle, and is very rarely fired upon, excepting in sudden discharges of inflammable gas. The show upon the top of the candle varies very much, according to the length of run or distance which the current of air has passed through before it is mixed with the inflammable gas. The shorter the run of the current of air before it is mixed with the inflammable gas, the less will be the show upon the candle when at the first firing point, and *vice versa*.

The same size of spire which would indicate danger in a current which had passed only one mile, might be perfectly harmless in a current that had ran five or six miles; consequently the length of run of the current of air is to be taken into consideration, as well as the appearance of the top of the candle. The air-course, too, for a short distance be-

yond a small discharge of fire-damp may be highly inflammable; but by passing a few yards further, it becomes so diluted as to be perfectly secure. The distance, therefore, within which a blower can be safely approached with candles, is regulated entirely by the magnitude of the discharge and power of the current of air. Long experience and attentive observation are consequently necessary to obtain a thorough practical knowledge of this art.

The workings of a colliery are very often inaccessible with candles near the downcast pit, called the first of the air, while they may be safely entered with any description of light near the upcast pit, called the last of the air. This arises from the inflammable gas, as it is carried from the place of its discharge, being gradually diluted by the atmospheric current. Hence the advantage of sufficient extent of pit-room, to obtain length of run to dilute the inflammable air. It is from the want of pit-room, that the explosions in newly-opened collieries are generally the most violent. The distance which the current of air passes through, between the downcast and the upcast pits, varies much according to circumstances. Mr. Buddle has known it to exceed thirty miles.

After the current of atmospheric air is so highly mixed with inflammable air as not to be accessible with lighted candles, steel-mills may be employed with safety. We shall further notice Mr. Buddle's observations on steel-mills, but we believe the discovery of the safety-lamp will entirely supersede their use. "Although the inflammable air has frequently fired at the sparks of the steel-mills, it only happens, from all the facts which I have been able to collect, when the mills are played near the place where the hydrogen gas is discharged, and this by due attention may be easily avoided.

"I never indeed witnessed an explosion from the sparks of flint; but from my own observations on their appearance in dangerous states of the air, as well as from the observations of several intelligent men, I believe that in most cases the change of the appearance of the sparks, if attentively observed, gives sufficient notice of the threatening danger. When elicited in atmospheric air, they are of a bright appearance, rather inclining to a reddish hue, and as they fly from the wheel seem sharp and pointed. In a current of air mixed with inflammable gas above the firing point with candles, they increase considerably in size and become more luminous. On approaching the firing point with steel-mills, they grow still more luminous, and assume a sort of liquid appearance, nearly resembling the sparks arising under the hammer from iron at the welding heat. They also adhere more than usual to the periphery of the wheel, encompassing it as it were with a stream of fire, and the light emanating from them is of a blueish tint. When the inflammable gas predominates in the circulating current, the sparks from the steel-mill are of a blood-red colour; and as the mixture increases, the mill totally ceases to elicit sparks. They have the same bloody colour in carbonic acid." The steel-mill here mentioned is what has been used till very recently in coal-mines, consisting of a wheel and spring, which is wound up and set in motion, whereby a constant collision of flint and steel is effected, eliciting a copious stream of sparks. With the concluding remarks of Mr. Buddle's letter we can by no means agree, when he adds, "On the strength of my own experience in collieries thus circumstanced, I freely hazard my opinion, that any further application of mechanical agency towards preventing explosion in coal-mines would be ineffectual." Among the means enumerated by this gentleman, the very obvious one of depending on the greater specific levity of the carburetted hydrogen gas is entirely omitted;

omitted; nor is it even stated, that the general inclination of the strata present facilities for the ascent of the inflammable air, were requisite precautions taken to conduct it by channels to the mouth of the upcast pit, which in many situations might be done at a trifling expence.

The public have been given to understand, that an improved and complete system of ventilation, depending on this principle, had been introduced into some of the Staffordshire collieries; but on recent inquiry at the place, we were informed, that the method of ventilation proposed by Mr. Ryan had never been carried into practice to the full extent stated, but considerable advantage had been derived from a partial application of the principle, by making channels near the roof of the mine for the escape of the inflammable gas.

Where the strata rise regularly for a considerable extent, unbroken by faults, it appears easy to discharge the inflammable gas as fast as it is generated. The specific gravity of carburetted hydrogen is little more than one-half the weight of atmospheric air, being as .555 to 1000. If, therefore, it were conducted along the roof by an unobstructed passage to the upcast shaft, it would rise and discharge itself.

Explosions not unfrequently take place at the upcast shaft, from the inflammable air passing near the fire placed at the bottom to rarefy the air and increase the circulation. The only expedient at present suggested is the use of charcoal, as the gas will not ignite at a red heat without flame; but charcoal does not promote so rapid a circulation of air as coal or wood, which produce smoke and flame. The carbonic acid gas generated by the combustion of charcoal, being also heavier than atmospheric air, would in some degree retard the ascent of air from the upcast shaft; and if a small particle of coal fell upon the charcoal fire, it would produce flame, which might cause an explosion.

A series of most interesting experiments was undertaken by Sir H. Davy in 1815, on the degree of inflammability of different admixtures of carburetted hydrogen when passed through small tubes or apertures, which led to the very important and unexpected result, that carburetted hydrogen, mixed with atmospheric air in the proportion which is most explosive, and then ignited, will not set fire to another portion of the same air, separated from it by a sieve of small wire, the meshes of which amount to two hundred and fifty in the square inch. On this principle he constructed a lamp surrounded by a small wire-sieve in the place of horn or glass, having no aperture for the admission or transmission of air but through the meshes of the sieve. This lamp, when lighted, was found to burn in explosive mixtures with perfect safety, the flame being confined within the lamp by the intervening wire-sieve. This lamp has since undergone considerable improvements, and some of the objections to which it was first exposed have been removed. Important additions to it are still making by its illustrious inventor. For a full account of its construction and recent improvements, we must refer to the article *WIRE-GAUZE SAFETY-LAMP*.

VENTILATOR, a machine by which the noxious air of any close place, as an hospital, gaol, ship, chamber, &c. may be discharged and changed for fresh.

The noxious qualities of bad air have been long known; and no one has taken greater pains to set the mischiefs arising from foul air in a just light than Dr. Hales; who has also proposed an easy and effectual remedy by the use of his ventilators; his account of which was read to the Royal Society in May, 1741. In the November following, Mr. Triewald, military architect to the king of

Sweden, informed Dr. Mortimer, secretary to the Royal Society, that he had in the preceding spring invented a machine for the use of his majesty's men of war, in order to draw out the bad air from under their decks, the least of which exhausted 36,172 cubic feet of air in an hour, or at the rate of 21,732 tons in twenty-four hours. In 1742 he sent one of them, formed for a sixty-gun ship, to France; which was approved of by the Royal Academy of Sciences at Paris; and the king of France ordered all the men of war to be furnished with the like ventilators.

The ventilators invented by Dr. Hales consist of a square box A B C D (*Plate XVII. Pneumatics, fig. 1.*) of any size: in the middle of one side of this box a broad partition, or midriff, is fixed by hinges X, and it moves up and down, from A to C, by means of an iron rod Z R, fixed at a proper distance from the other end of the midriff, and passing through a small hole in the cover of the box up to R. Two boxes of this kind may be employed at once, and the two iron rods may be fixed to a lever F G (*fig. 2.*) moving on a fixed centre O; so that by the alternate raising and pressing down of the lever F G, the midriffs are also alternately raised and depressed, by which these double bellows are at the same time both drawing in air, and pouring it out through apertures with valves made on the same side with, and placed both above and below the hinges of the midriffs. In order to render the midriffs light, they are made of four bars lengthwise, and as many across them breadthwise, the vacant spaces being filled up with thin panels of fir-board; and that they may move to and fro with the greater ease, and without touching the sides of the boxes, there is an iron regulator fixed upright to the middle of the end of the box A C (*fig. 1.*) from N to L, with a notch cut into the middle of the end of the midriff at Z, so that the midriffs, in rising and falling, suffer no other friction than what is made between the regulator and the notch. Moreover, as the midriff Z X moves with its edges only one-twentieth of an inch from the sides of the box A B C D F E, very little air will escape by the edges, and, therefore, there will be no need of leathern sides, as in the common bellows. The end of the box at A C is made a little circular, that it may be better adapted between A and C to the rising and falling midriff; and at the other end, X, of the midriff, a slip of leather may be nailed over the joints, if needful. The eight large valves, through which the air is to pass, are placed at the hinge-end of the boxes B K (*fig. 2.*) as at 1, 2, 3, &c. The valve 1 opens inward to admit the air to enter, when the midriff is depressed at the other end, by means of the lever F G. And at the same time the valve 3 in the lower ventilator is shut by the compressed air which passes out at the valve 4. But when that midriff is raised, the valve 1 shuts, and the air passes out at the valve 2. And it is the same with the valves 5, 6, &c. of the other box; so that the midriffs are alternately rising and falling, and two of the ventilators drawing in air, and two blowing it out; the air entering at the valves 1, 3, 6, 8, and passing out at the valves 2, 4, 5, 7. Before these last valves there is fixed to the ventilator a box Q Q N M (*fig. 3.*), as a common receptacle for all the air which comes out of these valves: which air passes off by the trunk P, through the wall of a building.

For a farther account of this machine we refer to the author himself, who gives a full detail of it, and of its manner of working. See Description of Ventilators, by Stephen Hales, D.D. Lond. 1743, 8vo.

The doctor has shewn the use of his ventilators very fully. As to ships, in particular, he observes, that the *wind-sail*, (see *WIND-SAIL*), made use of at sea to introduce fresh air between

VENTILATOR.

between decks, is far from being sufficient for that purpose; nor can it be used with equal safety to the sick, and those who are sleeping, by means of the strength of the wind, which conveys the air with too much violence. But when the foul air is carried off by means of ventilators, notwithstanding the great velocity with which they throw out the air, which they may do at the rate of sixty tuns in a minute, yet the motion of it downwards into the hold, to supply what was carried off, is so very gentle that it cannot be perceived; because the sum of all the open passages for it through the deck exceeds the opening of the trunk of the ventilator, in so great a proportion as 100 to 1, or more. Besides, in a calm, the wind-fail can do little or no good: nor when the ship is under fail, at which time the wind-fail is not used. And it is to be observed, that it is not the ventilating of a ship now and then with a wind-fail, when wind and weather serve, that will suffice; it ought to be done daily, if due regard be had to the health of the ship's crew. The great quantity of rancid noxious vapours, which are incessantly exhaling from a number of living human bodies, the stench that incessantly arises from the bilgewater, and from the hot, stagnant, putrid air in the hold, makes it very advisable to refresh so bad an air continually, either with the wind-fail, when that can be properly used, or else with ventilators, which are intended to supply the defects of the wind-fail.

Ventilators must also be of particular service in new ships, which are observed to be more unhealthy, on account of a greater quantity of sappy wreck which arises from new timber, and makes the confined air the more unwholesome.

They will also be an effectual preservative of horses in transports, where they are sometimes suffocated, when in a storm there is a necessity to shut the hatches down.

These ventilators will also drive out of the hold of a ship that dangerous vapour which arises from corn, which is so noxious, that sometimes they dare not venture into the hold, till after the hatches have been opened for some time.

Ventilation will not only be of service to preserve several kinds of goods, but also the timbers and planks of the hold itself, when laid up in ordinary, as well as when in use, and will make the air in the hold less noxious, though it will still be offensive to the smell, by reason of the bilgewater. But this may be made less offensive, by often letting in sweet water from the sea, and then pumping it out; which good practice ought to be continued, notwithstanding the use of the ventilators.

What is here said of the foul air of ships may be applied to that of mines, gaols, workhouses, barracks, and hospitals. In mines, ventilators may guard against the suffocations, and other terrible accidents arising from *damps*; which see. (See also VENTILATION.) The air of gaols has been often known to be infectious; and we had a fatal proof of this, by the accident that happened some years ago at the sessions at the Old Bailey. To guard against the like for the future, as well as to preserve the health of the prisoners, a worthy magistrate, in 1752, had ventilators placed in Newgate, which were wrought by a windmill; and in the beginning of the year 1753, Dr. Hales gave an account of the good success attending the use of these machines, by a remarkable decrease in the usual mortality and sickness of that place.

Although the old prison at Newgate is now taken down, and a much more commodious one erected near the same spot, it may not be improper to give a brief account of

the manner in which the ventilators of Dr. Hales were constructed, and how they were moved by the windmill annexed to them. The midribs *b, b*, (*fig. 4.*) of these two ventilators, two pair of which were laid upon one another, were each nine feet long, and four and a half wide, and moved up and down by the flat iron rods *e, f*, passing through the lower and upper ventilators, and through an iron plate at *z*, about three inches square; over which is another broader iron plate, with a wide hole in its middle, to give room for the iron rod at *g* to move sideways to and fro, with the under plate, the hole of which exactly fits the iron rod, so that no air can escape at *g*; and there are the like plates at *i*, the top of the ventilator; and at *f, g*, are joints, where the iron rods are fixed to the midribs, by which means both are moved up and down at the same time; and the iron rods of both sides of the ventilators being fixed to one common lever at *e e*, all the four midribs are thereby alternately worked up and down at the same time. The valve-holes *v, v, x, x*, &c. are twenty-three inches long, and six and a half wide, covered with buckram glued on them, and move on lifts of tanned sheep-skin, and fall on lifts of woollen cloth nailed round the valve-holes. A very large nose (*fig. 5.*) is fixed with iron hooks *k, k*, to the ventilators *l, l*; and this nose is divided into three spaces, the middle and largest of which, *m m*, receives all the foul air blown into it from the eight middle valves *x, x, x, x*, (*fig. 4.*), whence it passed through a trunk *t t*, sixteen inches wide, through the leads of the prison, into the open air; the top of this trunk being covered with weatherboards to keep the rain out, and the middle valves hanging so as to open outwards. The two other outer spaces of the nose *p p*, receive the foul air, drawn into them, from the several wards, through the trunks *p, p*, and passing off into the ventilators, through the eight outer valve-holes *v, v, v, v*, whose valves open inwards. In these outer partitions of the nose there are two holes *z, z*, (*fig. 5.*) covered with boxes, in the bottom of each of which there is a large moveable valve, opening upwards, and towards the ventilators: these are made of such a weight, as to open only when all the trunks to the several wards are shut: by which the ventilators will always be supplied with air, so as not to endanger the breaking of the midribs for want of it. These ventilators, about eighteen inches deep in the clear, were fixed in an upper room of Newgate, in order to be near the windmill on the leads, which worked them. From each of the outer nostrils there went a trunk, twelve inches in the clear withinside; and from these trunks, which descended through all the floors as far as a little below the ceiling of the ground rooms, lesser trunks, six inches square within, branched off, near the ceiling of every room; and extended more or less into the several wards, so that when the foul air was drawn out of any ward, the fresh air might enter on the opposite side, and drive out all the foul air before it. By other contrivances with sliding shutters and handles, the several wards might be ventilated at such a time, or in such a degree, as was found necessary. In the case of a prison that is built with an open area in the middle, Dr. Hales observes, that the side of the prison which is opposite to the side where the ventilators are, may be commodiously ventilated in its turn, by having a round brick air-gutter under ground; through which the foul air of those wards might easily be drawn.

The windmill for working the ventilators was contrived to move with a small degree of wind, and to obtain a sufficient power in a small compass. In *fig. 6*, *c* is one of the cross-trees which support the mill-post *d*, and the braces *e, e*; the

the cross-trees rest on the blocks *a, a*, and are fixed to the floor by strong iron bolts. The mill-post *d*, being hollow, admits the iron rod *b* to pass through from the crank of the iron axle-tree *i*; the turning-frame *g n* moves on the girder *f*, on which lies a broad circular iron plate, where is the bearing of the brass friction-wheels, whose iron axle-trees move in brass collars: the turning-frame *g n* carries the axle-tree *i i*, and the sails *l, k*, which are turned, so as always to face the wind, by the vane *h*; the frame is kept from wracking by iron braces *q, r*, represented by the double pricked lines. The crank *z* is six inches and a half long, and therefore gives a stroke of thirteen inches; but the lower end of the rod *x* is fixed to the lever of the ventilator (*fig. 4.*) at such a distance from the centre of its motion, as to raise and fall the midriffs fifteen inches. The iron axle-tree extends forward, about two feet and a half beyond the face of the sails; from the extremity of which, *s*, eight iron braces, *l, l*, go to each arm, to which they are fastened by iron screw-bolts, which bind them and the iron circle of pricked lines *m m* (*fig. 7.*) fast together: the diameter of this circle is six feet, and the sweeps or arms of the mill *k k* are seven feet three inches long, and they are mortised into the drum *y y*. A void space of about six inches breadth is left between the sails, as represented in the figure, that the direct current of the wind, as it passed through, might give a turn to the course of the wind; which otherwise, being driven obliquely from the face of the preceding sail, would be forced to act on the back of the following sail, and thereby abate the force, and retard the motion of the mill. The brake-pole (*fig. 6.*) is *n*; and the single pricked line *t* at the end of it is the sword which is to clasp round the nave to stop the mill, by pulling the rope *w: o o* is the bottom shear-tree of the turning-frame; and *p* expresses the manner of screwing the brass collars of the axle-tree nearer and nearer, as they wear away. For a farther account of this machine, see Hales's Treatise of Ventilators, part ii. 1758, p. 32, &c.

Dr. Hales farther suggests, that ventilators might be of use in making salt, in order to which there should be a stream of water to work them, or they might be worked by a windmill, and the brine should be in long narrow canals, covered with boards or canvas, about a foot above the surface of the brine, in order to confine the stream of air, so as to make it act upon the surface of the brine, and carry off the water in vapours. Thus it might be reduced to a dry salt, with a saving of fuel, in winter and summer, or in a rainy or dry state of the air. Ventilators, he apprehends, might also serve for drying linen hung in low, long, narrow galleries, especially in damp, rainy weather, and also in drying woollen cloths, after they are filled or dyed, and in this case they might be worked by the fulling water-mill. Ventilators might also be an useful appendage to malt and hop-kilns; in which case it would be best to have the air-trunk enter the kiln about eighteen or twenty-four inches from the ground, and just opposite to the fire; but in order to prevent the air's blowing too strongly on the fire, a screen of brick-work might be formed about a yard distant from the hole of the air-trunk, and a yard square; for thus the air from the ventilators would be better diffused through the whole kiln.

Dr. Hales is also of opinion, that a ventilation of warm dry air from the adjoining stove, with a cautious hand, might be of service to trees and plants in greenhouses; where it is well known that an air full of the rancid vapours, which perspire from the plants, is very unkindly to them, as well as the vapours from human bodies are to men.

For fresh air is as necessary to the healthy state of vegetables as of animals.

The larger kinds of ventilators used by the doctor, are ten feet long, five feet broad, and two feet high in the clear within. Those he used by way of experiment on board the Captain, a seventy-gun ship, were ten feet long, four feet three inches wide in the clear within, and thirteen inches deep; one inch of which being occupied by the midriff, there remained a foot depth for it to rise and fall in. A ventilator of these dimensions will, through a trunk of a foot square, drive the air at the rate of twenty-five miles in an hour, which is double of what Mariotte assigns for the velocity of a pretty strong wind.

But besides these large ventilators, the doctor made a smaller sort, four feet in length, sixteen inches in breadth, and thirteen inches deep, all in the clear within. This smaller ventilator may be very useful in preserving the bread, in the bread-room of a ship, sweet and dry. Pease also, and oatmeal, which are apt to heat and spoil in casks, may be preserved, by putting them into a large bin, with a false bottom of hair-cloth laid on bars, by which fresh air may be blown upwards through them with these small ventilators.

Ventilators are also of excellent use for the drying of corn, hops, and malt. See GRANARY.

Gunpowder may be thoroughly dried, by blowing air up through it by means of ventilators.

What advantage dry gunpowder has over that which is damp, may be seen by the experiment mentioned in the article GUNPOWDER.

These small ventilators will also serve to purify most easily and effectually the bad air of a ship's well, when there is occasion for persons to go down into it, by blowing air through a trunk, reaching within a yard of the bottom of the well, both for some time before, and during their stay there. They may be also made use of at sea to sweeten stinking water, &c. See SEA-WATER.

Dr. Hales made also several trials for curing ill-tasted milk by ventilation.

For these and other uses to which they might be applied, as well as for a particular account of the construction and disposition of ventilators in ships, hospitals, prisons, &c. and the benefits attending them, see Hales's Treatise on Ventilators, part ii. passim; and Phil. Trans. vol. xlix. p. 332, &c.

The ventilators in large ships, since the order for ventilating the fleet, issued by the lords of the Admiralty in 1756, are fixed in the gunner's fore-store-room, and generally a-head of the sail-room. The foul air is carried up through the decks and fore-castle, near the fore-mast, sometimes afore it, and sometimes abaft it, but more frequently on its starboard side; the lever, by which the ventilators are worked, is under the fore-castle in two-deck ships, and between the upper and middle decks in three-deckers; sometimes the lever is hung athwart-ships; in some ships afore and aft; and in others oblique. The iron rod, which communicates the motion from the lever, passes through the partners of the fore-mast, and is connected with another lever, suspended at or near the middle; in some ships over the ventilators; in others under them, when it is found necessary to fix them up to the deck. The best method to save room is to place the ventilators over one another, with their circular ends together; the air-trunk should be so high above deck, that the men on deck may not be incommoded by the foul air which blows out of it; and therefore the trunk comes through the upper deck, near and behind the

the fore-maft. Dr. Hales has calculated the following table for the fizes of ventilators, &c. adapted to fhips of war.

Guns.	Length.		Breadth.		Depth.		Trunk.
	Ft.	In.	Ft.	In.	Ft.	In.	Sq. In.
Three decks.	100	10 0	4 6		2 0		12
	90	10 0	4 6		1 10		11½
	80	10 0	4 6		1 8		11
	70	10 0	4 6		1 8		11
	60	10 0	4 6		1 8		11
	50	9 0	4 3		1 6		10
	40	8 6	4 0		1 6		9½
	20	8 0	4 0		1 6		9

The construction of twenty-gun fhips being various, the fizes of ventilators for thefe muft be left to the direktion of the officers of the yard.

When the hold is to be ventilated from one end to the other, the three doors of the gang-way into the gunner's ftore-room muft be opened, and all the gratings on the gun-deck be covered with tarpaulins, leaving all doors open, whofe rooms want ventilation, on the orlop and the fteward-room hatch. But when it is thought proper to ventilate between decks, then the doors of the gang-way into the gunner's ftore-room muft be fhut, and the fcuttle in the headmoft trunk or pipe upon the gun-deck muft be opened; and all the gratings of the middle deck, if the fhip be a three-decker, or of the upper deck, if it be a two-deck fhip, be laid with tarpaulins; and, if poffible, one of the ftern-pofts opened, or the aftermoft hatch-way, or a fcuttle on purpofe, through the deck, as near the ftern as poffible. Hales's Treat. part ii. p. 97, &c.

The method of drawing off air from fhips by means of fire-pipes, which fome have preferred to ventilators, was publifhed by fir Robert Moray in the Phil. Tranf. for 1665. Thefe are metalline pipes, about two inches and a half in diameter, one of which reaches from the fire-place to the well of the fhip; the other three branches go to other parts of the fhip; the ftoke-hole and afh-hole being clofed up, the fire is fupplied with air through thefe pipes. The defects of thefe, compared with ventilators, are particularly examined by Dr. Hales, ubi fupra, p. 113. See *Air-Pipe* and *SHIP*.

Mr. Erasmus King propofed to have ventilators worked by the fire-engines in mines; and Mr. Fitzgerald has fuggelted an improved method of doing this, which he has alfo illuftrated by figures. See Phil. Tranf. vol. i. p. 727, &c.

There are various ways of ventilating the air of rooms: Mr. Tidd contrived to admit frefh air into a room, by taking out the middle upper fafh-pane of glafs, and fixing in its place a frame-box, with a round hole in its middle, about fix or feven inches diameter; in which hole are fixed, behind each other, two or three fmall twirling windmills, with fails of very thin broad copper-plates, which fpread over and cover the circular hole, fo as to make the air which enters the room to fpread round in thin fheets fideways; and thus not to incommode perfons, by blowing direkly upon them, as it would do if it were not hindered by the fails, which turn on the fame axle-tree, each lefs than the other. See *ÆOLUS*.

This method of refrefhing rooms is much approved of, and ufed by many, not only in England, but alfo in other countries. For other methods of ventilating fhips, buildings, rooms, &c. fee *Air-Chamber*, *BELLOWS*, *Air-Pipe*, *Centrifugal WHEEL*, and *WIND-Sail*.

VENTILLA, in *Geography*, a town of Peru, in the diocefe of La Paz; 9 miles S. of La Paz.

VENTININA, a term ufed by Paracelfus and his followers, to exprefs the art of divining, or knowing by the winds and their courfes the good or ill effects of feafons.

VENTIS PONTE, in *Ancient Geography*, a town of Hifpania, in Betica, in the vicinity of Caracca.

VENTO, MATTEO, in *Biography*, a Neapolitan, and difciple of Jomelli. That, however, is not difcoverable in his compositions, which are eafy and graceful, but have none of the folidity or originality of his mafter. Arriving in England in 1764, at the inaufpicious termination of the reign of the Mingotti and Giardini at the Opera, he had the good fortune to be engaged by Gordon and Vincent, the new imprefarii, to compofe an opera, in which Manzoli was to perform the principal part. The opera which he had to fet was the Demofonte of Metaftafio, of which the airs are natural, graceful, and pleafing; always free from vulgarity, but never very new or learned. They were, however, in great public and private favour a confiderable time.

In 1765, on the fecond arrival of Elifi, he fet Sofonifba, in that eafy and graceful ftyle which pleafed more generally than what profefors would call better mufic. This drama was repeated more frequently than any other during the feafon, and the fongs, printed by the elder Wilckie, were long after in favour at concerts and public places, as well as among lifping miffes and diletanti.

In 1767, on the arrival of Guarducci, Vento fet the opera of "La Conquifta del Meflico," of which the airs, like thofe of his former operas, were elegant and pleafing. After this he feems to have filled up his whole time in teaching, till the arrival of Gabrielli, in 1776, when he fet "La Veftale," in his ufual eafy ftyle; and when we told him that his airs were fomewhat too familiar for great fingers, he faid, "God forbid I fhould ever compofe difficult mufic!"

This compofer's harpfichord pieces are fimfly, and fo much alike, that the invention, with refpect to melody and modulation of the eight fets, may be compreffed into two or three movements. In thefe fonatas, as well as in his fongs, he avoids vulgar paffages, and has a graceful, eafy, and flowing melody; but his bafes are too like Alberti's, and his trebles too like one another, either to improve the hand or delight the ear. He had a great number of fcholars, which ensured the expence of printing his pieces, though not their general and public favour. One or two fets of fuch eafy compositions would, indeed, have been very ufeul to fcholars in the firft ftages of their execution; but eight books, in which there is fo little variety, can never be wanted, or indeed borne, but by thofe who think it right implicitly to receive all their mafter's prefcriptions. His duos for voices are alike trivial and uninterefting, and the opera of "Artaferfe," which he compofed for the Harmonic Meeting, that was fet up in 1771 by the friends of Guadagni and Giardini againft the great Opera, under the management of Mr. Hobart, which people of the firft rank were fo impatient to hear in a clandestine way, as to run the rifk of pains and penalties for it, when publifhed, appeared to have lefs merit and novelty than any one of his former works.

Vento died in 1777, very rich, as there was every reafon of induftry, parfimony, and avarice, to imagine; but by fome ftrange difpofition of his property and affairs, none of his effects could be found at his death; and his widow and her mother were left wholly deltitute of fupport, but from charity and the loweft menial labour.

VENTOSA, SPINA. See *SPINA Ventofa*.

VENTOSITY, in *Medicine*. See *FLATULENCE* and *TYPANITES*.

VENTOSO, CAPE, in *Geography*, a cape on the N.E. coast of the island of Cabrera, in the Mediterranean. N. lat. $39^{\circ} 10'$. E. long. $2^{\circ} 55'$.

VENTOTIENA, in *Geography*, an island in the Mediterranean, near the coast of Naples, anciently called *Pandataria*; according to Sir William Hamilton, composed of volcanic matter thrown up by fire. It is now, as it seems to have been for ages, used as a place of banishment for criminals of a superior rank. Hither Julia, the daughter of Augustus, was sent, accompanied by her mother Scribonia. Some years the virtuous Agrippina was also confined here; and Octavia, wife of Nero, and daughter of Claudius, was at the instigation of Poppæa banished and murdered in this island; 17 miles W. of Ischia. N. lat. $40^{\circ} 53'$. E. long. $13^{\circ} 19'$.

VENTRÆ, in *Ancient Geography*, a town of Italy; to which the Romans sent a colony about the year 351 from the foundation of Rome, according to Diodorus Siculus.

VENTRE, in *Geography*, a town of Hindoostan, in the circur of Ellore; 7 miles W. of Ellore.

VENTRE *Inspiciendo*, in *Laws*, a writ for the search of a widow that says she is with child, and thereby holds land from him that is, otherwise, next heir at law. See *Jury of MATRONS*.

VENTREVRE, in *Geography*, a small island in the Atlantic, near the coast of France. N. lat. $47^{\circ} 28'$. W. long. $2^{\circ} 59'$.

VENTRICULUS, in *Anatomy*, the stomach. See *STOMACH*.

VENTRICULI *Cordis*, the two cavities of the heart, which propel the blood into the arteries; they are the right and left, or pulmonary and aortic. See *HEART*.

VENTRICULI or *Ventricles of the Brain*, cavities in different parts of its substance. They are the two lateral, right and left, called also tricoines; the 3d, 4th, and 5th, or ventricle of the septum lucidum. See *BRAIN*.

VENTRICULI *Ardor*. See *ARDOR*.

VENTRICULUS *Succenturiatus*, in *Medicine*, a name given by some to the duodenum, when very large. *Med. Ess.* Edinb. abr. vol. ii. p. 34.

VENTRILOQUOUS, VENTRILOQUUS, compounded of *venter*, belly, and *loquor*, I speak, *gastriloquus*, or *engastrimythus*, a term applied to persons who speak inwardly; having a peculiar art of forming speech, by drawing the air into the lungs; so that the voice, proceeding out of the thorax, to a by-stander seems to come from some distance, or in any direction. See *ENGASTRIMYTHUS*.

Such a person we had formerly in London, a smith by profession, who had the faculty in such perfection, that he could make his voice appear, now, as if it came out of the cellar; and the next minute, as if in an upper room; and nobody present could perceive that he spoke at all. Accordingly, he has frequently called a person first up, then down stairs; then out of doors, then this way, then that; and all this without stirring from his seat, or appearing to speak at all.

We cannot forbear making a few extracts on this curious subject from a work, published in 1772, entitled "Le Ventriloque," &c. or the Ventriloquist, by M. de la Chapelle, censor royal at Paris, member of the Academies at Lyons and Rouen, and F.R.S. Some faint traces of the art or faculty of ventriloquism are to be found in the writings of the ancients; but many more are to be discovered there, if we adopt this author's opinion, that the responses of many of the ancient oracles were actually delivered by persons possessing this quality, so very capable of being applied to the purposes of priestcraft and delusion. The abbé de la

Chapelle, having heard many surprising circumstances related concerning one M. St. Gille, a grocer at St. Germain-en-Laye, near Paris, whose powers as a ventriloquist had given occasion to many singular and diverting scenes, formed the resolution of seeing him. Being seated with him on the opposite side of a fire in a parlour on the ground-floor, and very attentively observing him, the abbé, after half an hour's conversation with M. St. Gille, heard himself called, on a sudden, by his name and title, in a voice that seemed to come from the roof of a house at a distance; and whilst he was pointing to the house from which the voice had appeared to him to proceed, he was yet more surprised by hearing the words "it was not from that quarter," apparently in the same kind of voice as before, but which now seemed to issue from under the earth, at one of the corners of the room. In short, this factitious voice played, as it were, every where about him, and seemed to proceed from any quarter, or distance, from which the operator chose to transmit it to him. To the abbé, though conscious that the voice proceeded from the mouth of M. St. Gille, he appeared absolutely mute, while he was exercising this talent; nor could any change in his countenance be discovered. He observed, however, that M. St. Gille presented only the profile of his face to him, while he was speaking as a ventriloquist. On another occasion, M. St. Gille sought for shelter from a storm in a neighbouring convent; and finding the community in mourning, and enquiring the cause, he was told, that one of their body much esteemed by them had lately died. Some of the religious attended him to the church, and shewing him the tomb of their deceased brother, spoke very feelingly of the scanty honours that had been bestowed on his memory; when suddenly a voice was heard, apparently proceeding from the roof of the choir, lamenting the situation of the defunct in purgatory, and reproaching the brotherhood with their want of zeal on his account. The whole community being afterwards convened into the church, the voice from the roof renewed its lamentations and reproaches, and the whole convent fell on their faces, and vowed a solemn reparation. Accordingly they first chaunted a *de profundis* in full choir, during the intervals of which the ghost occasionally expressed the comfort he received from their pious exercises and ejaculations in his behalf. The prior, when this religious service was concluded, entered into a serious conversation with M. St. Gille, and inveighed against the absurd incredulity of our modern sceptics, and pretended philosophers, on the article of ghosts and apparitions; and M. St. Gille found it difficult to convince the fathers that the whole was a ludicrous deception.

Another instance of his extraordinary powers occurred in presence of a large party, consisting of commissaries from the Royal Academy of Sciences at Paris, and other persons of the highest quality, together with a certain lady, who was not in the secret, and who was only told, that an aerial spirit had lately established itself in the forest of St. Germain-en-Laye, and that they were assembled to enquire into the reality of the fact. When the party sat down to dinner, the aerial spirit began to address the lady with a voice that seemed to be in the air over their heads; sometimes he spoke to her from the trees around them, or from the surface of the ground at a great distance, and at other times from a considerable depth under her feet. The lady, being thus addressed for more than two hours, was firmly persuaded that this was the voice of an aerial spirit; and it was some time before she was undeceived.

Several other instances of M. St. Gille's talents are related; and the abbé, in the course of his inquiries, was informed,

formed, that the baron de Mengen, a German nobleman, possessed this art in a very high degree. He also relates, from Brodeau, a learned critic in the sixteenth century, one of the singular feats performed by a capital ventriloquist in his time, who was called Louis Brabant, and was valet de chambre to Francis I. Our countryman Dickenfon speaks of him particularly, in his tract entitled "Delphi Phœnicizantes," printed in duodecimo at Oxford, in 1655. Louis had fallen in love with a beautiful and rich heiress, but was rejected by the parents as an unfuitable match, on account of his low circumstances. However, the father dying, he visits the widow; and on his first appearance in the house, she hears herself accosted in a voice resembling that of her dead husband, and which seemed to proceed from above. "Give my daughter in marriage to Louis Brabant, who is a man of great fortune, and excellent character; I now endure the inexpressible torments of purgatory, for having refused her to him; obey this admonition, and I shall be soon delivered; you will provide a worthy husband for your daughter, and procure everlasting repose to the soul of your poor husband." The dread summons, which had no appearance of proceeding from Louis, whose countenance exhibited no change, and whose lips were close and motionless, was instantly complied with; but the deceiver, in order to mend his finances for the accomplishment of the marriage-contract, applies to one Cornu, an old and rich banker at Lyons, who had accumulated immense wealth by usury and extortion, and was haunted by remorse of conscience. After some conversation on demons and spectres, the pains of purgatory, &c. during an interval of silence, a voice is heard like that of the banker's deceased father, complaining of his dreadful situation in purgatory, and calling upon him to rescue him from thence, by putting into the hands of Louis Brabant, then with him, a large sum for the redemption of Christians in slavery with the Turks; threatening him at the same time with eternal damnation, if he did not thus expiate his own sins. Upon a second interview, in which his ears were saluted with the complaints and groans of his father, and of all his deceased relations, imploring him for the love of God, and in the name of every saint in the Calendar, to have mercy on his own soul and others, Cornu obeyed the heavenly voice, and gave Louis ten thousand crowns, with which he returned to Paris, and married his mistress. The miser, being afterwards undeceived, was so mortified, that he took to his bed and died.

The abbé de la Chapelle takes occasion to account for all the circumstances attending Saul's conference with the WITCH of Endor, (which see,) and endeavours to shew that the speech, supposed to be addressed to Saul by the ghost of Samuel, actually proceeded from the mouth of the reputed forceress, whom he supposes to have been a capital ventriloquist. On these grounds he explains that transaction, and reconciles all its circumstances to the relation given of it in Scripture; where, it is to be observed, that Saul is not said to have seen Samuel, but only to have heard a voice, which a ventriloquist can produce and transmit from any quarter, and with any degree of strength whatever. He afterwards brings many instances to prove, that the ancient oracles principally supported their credit, and derived their influence, from the exercise of this particular art. Many other learned men have given the same account of the witch of Endor. Though she is said to have a *familiar spirit*, yet the Hebrew word *ob*, and the plural *oboth*, is generally rendered by the LXX *ὑψαστεμυθοί*, *ventriloquists*. Thus it is rendered Isaiah, xix. 3. It appears from Plutarch (De Defect. Orac. tom. ii. p. 414.), Suidas (tom. i. ad voc. *ὑψαστεμυθοί*, p. 667.), and Josephus (Antiq. lib. xiv. p. 354.),

that those who were anciently called ventriloquists had afterwards the name of *Pythoneffes*, which implies a pretence to divination. Accordingly *Pythos* is the word used by the Vulgate version, 1 Sam. xxviii. 7, 8; though not, as Voltaire seems to intimate, in the Hebrew; and, therefore, there is no ground for the conclusion which he draws, *viz.* that the history was not written till the Jews traded with the Greeks, after the time of Alexander, *i. e.* for determining the date of a Hebrew book from the use of a word in a Latin translation, made many hundred years after it, and not to be found in the original.

From baron de Mengen's account of himself, and the observations made by M. de la Chapelle in his frequent examinations of M. St. Gille, it seems that the factitious voice produced by a ventriloquist does not (as the etymology of the word imports) proceed from the belly, but is formed in the inner parts of the mouth and throat. The art, according to this author, does not depend on a particular structure or organization of these parts, peculiar to a few individuals, and very rarely occurring, but may be acquired by almost any ardently desirous of attaining it, and determined to persevere in repeated trials. The judgments we form concerning the situation and distance of bodies, by means of the senses mutually assisting and correcting each other, seem to be entirely founded on experience (see Reid's Inquiry into the Human Mind, p. 70. edit. 2.); and we pass from the sign to the thing signified by it immediately, or at least without any intermediate steps perceptible to ourselves. Hence it follows, that if a man, though in the same room with another, can by any peculiar modification of the organs of speech produce a sound, which in faintness, tone, body, and every other sensible quality, perfectly resembles a sound delivered from the roof of an opposite house, the ear will naturally, without examination, refer it to that situation and distance; the sound which the person hears being only a sign, which from infancy he has been accustomed, by experience, to associate with the idea of a person speaking from a house-top. A deception of this kind is practised with success on the organ, and other musical instruments; and there are many similar optical deceptions.

Rolandus, in his *Aglossostomographia*, mentions, that if the mediastinum, which is naturally a single membrane, be divided into two parts, the speech will seem to come out of the breast; so that the by-standers will fancy the person possessed.

For some facts and observations tending to explain the curious phenomena of ventriloquism by Mr. John Gough, we refer to the Manchester Memoirs, vol. v. part 2. p. 622. London, 1802, in which the ingenious author investigates the method whereby men judge by the ear of the position of sonorous bodies relative to their own persons. This author observes in general, that a sudden change of direction in sound, our knowledge of which, as he conceives, does not depend on the impulse in the ear, but on other facts, will be perceived, when the original communication is interrupted, provided there be a sensible echo. This circumstance will be acknowledged by any person who has had occasion to walk along a valley, intercepted with buildings, at the time that a peal of bells was ringing in it. For the sound of the bells, instead of arriving constantly at the ears of a person so situated, in its true direction, is frequently reflected in a short time from two or three different places. These deceptions are in many cases so much diversified by the successive interpositions of fresh objects, that the steeple appears, in the hearer's judgment, to perform the part of an expert ventriloquist on a theatre, the extent of which is adapted to its own powers, and not to those of the human voice.

voice. The similarity of effect which connects this phenomenon with ventriloquism convinced the author, whenever he heard it, that what we know to be the cause in one instance is also the cause in the other, *viz.* that the echo reaches the ear, while the original sound is intercepted by *accident* in the case of the bells, but by *art* in the case of the ventriloquist. In order that the cause which gives rise to the amusing tricks of this uncommon talent may be pointed out with the greater clearness, it will be proper to describe certain circumstances that take place in the act of speaking, because the skill of the ventriloquist seems to consist in a peculiar management of them. Articulation is the art of modifying the sound of the larynx, by the assistance of the cavity of the mouth, the tongue, teeth, and lips. The different vibrations, which are excited by the joint operation of the several organs in action, pass along the bones and cartilages, from the parts in motion to the external teguments of the head, face, neck, and chest; from which, a succession of similar vibrations is imparted to the contiguous air, thereby converting the superior moiety of the speaker's body into an extensive seat of sound, contrary to general opinion, which supposes the passage of the voice to be confined to the opening of the lips.

When an orator addresses an audience in a lofty and spacious room, his voice is reflected from every point of the apartment, of which all present are made sensible by the confused noise that fills up every pause in his discourse; nevertheless, every one knows the true place of the speaker, because his voice is the prevailing sound at the time. But were it possible to prevent his words from reaching any one of the audience directly, what would then follow? Undoubtedly a complete case of ventriloquism would be the consequence, and the person so circumstanced would transport the orator, in his own mind, to the place of the principal echo, which would perform the part of the prevailing sound at the instant. This he would be obliged to do, because the human judgment is bound, by the dictates of experience, to regard the person as inseparable from the voice; and the deception in question would be unavoidable, being produced by the same concurrence of causes which makes a peal of bells, situated in a valley, seem to change place in the opinion of a traveller. It is the business of a ventriloquist to amuse his admirers with tricks resembling the foregoing delusion; and it will be readily granted, that he has a subtle sense, highly corrected by experience, to manage, on which account the judgment must be cheated as well as the ear. This can only be accomplished by making the pulses, constituting his words, strike the heads of his hearers, not in the right lines that join their persons and his. He must, therefore, know how to disguise the true direction of his voice, because the artifice will give him an opportunity to substitute almost any echo he chuses in the place of it. But the superior part of the human body has been already proved to form an extensive seat of sound, from every point of which the pulses are repelled, as if they diverged from a common centre. This is the reason why people, who speak in the usual way, cannot conceal the direction of their voices, which in reality fly off towards all points at the same instant. The ventriloquist, therefore, by some means or other, acquires the difficult habit of contracting the field of sound within the compass of his lips, which enables him to confine the real path of his voice to narrow limits. For he, who is master of the art, has nothing to do but to place his mouth obliquely to the company; and to dart his words, if the expression may be used, against an opposing object, whence they will be reflected immediately, so as to strike the ears of the audience from an unexpected quarter, in consequence of which the reflector

will appear to be the speaker. Nature seems to fix no bounds to this kind of deception, only care must be taken not to let the path of the direct pulses pass too near the head of the person who is to be played upon; for, if a line, joining the exhibitor's mouth and the reflecting body, approach one of his ears too nearly, the divergency of the pulses will make him perceive the voice itself, instead of the reverberated sound.

The author has given the following narrative of a ventriloquist, whom he attended in the exercise of his art. His audience was arranged in two opposite lines, corresponding to the two sides of a long narrow room. The benches on which they were seated reached from one end of the place to the middle of it, the other part remaining unoccupied. The feats exhibited by him were the three following. First: he made his voice come from behind his audience, but it never seemed to proceed from any part of the wall, near the heads of the people present; on the contrary, it was always heard resembling the voice of a child, who seemed to be under the benches. He stood during the time of speaking in a stooping posture, having his mouth turned towards the place from which the sound issued; so that the line, joining his lips and the reflecting object, did not approach the ears of the company. Second: advancing into the vacant part of the room, and turning his back to the audience, he made a variety of noises, that seemed to proceed from an open cupboard which stood directly before him, at the distance of two or three yards. Third: he placed an inverted glass cup on the hands of his hearers, and then imitated the cries of a child confined in it. His method of doing it was this; the upper part of the hearer's arm laid close along his side; then the part below the elbow was kept in a horizontal position, with the hand turned downwards, which was done by the operator himself. After taking these preparatory steps, the man bent his body forwards in a situation which presented the profile of his face nearly to the front of his hearer, whilst his mouth pointed to the cup; in which posture he copied the voice of a confined child so completely, that three positions of the glass were easily distinguished by as many different tones, *viz.* when he pressed the mouth of the cup close against the palm, when one edge of it was elevated, and when the vessel was held near the hand, but did not touch it. The second and third instances of ventriloquism afford strong proofs, that this delusive talent is nothing more than the art of substituting an echo for the primary sound; for, besides the change perceivable in the direction of the voice, it was found to be blended with a variety of secondary sounds; such as we know by experience are produced, as often as a noise of any kind issues from a cavity.

The method of preventing the vibration of the vocal organs from reaching the external teguments is still wanting, as our author acknowledges, to complete his theory of ventriloquism; and this, he presumes, can only be supplied by an adept in the art.

VENTRY, in *Geography*, a small town of the county of Kerry, Ireland, situated on a harbour to which it gives name, on the Atlantic ocean. It is $4\frac{1}{2}$ miles W. of Dingle.

VENTURINE, or ADVENTURINE, is sometimes used for the finest and slenderest gold wire, used by embroiderers, &c.

When reduced into powder, as fine as it can be clipped, or filed, this powder may be strewed on the first layer of pure varnish, made use of in japaning, after the varnish is dry, in order to lay any colour over it.

VENUE, or VENUEW, in *Law*, a neighbouring or near place. *Locus quem vicini habitant.*

Thus we say, twelve of the affizes ought to be of the same venue where the demand is made.

In transitory actions, the courts will very often change the venue, or county, in which the cause is to be tried. The statute 6 Ric. II. cap. 2. having ordered all writs to be laid in their proper counties, this, as the judges conceived, empowered them to change the venue, if required, and not to insist rigidly on abating the writ, which practice began in the reign of James I.; and this power is discretionally exercised, so as not to cause, but prevent a defect of justice. Therefore the court will not change the venue to any of the four northern counties, previous to the spring circuit; because there the affizes are holden only once a year, at the time of the summer circuit. And it will sometimes remove the venue from the proper jurisdiction, (especially of the narrow and limited kind,) upon a suggestion, duly supported, that a fair and impartial trial cannot be had therein. Blackst. Comm. book iii.

VENUS, in *Astronomy*, one of the inferior planets; denoted by the character ♀.

Venus is easily distinguished by her brightness and whiteness, which exceeds that of all the other planets; and which is so considerable, that, in a dusky place, she projects a sensible shadow. Her place is between the earth and Mercury.

She constantly attends the sun, and never departs from him above $47^{\circ} 48'$ or $44^{\circ} 57'$. If S be the sun (*Plate XXI. Astronomy, fig. 8.*), E the earth, V Venus or Mercury, and EV a tangent to the orbit of the planet, then will the angle SEV be the greatest elongation of the planet from the sun; which angle, if the orbits were circles having the sun in their centre, would be found by saying, ES : SV :: rad. : fin. SEV. But the orbits are not circular, in consequence of which the angle EVS will not be a right angle, unless the greatest elongation happens when the planet is at one of its apsidæ. The angle SEV is also subject to an alteration from the variation of SE and SV. The greatest angle SEV happens, when the planet is in its aphelion, and the earth in its perigee; and the least angle SEV, when the planet is in its perihelion, and the earth in its apogee. M. de la Lande has calculated these greatest elongations, and finds them $47^{\circ} 48'$ and $44^{\circ} 57'$ for Venus, and $28^{\circ} 20'$ and $17^{\circ} 36'$ for Mercury. If we take the mean of the greatest elongations of Venus, which is $46^{\circ} 22'.5$, it gives the angle VSE = $43^{\circ} 37'.5$; and as the difference of the daily mean motions of Venus and the earth about the sun is $37'$, we have $37' : 43^{\circ} 37'.5 :: 1 \text{ day} : 70.7 \text{ days}$, the time that would elapse between the greatest elongations and the inferior conjunction, if the motions had been uniform, which will not vary much from the true time. See ELONGATION.

To find the position of a planet when stationary. Let S be the sun (*fig. 9.*), E the earth, P the contemporary position of the planet, Xy the sphere of the fixed stars, to which we refer the motions of the planets; let EF, PQ, be two indefinitely small arcs described in the same time, and let EP, FQ, produced, meet at L; then it is manifest, that whilst the earth moves from E to F, the planet appears stationary at L; and on account of the immense distance of the fixed stars, EPL, FQL may be considered as parallel. Draw SE, SFw, SvP, and SQ; then, as EP and FQ are parallel, the angle QFS - PES = PwS - PES = ESF, and SPw - SQF = SvF - SQF = PSQ; that is, the contemporary variations of the angles E and P are as ESF : PSQ, the contemporary variations of the angular velocities of the earth and planet, or, (because the angular velocities are inversely as the pe-

riodic times, or inversely in the sesquuplicate ratio of the distances) as $SP^{\frac{3}{2}} : SE^{\frac{3}{2}}$, or (if $SP : SE :: a : 1$) as $a^{\frac{3}{2}} : 1^{\frac{3}{2}}$. But fin. SEP : fin. SPE being as $SP : SE$, or $a : 1$, the contemporary variations of these angles will be as their tangents. Hence, if x and y be the sines of the angles SEP and SPE, we have $x : y :: a : 1$, and

$$\frac{x}{\sqrt{1-x^2}} : \frac{y}{\sqrt{1-y^2}} :: a^{\frac{3}{2}} : 1, \text{ whence } x^2 = \frac{a^3 - a^2}{a^3 - 1}$$

$$= \frac{a^2}{a^2 + a + 1}, \text{ and } x = \frac{a}{\sqrt{a^2 + a + 1}}, \text{ the sine of the}$$

planet's elongation from the sun, when stationary.

Ex. If P be the earth, and E Venus; and we take the distances of the earth and Venus to be 100000 and 72333, we find $x = 0.48264$ the sine of $28^{\circ} 51' 5''$, the elongation of Venus when stationary, upon the supposition of circular orbits.

For excentric orbits, the points will depend upon the position of the apsidæ and places of the bodies at the time. We may, however, get a very near approximation thus. Find the time when the planet would be stationary, if the orbits were circular, and compute for several days, about that time, the geocentric place of the planet, so that you get two days, on one of which the planet was direct, and on the other retrograde, in which interval it must have been stationary, and the point of time when this happened may be determined by interpolation.

To find the time when a planet is stationary, we must know the time of its opposition, or inferior conjunction. Let m and n be the daily angular velocities of the earth and planet about the sun, and v the angle PSE, when the planet is stationary; then $m - n$, or $n - m$, is the daily variation of the angle at the sun between the earth and planet, according as it is a superior or inferior planet;

hence, $m - n$, or $n - m$, : $v :: 1 \text{ day} : \frac{v}{m - n}$, or $\frac{v}{n - m}$, the time from opposition or conjunction to the sta-

tionary points both before and after. Hence, the planet must be stationary twice every synodic revolution.

Ex. Let P be the earth, E Venus; then the angle SPE = $20^{\circ} 51'.5$; therefore, PSE = 13° ; also, $n - m = 37'$; hence, $37' : 13^{\circ} :: 1 \text{ day} : 21 \text{ days}$, the time between the inferior conjunction and stationary positions.

If the elongation be observed when stationary, we may find the distance of the planet from the sun, compared with the earth's distance, supposed to be unity. For $x^2 =$

$$\frac{a^2}{a^2 + a + 1}; \text{ hence, } a^2 + \frac{x^2}{x^2 - 1} \times a = -\frac{x^2}{x^2 - 1}$$

$$= (\text{if } t = \text{the tangent of the angle whose sine is } x) a^2 - t^2$$

$$a = t^2; \text{ consequently, } a = \frac{1}{2} t^2 + t \sqrt{1 + \frac{t^2}{4}}, \text{ upon}$$

the supposition of circular orbits.

A superior planet is retrograde in opposition, and an inferior planet is retrograde in its inferior conjunction; for let E be the earth (*fig. 10.*), P a superior planet in opposition; then, as the velocities are as the inverse square roots of the radii of the orbits, the superior planet moves slowest; hence, if EF, PQ, be two indefinitely small contemporary arcs, PQ is less than EF, and on account of the immense distance of the sphere YZ of the fixed stars, FQ must cut EP in some point x between P and m , consequently the planet appears retrograde from m to n . If P be the earth, and E an inferior planet in inferior conjunction, it will appear

pear retrograde from v to w . These retrograde motions must necessarily continue till the planets become stationary. Hence, a superior planet appears retrograde from its stationary point before opposition to its stationary point after; and an inferior planet, from its stationary point before inferior conjunction to its stationary point after.

When Venus appears west of the sun, that is, from her inferior conjunction to her superior, she rises before him, and is called *Phosphorus*, or *Lucifer*, or the *Morning star*; and when she appears east of the sun, that is, from her superior conjunction to her inferior, she sets after him, or shines in the evening after he sets, and is called *Hesperus*, or *Vesper*, or the *Evening star*: being each in its turn for two hundred and ninety days.

To delineate the appearance of a planet at any time. Let S be the sun (fig. 11.), E the earth, V Venus, for example; aVb the plane of illumination perpendicular to SV , cVd the plane of vision perpendicular to EV , and draw av perpendicular to cd ; then ca is the breadth of the visible illuminated part, which is projected by the eye into cv , the versed sine of Cva , or SVZ , for SVc is the complement of each. Now the circle terminating the illuminated part of the planet, being seen obliquely, appears to be an ellipse; therefore, if $cmdn$ represent the projected hemisphere of Venus next to the earth, mn , cd , two diameters perpendicular to each other, and we take $cv =$ the versed sine of SVZ , and describe the ellipse mvn , then cv is the axis minor, and $mcnv$ will represent the visible enlightened part, as it appears at the earth; and from the property of the ellipse, this area varies as cv . Hence, the visible enlightened part : the whole disc :: the versed sine of SVZ : diameter.

Hence, Mercury and Venus will have the same phases from their inferior to their superior conjunction, as the moon has from the new to the full; and the same from the superior to the inferior conjunction, as the moon has from the full to the new. Mars will appear gibbous in quadratures, as the angle SVZ will then differ considerably from the two right angles, and consequently the versed sine will sensibly differ from the diameter. For Jupiter, Saturn, and the Georgian, the angle SVZ never differs enough from two right angles to make those planets appear gibbous, so that they always appear full-orbed.

Dr. Halley proposed the following problem: To find the position of Venus when brightest, supposing its orbit, and that of the earth, to be circles, having the sun in their centre. Draw Sr perpendicular to EVZ , and put $a = SE$, $b = SV$, $x = EV$; $y = Vr$; then $b - y$ is the versed sine of the angle SVZ , which versed sine varies as the illuminated part; and as the intensity of light varies inversely as the square of its distance, the quantity of light

received at the earth varies as $\frac{b-y}{x^2} = \frac{b}{x^2} - \frac{y}{x^2}$; but

$a^2 = b^2 + x^2 + 2xy$; hence, $y = \frac{a^2 - b^2 - x^2}{2x}$; substitute this for y , and we get the quantity of light to be as

$$\frac{b}{x^2} - \frac{a^2 - b^2 - x^2}{2x^3} = \frac{2bx - a^2 + b^2 + x^2}{2x^3} = \text{a maxi-}$$

mum; put the fluxion = 0, and we get $x = \sqrt{3a^2 + b^2} - 2b$. Now, if $a = 1$, $b = .72333$, as in Dr. Halley's tables, then $x = .43036$; hence, the angle $ESV = 22^\circ 21'$, but the angle ESV , at the time of the planet's greatest elongation, is $43^\circ 40'$; hence, Venus is brightest between its inferior conjunction and its greatest elongation; also, the angle $SEV = 39^\circ 44'$, the elongation of Venus from the

sun at the same time, and $\angle SVZ = VSE + VES = 62^\circ 5'$, the versed sine of which is 0.53, radius being unity; hence, the visible enlightened part : whole disc :: 0.53 : 2; Venus, therefore, appears a little more than one-fourth illuminated, and answers to the appearance of the moon when five days old. Her diameter here is about $30''$, and therefore the enlightened part is about $10''.25$. At this time, Venus is bright enough to cast a shadow at night. This situation happens about 36 days before and after its inferior conjunction; for, supposing Venus to be in conjunction with the sun, and when seen from the sun to depart from the earth at the rate of $37'$ in 1 day, we have $37' : 22^\circ 21' :: 1 \text{ day} : 36 \text{ days}$ nearly, the time from conjunction till Venus is brightest.

If we apply this to Mercury, $b = .3171$, and $x = 1.00058$; hence, the angle $ESV = 78^\circ 55'$; but the same angle, at the time of the planet's greatest elongation, is $67^\circ 13'$. Hence, Mercury is brightest between its greatest elongation and superior conjunction. Also, the angle $SEV = 22^\circ 18'$, the elongation of Mercury at that time.

When Venus is brightest, and at the same time is at its greatest north latitude, it can then be seen with the naked eye at any time of the day, when it is above the horizon; for when its north latitude is the greatest, it rises highest above the horizon, and therefore is more easily seen, the rays of light having to come through a less part of the atmosphere, the higher the body is. This happens once in about eight years, Venus and the earth returning to the same parts of their orbits after that interval of time. Vince's Elements of Astronomy.

The diameter of Venus is to that of the earth as $11\frac{7}{12}$ to 10 nearly, her apparent diameter equal to $59'$, and real diameter equal to 9330 miles; her apparent diameter, when reduced to the mean distance of the earth, is, according to Dr. Herschel, $18''.79$, and her real diameter a little larger than that of the earth (see PLANET); her horizontal parallax about $30'$; her distance from the sun is to that of the earth from the sun as 72333 to 100000, and her real distance is 68,891,486 miles; her eccentricity is $\frac{1}{1750}$ ths of her mean distance from the sun (see EXCENTRICITY); the inclination of her orbit to the plane of the ecliptic $3^\circ 23' 35''$; her periodical course round the sun is performed in two hundred and twenty-four days seventeen hours nearly; and her motion round her own axis in twenty-three hours, or, according to the observations of Bianchini, in twenty-four days eight hours: according to Dr. Herschel, uncertain, but not so slow as twenty-four days. See DIAMETER, DISTANCE, EXCENTRICITY, NODE, PARALLAX, and PERIOD. See also PLANETS, PLANETARIUM, and Solar SYSTEM.

Venus, when viewed through a telescope, is rarely seen to shine with a full face, but has phases just like those of the moon; being now gibbous, now horned, &c. and her illuminated part is constantly turned towards the sun, i. e. it looks towards the east, when *Phosphorus*; and towards the west, when *Hesperus*.

These different phases of Venus were first observed by Galileo, who thus fulfilled the prediction of Copernicus: for when this excellent astronomer revived the ancient Pythagorean system, asserting, that the earth and planets moved round the sun, it was objected that in such a case the phases of Venus should resemble those of the moon; to which Copernicus replied, that some time or other that resemblance would be found out. Galileo sent an account of the first discovery of these phases in a letter, written from Florence in 1611, to William de Medici, the duke of Tuscany's ambassador at Prague; desiring him to communicate it

it to Kepler. The letter is extant in the preface to Kepler's *Dioptrics*, and a translation of it may be seen in Smith's *Optics*, p. 416.

Having recited the observations which he had made, he adds, "we have hence the most certain, sensible decision and demonstration of two grand questions, which to this day have been doubtful and disputed among the greatest masters of reason in the world. One is, that the planets in their own nature are opaque bodies, attributing to Mercury what we have seen in Venus: and the other is, that Venus necessarily moves round the sun, as also Mercury, and the other planets; a thing well believed indeed by Pythagoras, Copernicus, Kepler, and myself, but never yet proved, as now, by ocular inspection upon Venus." He closes with explaining the cypher that had been sent, in the following words: "Hæc immatura à me frustra leguntur, o, y; i. e. Cynthiæ figuræ æmulatur mater amorum, or, Venus imitates the phases of the moon."

M. Maraldi made several observations on Venus in 1729, but could perceive no spot; and, therefore, those observed by Bianchini must either have disappeared, or the air at Paris was not so clear as at Rome.

Martin Folkes, esq. formerly president of the Royal Society, spoke of Bianchini with respect, as too accurate to make any mistakes in astronomical observations, and too honest to publish any thing that was not exactly agreeable to truth. See *Nature of the PLANETS*.

Sometimes Venus is seen in the disc of the sun, in form of a dark round spot. This happens when the earth is about her nodes at the time of her inferior conjunction. These appearances, called transits, happen but seldom. We have had two in the last century, viz. one in June 1761, and another in June 1769. The next will not occur before the year 1874. See PARALLAX.

The effect of the parallax being determined, for computing which Dr. Maskelyne proposed a new method in relation to the transit of Venus in 1769, the transit affords a very ready method of finding the difference of the longitudes of two places where the same observations are made. For compute the effect of parallax in time, and reduce the observations at each place to the time, if seen from the centre of the earth, and the difference of the times is the difference of the longitudes. From the mean of sixty-three results from the transits of Mercury, Mr. Short found the difference of the meridians of Greenwich and Paris to be $9' 15''$; and from the transit of Venus in 1761, to be $9' 10''$ in time.

Except such transits as these, Venus exhibits the same appearances to us regularly every eight years; her conjunctions, elongations, and times of rising and setting, being very nearly the same, on the same days, as before.

In 1672 and 1686, Cassini, with a telescope of 34 feet, thought he saw a satellite moving round this planet, and distant from it about three-fifths of Venus's diameter. It had the same phases as Venus, but without any well-defined form; and its diameter scarcely exceeded one-fourth of that of Venus. Dr. Gregory (*Alt. lib. vi. prop. 3.*) thinks it more than probable that this was a satellite; and supposes the reason why it is not usually seen, to be the unfitness of its surface to reflect the rays of the sun's light; as is the case of the spots in the moon: of which, if the whole disc of the moon were composed, he thinks, that planet could not be seen as far as to Venus.

Mr. Short, in 1740, with a reflecting telescope of $16\frac{1}{2}$ inches focus, perceived a small star near Venus; with another telescope of the same focus, magnifying fifty or sixty times, and fitted with a micrometer, he found its distance from Venus about 10° : with a magnifying power of

240, he observed the star assume the same phases with Venus; its diameter seemed to be about one-third, or somewhat less, of the diameter of Venus; its light not so bright and vivid, but exceeding sharp and well defined. He viewed it for the space of an hour, but never had the good fortune to see it after the first morning. *Phil. Transf. N^o 459. p. 646, or Martyn's Abr. vol. viii. p. 208.*

M. Montaigne, of Limoges in France, was told in the *Encyclopédie*, art. *Venus*, preparing for observing the transit of 1761, discovered in the preceding May a small star about the distance of $20'$ from Venus, and its diameter was about one-fourth of the planet. He made other observations for several days, which were communicated to M. Baudouin, who read two memoirs on the subject to the Royal Academy of Sciences, in which he endeavoured to state the elements of the orbit of this satellite; but it is to be considered, that Montaigne's telescope had no micrometer, and that his distances must be very vague and uncertain. If Venus has a satellite, it must, according to Dr. Herschel, be less in appearance than a star of the eighth or ninth magnitude. *Phil. Transf. for 1795.*

After all, it must be acknowledged, that Venus may have a satellite, though it is difficult for us to see it. Its enlightened side can never be fully turned towards us, but when Venus is beyond the sun; in which case, Venus appears little bigger than an ordinary star, and, therefore, her satellite may be too small to be perceived at such a distance. When she is between us and the sun, her full moon has her dark side turned towards us; and when Venus is at her greatest elongation, we have but one half of the enlightened side of her full moon towards us, and even then it may be too far distant to be seen by us. But it was presumed, that the two transits of 1761 and 1769, would afford opportunity for determining this point; and yet we find that, although many observers directed their attention to this object, no satellite was seen in the sun's disc; and, therefore, it is reasonable to conclude, that Venus has no satellite.

The phenomena of Venus evidently shew the falsity of the Ptolemaic system: for that system supposes, that Venus's orb, or heaven, incloses the earth, passing between the sun and Mercury. And yet all our observations agree, that Venus is sometimes on this side of the sun, and sometimes on the other; nor did ever any body see the earth between Venus and the sun; which yet must frequently happen, if Venus revolved round the earth in an heaven below the sun.

Dr. Desaguliers contrived a planetarium to represent the phenomena of Venus, according to the discoveries of Bianchini; as did also Mr. Ferguson an orrery for the same purpose. The principal properties of these machines are the following: that the angle of the axis of the globe representing Venus makes, with the ecliptic, an angle of 15° ; that the tropics are 75° from the equator; that the tropics are 15° from the equator; that the plane of a solar horizon for the longest day cuts the plane of the equator at an angle of 15° ; that the sun's greatest declination is 75° ; that there are but $9\frac{1}{4}$ days in every revolution round the sun; and that to bring the days to an even reckoning, every fourth year must be a leap year, which, taking in the four quarters of a revolution, will make the leap year in Venus consist of ten of her days, equal to $7\frac{1}{2}$ months of our time; and that the long day for the north pole will contain $4\frac{2}{3}$ apparent diurnal revolutions of the sun. For a detail and illustration of the phenomena resulting from these properties, see Desaguliers's *Exp. Phil. vol. ii. p. 552, &c.* *Phil. Transf. vol. xlv. p. 127, &c. &c.* *Ferguson's Astron. p. 8, &c.* For the history and account of various instruments of this kind, see ORRERY and PLANETARIUM.

Explanation of the Tables.—Table I. contains the epochs of the mean longitude, of the aphelion and node. Table II. contains the mean motions of the same, for years. Table III. contains their mean motions for days. Table IV. contains their mean motions for hours, minutes, and seconds. Table V. contains the equation of the orbit for the year 1780; but this equation diminishes 25" in 100 years. Table VI. contains the logarithm of the distance of Venus from the sun, for the year 1780, with the corrections for 100 years, owing to a change of the excentricity. Table VII. contains the heliocentric latitude of Venus, the reduction in longitude to the ecliptic, and the reduction of the logarithm of the distance, in order to get the curtate distance from the sun.

The greatest equation (Table V.) of the orbit is 47' 20", and this diminishes at the rate of 25" in 100 years; that is, the diminution for every minute of the equation is very nearly 0".5; we shall, therefore, take the secular diminution at the rate of 0".5 for every minute of the equation: thus, if the equation be 16', the diminution is 4" for 100 years; and for any other number of years, the diminution is in proportion. For any time *before* 1780, this correction must be added to the equation.

In Table VI. there is a small table for the correction of the logarithms of the distance of Venus from the sun, for 100 years; entering it with the mean anomaly of Venus, and applying the correction according to the sign, for any time *after* 1780; but with a contrary sign, *before* 1780.

To find the heliocentric Latitude and Longitude of Venus, and the Logarithm of her Distance from the Sun.—From Table I. take out the epochs of the mean longitude, the aphelion and node, for the given year; and place them in a horizontal line. But if the given year be not found in that Table, take the nearest year preceding the given year, as an epoch, and take out as before; under which (Table II.) place the mean motion in longitude, of the aphelion and node, answering to the number of years elapsed since the epoch, to the given year.

Under these, write down (Table III.) the mean motions of the same, for the given day of the month.

Under these, write down (Table IV.) the mean motions of the same, for the given hours, minutes, and seconds.

Add together the numbers in the several columns, re-

jecting 12 S, or any multiple thereof, if they occur, and you get the mean longitude, places of the aphelion and node, for the given time.

Subtract the longitude of the aphelion from the mean longitude, and the remainder is the mean anomaly.

With the mean anomaly enter Table V., and take out the equation of the orbit with its proper sign, making proportion for the minutes and seconds, if there be any. But this requires a correction, at the rate of 0".5 for every minute of the equation for 100 years; and for any other time, the correction will be in proportion; to be subtracted *after* 1780, and added *before* that time.

Apply the equation with its proper sign to the mean longitude, and you get the longitude on the orbit, from the mean equinox.

From the longitude of Venus in her orbit, subtract the longitude of the node; and you have the argument, called the Argument of Latitude.

To the longitude on the orbit, apply the reduction (Table VII.) with its proper sign, and you have the longitude upon the ecliptic, from the mean equinox.

To the longitude thus found, apply the nutation with its proper sign, and you get the true longitude of Venus on the ecliptic, from the true equinox.

With the argument of latitude enter Table VII., and take out the latitude, making proportion for the minutes and seconds, if necessary; and this is the true heliocentric latitude of Venus.

With the mean anomaly of Venus enter Table VI., and take out the logarithm of her distance from the sun, making proportion for the minutes and seconds, if necessary. But this must be corrected by the small Table, to be entered with the mean anomaly, and you get the correction for 100 years; and for any other time, the correction will be in proportion, to be applied with a contrary sign, *before* 1780.

With the argument of latitude enter Table VII., and take out the reduction in the column under Sub. Log., making proportion for the minutes and seconds, if necessary; and subtract it from the logarithm of the distance last found, and you have the logarithm of the curtate distance.

Ex.—On June 23, 1690, new style, at 1^h 18' 11" mean time at Greenwich; to find the heliocentric latitude and longitude of Venus, and the logarithm of her distance from the sun.

VENUS.

VENUS, in *Chemistry*, is used for the metal *Copper*; which see. Its character is ♀; which, say the adepts, expresses it to be gold, only joined with some corrosive and arsenical menstruum; which, removed, copper would be gold.

Venus is universally allowed, by the chemists, &c. to be one of the most powerful medicines in nature: of this, is said to have been composed the famous Butler's stone, which cured most diseases by only licking it. Of this is composed that noble remedy of Van Helmont, viz. the sulphur of vitriol, or ens vitrioli, fixed by calcination and cohobation. Of the ens vitrioli of Venus is likewise composed Mr. Boyle's arcanum, the colcotlar vitrioli.

It is certain copper is a powerful emetic, and an antidote against poisons; for it is no sooner taken, than it exerts its force: whereas other vomitories lie a good while in the stomach: but one single grain of rust of Venus immediately vomits. Hence syrups, that have stood over night in copper vessels, create a vomiting.

However, pure copper, in its metallic state, or calcined by fire, appears to be indissoluble, and of no considerable effect, in the bodies of animals: but dissolved in the nitrous or marine acids, and crystallized or exsiccated by heat, it proves a strong caustic. Preparations of this kind, though formerly used, are now laid aside. Copper, combined with the vitriolic acid, or with vegetable acids, or corroded by the air, acts outwardly, as an efficacious detergent and a gentle escharotic, and internally as a virulent emetic and cathartic. Some have ventured on small doses, as quick emetics for expelling poisons; but the end may be obtained by less dangerous means.

It has been also reckoned an excellent medicine in chronic cases: hence a famous physician is recorded to have cured Charles V. of a dropsy by the use of copper.

A saturated solution of the metal in volatile spirits is recommended by Boerhaave in disorders proceeding from an acid, weak, cold, phlegmatic cause. He says, that if three drops be taken in the morning in a glass of mead, and the dose doubled every day, to twenty-four drops, it proves attenuating, warming, and diuretic; that by this medicine he once cured a confirmed ascites; though in other similar cases it failed; that it is the only preparation of copper which does not prove emetic; and that it may be tried with safety. Dr. Lewis, however, is of opinion, that in considerable doses it would exert the same virulent operation with the other soluble preparations or solutions of copper. A solid preparation of this kind, made by rubbing together in a glass mortar two parts of blue vitriol, and three of the volatile salt, procured from sal ammoniac, till all effervescence has ceased, and then gently drying the concrete, is ordered in the last Edinburgh Pharmacopeia, under the name of *cuprum ammoniacum*. It has frequently been given with success in epileptic and convulsive disorders. Lewis. See *SULPHATE of Copper*. See also *SAPPHIRINA Aqua*, and *AQUA Cupri Ammoniaci*.

Venus is dissoluble by all the salts known, both acid, alkaline, and nitrous; nay, even by water and air, considered as they contain salt.

It is from this common reception of all menstrua, that copper is called *Venus*, q. d. *meretrix publica*, a common prostitute: though others take the denomination to have been occasioned by its turning of a sea-green colour, when dissolved by acid. It must be given internally, with great caution.

VENUS, *Crystals of*. See *CRYSTAL*, *VERDEGREEN*, and *COPPER*.

VENUS, *Spirit of*. See *ACETIC Acid*.

VOL. XXXVI.

VENUS, in *Mythology*, the goddess of love, thus invoked by Lucretius:

“ Quæ quoniam rerum naturam sola gubernas,
Nec sine te quicquam dias in luminis oras
Exoritur, neque fit lætum, nec amabile quicquam.”

She is represented by the poets, painters, and statuary of antiquity, in a variety of alluring forms: with her hair sometimes waving over her naked shoulders, and sometimes negligently tied behind in golden tresses; with a mantle, exhibiting all the colours of the rainbow, and glittering with diamonds, sometimes flowing loosely, and at other times bound with a girdle or belt, called *cestus*, of which it is said that, “in eo deliramenta omnia inclusa erant; ibi inerat amor, inerat desiderium, inerat et amantium colloquium, itinerat et blanda loquentia quæ furtim mentem prudentium subripit:” accompanied by two Cupids, the three Graces, and followed by the beautiful Adonis, who held up her train; and riding in a chariot of ivory, finely carved, and beautifully painted and gilt, and drawn by swans, doves, or swallows. She is sometimes exhibited like a young virgin rising from the sea, and riding in a shell; at other times with a shell in her hand, and her head crowned with roses; sometimes with a mirror in her hand, and golden sandals and buckles on her feet; sometimes with poppy in one hand, and an apple in the other; and at Elis she was represented as treading on a tortoise; the tortoise being an emblem of reserve and modesty.

According to Cicero (*De Nat. Deorum*, lib. iii.) there were four principal deities under the denomination of Venus; one, the daughter of Cælum and Dies, called *Venus Urania*, who had a temple at Cythera, and also at Elis, with a statue of gold and ivory, executed by Phidias: the second, produced from the froth of the sea, called by the Greeks *Aphrodite* and *Anadomenè*, whose cradle was a shell, in which she was driven by Zephyrus upon the island Cyprus, and received by the Hours, or *Hora*, who educated her, and presented her to the gods, and who was at length, as some say, married to Vulcan: the third, born of Jupiter and Dione, and, as Cicero says, married to Vulcan: and the fourth, born of Syria and Tyrus, called *Astarte*, and said to have been married to Adonis. Plato, in his “*Banquet*,” allows only two; one, the daughter of Cælus, and the other, of Jupiter. Pausanias distinguishes three; one celestial, which presided over chaste loves; one terrestrial, or popular, who was the goddess of marriages; and a third, named *Apostrophia*, or the averting Venus, who banished infamous passions. Among the moderns, sir Isaac Newton, in his “*Chronology*,” seems to own no other Venus besides *Calycopis*, the mother of Eneas, and daughter of Otreus, king of Phrygia, whom Thoas (or Vulcan), furnished Cinyras, married, and erected temples to her at Paphos, at Amathus, in the island of Cyprus, and at Byblos in Syria; instituting priests to her honour, a sacred worship, and the scandalous feasts called the “*Orgies*,” for which reason she acquired the name of the Cyprian and Syrian goddess. This celebrated author relies on the authority of Tacitus (*Hist. l. ii. c. 3.*) who thus speaks of her: “We are told that Cinyras consecrated an ancient temple to Venus of Paphos, the landing-place of this goddess, who sprung from the foam of the sea.” His opinion may be easily reconciled to Lactantius's account, extracted from Euhemerus's sacred history, viz. that this was a woman of Cyprus, who by her behaviour encouraged gallantry, and gave rise to the fable of Venus.

Banier traces the origin of the fable of Venus to Phœnicia. He is of opinion that there never was another Venus worshipped among the Orientals but the *Venus*

Celestis, that is to say, the planet of that name; and Astarte, the wife of Adonis, whose worship was intermixed with that of the planet, or, which comes to the same, that Syrian Venus, the fourth in Cicero, so celebrated in antiquity. The Phœnicians, in conducting their colonies into the islands of the Mediterranean sea, and into Greece, introduced thither the worship of this goddess. They stopped first in the island of Cyprus, which lies next the coasts of Syria; and there the worship of this goddess was generally received. From thence they went to Cythera, an isle near the continent of Greece: there the Greeks began to traffic with them, and to get some knowledge of their religion; and this is the reason of their giving out, that it was near this island the goddess was seen for the first time, because it was there they came to hear of her first. A very convincing proof that the worship of Venus was established in that island, before it passed into the continent, is, that the temple of Cythera was accounted the most ancient of any that Venus had in Greece, as Pausanias remarks.

From Cythera the worship of this goddess passed into Greece; and as those who had brought it thither came by sea, the Greeks, who endeavoured to give every thing a marvellous dress, say she had sprung from the sea, and gave her the name of Aphroditè, a word which imports foam. This, no doubt, is the true explication of this fiction, and it is needless to search into it for any other mystery. The Greek poets embellished this fable according to their own fancy. Having heard of Astarte's passionate love of Adonis, they took care to apply this circumstance to their Venus: and, moreover, they considered Love as the son of this goddess, and gave her the three Graces for her daughters. In fine, they formed that love-system, of which the ideas have served, in after-ages, to embellish the works of their brother-poets. A young virgin rises out of the foam of the sea, and appears upon a shell-fish; she sits down on mount Cythera, where the flowers spring up under her feet; the Hours, charged with the care of her education, conduct her to heaven, where all the gods, charmed with her beauty, make love to her; she matches with Vulcan, the most deformed of all; she disgraces herself by her gallantries with Mars and Mercury; by the one she has Cupid, and by the other Anti-Cupid; Bacchus is her squire; in fine, she pre-fides over marriages and gallantry; and, therefore, has a mysterious girdle given her, called the *cellus* of Venus, which not only makes herself amiable, but has virtue to kindle the flame of an extinguished passion, &c.

This was not all, they foisted into the history of the goddess Venus, most of the celebrated pieces of gallantry. Some beauty being surpris'd in an intrigue, gave rise to the adultery of Mars with Venus, and to the stratagem of Vulcan.

Venus, whatever might be the dishonourable ideas entertained concerning her, was nevertheless regarded as one of the principal deities; and as she patronized scandalous passions, she was worshipped in a manner worthy of her. Her temples, open to prostitution, taught the corrupt world, that in order to pay due honour to the goddesses of love, they were to have no regard to the rules of modesty. The virgins prostituted themselves publicly in her temples, and there the married women shewed as little reserve. Amathus, Cythera, Gnidos, Paphos, Idalia, and the other places especially consecrated to this goddess, were distinguished by the most infamous abuses.

Farther, as there were several Venuses, her worship was not every where the same. In some places they only burned

incense upon her altars; elsewhere they made her an offering of sweet odours, one ingredient of which was the flesh of a sparrow; in other places they sacrificed to her a white goat. The women had also a custom of consecrating their hair to this goddess; and the tresses of Berenice, which she had vowed to Venus, were placed among the stars.

Among the flowers, the rose was particularly consecrated to this goddess, because this flower had been tinged with the blood of Adonis, whom one of its thorns had wounded, which changed it into red from white, which it was before this adventure. The myrtle, too, was dedicated to her, because it commonly grows upon the borders of the water where this goddess was born. The swans and sparrows were peculiarly consecrated to her, but above all the pigeons, from the fable which sets forth, that while this goddess was one day playing with Cupid, the little god would needs wager to gather more flowers than she, and a nymph named Pteris, having assisted the goddess, she won the wager, with which Cupid was so provoked, that he transformed the nymph into a pigeon. As there were several persons who bore the name of Venus, her worship was not every where the same.

Venus was known under several appellations and characters; derived either from the places where she was worshipped, or from some particular circumstances that had given rise to her worship. Accordingly we read of the Venus *Amathusia*, *Amica*, *Anaitis*, *Apaturia* or *Desidiosa*, *Aphrodita*, *Archytis*, *Argynnis*, *Armata*, *Aurea*, *Barbata*, *Basilis*, *Callypiga*, *Calva*, *Cluacina*, *Colias*, *Cypria*, *Cytherea*, *Elephantina*, *Elycopis*, *Erycina*, *Etaira*, *Genitrix*, *Hortensis*, *Improba*, *Libuina*, *Marina*, *Nephthe*, *Paphia*, *Praxis*, *Ridens*, *Verticordia*, *Vitrix*, *Zerynthia*, &c. &c.

Praxiteles executed two statues of Venus, one clothed, bought by the inhabitants of Cos, and another naked, which he sold to the Cnidians. See ANADUOMENÈ, and VENUS *de Medicis*.

The Venus of M. Maffei seems to have been formed in conformity to the well-known passage of Terence,

“Sine Cerere & Baccho friget Venus.”

The goddess in this statue is accompanied with two Cupids, and crowned with ears of corn, holding a thyrsus, wrapped about with leaves and clusters of grapes; and as she carries in her hand three arrows, she seems to teach us that her arrows fly more unerringly when Ceres and Bacchus concur. Pausanias informs us that he had seen in Elis a fine statue of Venus Urania or Celestial, whose feet rested upon the back of a tortoise; and another of terrestrial Venus, placing her feet upon a he-goat.

We have on medals the Venus Urania, or Celestis, with a star or sun, or celestial globe in her hand; and the Venus Paphia, almost naked, leaning on a column, with a helmet and the arms of Mars in her hands, bearing an inscription *Veneri Vitrici*, or *Veneri Genitrici*. She is sometimes seen armed, sometimes resting upon a dolphin, holding a pigeon in her lap, or with Adonis, accompanied by his dogs, or with Cupid and the three Graces; but more frequently rising from the sea, seated upon a shell borne by two Tritons, or upon a chariot drawn by two sea-horses, or by a female sea-goat, or rather he-goat; for, according to Pausanias, her statue, made by the famous statuary Scopas, was upon that animal, and in that case she is accompanied by Nereids and Cupids, mounted upon dolphins, one of the Nereids holding a lute in her hand, and mounted upon a sea-centaur; but more frequently her chariot is drawn by swans or pigeons, birds consecrated to her. Sometimes she

she appears herself supported by a Triton, having a buckler in her hand, on which is represented a head; sometimes mounted upon sea-horses, she seems to skim over the waves of the sea, her head being covered with a veil which swells in the wind, with Cupid swimming at her side. An oar at the foot of the goddess seems to represent the Venus Pelagia or Marine: and the figure which she holds in her hand, a cornucopia, expresses the blessings produced by maritime commerce. There is also a picture of the Venus Desidiofa in the Barberini palace at Rome, which is one of the finest-coloured pictures that is left us by the ancients; the hair of whose head may be compared with Guido's, and the colouring of the flesh reminds us of Titian. Part of this picture is lost, and part restored by Carlo Marat. Venus is described by Statius (lib. i. l. v. 56.) much in the same manner as she is represented in the Barberini picture.

We shall only add, that Venus is sometimes described by the poets of the third age under the character of the goddess of jealousy, rather than as the goddess of love; in which Valerius Flaccus (Argon. ii. v. 106.) and Statius (Theb. v. v. 69.) have drawn two very terrible pictures of her. Spence's Polymetis, p. 74.

VENUS *de Medicis*, in the history of *Ancient Sculpture*, a famous statue of white marble, about five feet high, brought from the Medicis palace at Rome to Florence, by order of duke Cosmo III., and now standing in the great duke's palace. The hips, legs, and arms, were broken off by the removal of this statue; but they have been rejoined with an art, that renders their former separation imperceptible. The inscription on the base intimates that this was the work of Cleomenes, an Athenian, the son of Apollodorus: the pedestal is modern; the statue seems to bear a little forwards; the right knee advances a little; the left-hand is placed before that part which distinguishes the sexes, and the right across her breasts; yet without touching the body. The head inclines a little to the left shoulder; so that her face seems to be turned away a little from the observer: and from this circumstance some have taken occasion to remark, that the hair of the head of this Venus expresses three different passions; as you first approach her, you perceive aversion or denial in her look; as you advance a step or two nearer, she shews compliance; and one step more to the right, it is said, turns into a little insidious and insulting smile: but Mr. Spence does not allow that this account is justified by the statue itself.

The attitude of the Venus de Medici is peculiarly graceful: that attitude may be described in two verses of Ovid, Art. Am. v. 614.

“ Ipse Venus pubem, quoties velamina ponit,
Protegitur læva semi-reductâ manu.”

The bloom of youth, the pleasing softness of her look, and her beauty and modesty, seem to rival each other in the charms of her countenance. Her person is somewhat plump, and the flesh is so admirably executed, that it seems so soft as if it would yield to the touch. Time has given to the white marble a yellowish hue, though still in the sun-shine it is almost transparent: her hair is brown, which may be no more than the faded gilding not unusual among the ancients. The head, which is said to be too small in proportion to the other parts, is suspected by some not to have been executed by the same artist who made the body: this will ever be the standard of female beauty and softness: the breasts are also the finest that can be conceived, small, distinct, and delicate, suggesting an idea of softness, which

no copies can imitate, and also of firmness: from the breasts, her shape begins to diminish gradually down to her waist; but with an exquisite fineness of shape, the Venus of Medici has what the Romans call *corpus solidum*, and the French the *enbonpoint*; and her waist in particular is not represented as flinted by art, but as exactly proportioned by nature to all the other parts of her body. There is also a tenderness and elegance in every other part of her form: her legs are neat and slender: the small of them is finely rounded, and her feet are little, white and pretty: so that she possesses all those lesser beauties which the poets have marked out in the female make; the *teretes suræ* (Hor. lib. ii. od. iv. ver. 21.), and the *pes candidus* (Id. lib. iv. od. i. v. 27.), and *exiguus* (Ovid. Am. lib. ii. el. iii. ver. 7.) And one may well say of this statue, what one of the persons in Plautus's Epidicus (act v. sc. 1.) says of a complete beauty:

“ Ab unguiculo ad capillum summum, est festivissima.”

Though the Venus of Medici has not escaped censure, with regard to the smallness of her head and hips, the largeness of the nose, the depth of the partition along the vertebrae of the back, the length of the fingers, which, excepting the little finger on the left-hand, are without joints; and though, in comparing the parts separate, as the head, nose, &c. of this statue, with those of others, the similar parts might be found even of superior workmanship; yet for such a combination of beauties, the delicacy of shape and attitude, and symmetry of the whole, it is universally allowed that the world doth not afford its equal. This incomparable statue stands between two others, which in any other place would be esteemed admirable pieces: that on the right of the Venus de Medici is twice as big, with the golden apple in her hand, and is called *Venus Viratrix*; the other, by Hercules Ferrata, is distinguished by the name of *Venus Urania*. Spence's Polymetis, p. 6, &c. Keyser's Travels, vol. i. p. 434.

VENUS, in *Heraldry*, is used for the colour vert.

VENUS, in the Linnæan system of *Natural History*, a genus of the Testacea order of worms. See CONCHOLOGY.

VENUS, *Mount of*, *Mons Veneris*, among *Anatomists*, is a little hairy protuberance in the middle of the pubes of women; occasioned by the collection of fat under the skin in that place.

Among chiromancers, the mount of Venus is a little eminence in the palm of the hand, at the root of one of the fingers.

VENUS's *Comb*, in *Botany*. See SCANDIX.

VENUS's *Fly-Trap*. See DIONÆA.

VENUS's *Looking-Glass*. See CAMPANULA and SPECULUM *Veneris*.

VENUS's *Navel-Work*. See COTYLEDON, n. 19, and CYNOGLOSSUM, n. 18.

VENUS, *Cape*, in *Geography*, a cape on the coast of Otaheite. N. lat. 17° 29'. W. long. 149° 36'.

VENUSIA, VENOSA, in *Ancient Geography*, a town of Italy, in Apulia, near mount Vultur, watered by a small river called Aufidus. It is said to have been denominated Aphrodisia. It became a Roman colony in 460 U.C. It was formerly a magnificent city, but its baths, theatres, and temples have been destroyed. It was the birth-place of Horace.

VENUSTI, MARCELLO, in *Biography*. This painter was born at Mantua in 1515, and was a pupil of Pierino del Vaga. He is however far better known as the painter of several designs of Michael Angelo, (to which he gave a colour unknown to that great composer,) than by any original

ginal works of his own. The cardinal Farnefe engaged him to copy the great work of the Last Judgment in the Capella Scitina, upon a small scale, which he accomplished very much to the satisfaction of M. Angelo, who in consequence engaged him to paint an altar-piece for the Capella de Cefi in the church of La Pace, from a design of his own, of the Annunciation. There are several pictures in England, which are called Michael Angelo's, that have every appearance of being painted by Venusti. Some works of his own are spoken of with respect, particularly the Martyrdom of St. Catherine, in the church of S. Agostino; and St. John in the Wilderness, in St. Catherine alli Funari. He died in 1576, aged sixty-one.

VENZONE, in *Geography*, a town of Italy, in the country of Friuli, on the Tajamento; 18 miles W.N.W. of Friuli.

VEPILLIUM, or VEPILLUM, in *Ancient Geography*, a town of Africa, S. of Carthage, situated two leagues S.E. of Almana, which has still some vestiges of the Romans.

VEPREULÆ, in *Botany*, the thirty-first natural order among the *Fragmenta* of Linnæus, named from *vepres*, a briar or bramble, because the plants which compose this order are pliant shrubs, of humble growth. The genera mentioned at the end of the *Genera Plantarum* are *Dais*, *Quisqualis*, *Dirca*, *Daphne*, *Gnidia*, *Lachnea*, *Passerina*, *Stellera* and *Thefum*; to which Linnæus has added in manuscript, *Strubiola*, *Santalum* (with a doubt whether it should not rather be referred to the *Bicornes*), and *Scleranthus*. No remark occurs, in Giseke's publication of the *Praelectiones* of Linnæus, on this order. As far as concerns the eight first named of the above genera, with *Strubiola*, it is precisely analogous to Jussieu's ΤΗΥΜΕΛÆÆ, see that article. *Thefum* and *Santalum* belong to Mr. Brown's SANTALACEÆ, an order extracted from the *Onagræ* and *Elæagni* of Jussieu, which the reader will find in its proper place. *Scleranthus* seems naturally one of the *Caryophyllei*, notwithstanding the insertion of its stamens into the *calyx*, which obliged Jussieu to range it with his *Portulacææ*. Perhaps this decision may partly be supported by the habit, and the aspect of the *flower*.

VEPRIS, Juss. 371, a name given by Commerçon to what is now called SCOPOLIA; see that article.

VER-PUERON, in *Natural History*, a name given to a kind of insects which are fond of eating the puceron, and destroy them in vast numbers.

They are thus called, as the ant-eater is, *fornica-leo*, from their destroying great numbers of them.

These ver-pucerons are a sort of worms produced from the eggs of flies, and are of two principal kinds; the one having legs, the other none.

When we observe the vast number of young produced by every puceron, and the quick progress they make in their multiplication, we are apt to wonder, that every plant and tree in the world are not covered with them; but on the contrary, when we observe the devastation these devourers make among them, we are apt to wonder how any of them escape at all, to perpetuate the species. These worms indeed seem created for no other purpose but to destroy them; and this they do in so violent a manner as is scarcely to be conceived. As the flies of many kinds lay their eggs on meat and other substances, which they know will afford food for the young ones, when hatched from them: so the parents of these worms lay their eggs on the branches and leaves of trees loaded with pucerons, on which they know they will feed. The worms produced from them are devourers from the very instant they are hatched, and find themselves placed in the midst of prey, being every way surrounded by a nation of creatures which are their proper

food, and which are furnished with no weapons, either offensive or defensive, and which never so much as attempt to fly from them, but seem wholly ignorant of their danger, till seized upon by the devourers. Reaumur's *Hist. of Insects*, vol. vi. p. 111.

The flies, which are produced from these worms, are all of the two-winged kind; but there are several different species of them; the generality of them resemble wasps, and have a very flat body. Goedart, who has described some of these flies, was surpris'd to see them very small when first produced from the chrysalis, yet growing very large in a quarter of an hour's time, and that without taking any nourishment; but this was only owing to their several parts having been squeezed while in the chrysalis, and expanding themselves when they were at liberty from the compression. These are the changes of this kind of leo-puceron; but the other devourer of these creatures, which has six legs, is of a different kind, and indeed is in itself reducible to several species, some of these six-legged worms becoming four-winged flies, and others a kind of beetles. These, from their near resemblance to the formica-leo, are by Reaumur distinctly called puceron-lions.

VER-Polype, a name given by Reaumur, and some other authors, to a species of water-worm, by no means to be confounded with the creature called simply the polype, and which is so famous for its reproduction of parts cut off, and for many other singular properties.

This ver-polype is a species of water-worm, produced from the egg of a tipula, and had this name given it from some remarkable productions, placed at the anterior and posterior parts of the body, which are supposed to have some analogy with the parts of the sea-fish called the *polypus*. These worms are found in muddy ditches, usually either crawling upon, or buried in the mud. Reaumur's *Hist. Insects*, vol. ix. p. 49.

VER du Gard, in *Geography*, a town of France, in the department of the Gard; 6 miles S.E. of Uzes.

VERA, in *Ancient Geography*, a town of Asia, in Media, on an eminence, and strong by its situation.—Also, the name of a river of Gaul.

VERA, in *Geography*, a town of Spain, in Navarre; 25 miles N. of Pamplona.—Also, a town of Spain, in the province of Grenada; 34 miles N.E. of Almeria. N. lat. 37° 8'. W. long. 2° 4'.—Also, a river of European Turkey, which runs into the gulf of Salonichi, near the mouth of the Vardar.

VERA Billa. See BILLA.

VERABADURGAM, in *Geography*, a town of Hindoostan, in Myfore; 8 miles W.S.W. of Caveripatam.

VERACINI, ANTONIO, in *Biography*, uncle and master to Francesco Maria Veracini, the celebrated performer on the violin, published at Florence, in 1692, ten sonatas, the usual number, till Corelli's time; and afterwards, "Sonate da Chiesa," two sets; but this author not being possessed of the knowledge, hand, or caprice of his nephew, his works are now not sufficiently interesting to merit further notice, particularly as there was nothing marked or original in his style; the harmony indeed was correct; but "much may be right, yet much be wanting."

VERACINI, FRANCESCO MARIA, a native of Florence, and contemporary with Tartini, who were regarded as the greatest masters of the violin that had ever appeared; nor were their abilities confined merely to the excellence of their performance, they extended to composition, in which they both manifested great genius and science. But whatever resemblance there may have been in the professional skill of these two masters, it was impossible for any two men to be more dissimilar

diffimilar in disposition: Tartini was so humble and timid, that he was never happy but in obscurity; while Veracini was so foolishly vain-glorious as frequently to boast that there was but *one God, and one Veracini*.

Being at Lucca at the time of La Festa della Croce, which is celebrated every year on the 14th of September, when it is customary for the principal professors of Italy, vocal and instrumental, to meet, Veracini entered his name for a solo concerto; but when he went into the choir, in order to take possession of the principal place, he found it already occupied by Padre Girolamo Laurenti, of Bologna; who not knowing him, as he had been some years in Poland, asked him where he was going? Veracini answered to the place of first violin. Laurenti then told him, that he had been always engaged to fill that post himself; but that if he wished to play a concerto, either at vespers, or during high mass, he should have a place assigned him. Veracini, with great contempt and indignation, turned his back on him, and went to the lowest place in the orchestra. In the act or part of the service in which Laurenti performed his concerto, Veracini did not play a note, but listened with great attention. And being called upon, would not play a concerto, but desired the hoary old father would let him play a solo at the bottom of the choir, desiring Lanzetti, the violoncellist of Turin, to accompany him; when he played in such a manner as to extort an *e viva!* in the public church. And whenever he was about to make a clofe, he turned to Laurenti, and called out: "Cosi si fuona per fare il primo violino:" "this is the way to play the first fiddle." Many silly stories of this kind are handed about Italy concerning the caprice and arrogance of this performer, who was usually qualified with the title of *Capo pazzo*.

Veracini would give lessons to no one except a nephew, who died young. The only matter he had himself in his youth, was his uncle, Antonio Veracini, of Florence; but by travelling all over Europe he formed a style of playing peculiar to himself. Besides being in the service of the king of Poland, he was a considerable time at different courts of Germany, and twice in England, where, during the time of Farinelli, he composed several operas: among which was "Adriano," in London, in the winter of 1735 and 1736, which had a run of twelve nights; and in 1744, "L'Errore di Salomone," in which Monticelli performed.

Veracini's first arrival in England was in the year 1714, when in the advertisements of the time for the opera of Dorinda, it is said that "Signor Veracini, lately arrived, will perform symphonies;" and the same year, with the operas of Crespo, Arminio, and Ernelinda, solos on the violin were frequently performed by Veracini.

We saw and heard him perform in the year 1745, at Hickford's room, where, though in years, he led the band at a benefit concert for Jozzi, the second finger, at the opera, in such a bold and masterly manner as we had never heard before. Soon after this, in returning to the continent, Veracini was shipwrecked, and lost his two famous Steiner violins, thought to have been the best in the world, and all his effects. He used to call one of his violins St. Peter, and the other St. Paul.

As a composer he had certainly a great share of whim and caprice, but he built his freaks on a good foundation, being an excellent contrapuntist. The peculiarities in his performance were his bow-hand, his shake, his learned arpeggios, and a tone so loud and clear, that it could be distinctly heard through the most numerous band of a church or theatre.

Veracini and Vivaldi had the honour of being thought mad for attempting in their works and performance what many a sober gentleman has since done uncensured; but

both these musicians, happening to be gifted with more fancy and more hand than their neighbours, were thought insane; as friar Bacon, for superior science, was thought a magician, and Galileo a heretic.

VERA-CRUZ, in *Geography*, a sea-port of Mexico, in the province of Tlascala, with a secure harbour, defended by a fort, upon a rock of a neighbouring island, called St. John d'Alva, in the gulf of Mexico. This is fortified with 300 pieces of cannon; and signals are made from a high tower. This is a place of very great extent, and perhaps one of the most considerable in Spanish America for trade, it being the natural centre of the American treasure, and the magazine of all the merchandize sent from New Spain, or of that transported hither from Europe. It receives a prodigious quantity of East India goods over land from Acapulco, brought from the Philippine isles. Upon the annual arrival of the flota here from Old Spain, a fair is opened, which lasts many weeks, when this place may be said to be immensely rich. Its situation is unhealthy, from the bogs round it, and the barrenness of the soil. It parts the sea in a semicircle, and is inclosed with a single wall or parapet, six feet high and three broad, surmounted by a wooden pallisade much decayed. The wall is flanked with six feeble bastions, on square towers twelve feet high. On the shore to the S.E. and N.W. are two redoubts, with some cannon to defend the port. The houses are well built with stone and lime, and have wooden balconies. The streets are wide, well paved with pebbles, and kept in excellent order. The churches are much decorated with silver; and in the dwelling-houses, the chief luxury consists of porcelain and other Chinese articles. The principal inhabitants are merchants; but European commerce is mostly carried on at Xalapa. The population is about 7000 or 8000: the inhabitants are generally proud, indolent, and devout; but commerce is well understood, and here are seven or eight houses, each worth a million of dollars. The women are rarely handsome, and live in retirement; the only amusements being a coffee-house and processions, or religious masquerades, the penitents whipping themselves with much bloodshed. A charity of 6000 dollars to marry four poor girls has, as is usual in such cases, reverted to the rich. The harbour of Vera-Cruz might offer anchorage to 40 or even 60 ships of war in four to ten fathoms; but the northerly winds are terrible, and often drive vessels on shore. In the rainy season the marshes on the south are haunted by caymans, or alligators, from seven to eight feet in length, but innocent. The sea-fowl are innumerable, and the mosquitoes very troublesome. The north winds are said to be so violent, that the ladies are excused from going to mass; and these gales sometimes load the walls with sand. In the rainy season the water regularly falls in the night. Earthquakes are frequent. Vera-Cruz having been taken and plundered several times by the Buccaneers, the Spaniards have built forts, and placed centinels along the coast: their ordinary garrison consisting only of 60 horse and two companies of foot; 180 miles E.S.E. of Mexico. N. lat. 19° 5'. W. long. 97° 26'.

VERA-CRUZ, a port in the bay of St. Philip and St. Jago, in Terra Australis del Espiritu Santo, discovered by Quiros in 1606, and, according to him, capable of containing 1000 ships, with clear soundings of black sand, and water from three feet to 40 fathoms.

VERA-CRUZ, *Old*, a sea-port of Mexico, in the province of Tlascala. This is the port where Cortez landed in 1518; 15 miles N. of Vera-Cruz. This is situated infalubriously; and the river is full of caymans, so strong as to draw an ox under water. They are fond of the flesh of dogs. N. lat. 19° 20'. W. long. 97° 40'.

VERACUNDALORE, a town of Hindoostan, in the Carnatic; 20 miles S.W. of Bomrauzepollam.

VERAGILA, a small island in the gulf of Venice. N. lat. $44^{\circ} 12'$. E. long. $15^{\circ} 32'$.

VERAGRI, in *Ancient Geography*, a people of the Alps, in the Pennine valley. Cæsar places them between the Nantuates and the Seduni.

VERAGUA, in *Geography*, a province of Mexico, bounded on the N. by the gulf of Mexico, on the E. by the province of Darien, on the S. by the Pacific ocean, and on the W. by Costa Rica. This coast was first discovered by Columbus, in the year 1503, to whom it was granted, with the title of duke. To the river now called Veragua, he gave the name of "Verdes-aguas," on account of the green colour of its water; or, according to others, because the Indians called it by that name in their language. But however that may be, it is from this river that the province derives its name. In 1538, the captains Gasper d'Espinoza and Diego de Alvarez, renewed the discovery by land; but, being repulsed by prince Urraca, were obliged to content themselves with a settlement in the neighbourhood; and even here the Spaniards were not able to maintain their ground against the frequent incursions of the Indians; so that finding the absolute necessity of a stronger settlement, they built the city Santa Fé, on the spot where it now stands. This province, though geographically belonging to North America, is included within the kingdom or territory of Terra Firma. The country is rugged and mountainous, but abounding with beautiful and excellent woods, and having vales that afford rich pastures. The monkeys found here are small but beautiful, being of a buff-colour, with a white crown; but too delicate to be removed from their native clime. It is said to rain here every day in the year; and the rain is attended with tremendous thunder and lightning, and produces torrents that descend with rapidity and violence from the mountains. Its gold-mines are rich, but little wrought, because every article must be carried on the shoulders of the Indians over steep mountains. The Doraces, and other savage tribes, live naked in the mountains, on roots and fruits; but several have been converted since the year 1760 by the Franciscans, who have founded some Indian villages. The capital of this province is called by the same name, and also *St. Jago de Veragua* (which see); it is situated in a warm and moist climate, abounding in maize, yucca, a root of which bread is made, plantains, and cattle, but principally in swine. The natives dye their cotton of a rich and permanent purple, with the juice of a sea-snail found on the coast of the Pacific, akin to the murex of the ancients; with which, and some gold from the mines, they carry on trade with Panama, and the provinces of the kingdom of Guatemala. Here is an elegant hospital; and fourteen villages are subject to the jurisdiction of this town, which is ruled by a governor.

VERAL, a river of Spain, which runs into the Aragon.

VERALA, in *Ancient Geography*, a town of Hispania Citerior, between Calaguris and Trifium.

VERAMALLY, in *Geography*, a town of Hindoostan, in the Carnatic; 18 miles S. of Tritelinopoly.

VERANO AVE, or *Ave de Verano*, in *Ornithology*, the name by which the Portuguese in the Brazils call a large bird of the thrush kind, approaching to the size of a small pigeon, remarkable for its loud noise; and more commonly known by its American name *guirapanga*.

VERANOCA, in *Ancient Geography*, a town of Asia, in Phœnicia.

VERAPATCHY, in *Geography*, a town of Hindoostan, in the Myfore; 20 miles W.N.W. of Dindigul.

VERA-PAZ, a province of Mexico, in the domain of

Guatemala, bounded on the N. by the province of Chiapa, on the E. by the bay and province of Honduras, on the S. by Guatemala, and on the W. by Soconusco; about 120 miles in length, and 74 in breadth. In one part of the country the air is healthy, in the other not. The country is subject to earthquakes, thunder, and nine months' rain. The soil is mountainous, yielding little corn, but abounding in forests of cedar, &c. in which are many wild beasts. The principal commodities are drugs, cocoa, cotton, wool, honey, &c.

VERA-PAZ, or COBAN, a town of Mexico, and capital of the province of Vera-Paz, situated on a river which runs to the bay of Honduras; 600 miles S.E. of Mexico. N. lat. $15^{\circ} 50'$. W. long. $91^{\circ} 14'$.

VERATO, a town of Naples, in the province of Otranto; 4 miles S. of Alessano.

VERATRUM, in *Botany*, which some derive from *verè atrum*, truly black, because the root is, externally at least, of that colour; may more safely be left among those ancient names whose origin is unknown. It occurs in Lucretius and Pliny, indicating some very active or poisonous plant; and is generally supposed synonymous with the ἰλλεβορος λυκο of Dioscorides, itself rather doubtful, and whose particular designation is a contradiction to the above etymology. Whatever difficulties may attend the determination of the ancient *Veratrum*, this name is now universally applied to the genus we are about to describe, one of whose original species having nearly white, and the other as nearly black, flowers, the English appellations, of White and Black Hellebore, suit them so well, as to efface all memory of old uncertainties.—Linn. Gen. 540. Schreb. 715. Willd. Sp. Pl. v. 4. 895. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 425. Pursh 242. Juss. 47. Tournef. t. 145. Lamarck Illustr. t. 843. Gærtner. t. 18.—Class and order, *Polygamia Monoecia*, or more properly *Hexandria Trigynia*. Nat. Ord. *Coronariæ*, Linn. *Junci*, Juss. *Melanthaceæ*, Brown.

Gen. Ch. *Cal.* none, unless the corolla be taken for such. *Cor.* Petals six, elliptic-oblong, sessile, thinner at the margin towards the base, and finely serrated or fringed in that part, permanent. *Stam.* Filaments six, inserted into the base of the petals, awl-shaped, converging round the germens, spreading at the summit; anthers quadrangular, versatile, attached by the back. *Pist.* Germens three, superior, oblong, compressed, erect, combined, terminating in three very short styles, with simple spreading stigmas. *Peric.* Capsules three, oblong, erect, compressed, of one cell and one valve, bursting at their inner margins by which they are originally connected. *Seeds* several, obliquely imbricated, inserted into each margin of the capsule, oblong, compressed, winged at each end; the wing at the lower part rounded. Several flowers, on the same plant, have only slight rudiments of a pistil.

Ess. Ch. Calyx none. Petals six, permanent, sessile, equal, bearing the stamens. Styles permanent. Capsules three, bursting at the inner edge. Seeds numerous, compressed, imbricated, winged at each end. Some flowers male.

Obs. This genus has been thought too near MELANTHUM, see that article. The capsules of the latter are single, of three cells, and in some species the cells burst externally, but this is not the case with *M. sibiricum*, whose cells burst at the inner angle only. The subject wants revision. The habit of *Melanthium*, for the most part an African genus, is very unlike *Veratrum*, the leaves being slender, and *inflorescence* more simple. The corolla is more coloured, with elongated claws; and though permanent, has less of the coriaceous nature of a calyx. HELONIAS, (see that article,)

ticle,) which Mr. Ker would unite with *Veratrum*, has a roundish three-celled capsule, and a different habit.

1. *V. album*. White Veratrum, or Common White Hellebore. Linn. Sp. Pl. 1479. Willd. n. 1. Ait. n. 1. Jacq. Austr. t. 335. Fl. Dan. t. 1120. Mill. Ic. t. 271. Mill. Illustr. t. 98. Woodv. Med. Bot. t. 100. (Helleborus præcox; Ger. Em. 440. Elleborum album; Matth. Valgr. v. 2. 559.)—Panicle thrice compound. Petals ascending, elliptical.—Native of alpine meadows in most parts of Europe, from Norway to Greece; but not of Britain. It is, of course, a hardy perennial in our gardens, where it has been cultivated time out of mind, flowering from June to August. The root is tuberous, black on the outside, with long, simple, white, cylindrical fibres. Stem from two to four or five feet high, stout, erect, simple, leafy, terminating in a large, branching, downy panicle, of innumerable greenish-white flowers, with little or no scent, an inch broad, whose petals when in full perfection spread horizontally, but in fading return to their original ascending posture, becoming green, leafy, and coriaceous. The leaves are large, elliptical, entire, with many ribs, plaited, smooth, of a fine green; the uppermost becoming oblong or lanceolate bracteas. Each partial flower-stalk is also accompanied by an elliptic-lanceolate downy bractea, various in length. This stately plant, accompanied by *Gentiana lutea*, makes a magnificent appearance in rich pastures on the alps of Switzerland and Savoy, where they both grow more luxuriantly than in gardens.—Mr. Sieber of Prague has sent us from the alps of Austria, under the name of "*V. viride* Bernhardi," what seems a greener-flowered variety of the *album*, and different from the following; but it is extremely difficult to decide on this point, without seeing the plants alive.

2. *V. viride*. Green Veratrum. Ait. n. 2. Willd. n. 2. Pursh n. 1. Bigelow Bost. 246. [*V. album*; Michaux Boreal.-Amer. v. 2. 249. *Helonias viridis*; Curt. Mag. t. 1066.]—Spikes panicled, dense, cylindrical. Petals ascending, elliptical.—In swamps and on mountain bogs, from Canada to Carolina, flowering in July. A stately plant, from three to six feet high. Pursh. Dr. Bigelow, in his *Flora Bostonensis*, says this plant, not infrequent in meadows and swamps about Boston, is called Poke root, or Swamp Hellebore. It was cultivated in England by Peter Collinson, in 1742. The foliage and habit are like the preceding, but the panicle is larger and greener; its branches longer and more cylindrical, spiked, not racemose, each flower being nearly or quite sessile. The petals are broader; their margins thickened and mealy about the base.

3. *V. nigrum*. Dark Veratrum. Linn. Sp. Pl. 1479. Willd. n. 3. Ait. n. 4. Jacq. Austr. t. 336. Curt. Mag. t. 963. (Helleborus albus præcox; Ger. Em. 440. f. 2.)—Clusters panicled, dense, cylindrical. Petals obovate, widely spreading; at length reflexed.—Native of dry mountainous situations, in Siberia, Hungary, Austria and Greece, flowering in July. Perfectly hardy in our gardens, where it blossoms freely, and increases without any care, provided the soil be dry. It agrees with the first species in habit and leaves, but is rather taller, and is very remarkable for the dark purplish-brown, almost black, hue of its flowers, which exhale a faint cadaverous scent. They compose long, cylindrical, sessile clusters, assembled into a long panicle, accompanied by narrow strap-shaped bracteas in the lower part. Each flower is but half as broad as those of *V. album*, and the petals turn backward as they fade, becoming finally of a dull green.

4. *V. virginicum*. Virginian Veratrum. Ait. n. 3. (Melanthium virginicum; Linn. Sp. Pl. 483. Willd. Sp. Pl. v. 2. 266. Pursh 240. *Helonias virginica*; Curt. Mag. t. 985. *Aphodelo affinis floridana*, ramofo caule, floribus

ornithogali obfoletis; Pluk. Amalth. 40. t. 434. f. 8.)—Clusters panicled, loose. Petals elliptical, spreading, with two spots at the base; hairy at the back.—In low grounds, amongst luxuriant herbage, from New York to Carolina, flowering in June and July, perennial. Rather scarce in gardens, though tolerably hardy. The stem is from three to five feet high, downy. Leaves linear-lanceolate, folded, ribbed, pointed. Panicle pyramidal, of numerous, loosely racemose, many-flowered branches, whose partial stalks are about half as long again as the petals. Flowers green, with two brown spots on each petal. After being expanded for some time, they turn to a red-brown.

5. *V. parviflorum*. Small-flowered Veratrum. Michaux Boreal.-Amer. v. 2. 250. Willd. n. 4. Ait. n. 5. Pursh n. 2.—Clusters panicled, with slender branches. Petals oval-lanceolate, acute at each end. Leaves elliptical, flat, smooth.—On high mountains in Carolina, flowering in July. Flowers small, green. Root perennial. Pursh. The leaves are like those of a *Veratrum*, but not so much furrowed, or plaited. Petals without glands. Inflorescence that of a *Melanthium*. Michaux. We have seen no specimen nor figure, neither of this nor the following.

6. *V. angustifolium*. Narrow-leaved Veratrum. Pursh n. 3.—Dioecious. Panicle simple. Petals linear. Leaves very long, linear, keeled.—On high mountains of Virginia and Carolina. Perennial, flowering in June. Stem tall. Flowers greenish-yellow. Pursh.

7. *V. Sabadilla*. Caustic Veratrum, or Indian Caustic Barley. Retz. Obs. fasc. 1. 31. n. 107. Willd. n. 5. (Cevadilla; Dale Pharm. 286. *Hordeum causticum*; Bauh. Pin. 23. Theatr. 467, with a probably fictitious figure. Ytzevimpatti, seu Canis interfecto, vel Hordeolum; Hernand. Mex. 307, with an apparently authentic figure.)—Leaves linear-lanceolate, ribbed. Cluster simple, dense, solitary, terminal.—Native of the colder regions of Mexico. The leaves appear to be all nearly radical. Stem solitary, simple, erect, almost naked, three spans high. Cluster erect, cylindrical, a span long, nearly or quite simple. Flowers turned to one side, of a very dark purple. Petals ovate.—Retzius, who first introduced this plant into a scientific botanical work, found a specimen of the flowers, imported along with the seeds, in a druggist's shop. They answered to the character of a genuine *Veratrum*, as might be expected from the seeds and capsules, which we have occasionally met with, and whose qualities are analogous to those of *V. album*. But the learned professor never thought of tracing out the synonyms, or searching for any figures, of this little-known plant; which defect we have endeavoured to supply. For the medical properties of the seeds in question, see CEVADILLA.

For *V. luteum*, Linn. Sp. Pl. 1479. Willd. n. 6, see HELONIAS, n. 3.

VERATRUM, in Gardening, contains plants of the hardy, herbaceous, perennial kind, among which the species cultivated are, the white-flowered veratrum, or white hellebore (*V. album*); the dark-flowered veratrum (*V. nigrum*); and the yellow-flowered veratrum (*V. luteum*).

The first sort has the stems three or four feet high, and branching out on every side almost their whole length: the branches and principal stem being terminated by spikes of flowers set very close together, which are of a greenish-white or herbaceous colour, and appear in July.

The second sort has the stalks rising higher, but the flowers are of a dark-red colour, which appear almost a month sooner.

The third sort has a large tuberous root with a single stem, about a foot high, having the flowers produced at the top, in a single thick close spike, which are small, and of a yellowish-white colour, appearing in June.

Method of Culture.—All these plants may be increased by seed and parting the roots.

The seed should be sown in the autumn or early spring, upon a bed or border of light earth, or in a box filled with the same sort of mould. When the plants are come up in the spring, keep them clear from weeds, and refreshed with water occasionally when the season is hot and dry; and in the following autumn, when the leaves decay, take them up carefully without injuring the roots, and plant them out about half a foot square in a fresh bed of light mould; and when they have remained in it till fit for flowering, they should be removed into the borders, clumps, or other parts. This is, however, a tedious method, as they seldom flower in less than four years; therefore the root method is mostly had recourse to.

The roots may be divided in autumn, when the leaves decay, and be planted out in a light, fresh, rich mould where they are to grow; they should not be removed oftener than once in about four years. The roots should not be parted too small.

These plants have a fine effect in the middle of large borders, clumps, and other similar situations, in pleasure grounds and other places by the singularity of their large furrowed leaves, and their different modes of flowering.

The first sort is much cultivated as a medicinal plant for the use of its root, as well as the black sort occasionally; in which intention the plants should be set out in beds or borders in any common parts of the ground.

VERATRUM, in the *Materia Medica*. See HELLEBORE.

Mr. James Moore has suggested that a vinous infusion of the root of the *veratrum album*, or white hellebore, constitutes the active ingredient in the *eau médicinale d'Huffon*. Mr. Moore gives the following preparation: take of white hellebore-root, eight ounces; white wine, two pints and a half. The root is to be cut in thin slices, and infused for ten days, occasionally shaking the bottle. Let the infusion be then filtered through paper.

The dose of the mixture, in cases of gout, may be from one fluid-drachm to three fluid-drachms.

VERB, in *Grammar*, a word serving to express what we affirm of any subject, or attribute to it; or, it is that part of speech, by which one thing is attributed to another, as to its subject; as the words *is*, *understands*, *hears*, *believes*, &c. This is, in other words, the definition of a verb adopted by Dr. Priestley in his *Grammar*. But this definition seems to include not only verbs, but likewise all adjectives, and abstract nouns signifying qualities; for when we say "God is good," or "Goodness belongs to God," do not the words "good" and "goodness" express what is affirmed of or attributed to the Deity? But if in this definition it is merely asserted, that the essence of the verb consists in affirmation, it might have been expressed with greater precision, thus: "a verb is a word affirming something of, or attributing something to, a thing." It is, says Dr. Blair, the affirmation that seems to be that which chiefly distinguishes the verb from the other parts of speech, and gives it its most conspicuous power. Hence there can be no sentence, or complete proposition, without a verb either expressed or implied; for whenever we speak, we always mean to assert, that something is or is not; and the word which carries this assertion, or affirmation, is a verb. This ingenious writer, however, seems to have improperly included time as one of the three things implied in all verbs, adding this to the attribute of some substantive, and an affirmation concerning that attribute. The definition of Dr. Beattie seems to be more objectionable. He defines a verb to be "a word necessary in every sentence,

signifying the affirmation of some attribute, together with the designation of time, number, and person." According to this definition, neither infinitive moods, nor gerunds, nor supines, nor participles are verbs; for they neither contain an affirmation, nor signify time, nor are limited either to number or person. If affirmation, which we conceive to be the case, be essential to verbs, it is possible to form a tolerably copious language with only *one verb* in it; for infinitives, participles, adjectives, &c. may be so united to nouns by the copula, or verb *is*, *alone*, as to express almost any idea which we can have occasion to communicate. But if the circumstances of time, person, and number, be essential to verbs, it is more than probable that languages may subsist in the world, which have not a single verb in them. And in this case Dr. Beattie cannot consistently maintain, as he asserts, that a verb is "a word necessary in every sentence." In the Malayan language, *e. g.* which is held in high estimation, and which has wide extent in the East Indies, the verb admits of no modification whatever, on account either of person, tense, or voice; in all these respects, the personal pronouns only, with particles prefixed, determine the sense.

The verb is thus called of the Latin *verbum*, word, by way of eminence; as being the principal word of a sentence. Accordingly verbs, as Dr. Adam Smith observes, must have been coeval with the first attempts towards the formation of language. No affirmation can be expressed without the assistance of some verb. This writer suggests, that the radical verb, or the first form of it, in most languages, would be what we now call the *impersonal verb*: as "it rains," and the like: as this is the simplest form of the verb, and merely affirms the existence of an event, or of a state of things. By degrees, after pronouns were invented, such verbs became personal, and were branched out into all the varieties of tenses and moods. On this subject, see VERB, *Substantive, infra*.

The common definition given by grammarians is, that the verb is a word which betokens *being*, *doing*, or *suffering*. This is the definition of the learned bishop Lowth, and it includes nothing more than what is essential; so that it is equally applicable to the verb in all languages, in all its various forms, comprehending not only infinitives and participles, but likewise gerunds and supines. If it is in any respect defective, it is because it does not in all cases sufficiently distinguish verbs from verbal nouns. Infinitives and participles, gerunds and supines (see each in its place), not only signify actions, but govern the cases of nouns and pronouns in the same manner with the verbs, and therefore should be comprehended under the name of verbs. But those verbal nouns which do not govern accusative cases have not the same pretensions; for they have not the regimen of verbs, but of substantives, and consequently more properly belong to that class.

To conceive the origin and office of verbs, it may be observed, that the judgment we make of any thing, as when I say *the earth is round*, necessarily includes three terms. The first, called the *subject*, is the thing we affirm of, *e. g.* earth. The second, called the *attribute*, is the thing affirmed, *e. g.* round. The third, *is*, connects those two terms together, and expresses the action of the mind, *affirming* the attribute of the subject.

This last is what we properly call the verb; and which some of our later grammarians, particularly the Port Royalists, choose to call by a more significant word, *affirmation*. The reason is, that its principal use is to signify affirmation; that is, to shew the discourse in which that word is used, is the discourse of a man who does not only conceive things, but judges and affirms somewhat of them.

By this circumstance, a verb is distinguished from nouns, which also signify an affirmation, as *affirmans affirmatio*; those only signify affirmation, as that, by a reflection of the mind, is rendered an object of thought: so that they do not shew, that the person who uses them *affirms*, but only that he conceives an *affirmation*.

Though the principal use of verbs be to signify affirmation or assertion, they also serve to express the other motions of the soul; as to desire, pray, command, &c.; but this they only do, by changing the mood, or inflexion.

Here, we only consider the verb in its primary signification, which is that it has in the indicative mood. On this footing, the verb should have no other use, but to mark the connection which we make in the mind, between the two terms of a proposition; but the verb *esse, to be*, is the only one that has retained this simplicity: nor, in strictness, has this retained it, but in the third person, as *est, is*.

In effect, men being naturally inclined to shorten their expressions, to the affirmation they have almost always added other significations in the same word: thus, *e. g.* they add that of some attribute, so as that two words make a proposition; as in *Petrus vivit*, Peter lives: where *vivit* includes both the attribute and affirmation; it being the same thing to say *Peter lives*, as that *Peter is living*. And hence the great variety of verbs in every language.

For if people had been contented to give the verb its general signification, without any additional attribute, each language would only have needed one verb, *viz.* the verb substantive *est, is*.

Again, on some occasions, they also superadd the subject of the proposition, as *sum homo*, I am a man; or *vivo*, I live: and hence the diversity of persons in verbs.

Again, we also add to the verb, a relation to the time, with regard to which we affirm; so that one single word, as *cenâsti*, signifies that I attribute to the person I speak the action of supping, not for the present time, but for the past: and hence the great diversity of tenses in most verbs.

The diversity of these significations, or additions in the same word, has perplexed and deceived many of our best authors, in the nature of a verb; and has led them to consider it, not according to what is essential to it, which is to affirm; but according to some of these its accidental relations.

Thus, Aristotle, taking up with the third of those additional significations, defines verb to be *vox significans cum tempore*; a word signifying something with time.

Others, as Buxtorf, adding the second relation, define it, *vox flexilis cum tempore et persona*; a word admitting of divers inflexions, in respect of time and person.

Others, taking up with the first of the additional significations, which is that of the attribute, and considering that the attributes men ordinarily add to the affirmation, were actions and passions, have supposed the essence of a verb to consist in signifying *actions or passions*.

Lastly, Scaliger imagined he had made a great discovery in his book of the Principles of the Latin Tongue, in saying, that the distinction of things into *permanentes*, and *fluentes*, into what remain, and what pass away, is the proper source of the distinction between *nouns and verbs*; the first being to signify what remains, and the second what passes.

But from what we have said, it is easy to perceive, that these definitions are all false: and that the only true definition is *vox significans affirmationem*: this definition includes all that is essential to the verb: but if one would likewise include its principal accidents, one might define it, *vox significans affirmationem, cum designatione personæ, et temporis*; a

word which signifies an affirmation, with a designation of person, number, and tense; which is what properly agrees to the verb substantive *est*.

For as to other verbs, considered as becoming different by the union of certain attributes, one may define them thus: *vox significans affirmationem alicujus attributi, cum designatione personæ, numeri, et temporis*; a word which expresses the affirmation of some attribute, with a designation of person, number, and time.

Verbs, according to Mr. Harris, are those *attributives*, which have a complex power of denoting both an attribute and an assertion: those which take the attribute alone without the assertion are *participles*; and all other attributives are included under the general name of *adjectives*. And as some attributes have their essence in motion, *e. g.* *to walk, to live*, &c. others in the privation of motion, *e. g.* *to rest, to die*, &c. and others again in subjects, which have nothing to do with either motion or its privation, as *great and little, white and black*, &c. these last are adjectives, and those which denote motion or its privation are either verbs or participles. But motions and their privation, comprehended under the general term energy, imply time as their concomitant, and hence, he says, verbs which denote them, come to denote time also. See TENSE. See also MOOD.

Every energy has a reference, says this ingenious writer, to some energizing substance, and is conversant about some subject; and hence he derives the distinction between verbs *active and passive*: and as every energy respects an energizer, or a passive subject; hence appears the reason why every verb, whether active or passive, has in language a reference to some noun for its nominative case. When among the infinite subjects, to which the energy refers, that happens to occur, which is the energizer also, as *Brutus loved himself, slew himself*, &c. in such case the energy hath to the same being a double relation, both active and passive; and this gave rise among the Greeks to that species of verbs, called *verbs middle*; but in other languages, the verb still retains its active form, and the passive subject (*se or himself*) is expressed like other accusatives. Again, in some verbs, it happens that the energy always keeps within the energizer, and never passes out to any foreign subject, because the energizer and the passive subject are united in the same person; and then we obtain that species of verbs, called by grammarians *verbs neuter*, as if they were void both of action and passion, though they may rather be said to imply both. Of the above species of verbs, the middle cannot be called necessary, because most languages have done without it: those remaining are, therefore, the *active*, the *passive*, and the *neuter*, which seem essential to all languages whatever. Mr. Harris observes, that though the greater part of verbs denotes attributes of energy and motion; there are some which appear to denote nothing more than a mere simple adjective, joined to an assertion, as *ἰσχυρὸς* in Greek, *equalleth* in English, *albo* and *tumeo* in Latin; and there are also verbs, which are formed out of nouns, or in which the substantive is converted into an attributive. There are other supposed affections of verbs, besides moods and tenses, such as number and person. But these are, in fact, the properties not of attributes, but of substances. Hermes, chap. vi. viii. and ix.

Verbs are variously divided: with respect to the subject or signification, they are divided into *active, passive, neuter*, &c.; with respect to their construction, into *transitive and intransitive*; with respect to their formation or inflexions, into *regular and irregular, personal and impersonal; auxiliary, substantive*, &c. See LANGUAGE, GRAMMAR, and the subsequent articles.

VERB *Active*, is a verb which expresses an action that falls on another subject, or object. It is called also *transitive*, because the action passeth over to the object, or hath an effect upon some other thing. See ACTIVE.

VERB *Passive*, is that which expresses a passion; or which receives the action of some agent, and necessarily implies an object acted upon, and an agent by which it is acted upon: it is conjugated, in the modern tongues, with the auxiliary verb *I am, je suis, je sono, &c.*

Some do not allow of any verbs passive in the modern language; the reason is, what we call passive is nothing but the participle of the verb, joined with the auxiliary verb, *to be*; whereas the verbs passive of the Latin, &c. have their particular terminations. See PASSIVE.

VERB *Neuter*, is that which signifies an action that has no particular object on which to fall; but which, of itself, takes up the whole idea of the action: or a verb neuter expresses being, or a state or condition of being; when the agent and the object acted upon coincide: as, *I sleep, thou yawnest, he snores, we walk, you run, they stand.*

The Latins call them *neuters*, because they are neither active nor passive: though they have the force and signification of both; as, *I languish*, signifies as much as, *I am languishing*; *I obey*, as much as *I exercise obedience, &c.* only that they have no regimen to particularize this signification. The verb neuter is called *intransitive*; because the effect is confined within the agent, and doth not pass over to any object.

The distinction between verbs absolutely neuter, as, *to sleep*, and verbs active intransitive, as, *to walk*, though founded in nature and truth, is of little use in grammar; the construction of both is the same. Lowth's Gram. p. 62.

Of these verbs, there are some which form their tenses by the auxiliary verb *to have*; as, *I have slept, you have run.* These, grammarians call *neuter active*.

Others there are, which form their compound parts by the auxiliary *to be*; as, *to come, to arrive, &c.*; for we say, *I am come, not I have come, &c.* These are called *neuters passive*.

The neuter verb is varied like the active; but, having somewhat of the nature of the passive, admits in many instances of the passive form, retaining still the neuter signification; chiefly in such verbs as signify some sort of motion, or change of place or condition; as, *I am come, I was gone, &c.*

In English, many verbs are used both in an active and neuter signification, the construction only determining of which kind they are.

VERB *Substantive*, is that which expresses the being, or substance, which the mind forms to itself, or supposes in the object; whether it be there, or not: as, *I am, thou art.*

Existence, says Mr. Harris, may be considered as a universal genus, to which all things of all kinds are at all times to be referred. The verbs, therefore, which denote it, claim precedence of all others, as being essential to the very being of every proposition in which they may still be found, either express, or by implication; express, as when we say, *the sun is bright*; by implication, as when we say, *the sun rises*, which means, when resolved, *the sun is rising*. The verbs *is, groweth, becometh, est, sit, ὑπάρχει, ἐστίν, πέλει, γίγνεται*, are all used to express this general genus; and are called by the Latins *verbs substantive*, and by the Greeks ῥήματα ὑπαρκτικά, *verbs of existence*, a name more apt, as being of greater latitude, and comprehending equally as well attribute as substance. The principal of these verbs is the verb *ἐστίν, est, is*. All existence is either absolute, as when we say, *B is*; or qualified, as

when we say, *B is an animal, B is black, &c.* And with respect to this difference, the verb, *is*, can by itself express absolute existence, but never the qualified, without subjoining the particular form; consequently, when *is* only serves to subjoin some such form, it has little more force than that of a *mere assertion*. Under the same character, it becomes a latent part in every other verb, by expressing that assertion, which is one of their essentials: *e. g. riseth* means *is rising, &c.* Moreover, as to existence in general, it is either mutable, as in the objects of sensation; or immutable, as in the objects of intellect and science. All mutable objects exist in time, and admit the several distinctions of present, past, and future: but immutable objects know no such distinction, but rather stand opposed to all things temporary. And hence result two different significations of the substantive verb *is*, as it denotes mutable or immutable being: *e. g.* if we say, *this orange is ripe*, *is* meaneth that it existeth so now at this present, in opposition to past time, when it was green, and to future time, when it will be rotten: but if we say, *the diameter of the square is incommensurable with its side*, we do not intend by *is* that it is incommensurable *now*, having been formerly commensurable, or being to become so hereafter: on the contrary, we intend that perfection of existence, to which time and its distinctions are utterly unknown. Under the same meaning, we employ this verb, when we say, *truth is, or God is*: the opposition is not of time present to other times, but of necessary existence to all temporary existence whatever. Hermes, p. 88, &c.

In every language, says Dr. Adam Smith, in his "Formation of Languages," annexed to his "Theory of Moral Sentiments," there is a verb, known by the name of the substantive verb, in Latin, *sum*, in English, *I am*. This verb, he says, denotes not the existence of any particular event, but existence in general. On this account it is the most abstract and metaphysical of all verbs, and consequently could by no means be a word of early invention. Nevertheless he allows, that it is in every language; and therefore in languages which are in their earliest infancy. Others are of opinion, not without reason, that the verb substantive, or copula, *is*, is not only the most necessary, but the most simple of all verbs, for it contains nothing more than an assertion, or affirmation, that a thing exists. The idea conveyed by this simple proposition is coeval with thought itself: for what can we think about, unless we think that something is, or exists? This copula, or verb of existence, *is*, must appear to be coeval with language itself. But we cannot reasonably infer from hence, that this was the case with respect to any other finite verb. It is probable, that people, in their first attempts to express their ideas by words, would be some time before they invented any other word containing in itself an assertion or affirmation: for they would not, at a very early period, think of contriving words so complex in their nature as to include in them both the name of an action and an assertion.

An ingenious writer on the subject of verbs (see Pickbourn's Dissertation on the English Verb) conjectures that the first mode of expressing actions or passions would be by *participles* or *verbal nouns*; *i. e.* words signifying the names of the actions or passions they wanted to describe: and these words, connected with their subject by the copula *is* (a word coeval with speech itself), might, in these rude beginnings of language, tolerably well supply the place of verbs; *e. g.* from observing the operations of nature, such words as *rain* or *raining, thunder* or *thundering*, would soon be invented; and, by adding the copula *is*, they would say, *thundering, or thunder, is, or is not; raining, or rain, is*; which, by the rapidity of pronunciation, might in time

time form the verbs *rains, thunders, &c.* The observation of their own *actions*, or the *actions* of the animals around them, would soon increase their stock of ideas, and put them upon contriving suitable expressions for them. Hence might arise such words as these: *sleep, or sleeping; stand, or standing; run, or running; bite, or biting; hurt, or hurting*: and by joining these to substantives, by means of the copula *is*, they might form such sentences as these, *Lion is sleeping, or perhaps Lion sleep is, stand is, &c.*; which would soon be contracted into *Lion sleeps, stands, runs, bites, hurts, &c.* Thus our little insulated family might become possessed of verbs including an *attribute* and an *affirmation* in one word. The next step would probably be a distinction between actions in their *progressive* and in their *finished* state; *i. e.* actions *going on* in their presence, and perceived by their *senses*; and such as were *ended*, and consequently only known to them by *memory*, by *report*, or by their *effects*: and they might perhaps apply such words as *raining, thundering, sleeping, &c.* to the former kind of actions; and such as *rained, thundered, slept, &c.* to the latter. And by joining the copula *is* to these words signifying perfect actions, in the same manner in which they had joined it before to the words signifying imperfect ones, and afterwards contracting them into single words, they might soon acquire a verb expressing a finished action and an affirmation in one word. This improvement would probably suggest to them the idea of making such further alterations in, or additions to, their verbs, as would make them significant of all the grand divisions of time.

But still their verbs would have neither *person* nor *number*, and would probably remain in that state till the invention of pronouns. But this, requiring some degree of abstraction, would probably not happen very early; for, in their first efforts to express themselves, they would be more likely to say, "*Thomas loves William and Henry,*" than "*I love thee and him.*" However, in process of time, pronouns would no doubt be introduced: and they might perhaps make such alterations in their verbs, as to accommodate them to their numbers and persons, though such an accommodation does not seem absolutely necessary. Languages may therefore exist which do not vary their verbs to express either number or person. And, further, it is *possible* that there may be languages so constructed as not to admit any variation in their verbs, even to express *time*; for if the verb only contains, in itself, an assertion and an attribute, the time of it may be fixed by adverbs and other adjuncts. This author concludes that a definition applicable to the verb in all languages, and in all its forms, cannot comprehend in it any thing more than what bishop Lowth has expressed by saying, "A verb is a word signifying *to be, to do, or to suffer.*"

The copula, or substantive verb, *is*, according to this author, is, as we have already stated, the simplest of all verbs; and must necessarily have been contemporary with the first efforts of mankind to express their ideas by words. Without this we cannot unite an adjective to a substantive, or affirm that any thing is good or bad, or possess any quality whatever, or even exist. But this is the only verb, containing an affirmation, which is so perfectly simple in its nature as not to comprehend, at least, two ideas, which may be easily separated, nay which must necessarily be separated, in the operations of the mind, whenever it endeavours to express them. *Pluit, it rains, or is raining*, comprehends the idea which the mind forms of that operation of nature which we call rain or raining, and likewise an affirmation of the judgment which the mind forms concerning its present existence; and therefore cannot be expressed more simply and

naturally than by *is raining, or rain is*, which is easily contracted into, *rains*.

VERBS, *Auxiliary*, or *Helping*, are those which serve in conjugating active and passive verbs; such are, *I am, I have &c.*

The auxiliary verbs are like prepositions, words of a very general and abstract nature. They imply the different modifications of simple existence, considered alone, and without reference to any particular thing. In the early state of speech, the import of them would be incorporated with every particular verb in its tenses and moods, long before words were invented for denoting such abstract conceptions of existence, alone and by themselves. But after these auxiliary verbs, in the progress of language, came to be invented and known, and to have tenses and moods annexed to them, like other verbs; it was found, that as they carried in their nature the force of that affirmation which distinguishes the verb, they might, by being joined with the participle which gives the meaning of the verb, supply the place of most of the moods and tenses.

The abbot de Dangeau distinguishes all verbs into two general kinds; auxiliary verbs, and verbs which make use of auxiliaries.

This distinction some may tax as not very just: in regard auxiliary verbs sometimes make use of auxiliaries themselves: but this does not destroy the division; it only shews, that the auxiliary verb has two formalities, or two different qualities, under which it is to be considered; in virtue whereof, it constitutes, as it were, two sorts of verbs.

The verbs which make use of auxiliaries, he divides into *active, neuter, and pronominal*. *Verbs neuter*, he farther distinguishes into *neuters active and neuters passive*. *Pronominals* he distinguishes into *identical, reciprocal, neuterized, and passived*. But several of these are peculiar to the French language. See *AUXILIARY Verbs*:

When an auxiliary is joined to the verb, the auxiliary goes through all the variations of person and number; and the verb itself continues invariably the same. When there are two or more auxiliaries joined to the verb, the first of them only is varied according to person and number. The auxiliary *must* admits of no variation.

VERBS, *Regular*, are those which are conjugated after some one manner, rule, or analogy.

VERBS, *Irregular, or Anomalous*, are those which have something singular in the terminations or formations of their tenses. See *ANOMALOUS Verbs*.

The formation of verbs in English, both regular and irregular, is derived from the Saxon. The irregular verbs in English are all monosyllables, unless compounded; and they are for the most part the same words which are irregular verbs in the Saxon. The first class of irregulars comprehends those that are become so from some kind of contraction: thus, some verbs ending in *d* or *t* have the present, the past time, and the participle perfect and passive, all alike without any variation; as, *beat, burst, cost, &c.* which are contractions from *beated, bursted, costed, &c.* because of the disagreeable sound of the syllable *ed* after *d* or *t*. Others in the past time and participle perfect and passive, vary a little from the present, by shortening the diphthong, or changing the *d* into *t*; as, *lead, led; meet, met; bend, bent, &c.* Others not ending in *d* or *t* are formed by contraction; as, *have, had, for haved; flee, fled, for flee-ed, &c.* The following, beside the contraction, change also the vowel: *sell, sold; tell, told; clothe, clad*. The second class of irregulars are those that end in *ght*, both in the past time and participle, and change the vowel or diphthong into *au* or *ou*: they are taken from the Saxon, in which the termination is *hte*: as, *bring, brought; buy, bought; seek,*

seek, sought, &c. The third class of irregulars form the past time by changing the vowel or diphthong of the present; and the participle perfect and passive, by adding the termination *en*: these also derive their formation from the Saxon: such are, *fall, fell, fallen*; *shake, shook, shaken*; *draw, drew, drawn*; *slay, slew, slain, &c. &c.* When *en* follows a vowel or liquid, the *e* is dropped. Some verbs, which change *i* short into *a* or *u*, and *i* long into *ou*, have dropped the termination *en* in the participle; as, *begin, began, begun*; *sing, sang, or sung*; &c. To this third class belong the defective verbs, *be, been*; *go, gone, i. e. gone*.

The whole number of verbs in the English language, regular and irregular, simple and compounded, taken together, is about four thousand three hundred. See in Dr. Ward's Essays on the English Language the catalogue of English verbs. The whole number of irregular verbs, including the defective, is about one hundred and seventy-seven. Lowth's Gram. p. 85. See CONJUGATION.

VERBS, *Defective*, are those which are not only for the most part irregular, but are also wanting in some of their parts. Such are the auxiliary verbs, most of which are of this number. They are in use only in some of their tenses and moods; and some of them are a composition of tenses of several defective verbs having the same signification.

VERBS *Inchoative*. See INCHOATIVE.

VERBS *Impersonal*. See IMPERSONAL.

There are also *reduplicative* verbs; as, *resound, recall, &c.*; and *frequentative* verbs, &c.

VERBS, *Transitive*. See TRANSITIVE, and VERB *Activa*, supra.

For the observations of an ingenious and learned coadjutor on the origin, nature, distribution, and properties of verbs, we must content ourselves with referring to the article GRAMMAR. It will be found that his sentiments differ in a variety of respects from those of much approved and popular writers, above stated: and we therefore prefer submitting them in the language of the author to the judgment of the philological reader, without any abridgment, and without any recapitulation, which would encroach too much on the limits to which we are confined. On this subject, see LANGUAGE.

VERBAL, something that belongs to verbs, or even to words spoken with the mouth.

Verbal nouns, are those formed from verbs. See INFINITIVE.

A verbal contract, is that made merely by word of mouth, in opposition to that made in writing.

VERBAL *Accident*. See ACCIDENT.

VERBANO, in *Geography*, a department of Italy, constituted of part of the duchy of Milan, situated on the side of lake Major, anciently called Verbanus Lacus, and the bailiwicks ceded by the Swifs. It contains 166,842 inhabitants, who elect twelve deputies. Varese is the capital.

VERBANUS, in *Ancient Geography*, a lake of Gallia Transpadana: its northern part was in Rhætia, and its southern part in Gaul.

VERBAS, in *Geography*, a river of Bosnia, which runs into the Save; 25 miles N.N.E. of Banjaluka.

VERBASCULUM, in *Botany*, the diminutive of *Verbascum*, perhaps from some similarity of colour and aspect, which may be traced in the Primrose and Cowslip. Bauh. Pin. 241. This is precisely synonymous with PRIMULA; see that article.

VERBASCUM, a plant frequently mentioned by Pliny, which, from all that he says about it, evidently belongs to the present genus, being the $\phi\lambda\omega\mu\omicron\varsigma$ of the

ancient, as well as of the modern Greeks. The above name is supposed to be corrupted from *Barbascum*, which originated in *barba*, alluding to the shaggy hairiness of the plant. (See PHLOMIS.) We do not however find any good authority for this supposition.—Linn. Gen. 97. Schreb. 132. Willd. Sp. Pl. v. 1. 1001. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 383. Sm. Fl. Brit. 249. Prodr. Fl. Græc. Sibth. v. 1. 149. Pursh 142. Schrad. Monogr. 5. Juss. 124. Tourn. t. 61. Lamarck Illustr. t. 117. Gært. t. 55.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Luride*, Linn. *Solanea*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, small, permanent, in five deep, erect, acute, nearly equal, segments. *Cor.* of one petal, wheel-shaped, unequal; tube very short; limb spreading, in five deep rounded segments. *Stam.* Filaments five, awl-shaped, unequal, distant, declining, woolly, shorter than the corolla, inserted into its base; anthers compressed, erect, more or less kidney-shaped, bursting lengthwise, imperfectly two-celled. *Pist.* Germen superior, roundish; style thread-shaped, slightly swelling upwards, declining, rather longer than the stamens; stigma obtuse. *Peric.* Capsule roundish-ovate, or ovate-oblong, slightly compressed, of two cells and two valves, bursting in the upper part, the valves sometimes splitting half way down; partition double, from the inflexed parallel margins of the valves, but often incomplete. *Recept.* ovate or globular, central, connected at each side, in an early state at least, with the valves. *Seeds* numerous, minute, angular, dotted, inserted into the receptacle.

Eff. Ch. Corolla wheel-shaped, irregular. Stamens distant, declining, bearded. Capsule superior, of two cells, with inflexed valves, and many seeds. Stigma simple.

Obs. There is so great a space between the inner edges of the inflexed valves and the central receptacle, in *V. pulverulentum* and some other species, that the ripe capsule is literally of but one common cell, though originally of two. Hence arose an error in Engl. Bot. p. 58, 59, which is corrected at p. 487 of the same work. CELSIA (see that article) differs from this genus in having four stamens only, two long and two short. Professor Schrader, in the first part of an excellent monograph on *Verbascum*, published at Gottingen in 1813, p. 14, asserts that this difference is very constant and invariable, and therefore he is not disposed to concur with those botanists who combine these two genera. We heartily assent to this determination. With regard to the new genus of *Ranondia*, founded, if we mistake not, on *V. Myconi*, and distinguished by having a capsule of one cell, with two lateral linear receptacles; we must suspend our judgment till we can examine into that character, but the habit of the plant, and its oblong heart-shaped two-celled anthers, indicate a very distinct genus.

The species of *Verbascum* are among the most uncertain of any well-known genus. They are more than commonly variable in the colour and size of their flowers, and appear to be very subject to cross impregnation. Hence we are led to mistrust some reputed species, described even by the ablest writers. The production of several mule ones has been traced and recorded, and we have observed others. Professor Schrader indeed has long cultivated and studied what he has described, and his accuracy is indisputable. We shall give his new species, on his own authority, and we shall profit by his remarks in the general characters here prefixed to the particular descriptions.

The root is generally biennial, rarely perennial, its form tapering. Stem generally solitary, from a foot and a half to four or eight feet in height, erect, sometimes peculiarly stiff and straight, rarely a little zigzag, leafy, in several instances

VERBASCUM.

stems alternately branched, many-flowered, panicled, with racemose stalks; in *V. Myconi* only altogether wanting. *Leaves* all radical the first year, subsequently all cauline: stalked, sessile, or decurrent; always alternate, simple, oblong; undivided, lobed or pinnatifid; simply or doubly crenate or toothed, rarely entire; generally covered with dense, white, shaggy or starry, or mealy and deciduous, woolliness; sometimes nearly smooth. *Flowers* racemose, generally aggregate, crowded, and very numerous; mostly yellow, rarely yellowish-white, or purple, or brownish. *Bracteas* mostly ovate, or lanceolate, pointed, of two orders, external and internal. The whole genus is nearly, if not entirely, European, the species found in America, except perhaps *V. Claytoni* of Pursh and Michaux, having been apparently introduced from this quarter of the world. The Levant produces many fine ones, not well known to Linnæus.

SECT. 1. *Leaves decurrent.*

1. *V. Thapsus*. Great Mullein; or High Taper. Linn. Sp. Pl. 252. Willd. n. 1. Schrad. n. 1. Pursh n. 1. Fl. Brit. n. 1. Engl. Bot. t. 549. Fl. Dan. t. 631. (*Thapsus barbatus*; Ger. Em. 773. *φλωμος λευκη αερην*; Diof. book 4. chap. 104.)—*Leaves* decurrent, crenate, woolly on both sides. Stem simple. Cluster dense. Flowers almost sessile.—Frequent throughout Europe, on banks and waste ground, flowering in July and August; very common in Greece. Mr. Pursh observes that, though common in America, this plant was probably introduced from Europe; nevertheless it springs up abundantly in the most remote parts of the country, in fields newly cleared and burnt. The root is biennial. Stem from three to five feet high, erect like a staff, woolly, winged with decurrent acute leaves, which are clothed with white entangled starry wool, like cloth or flannel. *Flowers* very numerous, large, of a bright golden-yellow, with orange-coloured hairy *filaments*, and roundish red *anthers*. Mr. Robson of Darlington communicated to Dr. Withering a mule plant, produced under his own eyes, from this species impregnated by *V. nigrum*. Mr. D. Turner found a corresponding specimen, now before us, at Barton, near Swaffham, Norfolk. The leaves are but slightly decurrent. *Spike* elongated and slender.—The leaves of *V. Thapsus*, about a handful boiled in a pint of milk, sweetened with sugar, strained, and the milk taken at bed-time, are useful in coughs, and more especially serviceable in allaying the irritation of the piles. *V. pulverulentum* has the same qualities.—*V. thapsiforme*, Schrad. n. 2. seems scarcely more than a variety with a larger corolla, and two of the *anthers* oblong, instead of their being all round.

2. *V. crassifolium*. Thick-leaved Mullein. Schrad. n. 3. "Hoffmannegg and Link Lusit. v. 1. 213. t. 26."—*Leaves* decurrent, obscurely crenate, densely woolly; the upper ones rather acute. Cluster dense. Flowers almost sessile. Filaments smooth. Two of the *anthers* oblong.—Found in sandy ground in Portugal. The smooth filaments afford the chief distinction between this plant and the last, at least its variety called *thapsiforme*. Experience must shew, by cultivation, whether this be permanent.

3. *V. cuspidatum*. Pointed-leaved Mullein. Schrad. n. 4. t. 1. f. 1. (*V. Thapsus*; Ehrh. Pl. Off. n. 111.)—*Leaves* decurrent, crenate, woolly on both sides; the upper ones pointed. Cluster somewhat interrupted. Two of the *anthers* oblong.—Found in mountainous woods near Vienna. Schott. Near Upsal. Ehrhart. This Dr. Schrader mentions as the *V. Thapsus* of the Vienna botanists, agreeing in habit with the two foregoing, but the stem is of more humble stature, and more slender. *Leaves* smaller, less densely woolly; the upper ones taper-pointed. *Inflorescence* and *flowers* more like *V. phlomisoides*, the cluster being interrupted,

the flowers more stalked, and aggregate in little tufts. *Corolla* large. Two longer *filaments* having oblong *anthers*; and in our specimen from Ehrhart smooth filaments, though the rest are hairy.

4. *V. niveum*. Snow-white Mullein. Tenore Hort. Neap. 109. Schrad. n. 5.—*Leaves* half-decurrent, crenate; woolly and very white beneath; more slightly so above. Cluster dense. Flowers nearly sessile. *Anthers* uniform.—Found near Naples. Stem two or three feet high, round; at length smooth and brownish. *Leaves* thickish, soft; their upper surface becoming green and slightly downy, though the under is snow-white. *Flowers* yellow, in tufts, almost sessile, about the size of *V. Thapsus*. *Filaments* clothed with white wool. Schrader. This appears to be really a very distinct species.

5. *V. densiflorum*. Dense-flowered Mullein. "Bertol. Pl. Rar. Ital. v. 3. 52." Schrad. n. 4.—*Leaves* downy; the radical ones lanceolate, elongated, crenate, deeply serrated at the base; upper stem-leaves pointed, toothed, half-decurrent. Cluster dense. Flowers aggregate, nearly sessile.—Found on the summit of mount Bruciana, between Carrara and Massa. Stem four or five feet high, angular, clothed with tawny woolliness, especially the upper part. Radical leaves more than eighteen inches long, two or three broad in the middle; green above; most hairy beneath; those of the stem gradually shorter upward, ovate, pointed, sessile, with a small decurrent wing on each side, more downy all over, especially the uppermost. Cluster very dense, above a foot long. *Flowers* large, yellow, in tufts on extremely short stalks. Pubescence of the whole plant yellowish or tawny, composed of branched entangled hairs, and much the most dense in the upper part. Bertolini.

6. *V. thapsoides*. Long-spiked Mullein. Schrad. n. 7. t. 5. f. 2. "Hoffmannf. et Link Lusit. v. 1. 214, excluding the synonyms."—*Leaves* finely crenate, downy; radical ones oblong-lanceolate; the rest oblong, acute, half-decurrent. Flowers on short stalks, aggregate, rather crowded. *Anthers* nearly equal.—Native of Portugal. Perennial. Stem three or four feet high, or more, generally branching at the top into several long, rather slender, tolerably dense clusters of yellow flowers, smaller than *V. Thapsus*. Schrader. We conceive this to be no other than the Linnæan *V. Thapsus*; see *V. Lychnitis*.

7. *V. macranthum*. Great-flowered Mullein. Schrad. n. 8. "Hoffmannf. et Link Lusit. v. 1. 215. t. 27."—*Leaves* finely crenate, downy; radical ones elliptic-oblong, tapering at the base; the rest oblong, acute, half-decurrent. Cluster interrupted, with distant tufts of flowers. Two of the *anthers* oblong.—Found by way sides, in the northern part of Portugal. Root supposed to be biennial. Stem two or three feet high, erect, simple, at length smooth and of a purplish-brown. *Leaves* thick, reticulated with veins beneath; their upper side becoming green and almost naked by age: radical ones stalked, three or four inches long, and half as broad. *Flowers* large, handsome, yellow. Hair of the *filaments* orange-coloured. Capsule small. Schrader.

8. *V. phlomisoides*. Southern Woolly Mullein. Linn. Sp. Pl. 253. Willd. n. 5. Ait. n. 6. Schrad. n. 10. Sm. Fl. Græc. Sibth. t. 224, unpubl. (*V. foliis radicalibus ovatis petiolatis, &c.*; Mill. Ic. 182. t. 273. *V. rugulosum*; Willd. Enum. 224. *V. thapsoides*; Villars Dauph. v. 2. 490, according to a specimen from the author. Schrad.)

β. *V. australe*; Schrad. n. 9. t. 2.

Leaves ovate, finely crenate, downy on both sides; lower ones stalked; upper pointed, clasping the stem, slightly decurrent. Cluster interrupted.—Native of barren waste ground

ground in the fourth of Europe, and east of Asia. We gathered it on the ramparts of Pavia; and Dr. Sibthorp at Constantinople. A large biennial species, hoary all over, with dense, starry, entangled, woolly hairs. *Stem* solitary, erect, simple, round, leafy, ending in a long, interrupted, many-flowered, fasciculated *cluster*, sometimes accompanied at the base with one or more much shorter ones. *Radical leaves*, as well as those on the lower part of the stem, four inches or more in length, stalked, broadly ovate, bluntish, obscurely crenate, thick, rugged, reticulated with copious veins, each tapering at the base into a winged *footstalk*: the upper ones gradually smaller, pointed, sessile; heart-shaped at the base, clasping the stem, and somewhat decurrent; diminishing into taper-pointed *bractæas*, which project further than their respective tufts of flowers. *Flowers* large and handsome, of a golden-yellow, about five in each tuft, accompanied by small, lanceolate, partial *bractæas*. *Partial stalks* shorter than the *calyx*, which is smooth internally. *Stamens* purple, either all densely hairy, with yellow, nearly uniform, *anthers*, or two of them bear more or less oblong and imperfect *anthers*; in which case the respective filaments are less hairy, or quite naked. *Germs* clothed with very dense wool, which comes off as the *capsule* ripens.

We scarcely discover any difference between the *V. australe* of our learned friend, and the *phlomoides*, of which his description answers exactly to our specimens. The *radical leaves* of the *australe* perhaps are larger and more lanceolate, but this can hardly indicate more than a variety. The *anthers* and *filaments* are acknowledged to vary in both, and we have found them to do so in *phlomoides*.

9. *V. condensatum*. Dense-flowered Round-leaved Mullein. Schrad. n. 11. t. 3.—“Leaves downy; radical ones elliptic, oblong, tapering at the base, doubly and unequally crenate; those of the stem oblong, acute, simply crenate; uppermost roundish-ovate, pointed, slightly decurrent. Clusters dense. Two of the anthers oblong.”—Observed by Mr. Schott in Austria, on a barren soil. Biennial. We cannot but suspect this to be a variety of the last, with a more dense *inflorescence*; larger, more strongly crenate, *radical leaves*, and broader upper ones. The two species are, at least, very nearly akin.

10. *V. nemorosum*. Grove Mullein. Schrad. n. 12. t. 1. f. 2.—“Leaves acute, crenate, downy; radical ones oblong, tapering at each end; lower stem-leaves lanceolate, contracted at the base; middle ones oblong-lanceolate; upper oblong, slightly decurrent. All the tufts of flowers a little remote. Two anthers oblong.”—Found by Mr. Schott in groves in Austria. Biennial. Akin to *V. phlomoides*, but distinguished by its straight, wand-like stem, four feet high, with a solitary lax *cluster*, and the narrow elliptic-lanceolate shape of all its *leaves*, which are of a yellowish green, the radical ones becoming finally rather naked on the upper surface.

11. *V. montanum*. Mountain Mullein. Schrad. n. 13. “Hort. Gotting. fasc. 2. 18. t. 12.”—“Leaves downy; radical ones oblong-elliptical, crenate, stalked; those of the stem oblong, rather acute, slightly crenate; uppermost acute, rather decurrent. Flowers nearly sessile, in rather crowded tufts. Anthers almost equal.”—Native of the Pyrenees, as well as of the alps of Switzerland and Germany. Biennial. Stem eighteen inches or two feet high, erect, simple, clothed, like the rest of the herbage, with yellowish rusty pubescence. *Leaves* somewhat wrinkled, reticulated beneath; the radical ones three to four and a half inches long, two to two and a half broad, obtuse, losing part of their thick downiness by age: lower stem-leaves tapering into a *footstalk*; the rest acute, sessile, or, about

the top of the stem, slightly decurrent. *Cluster* from about three to six inches long. *Flowers* nearly sessile, in tufts more or less crowded; some solitary. *Bractæas* ovato-lanceolate, pointed, scarcely exceeding the flowers, except the lowermost. *Calyx* as in *V. phlomoides*. *Corolla* most like *V. Thapsus*. Two of the *filaments* more slightly hairy than the rest, sometimes naked; their *anthers* perfect, but rather larger and more oval than the three others. If cultivated in shady situations, the *stem* sometimes reaches the height of six feet, and becomes branched in the flowering part; the *leaves* also grow much larger, of a dirty green, a little polished on the upper side; the *clusters* above a foot long, thicker, and more compact. Schrad.

12. *V. collinum*. Hill Mullein. Schrad. n. 14. t. 5. f. 1.—“Leaves crenate, downy; lower ones elliptic-oblong, stalked: those about the middle of the stem oblong-lanceolate, rather acute, tapering at the base; uppermost oblong, acute, slightly decurrent. Tufts of flowers distant. Anthers equal.”—Native of hillocks, and dry grassy ground, in some parts of the north of Germany. Perennial. *Stem* two or three feet high, erect, simple, slightly angular in the upper part; reddish below. *Leaves* soft, wrinkled, downy on both sides; pale green above; hoary and reticulated beneath; radical ones four or four and a half inches long, and half as broad; the rest gradually smaller upwards, the top ones being about an inch and a half in length. *Cluster* twelve or eighteen inches long, rarely having a branch at the base. *Flowers* yellow, sweet-scented, resembling *V. nigrum*, with purple-bearded *filaments*, and composing numerous little tufts, often near an inch from each other. Schrad. We should suspect this might be a male progeny of *V. nigrum*, impregnated by some of the foregoing species; having found near Norwich what has every appearance of being a similar offspring of *nigrum*, from the pollen of *V. pulverulentum*.

13. *V. veriflorum*. Various-flowered Mullein. Schrad. n. 15.—“Leaves crenate, downy; lowermost elliptic-oblong, stalked; those of the stem oblong, acute, slightly decurrent; uppermost pointed. Clusters paniced. Tufts distant, of few flowers. Anthers equal.”—Found in sandy ground near Prague, but rarely. The herbage is clothed with dense down, of a dirty yellowish-green hue. *Stem* two or three feet, or more, in height, branched in the flowering part, rarely simple. *Leaves* rather thick and rugged; radical ones from three and a half to six inches long, one and a half to two and a half broad, most evidently and acutely crenate at the base; those about the middle of the stem only sessile. *Clusters* paniced, a foot long, or more. *Flowers* generally the size of *V. phanicum*, slightly fragrant, in rather distant tufts. *Partial stalks* half as long again as the *calyx*. *Bractæas* ovato-lanceolate, with long points; the inner ones linear, much smaller. *Corolla* of a rusty red, but variable, the base of its smaller segments bearded with the same kind of yellow wool that clothes the three smaller *filaments*. Two larger *filaments* covered entirely with purple wool, some of which also is seen about the middle of the three others. *Anthers* kidney-shaped; those of the two longer filaments rather larger, and finally more oval. *Pollen* whitish. Sometimes the *corolla* is found twice its usual size, and the partial *flower-stalks* are occasionally more long and slender than above described. Professor Schrad. received this from Mr. Taufsch, a Bohemian botanist, as *V. rubiginosum* of Waldstein and Kitaibel; a species unknown to us, but which he says is widely different.

14. *V. ramigerum*. Branched Decurrent Mullein. Schrad. n. 16. t. 4.—“Leaves finely downy; radical ones oblong-lanceolate; those of the stem oblong, acute, doubly crenate;”

VERBASCUM.

nate, half-decurrent; uppermost pointed. Clusters panicled. Tufts distant, many-flowered. Anthers equal."—Native of the duchy of Mecklenberg-Swerin. *Link.* The habit of this species resembles *V. Lychnitis*. *Root* biennial. *Stem* from four to six feet high, erect, thick; rather angular, brown, and much branched in the upper part; the branches spreading, angular, and, like the rest of the stem, slightly downy. Upper side of the leaves covered with very thin pubescence; under more hoary, and more thickly clothed; the radical, and lower stem-leaves, often a foot or more in length, four or five inches wide, tapering down into the footstalk. *Flowers* yellow, from fifteen to twenty in each tuft of the principal cluster, on stalks twice the length of the calyx; fewer in the lateral clusters; the lower tufts many of them very distant from each other. *Braçteas* ovato-lanceolate. *Calyx* and *corolla* larger than in *V. Lychnitis*. *Stamens* like those of that species. *Schrader*.

15. *V. mucronatum*. Pointed-leaved Mullein. *Lamarck* Dict. v. 4. 218. *Schrad.* n. 17; excluding perhaps *Tournefort's* synonym.—“Leaves crenate, clothed with dense hoary down; radical ones oblong-lanceolate; those of the stem oblong, acute, half-decurrent; uppermost ovate, long-pointed. Spikes panicled. Flowers in nearly sessile heads.” Found in Crete by *M. Labillardiere*. *Root* biennial. Whole herbage covered with hoary down. *Stem*, in the cultivated plant at least, from six to eight feet high, straight, thick, branched upwards. Lower leaves one and a half, or two feet long, on short stalks, acute; the rest more pointed, and unequally decurrent. Spikes panicled, various in length, their points somewhat incurved. *Flowers* yellow, rather large, in distant, many-flowered, sessile heads, hoary with deciduous woolliness. *Braçteas* lanceolate. *Filaments* all clothed with whitish wool. *Schrader*.

16. *V. sinuatum*. Scalloped-leaved Mullein. *Linn. Sp. Pl.* 254. *Willd.* n. 12. *Ait.* n. 14. *Schrad.* n. 18. *Sm. Fl. Græc.* Sibth. t. 227, unpubl. (*V. crispum et sinuatum*; *Bauh. Hist.* v. 3. 860. *V. aliud*; *Camer. Epit.* 882. *Matth. Valgr.* v. 2. 492. *V. laciniatum* *Matthioli*; *Dalech. Hist.* 1302. *Φλομος μέλας*; *Diosc.* book 4. chap. 104.)—Leaves serrated, powdery; radical ones pinnatifid and wavy; the rest undivided, decurrent. *Stem* panicled, many-flowered.—Native of dry barren exposed situations, in the south of Europe, and north of Africa; a hardy biennial, long known in our botanical gardens, but seldom long preserved. *Dr. Sibthorp* observed this to be the most common Mullein throughout Greece and all the circumjacent islands. The root is brown, and rather woody. *Herb* of a dark green, besprinkled with loose tufts of powdery, hoary, starry pubescence, but far less woolly, or uniformly hoary, than any of the preceding species. The leaves also differ widely from all the foregoing, in being pinnatifid half way to the midrib, with jagged and plaited lobes; the radical ones a span long, on shortish stalks; the rest smaller, sessile, decurrent; the upper ones very small, ovato-lanceolate, undivided, more decurrent, reflexed; all of them reticulated with veins, rugose; most hoary beneath. The stem is erect, one and a half or two feet high, zigzag, alternately branched from top to bottom, panicled, often tinged with dark purple. *Panicle* spreading, with copious, hoary, somewhat winged branches. *Flowers* generally tufted, stalked, yellow, with purple hairy filaments. *Capsule* small, roundish. The figure of *Matthioli*, copied by *Dalechamp* and *Tabernæmontanus*, is more like the cultivated variety of the following species, but differs in its branching panicled stem.

Set. 2. *Leaves not decurrent.*

17. *V. plicatum*. Plaited-leaved Mullein. *Prodr. Fl.*

Græc. n. 524. *Fl. Græc.* t. 226, unpubl. (*V. sinuatum* β; *Linn. Sp. Pl.* 255. *V. pinnatifidum*; *Ait.* n. 15, but not of *Vahl* nor *Willdenow*. *V. græcum fruticosum, folio sinuato candidissimo*; *Tourn. Cor.* 8. *Voyage*, v. 1. 128, with a figure. *Φλομος λευκη θηλη*; *Diosc.* book 4. chap. 104.)—Leaves lyrate-sinuuated, crisped, somewhat crenate, downy on both sides. *Spike* simple, interrupted, leafy.—Native of the isle of Hydra, and very plentiful about Athens. *Root* tapering, possibly perennial. *Stem* ascending, simple, leafy, clothed, like the foliage and calyx, with dense, starry, rigid, yellowish woolliness. *Leaves* obovate-oblong, thick; plaited or crisped at the margin; their upper surface even, and almost without sign of veins; under reticulated; radical ones stalked, near a span long; the rest sessile, clasping the stem, and gradually smaller upward; floral ones very small and pointed. *Spike* solitary, erect, a foot long, leafy or bracteated. *Flowers* three or four sessile together in the bosom of each bractea, yellow, almost an inch broad. *Filaments* yellow, bearded from the middle to the summit. *Anthers* all nearly alike. *Capsule* ovate, acute, hard, smooth when ripe. The leaves vary in acuteness; and in the garden plant, raised from *Dr. Sibthorp's* seeds, become more dilated, flattened, and less crisped, resembling the figure of *Matthioli*, cited under our preceding species, but the pubescence still remains totally different.

18. *V. auriculatum*. Auricled Mullein. *Prodr. Fl. Græc.* n. 523. *Fl. Græc.* t. 225, unpubl. (*V. orientale maximum candidissimum, ramis candelabrum æmulantibus*; *Tourn. Cor.* 8.)—Leaves elliptic-oblong, downy on both sides, auricled at the base. Clusters panicled, zigzag.—Native of the island of Samos. Biennial. The whole herb is clothed with dense snow-white down. *Stem* two feet high, stout, leafy; branched and becoming smooth in the upper part. *Leaves* crowded, sessile, two or three inches long, bluntly pointed, accompanied by axillary tufts of smaller ones; their upper surface covered with a dense and even coat of wool, hardly marked by rib or veins; the under reticulated, scarcely less densely clothed with a starry cobweb-like pubescence: their base contracted, but augmented with a rounded lobe at each side, embracing the stem. *Flowers* yellow, stalked, tufted and bracteated, as in *V. phlomoides*, but only half as large. *Calyx* with smooth points. *Beard of the filaments* yellowish-white. *Anthers* orange-coloured, nearly uniform. We think *Tournefort's* synonym is here rightly applied, though cited by *Lamarck* and *Schrader* for *mucronatum*, n. 15, which must be a different plant from the present, unless it be inaccurately described.

19. *V. pinnatifidum*. Pinnatifid Mullein. *Vahl Symb.* v. 2. 39. *Willd.* n. 13, excluding the synonym of *Tournefort*, which belongs to our n. 17.—Leaves flat, pinnatifid, cut, powdery; nearly naked on the upper side; radical ones stalked. *Stem* panicled, many-flowered.—Gathered by *Dr. Sibthorp*, on the sandy sea-shore near Yalva, in Bithynia. *Root* perennial, blackish, divided at the summit. *Stem* one to two feet high, erect, very much branched in all directions, leafy, round, dark-purple, sprinkled with downy mealiness. *Radical leaves* three inches long, on long stalks, flat, deeply pinnatifid, cut, wrinkled and veiny; dark green and almost naked above; paler, and powdery with starry hairs, beneath; the younger ones very densely woolly; those of the stem not half so large, sessile, not decurrent, less divided; floral ones aggregate, spreading, extending for the most part beyond the flowers, which are sessile, crowded, yellow, hoary externally, with orange-coloured stamens. *Capsule* nearly globose.

20. *V. Boerhaavii*. Boerhaavian Mullein. *Linn. Mant.* 45, excluding the reference to *Miller*; see n. 8. *Willd.* n. 3. (*V. blat-*

(*V. blattariæ* foliis nigrum, amplioribus floribus luteis, apicibus purpurascens; Boerh. Lugd.-Bat. v. 1. 228.)—Leaves obovate, somewhat lyrate, doubly crenate, veiny, slightly downy. Spike interrupted. Flowers in nearly sessile tufts. Bractæas all linear.—Said to be a native of the south of Europe. The Linnæan specimen grew in the Upsal garden. This species is very little known, perhaps from Linnæus having cited a plate of Miller's, which is as little like his specimen as almost any *Verbascum* can be, and belongs to *V. phlomidoides*. Hence *V. Boerhaavii* is admitted, without sufficient grounds, into the catalogue of our garden plants. We have, at least, never seen any thing answering to it. The leaves are a foot long, and almost four inches broad, membranous, copiously reticulated with veins; pinnatifid, in a lyrate manner, at the base; nearly smooth on the upper surface; the under partly clothed with light, deciduous, starry wool, resembling mouldiness. Spikes (whether solitary or numerous, does not appear from the specimen) a foot long, slightly and loosely woolly, of numerous scattered tufts of large yellow flowers with purple stamens.

21. *V. hæmorrhoidale*. Madeira Mullein. Ait. n. 5. Willd. n. 4.—“Leaves ovate-oblong, downy, slightly and minutely crenate; tapering at the base. Clusters elongated. Flowers in sessile tufts, without bractæas.”—Native of Madeira, from whence it was brought to Kew by Mr. Maffon, in 1777. This is marked as a biennial greenhouse plant, flowering from June to August.

22. *V. Lychnitidis*. White Mullein. Linn. Sp. Pl. 253. Willd. n. 6, β . Fl. Brit. n. 2. Engl. Bot. t. 58. Fl. Dan. t. 586. Villars Dauph. v. 2. 490. Math. Valgr. v. 2. 491. Ger. Em. 775. (*V. flore albo parvo*; Bauh. Hist. v. 3. 857. Raii Syn. 287.)

β . *V. Thapsi*; Linn. Sp. Pl. 1669. (*V. Thapsoides*; Willd. n. 2. Ait. n. 3. Hudf. 90. Schrad. n. 7. “Hoffmannf. et Link Lusit. v. 1. 214.” *V. angustifolium* ramosum, flore aureo, folio crassiore; Bauh. Hist. v. 3. 860.)

Leaves wedgeshaped-oblong; stripped of down on their upper side. Stem angular, paniced.—Native of pastures, road-sides, and waste ground, in various parts of Europe, flowering in July and August. In England it rarely occurs, except on chalky ground in Kent, where it abounds. The root is biennial, scarcely perennial. Stem a yard high, straight and upright, finely downy; copiously paniced at the top. Leaves elliptic-oblong, tapering at the base, crenate, reticulated with veins; white and woolly beneath; dark green and slightly downy, or quite naked, above; those at the root, and lower part of the stem, stalked; the rest sessile, not decurrent, all narrow at the base. Branches of the panicle racemose, with many woolly tufts of stalked, rather small, flowers, whose corolla is cream-coloured, tinged with yellow. Filaments yellowish, hairy. Anthers orange-coloured, uniform.

The variety β , a very celebrated and much disputed plant, is not preserved in the Linnæan herbarium. It is described as the mule offspring of *V. Lychnitidis*, from the pollen of *V. Thapsus*. We have specimens, artificially produced in this manner, by Mr. Griffith, of Garn, Denbighshire. These agree with the Portuguese plant, sent by professor Link, as his *V. Thapsoides*. So that we conceive the real *V. Thapsi*, or *Thapsoides*, is before us. Yet there are parts of the Linnæan description, *Sp. Pl.* 1670, that puzzle us; such as the purple beard attributed to the filaments of *V. Lychnitidis* and of this variety. Our specimens are intermediate, in every respect, between *Lychnitidis* and *Thapsus*. Their corolla is yellow. Beard of the filaments white. Upper leaves somewhat decurrent. As the real

species of this genus evidently vary before our eyes, there can be little doubt that their mule progenies are still more uncertainly defined.

23. *V. pulverulentum*. Yellow Hoary Mullein. Norfolk Mullein. Fl. Brit. n. 3. Engl. Bot. t. 487. Ait. n. 8. Villars Dauph. v. 2. 490. (*V. Lychnitidis*; Willd. n. 6, α . *V. pulverulentum*, flore luteo parvo; Bauh. Hist. 860. Raii Syn. 287. V. n. 583, α ; Hall. Hist. v. 1. 257.)

β . *V. nigro-pulverulentum*; Fl. Brit. *ibid*.

Leaves ovate-oblong, obscurely ferrated, covered on both sides with powdery deciduous wool. Stem round, paniced, much branched.—Native of banks, and the borders of fields, on a gravelly or chalky soil, in England, Austria, and Switzerland, flowering in July. This beautiful and stately plant is frequent about Norwich, and most parts of Norfolk; also near Bury, Suffolk; and, according to Ray, at Wollerton, near Nottingham. No species can be more distinct from the last, with which it has been confounded, even by Linnæus. The root is biennial. Stem three or four feet high, branched from top to bottom in a conical form, covered with innumerable golden flowers, larger than the last, whose filaments are clothed with white hairs, and their anthers are vermilion. The whole herbage is invested with white mealy down, easily rubbed off. Leaves all sessile, thick and woolly; the radical ones numerous, a foot long; upper ones ovate, pointed, clasping the stem, not decurrent. Mr. Sieber has sent an Austrian specimen of this species, named *V. floccosum*; but we know not of its having been published under that denomination.

Our variety β is found near Helleston, and in other parts of Norfolk. The leaves are like *pulverulentum*, flowers, and purple woolly stamens, like *nigrum*; so that, according to the opinion of Linnæus, the latter was the mother of this apparently mule production. We believe it moreover to be perennial.

V. pulverulentum displays a remarkable degree of irritability, if the stem be smartly struck, twice or thrice, with a small stick. In the space of a few minutes, the flowers close, and begin to drop off, all in their turn falling to the ground in the space of a quarter of an hour, if the weather be warm and still; if otherwise, this quality is less perceptible. We were first informed of it by the very ingenious Mr. Correa de Serra.

24. *V. gallicum*. Dauphiny Mullein. Willd. n. 11. (*V. Chaixi*; Villars Dauph. v. 2. 491. t. 13; synonyms all very doubtful.)—Leaves ovate-oblong, crenate, downy beneath; radical ones stalked; heart-shaped and pinnatifid at the base. Stem angular, paniced at the top.—Native of several parts of Dauphiny, in rocky situations. The habit of this plant, its panicle, and the soft durable pubescence of the backs of its leaves, as well as the shape of such as grow on the stem, most resemble *V. Lychnitidis*; the yellow flowers, purple hairy stamens, as well as the size, form, and long footstalks of the radical leaves, which are doubly crenate, rather accord with *V. nigrum*. But these radical leaves are remarkable for a few deep parallel segments at their base. We have a specimen from the author himself, or his bad figure would little avail us.

The late Mr. Donn favoured us with a specimen, above twenty years ago, from the Cambridge garden, of a tall Mullein, agreeing with this in most respects: but the lower leaves are taper at the base, and scarcely pinnatifid. This came from Poland, and is doubtless *V. polandicum* of his Hort. Cantab. ed. 5. 45; but unfortunately a name does not make a species, any more than *floccosum* of the same useful work, see our n. 23. This Polish plant seems a mule

VERBASCUM.

between *nigrum* and *Lychnitis*; or it may be a variety of *gallicum*.

25. *V. nigrum*. Dark, or Black, Mullein. Linn. Sp. Pl. 253. Willd. n. 8. Fl. Brit. n. 4. Engl. Bot. t. 59. Ger. Em. 775. Fl. Dan. t. 1088. (*V. tertium*; Matth. Valgr. v. 2. 489.)—Leaves oblong-heartshaped, stalked, waved and crenate, slightly downy. Cluster solitary, spiked, many-flowered.—Native of banks, and road-sides, in most parts of Europe. With us it occurs chiefly on a chalky or gravelly soil, in shady lanes, or on grassy hillocks, flowering in July and August. The root is perennial. Stem erect, simple, angular, leafy, brown or purplish, two or three feet high, rarely branched. Leaves of a fine deep green, not hoary, though somewhat downy; all stalked, except the very small upper ones. Cluster very long, slender, compact, though here and there interrupted, composed of innumerable tufted golden flowers, with bearded violet filaments, and orange anthers. This is altogether a very elegant species.

We received, many years since, from the late Mr. Davall, specimens and seeds of a variety of this species, having white flowers. These dried specimens differ little from our wild plant, except a slight degree of luxuriance, owing to culture, nor can it be doubted that they are the white-flowered variety, mentioned by Caspar Bauhin, and others. But the far more luxuriant progeny from their seeds, in lady Amelia Hume's garden, bore large copper-coloured flowers, almost like *V. cupreum*, Curt. Mag. t. 1226, which, but for its solitary flower-stalks, we should believe to be our plant. Such is the Proteus-like nature of this whimsical genus!

26. *V. ferrugineum*. Rusty Mullein. Ait. n. 9, excluding the reference to Andrews. Willd. n. 7.—“Leaves somewhat villous, wrinkled; those on the stem nearly sessile, equally crenate; radical ones oblong-heartshaped, doubly crenate.”—Native of the south of Europe; said to have been cultivated, at Edinburgh, by Mr. Sutherland, in 1683, and marked by Mr. Aiton as a hardy perennial, flowering from May to August. We have no specimen, but we remember to have examined an authentic one in Sir Joseph Banks's herbarium, which proved totally unlike the Greek plant of Dr. Sibthorp, figured as *ferrugineum* by Mr. Andrews, which is our *V. trifide*, hereafter described. Such errors are excusable in such a tribe. We have a notion that the specimen betrayed some affinity to *V. Boerhaavii*, n. 20, but we dare not assert it.

27. *V. trifide*. Brown-flowered Mullein. Prodr. Fl. Græc. n. 529. (*V. ferrugineum*; Andr. Repof. t. 162.)—Leaves elliptical, wavy and partly toothed, nearly smooth; radical ones stalked. Cluster solitary, simple. Stem leafy.—Gathered by Dr. Sibthorp on mount Athos. By his means the plant has been introduced into the gardens of England, where it proves a hardy perennial, flowering most part of the summer, and propagating itself copiously by seed, without requiring any care. This species differs from all the foregoing, in its very long simple cluster terminating the stem, at first drooping, but gradually becoming erect, and, as it flowers, extending itself to the height of five feet, being composed of innumerable, scattered, solitary, spreading, almost capillary partial stalks, each three or four times as long as its accompanying lanceolate bractea, and bearing a solitary inodorous flower, an inch broad, of a peculiarly dull greenish or yellowish brown, whose filaments are densely bearded with purple. Sometimes, from luxuriance, two of these stalks grow together, but each has always its own bractea. The whole cluster, bracteas, and obtuse calyx, are clothed with glandular viscid hairs. The radical leaves

are numerous, on longish stalks, wrinkled, slightly downy, a little viscid, green, reticulated with veins; their margin variously waved, or bluntly toothed: those on the stem are nearly sessile, ovate or heart-shaped, more or less acute. We cannot perceive any alteration in this plant after cultivating it for fifteen years, and yet there is scarcely a permanent specific character, to distinguish it from the following. Can Tournefort's *Blattaria orientalis*, *bugule folio*, &c. Voy. v. 2. 83, with a plate, acknowledged to be a variable plant, possibly belong to our *trifide*?

28. *V. phaniceum*. Purple-flowered Mullein. Linn. Sp. Pl. 254. Willd. n. 9. Ait. n. 11. Jacq. Austr. t. 125. Curt. Mag. t. 885. (*Blattaria flore purpureo*; Ger. Em. 776.)—Leaves ovate, crenate, smooth, chiefly radical and sessile. Cluster solitary, simple. Stem nearly leafless.—Native of Austria, and the south of Europe. A hardy perennial, cultivated in England ever since Gerard's time. It is of more humble growth than the last. Leaves chiefly radical, and nearly sessile, scarcely at all downy; their margin simply or doubly crenate. Inflorescence like the preceding, but the flowers are of a dark violet hue, and the stamens less hairy. Sometimes the stem becomes leafy, as in Jacquin's figure, and perhaps, as he represents it, branched; but we have never seen an instance of the latter.

29. *V. ovalifolium*. Oval-leaved Mullein. Donn. Cant. ed. 5. 45. Sims in Curt. Mag. t. 1037. Ait. n. 2.—“Leaves oval, sessile, acutely crenate; smoothish on the upper side. Stem erect, simple. Flowers spiked.”—Native of mount Caucasus. Introduced into England by Mr. Loddiges, in 1804. A hardy biennial, flowering from July to September. This has the aspect of several species in our first section, the flowers being as large as any of those, yellow, with orange-coloured, partly hairy, stamens; and nearly sessile, in a long dense spike. But the leaves are not decurrent, nor, though downy, at all hoary or woolly. We have seen no specimen.

Dr. Sims has exhibited in Curt. Mag. t. 1226, by the name of *V. cupreum*, a Mullein, whose stalked leaves, and racemose flowers, variegated with tawny-buff and purple, each on a partial stalk of considerable length, all appear so different from *V. ovalifolium*, the bracteas, and calyx likewise, being altogether unlike the figure of this species, that, but for our confidence in its excellent cultivator Mr. Loddiges, we could scarcely believe it came up from seeds of the *ovalifolium*. Perhaps, as Dr. Sims suggests, the parent may have been impregnated by *V. phaniceum*, or we would rather say our *trifide*. When the plant blooms within-doors, the corolla is pale yellow, with a purple eye. The inspection of this plant is enough to daunt the most ardent student of species of *Verbascum*, and to cause a general mistrust of them all.

30. *V. virgatum*. Large-flowered Primrose-leaved Mullein. With. Bot. Arr. 250. Fl. Brit. n. 5. Engl. Bot. t. 550. Ait. n. 12. (*Blattaria flore amplo*; Ger. Em. 778. B. magno flore; Bauh. Hist. v. 3. 859. Lob. Ic. 564.)—Leaves ovato-lanceolate, toothed, sessile; heart-shaped at the base; radical ones downy, and somewhat lyrate. Stem branched. Flowers axillary, on short stalks, partly aggregate.—Native of Worcesterhire. Biennial, flowering in July and August. Stem five or six feet high. Whole plant green, not hoary, though more or less covered with short, prominent, often forked, glandular hairs. The radical leaves, which resemble those of a primrose, are always so clothed. Those of the stem are very numerous, acute, toothed or sharply crenate, broad and rounded at the base, gradually diminishing upwards. Flowers from the bosoms of many of the upper leaves, large, yellow,

some of the lowermost four, five, or six together, the rest solitary, as are all those of the weaker branches. *Flower-stalks* hairy and viscid, seldom so long as the *calyx*, whose segments are lanceolate, acute, and glandular. *Filaments* bearded with purple. *Anthers* uniform.

31. *V. Blattaria*. Moth Mullein. Linn. Sp. Pl. 254. Willd. n. 10. Fl. Brit. n. 6. Engl. Bot. t. 393. (*Blattaria flore luteo*; Ger. Em. 778.)—Leaves oblong-lanceolate, acute, smooth, serrated; lower ones bluntish, tapering at the base, or stalked. Stem branched, racemose. Flower-stalks much longer than the bractæas.—Native chiefly of the southern parts of Europe, rare in England, flowering in July. *Root* tapering, annual. *Stem* three or four feet high, leafy. *Leaves* much narrower, and more deeply serrated or notched than in the last, the upper ones becoming gradually more pointed, and smaller, to the bottom of the long simple *clusters*, where they are replaced by a small, solitary, lanceolate *bractea* under each *flower-stalk*, as in *V. trifida* and *phœniceum*. The *corolla* is smaller than the last, bright yellow, more or less streaked with purple. *Filaments* clothed with purple hairs: sometimes the *corolla* seems to become purplish all over.

A supposed variety, with large white *flowers*, marked partially with purplish-brown at the back, is common in gardens; coming up from seed, and remaining unaltered, through many successive years. This is *Blattaria alba*, *Bauh. Pin.* 241, but we can discover no specific difference between it and the wild or cultivated yellow-flowered kind.

32. *V. spinosum*. Thorny Mullein. Linn. Sp. Pl. 254. Amoen. Acad. v. 4. 307. Willd. n. 16. Vahl Symb. v. 2. 39. Sm. Fl. Græc. Sibth. t. 229. (*Leucoium spinosum creticum*; Cluf. Hist. 299. Ger. Em. 459. *L. spinosum cruciatum*; Alpin. Exot. 37. t. 36. *Galastivida prima di Candia*; Pon. Bald. 114.)—Stem leafy, shrubby, much branched, spinous. Leaves all stalked, hoary.—Native of the higher mountains of Crete; a stranger in our gardens, even by name. This differs widely from all the rest, in its hardy, shrubby, bushy *stem*, a foot high, whose very compound *branches* harden at their points into smooth rigid thorns. *Leaves* crowded, an inch or inch and half long, oblong, obtuse, deeply toothed, downy and white on both sides: contracted at the base into the *footstalks*. *Flowers* scattered, stalked, lateral and terminal, yellow, hardly above half an inch broad. *Stamens* orange-coloured. *Calyx* obtuse. *Capsule* small, villous.

Two other species, mentioned by Linnæus, remain to be noticed; *V. Osbeckii*, and *V. Myconi*, Linn. Sp. Pl. 255. The former we have shewn to be the *TRIGUERA* of Cavanilles (see that article); nor does it answer to the characters of a *Verbascum*. The latter, figured in Curt. Mag. t. 236, an elegant, herbaceous, stemless plant, long known in our gardens, appears to be the *Ramondia* of Schrader and others, as we have mentioned in our remarks subjoined to the generic character of the present genus, from which this species must, doubtless, be excluded.—Willdenow has a *V. Barmadesii*, adopted from Vahl's Symb. v. 2. 39, and compared with *V. Osbeckii*. With this we are quite unacquainted.

From the present view of *Verbascum*, more complete than any that has hitherto been given, and yet so far from perfect, the reader may chiefly learn that no certain limits have as yet been found for many of the species of this genus, while others, apparently much alike, remain permanent and distinct. To fix them all, a long course of experiment, by cross impregnation, would be necessary.

VERBASCUM, in *Gardening*, furnishes plants of the hardy, annual, biennial, and perennial kinds, among which the species cultivated are, the annual mullein (*V. boerhaavii*);

the moth mullein (*V. blattaria*); the great mullein (*V. thapsus*); the woolly mullein (*V. phlomoides*); the white mullein (*V. lychnitis*); the scollop-leaved mullein (*V. sinuatum*); the rusty mullein (*V. ferrugineum*); the purple mullein (*V. phœniceum*); and the borage-leaved mullein (*V. myconi*).

In the first sort the flowers have an agreeable scent at a little distance; but if smelt too long, or too near, it becomes less pleasant.

The second sort has yellow flowers, which are streaked more or less with purple, and is very ornamental, flowering from July to November, or even later in mild weather.

It varies with white flowers.

The third sort has a biennial root, and the flowers are of a bright yellow colour, and sometimes, but rarely, white.

The fifth sort is remarkable for its straight wand-like angular stem, and cream-coloured flowers, which are produced in great numbers in a compound clustered terminating raceme. Sometimes the colour of the flowers is yellow.

The ninth sort has the flowers large in proportion to the size of the plant, of a blueish-purple colour, and highly ornamental, somewhat like the auricula, appearing in May, and continue successively in blossom for several months. It is a desirable plant to cultivate, especially for decorating rock-work.

Method of Culture.—These plants may all be increased by seeds, and offsets taken from the roots.

The well-ripened seeds should be sown in the autumn, or early spring, in a bed of light mould, or in the borders or other parts where they are to remain, covering them lightly in. When the plants are up a few inches in height, in the bed method, they should be removed into nursery rows till the autumn, when they must be removed to where they are to remain.

The annual sort is, however, best sown at once where the plants are to grow, which is best done in patches.

The offsets of all the perennial sorts should be taken off in the autumn, or very early in the spring, and be planted out where they are to grow. This is better than afterwards transplanting them.

They are all hardy plants, that succeed in almost any common soil and exposure, in borders, &c.

They afford a good effect in their different foliage, modes of flowering, and sweet scent of their flowers, in the large borders, clumps, and other parts of pleasure-grounds; the larger sorts being placed backwards in them.

VERBELIËT, in *Geography*, a town of Hungary; 6 miles S.W. of Erlau.

VERBENA, in *Botany*, among the Romans, was the name of some evergreen aromatic shrub, esteemed sacred, and employed in various solemn ceremonies. Hence it was called *Hierobotane*, and *Herba sacra*. Some derive *Verbena* from *verro*, to sweep, or cleanse; because the plant might be used for cleaning the altars or temples: others from *Herbena*, corrupted from *herba bona*, or good herb. But these rather prove that no good Latin etymology was to be found. De Theis gives a much better, and indeed a direct, derivation of the word, from Bullet's *Dictionnaire Celtique*, where the Celtic name of the plant is said to be *Ferfaen*, whence comes, still less changed, its English appellation, *Vervain*. The Roman shrub, above alluded to, is sometimes thought to have been our *Rosemary*, which could hardly be the Celtic plant; and we must rely on tradition, which has handed down our Common *Vervain*, the Linnæan *Verbena*, with much superstitious celebrity, even to the present day, as the *Ferfaen* of our barbarous ancestors. It still, from time to time, makes the fortune of quacks and village

VERBENA.

village doctresses, whether they aim at notoriety or lucre; and a person named Morley once wrote a pamphlet, recommending the root, to be worn as a charm, in scrophulous disorders, but, as Mr. Curtis remarks, he accompanied it with powerful medicines.—Linn. Gen. 14. Schreb. 20. Willd. Sp. Pl. v. 1. 115. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 38. Brown Prodr. Nov. Holl. v. 1. 514. Sm. Fl. Brit. 608. Prodr. Fl. Græc. Sibth. v. 1. 401. Pursh 415. Juss. 109. Tourn. t. 94. Lamarck Illustr. t. 17. Gært. t. 66. (Blairia; Gært. t. 56. Zappania; Scop. Infubr. v. 1. 34. Brown Prodr. Nov. Holl. v. 1. 514. Pursh 417. Lam. Illustr. t. 17.)—Class and order, *Didynamia Gymnospermia*. (D. Angiospermia; Brown in Ait. Hort. Kew.) Nat. Ord. *Personatae*, Linn. *Vitices*, Juss. Gen. *Verbenaceae*, Juss. in Ann. du Mus. v. 7. 63. Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, angular, tubular, linear, with five teeth, one of which is smaller than the rest, permanent. *Cor.* of one petal, unequal; tube cylindrical, straight, the length of the calyx, soon dilated and incurved; limb spreading, cloven half way down into five, more or less unequal, rounded segments. *Stam.* Filaments four, setaceous, very short, inserted into the tube of the corolla, and concealing within it, two of them shorter than the rest; anthers oblong, incurved. *Pistl.* Germen superior, quadrangular; style simple, thread-shaped, shorter than the tube; stigma obtuse. *Peric.* scarcely any, except an evanescent membranous tunic, the calyx containing the seeds, which are either four, or only two, oblong, parallel, erect, straight at the inner edge, gibbous at the outer.

Eff. Ch. Corolla funnel-shaped, rather unequal, curved. Calyx with five teeth. Seeds two or four, with a membranous evanescent tunic.

Obf. We have concurred with many other botanists, in separating from this genus the diandrous species; which moreover have only four teeth to their calyx, and never more than two seeds. (See *STACHYDARPHETA*.) But it does not seem necessary to retain also *Zappania*, distinguished by its two seeds, and more dense inflorescence, which is as truly spicate as in acknowledged *Verbena*.

1. *V. mexicana*. Mexican Vervain. Linn. Sp. Pl. 28. Willd. n. 6. Ait. n. 1. (*V. mexicana*, trachelii folio, fructu aparines; Dill. Elth. 407. t. 302.)—Leaves ovate, acute, harsh. Spikes lax. Calyx of the fruit reflexed, hispid, of two round lobes. Seeds two.—Native of Mexico. Cultivated in Sherard's garden in 1726. A stove plant, flowering in summer. *Stem* herbaceous, two or three feet high, square, leafy, rough and furrowed, branched in the upper part. *Leaves* opposite, on short stalks, strongly serrated like those of a common nettle, rough with minute rigid bristles. *Spikes* terminal, stalked, erect, long and slender; lax and interrupted in the lower part. *Flowers* very numerous, small, pale purple. The *calyx* when in fruit becomes stalked, recurved, tumid, and is at all times hoary with bristly hairs. We are not certain that this species has always four perfect *stamens*. Two of the *anthers* are most visible in the mouth of the tube.

2. *V. stachadifolia*. Oval-spiked Vervain. Linn. Sp. Pl. 27. Willd. n. 7. Ait. n. 2. (*V. n. 4*; Browne Jam. 116. t. 3. f. 1. *Lavandula frutescens, foliis latioribus crenatis*; Plum. Ic. 154. t. 162. f. 1.)—Spikes dense, imbricated, ovato-cylindrical. Leaves lanceolate, wavy, toothed, clothed with depressed hairs; hoary beneath. *Stem* shrubby.—Native of the West Indies. *Stem* spreading five or six feet, woody, but not lasting above two or three years. The *leaves* are stalked, two or two and a half inches long, acute, reticulated with veins, flat, not plaited,

as the erroneous engraving, after Plumier's drawing, is made to express, but wavy at the margin, with small acute teeth; the upper surface is covered with rigid depressed bristles; the under with softer hairs. *Spikes* hairy, an inch long, about thrice the length of their stalks. Of the *stamens, seeds, or colour of the flowers*, we are ignorant.

3. *V. globiflora*. Round-headed Vervain. L'Herit. Stirp. 23. t. 12. Willd. n. 8. (*Nepeta maxima, flore albo, spicâ habitiori*; Sloane Jam. v. 1. 173. t. 108. f. 1.)—Spikes dense, imbricated, roundish-ovate. Leaves ovate, crenate, rugose, downy. *Stem* shrubby, erect.—Native of South America; perhaps, as L'Heritier thought, of Buenos Ayres. We have from thence a specimen somewhat like it, but smaller in every part, possibly because it is a wild one. L'Heritier's plant was cultivated at Paris, being a *shrub* of humble growth, of a strong disagreeable odour. The *leaves* are shorter and more ovate than in the last, differing also from that species in being finely and closely crenate, not wavy or toothed. The *spikes* also are much shorter, nearly globose. *Flowers* white. *Stamens* four, all perfect. *Seeds* two.

4. *V. javanica*. Java Vervain. Burm. Ind. 12. t. 6. f. 2. Willd. n. 9. (*Zappania javanica*; Poiret in Lam. Dict. v. 8. 840.)—Spikes dense, imbricated, cylindrical. Leaves elliptic-lanceolate, crenate, finely downy.—Native of Java. *Stem* ascending, roundish, clothed, like the rest of the plant, with fine, short, close hairs. *Leaves* an inch and a half long, acute at each end. *Flowers* in short cylindrical spikes, on axillary, often opposite, stalks, the length of the leaves. Linnæus suspected this not to be different from *V. stachadifolia*, but they are very unlike in the margin of their *leaves*, as well as in general appearance.

5. *V. nodiflora*. Knot-flowered Vervain. Linn. Sp. Pl. 28. Willd. n. 10. Ait. n. 3. Bauh. Prodr. 125. Burm. Ind. 12. t. 6. f. 1. Sm. Fl. Græc. Sibth. t. 553, unpublished. (*Zappania nodiflora*; Brown Prodr. Nov. Holl. v. 1. 514. Pursh 417. Poiret in Lam. Dict. v. 8. 839.)—Spikes dense, imbricated, ovate. Leaves wedge-shaped, toothed. *Stem* creeping.—Native of the south of Europe, Levant, East and West Indies, and North America, in watery situations, flowering at various seasons. The *root* is fibrous, perennial. *Stems* herbaceous, trailing and creeping to a great extent. *Leaves* an inch or inch and half long, somewhat spatulate, smooth; entire at the base. *Flowers* light purple, with dark-red *bractæas*. *Calyx* somewhat two-lipped. *Seeds* two.

6. *V. bonariensis*. Cluster-flowered Vervain. Linn. Sp. Pl. 28. Willd. n. 11. Ait. n. 5. Poiret in Lam. n. 13. (*V. bonariensis altissima, lavandulæ canariensis spicâ multiplici*; Dill. Elth. 406. t. 300.)—Spikes aggregate, tufted, level-topped. Leaves lanceolate, sessile, clasping the stem.—Native of Buenos Ayres, from whence it came into Sherard's garden; and is still seen in some curious collections, being a hardy biennial plant, flowering throughout autumn. The *stem* is often six feet high, square, rough, clothed with long, harsh, coarsely serrated *leaves*, and terminating in copious tufts of blue *flowers*, made up of short spikes, on very long, opposite, panicked stalks. *Seeds* four, linear, striated, curiously rough on the inner side.

7. *V. rugosa*. Rugose Vervain. Willd. Enum. 633. Pursh n. 8. (*V. angustifolia*; Michaux Boreal-Amer. v. 2. 14. Ait. n. 7. Poiret in Lam. n. 11.)—Spikes thread-shaped, solitary, terminal or axillary. Leaves lanceolate, sparingly serrated, furrowed with veins; tapering at the base.—In dry soil, by road-sides, particularly on limestone, from Pennsylvania to Tennessee, flowering from June

to August. Perennial. Not above a foot high. *Flowers* fine blue. *Pursh*.

8. *V. clavata*. Whorled Vervain. "Fl. Peruv. v. 1. 21. t. 33. f. B." Poiret in Lam. n. 15.—Flowers in umbellate heads. Uppermost anthers club-shaped at the back. Leaves whorled, wedge-shaped, undivided or lobed.—Native of Peru, in sandy situations, flowering in August and September. The stems are numerous, erect, much branched, hoary; naked below. Leaves five or six in each whorl; some entire, linear-lanceolate, revolute; others divided or three-cleft, hardly an inch long, moderately downy, a little fringed. Flowers terminal, sessile, collected into a head in the form of an umbel, each with one or two linear, oblong, downy, fringed bractees. Corolla purplish-red. Stamens four. Anthers heart-shaped, surmounted by a small club-shaped appendage. Seeds four. *Poiret*.

9. *V. hispida*. Bristly Vervain. "Fl. Peruv. v. 1. 22. t. 34. f. A." Poiret in Lam. n. 16.—"Spikes ternate, cylindrical. Leaves ovate or oblong, undivided or somewhat three-cleft, deeply serrated, half-embracing the stem."—Native of Peru, in dry chalky ground, flowering in March and April. The stems are numerous, herbaceous, spreading, hispid, a foot high, branched, quadrangular. Leaves opposite, sometimes ternate, sessile, contracted, and in a manner decurrent, at the base, wrinkled, strongly veined, hispid, with deep, tooth-like, often unequal, serratures; their length two or three inches, breadth one inch. Flowers much crowded, in terminal, stalked spikes, generally three upon each branch, thick, cylindrical, two or three inches long, the lateral ones much shorter. Bractees solitary to each flower, half-lanceolate, fringed. Calyx purplish. Tube of the corolla purple; limb pale blue. Stamens four. Seeds four. *Poiret*.

10. *V. hastata*. Halberd-leaved Vervain. Linn. Sp. Pl. 29. Willd. n. 12. Ait. n. 6. Pursh n. 4. (*V. altissima americana*, spicâ multiplici, urticæ foliis angustis, floribus cæruleis; Herm. Parad. 242, with a plate.)—Spikes panicled, linear, acute. Leaves lanceolate, pointed, deeply and doubly serrated; lower ones hastate, or pinnatifid.—By road-sides in wet situations, and on the banks of rivers, from Canada to Carolina, perennial, flowering in July and August. From two to five feet high. Flowers purple, sometimes white. *Pursh*. The leaves are three inches, or more, in length, rough to the touch, like a fine file. Spikes two inches long, becoming longer, and lax, after flowering.

11. *V. triphylla*. Lemon-scented Vervain. L'Herit. Stirp. 21. t. 11. Willd. n. 13. Ait. n. 4. Curt. Mag. t. 367. (*Zappania citrodora*; Poiret in Lam. Dict. v. 8. 845.)—Spikes panicled. Leaves lanceolate, minutely and distantly toothed, three in a whorl. Stem shrubby.—Native of Chili, where it was found by the unfortunate DOMBEY, (see that article,) and introduced into the gardens of Europe. In Italy, Spain, and the south of France, this valuable shrub is quite naturalized, and its delightfully scented leaves, having the flavour of lemon, are useful in fevers, and other inflammatory disorders, being taken as tea, like balm, hyssop, &c. With us it is a hardy greenhouse plant, flowering in summer. The leaves are of a light bright green, roughish, two inches long, apparently entire to a slight observer, soon drying, and fragrant for a long time afterwards if rubbed. Flowers small, pale lilac, in aggregate, panicled, loose, terminal spikes. The specific name of this plant is not well chosen, so many Peruvian and Chili shrubs having three leaves in a whorl. Ortega, who thought it a new genus, called it *Aloysia citrodora*, and the French retain the latter appellation, as if *citreæ* would not

far more elegantly express their meaning. But who shall weed the rank wilderness of recent botanic names? in which the venerable fabric raised by Linnæus is almost hidden, like the temples at Pæstum, before they were cleared.

12. *V. virgata*. Wand-like Verbena. "Fl. Peruv. v. 1. 20. t. 32. f. B." (*Zappania virgata*; Poiret in Lam. Dict. v. 8. 845.)—"Spikes axillary, ternate, slender. Flowers whorled. Leaves ovate, acute, crenate."—Native of the extensive forests of Peru, flowering in August and September. A branching shrub, ten or twelve feet high, with a very agreeable scent. Leaves stalked, opposite, spreading, three or four inches long, an inch and a half broad; rough on the upper side; veiny, wrinkled and downy beneath. Spikes generally three from the bosom of each leaf, composing a spreading panicle. Calyx downy. Corolla white. Seeds two. *Poiret*.

13. *V. lappulacea*. Bur Vervain. Linn. Sp. Pl. 28. Willd. n. 14. Swartz Obs. 16. Jacq. Obs. fasc. 1. 37. t. 24. (*Scorodonia floribus spicatis purpurascens pentapetaloides, femine unico majori echinato*; Sloane Jam. v. 1. 174. t. 110. f. 1.)—Clusters solitary, lax, simple. Calyx of the fruit inflated, roundish. Seeds oblong, tuberculated. Leaves ovate, acute, sharply serrated.—Native of waste ground and stony places, in the West Indies. The stems are herbaceous, two or three feet high, branched, leafy, square, smooth, hollow. Leaves stalked, two inches long, slightly bristly. Clusters from the forks of the stem, long, weak, and slender, of numerous, distant, little, pale-blue flowers, on short partial stalks. Calyx downy; as the fruit ripens becoming globose, inclosing the four hard seeds, which are closely combined, beset externally with four thick spines. Dr. Swartz, in his *Flora Ind. Occ.* 1090, points out the affinity of this species to his own genus GHINIA, (see that article,) founded on *Verbena curassavica* of Linnæus. The fruit of *Ghinia*, however, is a drupa, with a nut of four cells.

14. *V. Forskalei*. Arabian Vervain. Vahl Symb. v. 3. 6. Willd. n. 15. (*Phryma*; Forsk. Fl. Arab. Fel. n. 372.)—Clusters terminal, simple. Calyx of the fruit roundish, beaked, reflexed. Seeds rounded, corrugated. Leaves ovate-oblong, acute, bluntly serrated.—Found by Forskall in Arabia Felix. Very nearly akin to the last, but more robust and erect, with rougher, more deeply serrated, leaves. Seeds not oblong and spinous, but roundish and toothed, inflexed at the points. *Vahl*.

15. *V. caroliniana*. Carolina Vervain. Linn. Sp. Pl. 29. Willd. n. 16. Ait. n. 8. Pursh n. 9. (*V. carolinensis, melissæ folio, aspero*; Dill. Elth. 407. t. 301.)—Spikes aggregate, lax and slender. Leaves elliptic-lanceolate, acute at each end, serrated, nearly sessile; rough above; somewhat downy beneath.—In dry sandy fields, from Carolina to Georgia, perennial, flowering in June and July. *Pursh*. Herb erect, branched, somewhat hairy. Leaves harsh, with minute bristly tubercles, on the upper side, an inch and a half or two inches long, unequally, not deeply, serrated. Flowers pale red, very small. Calyx bristly, twice the length of the minute, ovate, pointed bractees. Seeds four, oblong.

16. *V. urticifolia*. Nettle-leaved Vervain. Linn. Sp. Pl. 29. Willd. n. 17. Ait. n. 9. Pursh n. 6. (*V. folio urticæ angustiore*; Rivin. Monop. Irr. t. 57. *V. recta canadensis*; Morif. sect. 11. t. 25. f. 3. *V. peregrina, foliis urticæ*; Dodart Mem. 627. t. 35.)—Spikes aggregate, lax and slender. Leaves ovate, acute, serrated, stalked, hairy on both sides.—About road-sides and cultivated grounds, from New England to Carolina, perennial, flowering from June to September. Flowers very small, white.

VERBENA.

white. *Pursh.* Akin to the last, but taller, and clearly distinguished by its stalked, coarsely serrated, nettle-like leaves. *Braçteas* ovate, slightly pointed, shorter than the calyx.

17. *V. stricta.* Stout Upright Vervain. Venten. Hort. Cels. t. 53. Ait. n. 10. Willd. Enum. 633. Pursh n. 10. Donn Cant. ed. 5. n. 10. (*V. rigens*; Michaux Boreal.-Amer. v. 2. 14. *V. paniculata*; Donn Cant. ed. 5. n. 8.)—Spikes aggregate, corymbose, straight, dense, obtuse. *Braçteas* taper-pointed, as long as the calyx. Leaves ovate, on short stalks, unequally serrated, downy and hoary on both sides.—Native of Carolina, and the Illinois country, perennial, flowering in July and August. *Pursh.* A tall, stout, hoary plant, whose stiff round stem is clothed with numerous, coriaceous, veiny leaves, an inch and a half to two inches long, acute, coarsely serrated; most downy beneath. *Spikes* from two to four inches long, in strong plants numerous, crowded at the top of the stem, in a corymbose manner, hoary, imbricated. *Braçteas* ovate, with taper points, generally exceeding the calyx, whose teeth are also long and slender. *Corolla* large, of a violet blue.

18. *V. diffusa.* Spreading Vervain. Poiret in Lam. n. 14. Pursh n. 7.—Spikes very long, lax, panicled, widely spreading. *Braçteas* acute, about as long as the calyx. Stem erect, much branched. Leaves ovato-lanceolate, serrated, somewhat downy.—Native of North America; cultivated at Paris, according to Poiret, on whose authority Mr. Pursh gave this species a place in his Flora. He speaks of it as having a near resemblance to *V. urticifolia*, with very small, somewhat purple, flowers. We have seen no specimen.

19. *V. paniculata.* Compound-panicled Vervain.—Lamarck Illustr. v. 1. 57. Dict. n. 8. Pursh n. 5.—Spikes compound, in a corymbose panicle. Leaves lanceolate, deeply serrated and jagged; tapering at the base; harsh on both sides, slightly downy.—In the natural meadows of the high mountains of Virginia and Carolina, perennial, flowering in July and August.—From four to six feet high. *Flowers* very numerous, purple. We have from the Paris garden a specimen marked *V. paniculata* of Jussieu, which answers well to the description by Poiret in Lamarck's Dictionary, and is doubtless what they all intended. Our specimen indeed is but eighteen inches high, and the leaves are about two inches, not four or five, in length. They taper down into short stalks, and are not much pointed. Both surfaces are rough like a file, as is likewise the square stem, which terminates in a corymbose panicle, of compound or branched spikes. The *braçteas* are ovate, with a fine point, shorter than the calyx. *Corolla* rather small.—What we received from the late Mr. Donn of Cambridge, as his *V. paniculata*, is not this, but our *stricta*, n. 17.

20. *V. corymbosa.* Corymbose Chili Vervain. "Fl. Peruv. v. 1. 22. t. 33. f. A." Poiret in Lam. n. 16.—Spikes aggregate, corymbose. Leaves sessile, triangular-heart-shaped, wrinkled, harsh, deeply serrated, pointed.—Native of Chili, in waste ground amongst rubbish, flowering in November and December. The stems are erect, herbaceous, square, a foot high, with opposite branches. Leaves about an inch and a half in length, distant, strongly veined, almost triangular. *Flower-stalks* at the summits of the stem and branches, opposite, three-cleft, the lowermost axillary, all forming a corymb of oblong spikes, of violet-coloured flowers. *Braçteas* lanceolate, taper-pointed. *Seeds* four. *Poiret.*

21. *V. officinalis.* Common Vervain. Linn. Sp. Pl. 29.

Willd. n. 20. Fl. Brit. n. 1. Engl. Bot. t. 767. Curt. Lond. fasc. 1. t. 41. Woodv. Suppl. t. 218. Fl. Dan. t. 628. Brown n. 1. (*V. communis*; Ger. Em. 718. Verbena; Rivin. Monop. Irr. t. 56. Verbenaca; Matth. Valgr. v. 2. 399. Camer. Epit. 797.)—Spikes slender, panicled. *Braçteas* ovate. Leaves deeply cut. Stems mostly solitary, somewhat prickly. Native of waste ground, and road-sides, in most parts of Europe, common in England, flowering in July. We received it among the first specimens, sent from New South Wales, in 1792, by Dr. John White. Mr. Brown also saw it there, and in the tropical part of New Holland. The root is perennial, woody, branching, sending up, from each of its summits, a solitary stem, about a foot high, curved at the base, acutely quadrangular, smooth, except a greater or less proportion of minute hooked prickles. Leaves variously jagged, somewhat hairy, tapering at the base into a broad footstalk. Flowers small, pale lilac, in acute spikes, at first dense, but becoming long and lax as the seeds ripen. *Braçteas* ovate, half the length of the calyx. Seeds while young enfolded in one common skin, or tunic, almost obliterated as they ripen, when each appears marked at the summit with excavated dots. This is the plant used by Mr. Morley to cure the king's evil, by hanging its root round the neck. Curtis has very justly exposed his pretensions, and his affected disinterestedness. Ray long ago remarked that the sensible qualities of the Vervain were too slight to make its many boasted virtues credible. Nevertheless it is still used, and we believe will do no harm; unless the patient be deluded by this means to neglect what might be more serviceable. Dioscorides, whose *ισσα βολων*, or Holy Herb, this is, first published its powerful use in incantations, and yet he has been believed for its other qualities.

22. *V. spuria.* Jagged-leaved Vervain. Linn. Sp. Pl. 29. Willd. n. 9. Ait. n. 12. Pursh n. 3.—"Spikes thread-shaped. *Braçteas* longer than the calyx. Stem decumbent, much branched and divaricated. Leaves in many jagged segments."—On slate hills and lime-stone rocks, in the Illinois country, Virginia and Kentucky, biennial, flowering in July and August. Flowers very small, blue. *Pursh.* We have never seen this plant, nor had Linnæus a specimen.

23. *V. supina.* Trailing Spanish Vervain. Linn. Sp. Pl. 29. Willd. n. 21. Ait. n. 14. Sm. Fl. Græc. Sibth. t. 554, unpubl. Cluf. Hist. v. 2. 46. (*V. sacra*; Ger. Em. 718.)—Spikes thread-shaped, solitary. *Braçteas* shorter than the calyx. Stems decumbent, branched. Leaves doubly pinnatifid. Native of Spain and the Levant, in spots overflowed in winter, flowering in July. Root annual. Herb somewhat downy, spreading every way, a little glaucous, with square stems a foot long. Leaves in many, narrow, wedge-shaped, notched segments. Spikes from the ends, as well as the forks of the branches. Flowers small, light purple, becoming distant as the seeds ripen. *Braçteas* ovate, bristly like the calyx, and about half its length. *Seeds* oblong, smooth.

24. *V. prostrata.* Prostrate Vervain. Ait. n. 15.—"Spikes thread-shaped, solitary. Calyx twice as long as the seeds. Leaves deeply serrated or cut."—Found by Mr. Menzies, on the north-west coast of America; and introduced in 1794 into Kew garden. It is perennial and hardy, flowering in June and July.

25. *V. cuneiformis.* Wedge-leaved Vervain. "Fl. Peruv. v. 1. 22. t. 32. f. A." Poiret in Lam. n. 3.—Spikes ternate, oblong. *Braçteas* lanceolate, acute, fringed. Leaves three-cleft, cut. Stem erect.—Native of sandy ground

ground in Peru, flowering from March to May. The whole plant is bristly, two feet high, branched. Leaves sessile, half clasping the stem; contracted at the base; divided almost half way down into three large, oblong, serrated lobes, rough and hispid on both sides, two or three inches long, and about as broad. Spikes short, ternate. Flowers blue. *Poiret*.

26. *V. bracteosa*. Bracteated Vervain. Michaux Boreal-Amer. v. 2. 13. Willd. Enum. 634. Pursh n. 2. (Zapana bracteosa; *Poiret* in Lam. v. 8. 843.)—Spikes solitary, with lanceolate spreading bractees, longer than the flowers. Stem decumbent. Leaves lacinated, very hairy.—Native of Illinois and Kentucky, perennial, flowering in July. Flowers light purple. *Pursh*. A small very hairy plant, said to have some resemblance to *V. supina*, n. 23, but the long wide-spreading bractees are peculiar. The stems are from six to nine inches in length. Spikes from the ends, as well as the forks, of the branches, two or three inches long. Seeds only two.

27. *V. Aubletia*. Rose-coloured Vervain. Jacq. Hort. Vind. v. 2. 82. t. 176. Linn. Suppl. 86. Willd. n. 18. Ait. n. 11. Pursh n. 1. Curt. Mag. t. 308. (Buchnera canadensis; Linn. Mant. 88. Obletia; Journ. de Rozier, v. 1. 367. t. 2. *Erinus laciniatus*; Linn. Sp. Pl. 879. *Lychnidea verbenæ tenuifoliæ folio*; Feuill. Peruv. v. 3. 35. t. 25.)—Spikes capitate, solitary; cylindrical after flowering. Bractees awl-shaped, as long as the taper-pointed calyx. Leaves three-lobed, cut. Stem erect.—Native of Carolina and Georgia, flowering in June and July. The seeds appear to have been brought to Europe by M. Richard, senior, and were sent by him to Kew garden, in 1774. The plant is biennial in our climate, requiring the shelter of a frame in winter. The herbage is green, roughish to the touch. Stem a foot high, or more, square, leafy, branched from the bottom. Leaves stalked, broadish, variously cut. Flowers larger than most of the genus, of a fine pink or crimson, numerous, in stalked heads, which afterwards become thick, close, cylindrical spikes. The bractees are very narrow, permanent, downy as well as the calyx, whose teeth are also very long and slender. Seeds four, oblong; furrowed in the lower, reticulated in the upper, part. This is undoubtedly a genuine and most obvious *Verbena*, nor can we account for the error of Linnæus, who, with the ripe naked seeds on his original specimen, and the long-pointed calyx, referred it to *Buchnera*. It was called *Obletia*, either by its discoverer, or by La Tourrette, who sent a specimen and figure to Linnæus, by which the latter corrected his mistake. Their intention was to honour Aublet, whose name was sometimes written Oblet. With respect to the other Linnæan synonym, hitherto neglected by most of those who have noticed this *Verbena*, it depends entirely on Feuillée's plate and description, which led Linnæus to refer this, as well as the following species, to *Erinus*, without seeing a specimen of either. Lamarck, *Poiret*, and Willdenow, apply these latter synonyms to their *V. crinoides*, Willd. Enum. 634, which is *V. multifida*, Fl. Peruv. v. 1. 21. t. 33. f. C.

28. *V. veronicifolia*. Speedwell-leaved Vervain. (*Erinus peruvianus*; Linn. Sp. Pl. 879. *Lychnidea veronicæ folio*, flore coccineo; Feuill. Peruv. v. 3. 36. t. 25.)—Spikes capitate, solitary, cylindrical after flowering. Bractees awl-shaped, as long as the taper-pointed calyx. Leaves ovate, serrated, acute at each end. Stem erect.—Found by Feuillée in fields on the north side of the river de la Plata, in Paraguay. This seems to agree with the last in the flowers and inflorescence, differing only in the simple undivided form of the leaves; but whether that

difference be constant and specific, can be determined by future comparison of the two plants. The other synonym of Feuillée having been misunderstood, and, as we presume, distinguished without reason from *V. Aubletia*, we have here recorded this for the consideration of those who may hereafter meet with materials for solving our doubts.

VERBENA, in *Gardening*, contains plants of the hardy, herbaceous, and tender exotic kinds, among which the species cultivated are, the Indian vervain (*V. indica*); the trailing vervain (*V. supina*); the betony-leaved vervain (*V. orbicula*); the Jamaica vervain (*V. jamaicensis*); the Mexican vervain (*V. mexicana*); the globe-flowered vervain (*V. globiflora*); the cluster-flowered vervain (*V. bonariensis*); the halbert-leaved vervain (*V. hastata*); and the three-leaved vervain (*V. triphylla*).

And there are many other species that may be cultivated for variety.

The first sort is an annual plant with a purplish flower. In the second sort the flowers are of a light blue colour, and large. The third arises with a shrubby stalk, and the flowers grow in thick terminating spikes about a foot in length; are large, and of a fine blue colour. The fourth sort is three or four feet high in the stem, and much branched, the flowers blowing in succession, beginning at the bottom, but very few together, violet-coloured, with the throat and long slender incurved tube of a white colour. The seventh has four-cornered stalks, which rise to the height of five or six feet, the flowers of which are blue, appearing late in summer. The eighth has many four-cornered furrowed stalks, which are terminated by spikes of blue flowers, in clusters, which appear in August. The ninth is a very sweet-smelling under shrub, and very pleasant, like that of the lemon.

Method of Culture.—These plants are not raised without difficulty or attention. They may be increased by seeds, which should be sown in pots, or on a hot-bed, in the early spring, plunging the pots in the bed. When they are in a state of growth to remove, they should be planted in separate pots, and replunged in a fresh hot-bed, shade being given till they have taken new root, when they must have the management of tender plants of the exotic kind. The annual sorts should be kept in the stove, or a glass case, where there is a bark-bed to plunge them in, when too large to be continued under the frames; and the perennial sorts may be placed simply in such cases, air being admitted in a cautious manner.

Of these kinds, such as do not afford good seeds in this climate, may be increased by planting cuttings in the summer months in pots of good mould, placing them in the bark-bed of the stove, where they may be preserved many years. The eighth sort may be raised from seeds by sowing them in the autumn, and by parting the roots and planting them out at the same time. They succeed best on a soft loamy soil, and are so hardy as to thrive in the open air. The ninth sort may be readily increased, by planting cuttings in the spring or autumn in pots of good mould. It should have the protection of the greenhouse or a glass case. They afford variety among other potted plants in the greenhouse and stove, and some of the hardy sorts occasionally in the open ground.

VERBENACA, in *Botany*, with the earlier botanists among the moderns, and even with Pliny himself, seems to be synonymous with VERBENA, see that article. Linnæus indeed uses this word as the specific name of a common English species of *Salvia*, not supposed by any body, that we can find, to have been the so much honoured *Verbenaca* of the Romans, see Pliny, book 25. chap. 9. He was led

to this adoption of the name by Triumphetti, who compares the division of the leaves of this plant to those of *Verbenaca*, or Vervain. The application, therefore, is faulty, and causes a confusion of ideas. See *SALVIA*.

VERBENICO, in *Geography*, a town of the island of Veglia, with a small harbour, containing about 1200 inhabitants.

VERBERATION, formed from *verbero*, I smite, in *Physics*, a term used to express the cause of sound, which arises from a verberation of the air, when struck, in divers manners, by the several parts of the sonorous body first put into a vibratory motion.

VERBERIE, in *Geography*, a town of France, in the department of the Oise: near it is a medicinal spring; 9 miles S. of Compeigne.

VERBESINA, in *Botany*, according to Ambrosinus, who is followed by Linnæus, *Phil. Bot.* 175, originated in *Forbesina*; which latter arose from the leaves being divided like a pair of forceps. Professor Martyn, however, derives *Forbesina* from *Coq'sn*, food, or fodder; the chief objection to which is, that the plants of this genus do not appear to be serviceable, or to have been recommended, for any such purpose. De Theis considers the above name as synonymous with *Verbena*, because, as he says, the undulated obtuse leaves of *Verbesina alata* resemble that plant; but this explanation is unauthorized.—Linn. Gen. 437. Schreb. 570. Willd. Sp. Pl. v. 3. 2221. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 120. Pursh 564. Juss. 188. Lamarck Illustr. t. 684. Gært. t. 171. (*Synedrella*: *ibid.* t. 171.)—Class and order, *Syngenesia Polygamia-superflua*. Nat. Ord. *Compositæ oppositifolia*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* concave, of several oblong, channelled-concave, erect, mostly equal leaves, in a double row. *Cor.* compound, radiated; that of the numerous perfect florets in the disk funnel-shaped, five-toothed, erect; of the few (about five) female florets of the radius ligulate, either broad and three-cleft, or very narrow and undivided. *Stam.* in the perfect florets, Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* in the same florets, Germen rather oblong; style thread-shaped, the length of the stamens; stigmas two, reflexed; in the female ones, the same. *Peric.* none, except the unchanged calyx. *Seeds* in all the florets alike, solitary, thickish, angular, crowned with a chaffy crown of two, or more, acute teeth. *Recept.* covered with deciduous chaffy scales.

Ess. Ch. Receptacle chaffy. Seed-down bristle-pointed. Calyx of two rows of scales. Florets of the radius about five.

Obs. We have shewn, under the article *PHAETHUSA*, that the genus established by Gærtner, with that name, is a real *Verbesina*, though a *Siegesbeckia* of Linnæus. The bristly-pointed crown of the seed in the genus before us being wanting in *V. Lavania*, *alba* and *prostrata* of Linnæus, the two latter are removed to *ECLIPTA*, and the first to *LAUVANIA*; see those articles. The number of radiant florets is uncertain in many species.

Sect. 1. *Leaves alternate.*

1. *V. alata*. Wing-stalked *Verbesina*. Linn. Sp. Pl. 1270. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 1716. (*Cannabina indica*, foliis integris, alato caule; Magn. Hort. 40. t. 8. *Chrysanthemum americanum*, caule alato flore aphylo globoso aurantio, foliis baccharidis; Commel. Hort. v. 1. 5. t. 3. *C. corassavicum*, alato caule, floribus aurantiis; Herm. Parad. 125, with a plate.)—Leaves alternate, decurrent, undulated, bluntish. Bristles of the seed two, very unequal.—Native of South America and the

West Indies. Cultivated ever since the beginning of the last century in our stoves, where it flowers most part of the summer, and being not uncommon, has been figured in more publications than we have thought necessary to quote, but which are cited by those mentioned above. The plant is perennial, hoary when young, erect, branched, three or four feet high, readily known by its winged stem. Leaves three or four inches long, veiny, wavy and toothed. Flowers of a very rich orange-colour, almost globular, three quarters of an inch broad, on long naked, alternate, often purplish, stalks, at the ends of the branches. Florets of the radius, in our gardens at least, numerous. Seeds bordered with a membrane; their terminal awns awl-shaped, rigid, one much longer than the other, incurved and hooked. Linnæus has hinted that this species differs so much in habit and structure from the rest, as almost to constitute a distinct genus. Gærtner makes it the type of *Verbesina*, and yet asserts that this genus is only *Spilanthus* with a radius. Indeed these two genera do run very much into each other, and the radius occasionally appears or vanishes in several species of each, nor are the bristles of the seed perhaps strictly constant even in the same species. We scarcely think the difficulty would be much lessened by removing *V. alata* to *SPILANTHUS*, see that article; though such a measure might be sanctioned by the habit of the plant. The remaining species, very various in habit, have not been sufficiently examined or compared to allow of a clear decision respecting them, and we must take them in general as we find them.

2. *V. chinensis*. Chinese *Verbesina*. Linn. Sp. Pl. 1270. Willd. n. 2.—Leaves alternate, stalked, ovato-lanceolate, obtuse. Seed-down with four bristly points.—Brought by Osbeck from China. Stem shrubby, with round, leafy, downy branches. Leaves an inch and a half long, bluntly serrated, finely downy. Flowers the size of the preceding, yellow, with numerous short rays, growing about the ends of the branches, on longish, slightly leafy, nearly simple, stalks. Seeds slender, quadrangular, each crowned with a jagged membrane, and four small, erect, straight bristles.

3. *V. virginica*. Virginian *Verbesina*. Linn. Sp. Pl. 1270. Willd. n. 3. Pursh n. 1. Michaux Boreal.-Amer. v. 2. 134.—Leaves alternate, stalked, lanceolate, nearly entire. Stem slightly winged. Corymb compound. Calyx oblong, downy.—In shady woods on the mountains, from Pennsylvania to Carolina, perennial, flowering from July to September. Rays three or four, white. Pursh.

4. *V. virgata*. Wand-stalked *Verbesina*. Cavan. Ic. v. 3. 38. t. 275. Willd. n. 4.—Leaves alternate, lanceolate, serrated, tapering at each end. Flowers corymbose.—Native of Mexico. Perennial, flowering in the garden at Madrid in December. Stem four feet high, erect, wand-like, leafy. Leaves a span long, tapering down into the footstalks. Flowers yellow, an inch broad, with about twelve elliptical radiant florets. Seeds black, elliptical, bordered with a whitish wing, and crowned with two small, erect, often deciduous bristles.

5. *V. mutica*. Parsley-leaved *Verbesina*. Linn. Sp. Pl. 1273. Willd. n. 5. Ait. n. 2. Swartz Obf. 314. t. 8. f. 1. (*Bidens apiifolia*; Linn. Am. Acad. v. 5. 405. *Chrysanthemum palustre minimum repens*, apii folio; Sloane Jam. v. 1. 263. t. 155. f. 3. *C. humile*, ranunculi folio; Plum. Ic. 75. t. 86. f. 2.)—Leaves alternate, deeply three-cleft, toothed; radical ones obovate, serrated. Stems procumbent. Seeds without awns.—Found in rather moist pastures, and by way-sides, in the West Indies. Swartz. Miller cultivated it in 1768, from seeds sent by Houftoun, from whom Gronovius received specimens in 1732. This species,

species, having no bristly crown to the seed, belongs rather, as Dr. Swartz observes, to *Anthemis*; but the habit is somewhat adverse. The stems, a span long, spread every way on the ground, and are leafy, more or less branched. Leaves much divided and toothed; glaucous beneath. Flowers small, yellow, with numerous radiant florets. Seed bordered.

6. *V. Boswallia*. Fennel-leaved Verbefina. Linn. Suppl. 379. Willd. n. 6.—Leaves alternate, three-cleft, with many capillary segments. Stems prostrate. Seeds hairy, with two bristles. Female floret solitary.—Native of the East Indies. Used by the natives in fomentations. An annual, herbaceous, decumbent plant, having the taste and smell of fennel; the divisions of the leaves also resembling that herb, only shorter and fewer. Flowers mostly solitary, axillary or terminal. Calyx-seales few, broad, elliptical, with a membranous edge. Florets five or six only; of which one is ligulate and female; the rest four-cleft. Seeds compressed, black, clothed with shaggy golden hairs, and crowned with two black bristles. Linnæus, or rather Koenig, who sent him this plant, appears to have had an intention of making it a new genus, by the name of *Boswallia*, which might have been done without violence to nature. We are not informed of the origin of the name.

7. *V. gigantea*. Great Pale Verbefina. Jacq. Coll. v. 1. 53. Ic. Rar. t. 175. Willd. n. 7. Ait. n. 3. Swartz Ind. Occ. 1368. (*Bidens frutescens*, sphondylii folio et facie; Plum. Ic. 41. t. 51.)—Leaves alternate, pinnatifid, sinuated, toothed. Stem shrubby.—Native of mountainous thickets, in Jamaica and other parts of the West Indies, flowering in December and January. Though often seen in our more curious stove collections, it very rarely flowers. The stem is ten or twelve feet high. Leaves deeply pinnatifid; downy beneath; the lower ones twelve to eighteen inches long. Flowers small, white, or flesh-coloured, numerous, in large, corymbose, terminal panicles. Seeds, according to Jacquin, crowned with a solitary bristle.

8. *V. Coreopsis*. Alternate-leaved Winged Verbefina. Michaux Boreal.-Amer. v. 2. 134. Pursh n. 3. (*Coreopsis alternifolia*; Linn. Sp. Pl. 1283. Willd. Sp. Pl. v. 3. 2257. Jacq. Hort. Vind. v. 2. 50. t. 110. Chrysanthemum virginianum, caule alato, ramofius, flore minore; Pluk. Phyt. t. 159. f. 3. C. caule alato, virginianum, &c.; Morif. sect. 6. t. 7. f. 75, 76.)—Leaves alternate, lanceolate, serrated, stalked. Stem winged. Panicle corymbose, leafy.—On the mountains of Virginia and Carolina; perennial, flowering from July to September. From three to seven feet high, the stem furnished with several narrow, green, entire, leafy wings. Leaves four or five inches long, roughest on the upper side; the lower ones opposite, or three or four in a whorl; but the greater part are alternate. Flowers several, in a downy-stalked branched panicle. Calyx widely spreading, almost flat, so that the disk becomes nearly globose, subtended by four or five orange-coloured, spreading, ligulate florets, near an inch long. Seed crowned with two short bristles. This species is naturally very nearly allied to *V. Siegesbeckia*, hereafter described, see n. 11, nor can they be generically separated.

Michaux and Pursh mention a white-flowered variety, always destitute of rays, found by the latter on the coast of Carolina, which is *Aibanafia paniculata*, Walt. Carol. 201. This Mr. Pursh strongly suspects to be a very distinct species.

9. *V. helianthoides*. Sun-flower Verbefina. Michaux Boreal.-Amer. v. 2. 135. Pursh n. 4.—Leaves alternate, broadly lanceolate, acute, slightly toothed; rough above; downy and hoary beneath. Stalks single-flowered, aggre-

gate.—In the western parts of the Allegany mountains, and in the Tennessee and Illinois countries; perennial, flowering in August and September. Flowers like a *Helianthus*. Michaux, Pursh.

SECT. 2. *Leaves opposite.*

10. *V. pinnatifida*. Pinnatifid Yellow Verbefina. Cavan. Ic. v. 1. 67. t. 100. Willd. n. 8. Jacq. Hort. Schoenbr. v. 3. 30. t. 305.—Leaves opposite, pinnatifid, serrated. Stem winged.—Native of Mexico, flowering in the European stoves in December and January, but not yet known in the English collections. The stems are several, rather shrubby, with four, slightly wavy, membranous wings. Leaves about a foot long, tapering at the base. Inflorescence like *V. gigantea*, but the flowers are more numerous, yellow, with several conspicuous rays. Seed crowned with two bristles.

11. *V. Siegesbeckia*. Half-rayed Verbefina. Michaux Boreal.-Amer. v. 2. 134. Willd. n. 9. Ait. n. 4. Pursh n. 2. (*Siegesbeckia occidentalis*; Linn. Sp. Pl. 1269. *Phacelthusa americana*; Gært. v. 2. 425. t. 169. Pursh 561. *Chrysanthemum americanum*, caule alato, amplioribus foliis binatis, floribus e pallide lutescentibus parvis; Pluk. Mant. 46. t. 342.)—Leaves opposite, ovato-lanceolate, serrated, stalked; tapering at each end. Stem winged.—In shady woods, from Virginia to Carolina; perennial, flowering from July to September. A tall herbaceous plant, with four, or more, narrow, uninterrupted wings, running along the stem and branches. Leaves six inches long, undivided, bright green; roughish above; downy beneath; the upper ones sometimes three in a whorl. Panicle terminal, forked, downy, leafy. Radiant florets from one to three, near an inch long, ligulate, bright yellow. We have already (see *PIRÆTHUSA*) given reasons for the above synonyms. Pursh rightly suspected these two plants to be the same, but retained *Phacelthusa* out of deference to Michaux, who nevertheless has omitted it in his *Flora*.

12. *V. serrata*. Serrated Downy Verbefina. Cavan. Ic. v. 3. 7. t. 214. Willd. n. 10. Ait. n. 5.—Leaves opposite, stalked, ovato-lanceolate, with tooth-like serratures; downy beneath. Flowers corymbose.—Native of Mexico. We have a garden specimen from the original author. Mr. Lambert received seeds from him in 1803. The root is perennial. Stems three feet high, erect, round, clothed with white cottony down, especially when young. Footstalks short, combined by a dilated downy base. Leaves three inches long, strongly and unequally serrated; green, but rather silky, above; more hoary, and densely downy, beneath, copiously reticulated with veins. Flowers yellow, numerous, in a downy corymbose panicle. Outer calyx-leaves obovate, recurved. Rays four or five, broad, toothed. Seeds bordered, crowned with two short bristles.

13. *V. ceanothifolia*. Five-ribbed Verbefina. Willd. n. 11.—Leaves opposite, ovate, serrated, with five combined ribs; their under side downy. Flower-stalks racemose, panicked, axillary.—Native of the neighbourhood of Acapulco, in Mexico. The stem is round, erect. Leaves on short stalks, oblong-ovate, bluntly serrated, veiny, clothed on both sides with short scattered hairs; rough beneath. Flower-stalks long, from the bosoms of all the upper leaves. Akin to the following. *Willdenow*.

14. *V. biflora*. Twin-flowered Verbefina. Linn. Sp. Pl. 1272. Willd. n. 12. (“*Valliamanga-nari*”; Rheede Hort. Malab. v. 10. 79. t. 40.” *Willd.*)—Leaves opposite, stalked, ovate, serrated, with three combined ribs; their under side paler, scarcely downy. Flowers solitary or in pairs, on axillary and terminal stalks.—Native of the East Indies. The stem appears to be herbaceous, or slightly shrubby,

shrubby, with forked and subdivided, striated, nearly smooth, leafy branches. *Leaves* two inches or more in length, pointed, their three ribs united a little above the base; their upper side rough with minute depressed bristles; under smooth, or besprinkled with softer hairs. *Flower-stalks* long, either from the forks of the branches, or about their extremities, bearing one or two yellow *flowers*, an inch broad, almost always accompanied by a lanceolate leaf opposite to each partial stalk. Outer *calyx-scales* ovate, bristly. *Radiant florets* several, elliptical, toothed at the end. *Seeds* abrupt, triangular, destitute of a crown, or terminal bristles. The scales of the *receptacle* are obovate, concave, furrowed, abrupt, rough at the extremity, resembling the inner leaves of the *calyx*. Linnæus points out the affinity of this species to his *V. Lavenia*; but this regards their habit only, for *LAVENIA*, now a separate genus, (see that article,) has a naked *receptacle*, and three bristles to the *seed*.

15. *V. fativa*. Oil-feed Verbefina. Sims in Curt. Mag. t. 1017. Ait. n. 6.—Leaves opposite, oblong, clasping the stem, distantly serrated. Calyx simple, of five leaves.—Native of the East Indies; cultivated in the Mysore country, and several other parts of India, for the sake of the expressed oil from its seeds, which serves as a substitute for that of *Sesamum*. Dr. Roxburgh sent some of these seeds in 1805, to Mr. William Salisbury, the assiduous possessor of the botanic garden at Brompton. The plant is annual, either to be kept in the stove, or raised on a hot-bed, and then planted out, flowering in autumn. *Leaves* four inches or more in length, green, not hoary. *Flowers* yellow, two inches broad, with about eight large broad radiant *florets*, jagged or toothed at the end. These *flowers* stand on long simple stalks, from the forks of the stem, and bosoms of the upper leaves. The simple *calyx*, of five broad leaves, agrees with that of the next species; so that, as Dr. Sims observes, if one be reckoned a *Verbefina* the other must. We are not inclined to disturb them, because the whole genus, though in many respects very natural, still labours under some strange exceptions and anomalies, which ought all to be well considered by those who attempt a reform.

16. *V. calendulacea*. Marigold Verbefina. Linn. Sp. Pl. 1272. Willd. n. 13. Ait. n. 7. (*Caltha* flore solitario, ex alis foliorum longissimo pedunculo prodeunte; Burm. Zeyl. 52. t. 22. f. 1. "Pee Cajoni; Rheede Hort. Malab. v. 10. 83. t. 42.")—Leaves opposite, oblong-lanceolate, very remotely serrated, sessile; tapering at the base. Calyx simple, of five leaves.—Native of Ceylon, and other parts of the East Indies; cultivated by Miller. An annual stove-plant, flowering from July to September. The *stem* is branched, clothed, as well as the *leaves*, with rigid depressed bristles. The upper surface of the latter is, besides, usually rough with callous tubercles: their length and shape are variable, and their marginal serratures are few and remote. *Flowers* yellow, not half the size of this last, on long, simple, mostly axillary, stalks. Radiant *florets* from five to eight or ten, elliptical, toothed. *Seeds* very numerous, composing a globular head, wedge-shaped, abrupt, each crowned with two short bristles.

17. *V. nodiflora*. Sessile-flowered Verbefina. Linn. Sp. Pl. 1271. Willd. n. 14. Ait. n. 8. (*Bidens nodiflora*, folio tetrahit; Dill. Elth. 53. t. 45. *Chrysanthemum conyzoides nodiflorum*, semine rostrato bidente; Sloane Jam. v. 1. 262. t. 154. *Synedrella nodiflora*; Gærtn. v. 2. 456. t. 171.)—Leaves opposite, ovate, serrated, with three combined ribs; tapering at the base. Flowers axillary, nearly sessile.—Native of the West Indies. Cultivated early

at Chelsea, and in Sherard's garden, being a tender annual, raised and kept in the stove, for the sake of curiosity, but having nothing to recommend it to popular notice. The *stem* is erect, a foot high, branched from the base. *Leaves* two or three inches long, broadly ovate, tapering suddenly into a winged *footstalk*. *Flowers* solitary, or in pairs, small, yellow, with several emarginate rays. *Calyx* certainly of two very different rows of scales, though the outermost consists of but two leafy ones. *Seed* crowned with two rigid awns.

18. *V. dichotoma*. Forked Verbefina. Willd. n. 15. Ait. n. 9. Murray in Comm. Goett. for 1779. 15. t. 4.—"Leaves opposite, ovate, pointed, serrated, hairy, with three combined ribs. Stalks axillary, single-flowered. Stem forked."—Native of the East Indies. Annual. Whole *herb* beset with copious, short, white hairs. We have seen no specimen.

19. *V. fruticosa*. Shrubby West Indian Verbefina. Linn. Sp. Pl. 1271. Willd. n. 16. Ait. n. 10. (*Bidens frutescens*, ilicis folio, flore luteo; Plum. Ic. 42. t. 52.)—Leaves opposite, stalked, ovate, serrated, rough, with three combined ribs. Stalks single-flowered, axillary. Stem shrubby.—Native of the West Indies. We have a specimen from Dr. Swartz, though this species is not mentioned either in his *Prodromus* or *Flora*. The *stem* is woody, repeatedly branched and forked. The *leaves* appear to vary in hairiness, as well as size, but are always rough with minute tubercles. *Flowers* yellow, with numerous broad rays. *Seed* compressed, crowned with two bristles.

VERBESINA, in *Gardening*, affords plants of the herbaceous and woody flowering exotic kinds, among which the species cultivated are, the wing-stalked verbefina (*V. alata*); the Chinese verbefina (*V. chinensis*); the sessile-flowered verbefina (*V. nodiflora*); the shrubby verbefina (*V. fruticosa*); and the tree verbefina (*V. gigantea*).

The first is an herbaceous perennial plant, with the flowers in single heads, of a deep orange-colour, appearing most part of the summer.

The second is a shrubby plant with yellow flowers.

The fourth rises with a shrubby stalk seven or eight feet high, and has yellow flowers.

Method of Culture.—These plants may be increased by sowing the seeds upon a moderate hot-bed, or in pots plunged into it, in the early spring months; and when the plants are of sufficient growth, they should be removed into separate pots, or into a new hot-bed, giving shade till they become new-rooted; afterwards managing them as tender annual plants, being careful not to draw them up weak: about the middle of summer they may be taken up with balls to their roots, and be planted in a warm sheltered border, being protected and watered till re-rooted, little care being afterwards necessary: these produce seeds often in the autumn; but in the stove they may frequently be preserved over the winter.

They produce variety in stove and greenhouse collections, and sometimes in the borders during the summer season, especially the first sort by its orange flowers.

VERBIAGE, in *Grammar* and *Rhetoric*. See VERBOSITY.

VERBICÆ, in *Ancient Geography*, a people of Africa, in Mauritania Tingitana.

VERBIEST, FERDINAND, in *Biography*, a celebrated missionary, was born in Flanders, and attained distinction as a mathematician in China about the beginning of the 17th century. He was appointed by the emperor Cam-Hi president in the tribunal of mathematics, and entrusted with the care of the Calendar. He also obtained permission to

preach the Christian religion in China, and made many efforts for inducing the emperor to embrace the Christian faith; but though Verbiest succeeded in prevailing with him to acknowledge his belief in one God, he failed in his attempts to convert him to Christianity. Such, however, was the respect which the emperor entertained for this missionary, that on occasion of his death, in 1688, he composed an eulogy upon him, and ordered him to be interred with Christian honours. The principal work of Verbiest is entitled, "Astronomia Europæa, sub Imperatore Tartarico-Sinico Cam-Hi, ex umbra in lucem revocata a P. Ferdinando Verbiest, Flandro-Belga, e S. J. Academiæ Astronomicæ in Regia Pequimensi Præfecto;" Dilingæ, 1687, 4to. He also caused to be constructed, at the request of the emperor, a variety of astronomical instruments, and wrote sixteen volumes, in the Chinese language, on their construction and use. Verbiest contrived likewise to convey over a long bridge, by means of pulleys, several immense blocks of stone for building a mausoleum for the emperor, which, it is said, 500 horses could not have drawn, and extended an aqueduct several furlongs over a wide plain. He moreover cast upwards of 130 pieces of brass cannon for the use of the Chinese government, and calculated astronomical tables with eclipses of the sun and moon for 2000 years. *Monucla Hist. des Mathem. Gen. Biog.*

VERBINUM, in *Ancient Geography*, a town of Belgic Gaul, belonging to the Veromandui, upon the route from Bagacum Nerviorum to Durocortorum, between Buronum and Catuacum. *Anton. Itin.*

VERBO, in *Geography*, a town of Hungary; 16 miles N.W. of Leopoldstadt.

VERBOSANIA, a town of European Turkey, in Bosnia; 15 miles W.N.W. of Bosnaferai.

VERBOSITY, in *Rhetoric*, an offence against energetic and vivid brevity or conciseness in writing. This differs from pleonasm; as in the latter, words are used which make no addition to the sense, whereas in the verbose manner, not only single words, but whole clauses, may have a meaning; but it would be better to omit them, because their meaning is unimportant; and therefore, instead of enlivening the expression, they make it languish. Another difference is, that in a proper pleonasm, a complete correction is always made by expunging; but this will not always answer the purpose in the verbose style, as it is often necessary to alter as well as to raise. Moreover, verbosity does not mean the same thing which the French express by the term "verbiage," which is commonly understood to denote a parade of fine words, plausibly strung together, so as either to conceal a total want of meaning, or to disguise something weak and inconclusive in the reasoning. The former, or verbosity, is merely an offence against vivacity; but the latter is more properly a transgression of the laws of perspicuity. One instance of a faulty exuberance of words is the immoderate use of circumlocution. In some circumstances circumlocution is a beauty, in others it is a blemish. It is often used for the sake of variety; sometimes for the sake of decency: at other times, propriety requires the use of circumlocution, as when Milton says of Satan, who had been thrown down headlong into hell,

"Nine times the space that measures day and night
To mortal man, he with his horrid crew
Lay vanquish'd rolling in the fiery gulf."

In this case, "nine days and nights" would not have been proper, when speaking of a period before the creation of the sun, and consequently before time was portioned out to any being in that manner. Sometimes even the vivacity of

the expression may be augmented by a periphrasis, as when it is made to supply the place of a separate sentence. An instance to this purpose occurs in the words of Abraham, (Gen. xviii. 25.) "Shall not the *judge of all the earth* do right?" This circumlocution for God serves as an argument in support of the sentiment, and conduces more to conciseness. Such also is the periphrasis employed by Cicero, who, instead of saying simply, Milo's domestics killed Clodius, says, "they did that which every master would wish his servants to do in such an exigence."

Another source of languor in the style is the insertion of such clauses, as to a superficial view appear to suggest something which heightens, but on reflection are found to presuppose something which abates the vigour of the sentiment. Such is the following sentence from Swift: "Neither is any condition of life more honourable in the sight of God than another, otherwise he would be a respecter of persons, *which he assures us he is not.*" The last clause enervates the thought, as it too plainly implies, that without this assurance from God himself, we should naturally conclude him to be of a character very different from that here given him by the preacher. Akin to this is the juvenile method of loading every proposition with asseverations. Such a practice in conversation tends to suggest a suspicion of the speaker's veracity, rather than to engage the belief of the hearer; and it has a somewhat similar effect in writing. Thus in our translation of Gen. ii. 17. God is represented as saying to Adam, concerning the fruit of the tree of knowledge, "In the day thou eatest thereof, thou shalt *surely* die." The adverb *surely*, instead of enforcing, enfeebles the denunciation. Another example, somewhat similar, is the manner in which our interpreters have attempted, in the New Testament, to strengthen the negative, wherever the double negative ($\epsilon\ \mu\eta$) occurs in the Greek, even in the most authoritative threatenings, by rendering it sometimes *in no case*, sometimes *in no wise*; neither of which phrases expresses more than the single adverb *not*; and as they partake of the nature of circumlocution, they in effect debilitate the expression. Another cause of a languid verbosity is the loading of the style with epithets. Epithets used sparingly, and with judgment, serve to enliven the expression; but a profusion of them has an opposite tendency. Besides, they lengthen the sentence, without adding proportionable strength. We may also add, that the crowding of epithets into a discourse betrays a violent effort to say something extraordinary; and nothing is a clearer evidence of weakness than such an effort, without a correspondent effect.

There is, however, one kind of composition, the paraphrase, of the style of which verbosity is the proper character; because it is the professed design of the paraphrast to say in many words what his text expresses in few. Another species of verbosity is a prolixity in narration, arising from the mention of unnecessary circumstances. *Campbell's Philosophy of Rhetoric*, vol. ii.

VERBOVETZ, in *Geography*, a town of Croatia, at the conflux of the Csernets and Glocovia; 7 miles N.E. of Ivanitz.

VERBRO AA, a river of Denmark, in North Jutland, which runs into the sea, 6 miles W.N.W. of Hioring.

VERBROECK, a town of Flanders; 8 miles E.S.E. of Hulst.

VERCEL, a town of France, in the department of the Doubs; 11 miles N.E. of Ornans.

VERCELLÆ, in *Ancient Geography*, a town of Italy, in Gallia Transpadana, and the capital of the people called Sessites. It had within its territory a temple and a wood consecrated

consecrated to Apollo. Here the Cimbri were defeated by the Romans, under Marius and Catullus. After the decline of the Roman empire, it became a republic, and from that state it fell under the dukes of Milan; and, lastly, it was given as a marriage portion to Amadeus III., duke of Savoy. See VERCELLI.

VERCELLI, or VERCEIL, in *Geography*, a town of Piedmont, and, under the French dynasty, the capital of the department of *Sesia*; which see. It is situated at the junction of the Cerva with the Sesia, and was anciently called Vercellæ. It is the see of a bishop, suffragan of the archbishop of Milan. There are two churches which are called cathedral, and twelve others, two abbeys, nineteen convents of both sexes, three provostships, two priories, three poor-houses, and five hospitals; the inhabitants are about 20,000. In 1800, the French took Vercelli from the Austrians, with considerable stores; 30 miles S.W. of Milan. N. lat. 45° 22'. E. long. 8° 26'.

VERCHATURSKY GORY, mountains which divide European and Asiatic Russia, extending almost north and south to a great length, and about 40 miles in breadth. They are covered with wood, firs, larch, birch, &c.

VERCHEN, a town of Anterior Pomerania; 6 miles S.W. of Demmin.

VERCHES, LES, a town of France, in the department of the Mayne and Loire; 10 miles S.W. of Saumur.

VERCHIERE, a town of Canada, on the right bank of the St. Lawrence. N. lat. 45° 47'. W. long. 73° 9'.

VERCHODVERSKOI, a town of Russia, in the government of Viatka; 40 miles N. of Viatka.

VERCHOIANSKOI, an ostrog of Russia, in the government of Irkutsk, on the Yana. N. lat. 65° 40'. E. long. 130° 14'.

VERCHOKIZILSKOI, a fort of Russia, in the government of Upha, at the union of the Kizil and Ural; 40 miles S. of Verchouralsk.

VERCHOLENSK, a town of Russia, in the government of Irkutsk, on the Lena; 120 miles N. of Irkutsk. N. lat. 54°. E. long. 105° 34'.

VERCHOTOMSKOI, a town of Russia, in the government of Kolivan; 32 miles N.N.W. of Mungatzkoi.

VERCHOTURA, a town of Russia, in the province of Ekaterinburg, near the river Tura. This was the first town which the Russians built in Siberia. It has four churches and two convents, besides chapels; and is the see of a bishop. Verchotura is situated on a rising ground, and fortified with palisades and a ditch, and defended by a garrison under a commandant. The adjacent country is inhabited by a people called Vogulitz, who live on fruits in huts among the woods, employing themselves in hunting and shooting, without agriculture. In the beginning of the 18th century, they were many of them converted to Christianity, and now mix probably with the rest of the people; 120 miles N. of Ekaterinburg. N. lat. 58° 45'. E. long. 60° 14'.

VERCHOVAGSKOI, a town of Russia, in the government of Vologda, on the Vaga; 48 miles S. of Vielk.

VERCHOURALSK, a town of Russia, in the government of Upha, on the Ural; 120 miles S.E. of Upha. N. lat. 53° 36'. E. long. 59° 14'.

VERD, or VERDE, *Cape*, a cape on the west coast of Africa. N. lat. 14° 48'. W. long. 17° 31'.

VERD, or *Verde Islands, Cape*, islands of Africa, in the Atlantic, deriving their name from the cape opposite to which they are situated, and discovered by the Portuguese in 1446. They are so called, as some say, from a green plant, called Sargosso, resembling water-cresses, and bearing fruit

like a gooseberry, which is found floating near them, and in such abundance as to impede the progress of vessels in their course. They are usually reckoned ten in number, and including rocks, they amount to fourteen. The two largest are St. Jago or Yago in the south-east and St. Anthony in the north-west. Four of these islands are situated towards the east, *viz.* Santiago, Mayo, Bonavista, and Salt isle; four towards the north-west, *viz.* St. Nicholas, St. Lucia, St. Vincent, and St. Anthony; and two are somewhat detached towards the south, *viz.* Brava and Fuego. (See each island respectively.) These islands are generally mountainous; some of them are barren and uninhabited; others are productive of rice, bananas, oranges, cotton, and sugar; and it is said the goats produce thrice a year, and the vines twice; they abound with poultry and rabbits, and turtles are plentiful on the shores. The air is hot and insalubrious, rain being very rare; but a north-east breeze commonly rises before four in the afternoon. The manufacture of leather and salt constitute the chief riches. Many of them have been furnished by their proprietors with cows, goats, hogs, asses, mules, &c. These islands are situate about 390 miles W. of Cape Verd, and between 15° and 18° of N. lat.

VERDACHELON, a town of Hindoostan, in the Carnatic; 20 miles S.W. of Trivady.

VERDAPETTY, a town of Hindoostan, in the province of Madura; 22 miles S. of Madura.

VERDE, CAPE, a mountainous cape on the coast of Peru. S. lat. 6° 20'.—Also, a cape on the coast of Genoa. N. lat. 43° 50'. E. long. 7° 50'.

VERDE, or *Green Island*, an island on the north coast of South America, at the mouth of the river S. Marth.

VERDE Island, or *Verde Key*, one of the small Bahamas. N. lat. 22° 54'. W. long. 75° 26'.

VERDEGREASE, VERDIGREASE, *Verdegris*, or *Verdigris*, a kind of rust of copper, formed from the corrosion of copper by a fermented vegetable, and into a blueish-green substance, of great use among painters for a green colour.

The word is formed from the Latin, *viride aris*: it is also called *arugo*. Others call it the *flower*, and others the *vitriolic salt of copper*; though, in reality, it is rather the proper substance of the metal.

The greatest quantities of verdigris have been manufactured at Montpellier, the wines of Languedoc being very proper for this preparation; and it has been exported thence in cakes, each weighing about twenty-five pounds. The following process for making it is described by M. Monet, of the Royal Society of Montpellier, and is published in the Memoirs of the Academy for the years 1750, and 1753. Vine-stalks, well dried in the sun, are steeped during eight days in strong wine, and afterwards drained. They are then put into earthen pots, and wine is poured upon them; the pots are carefully covered; the wine undergoes the acetous fermentation, which in summer is finished in seven or eight days, but requires longer time in winter, although the operation is always performed in cellars. When the fermentation is sufficiently advanced, which may be known by observing the inner surface of the lids of the pots, which during the process of the fermentation is continually wetted by the moisture of the rising vapours, the stalks are then to be taken out of the pots: these stalks are by this method impregnated with the acid of the wine, and the remaining liquor is but a very weak vinegar. The stalks are to be drained during some time in baskets, and layers of them are to be put into earthen pots with plates of Swedish copper, so disposed, that each plate shall rest upon and be covered with layers of stalks. The pots are to be covered with lids.

and the copper is thus exposed to the action of the vinegar, during three or four days, or more; in which time the plates become covered with verdigris. The plates are then to be taken out of the pots, and left in the cellar three or four days; at the end of which time they are to be moistened with water, or with the weak vinegar above-mentioned, and left to dry. When this moistening and drying of the plates have been thrice repeated, the verdigris will be found to have considerably increased in quantity, and it may be then scraped off for sale.

A solution or erosion of copper, and consequently a verdigris, may be prepared by employing ordinary vinegar instead of wine, as directed in the above process. But it will not have the unctuousity of ordinary verdigris, which is necessary in painting. Good verdigris must be prepared by means of a vinous acid or solvent, half acid and half spirituous. Accordingly, the success of the operation depends chiefly on the degree of fermentation to which the wine employed has been carried; for this fermentation must not have been so far advanced, that no sensibly vinous or spirituous part remained in the liquor. Macquer's Dict. Chem. See the process as described by Chaptal, under the article COPPER.

The Society of Arts, &c. offered a premium in 1756 for the making of verdigris in England; and in 1760 intimated, that it might be made by moistening with the cheapest and worst sort of cyder, the marc or remains of apples, pears, gooseberries, currants, sloes, crabs, blackberries, or any fruits deprived of their juice by expression, proceeding afterwards by the process above described. The premiums offered by the Society were several times claimed and allowed; and it was resolved, in 1763, that verdigris actually made of British materials, and submitted to various trials, was even superior to the foreign. Accordingly, a considerable manufactory was established, and successfully carried on for the purpose of making verdigris.

The goodness of verdigris is judged of from the deepness and brightness of its colour, its dryness, and its forming, when rubbed on the hand with a little water or saliva, smooth paste, free from grittiness. This concrete is partially dissoluble in water and rectified spirit, and almost totally in vinegar; from the acetous solution, well saturated, and left to exhale slowly in a warm air, the greatest part of the verdigris may be recovered in a crystalline form, called *distilled verdigris*. See CRYSTALS of Venus, and COPPER.

The crystals, distilled with a suitable fire, in a retort or other like vessel, give over the acetous acid in a highly concentrated state, but somewhat altered by the process. See ACETIC Acid.

The matter which distilled vinegar leaves undissolved, on being mixed with some borax and linseed oil, and fluxed in a crucible, yields a brittle metallic substance, of a whitish colour, not unlike bell-metal. Neum. Chem. by Lewis, p. 64, n. a.

Verdigris is employed externally for detaching foul ulcers, and as an escharotic; but it is seldom used, though milder than the sulphate or blue vitriol. It is employed as a collyrium in chronic ophthalmia. Hoffman recommends it particularly for destroying the callosities of old fistulæ; tents of powdered verdigris, made up with saliva, or other liquids, not fat or oily, consume, he says, the hardest callus in three or four days, so as to render it completely separable. A detergent ointment, called *mel ægyptiacum*, is prepared by boiling five parts of verdigris in fine powder with sixteen of honey, and seven of vinegar, till reduced to a clear consistence. The thinner matter which floats on the top of

this mixture, after standing for some time, is generally used, unless it be required more acid; in which case, the thick part which has subsided is shook up among it.

In the Edinburgh dispensatory, an ointment, called *unguentum ex æruginè*, has been directed, composed of white wax and resin, each two ounces, olive oil one pint, and verdigris half an ounce. When these kinds of applications are employed for venereal or other ulcerations in the mouth or tonsils, great caution is necessary, lest they should pass into the stomach; in which case, dangerous and even fatal consequences may ensue.

Verdigris is rarely or never given internally. It has been reckoned tonic, and administered with this view in a dose under gr. fs. Some recommend it, in the dose of a grain or two, as an emetic, which produces almost instantaneous effect, where poisonous substances have been taken, for the immediate rejection of them. But warm water, milk, and oils, are much less dangerous, and more proper. In too large doses, it quickly proves fatal; and, on dissection, the coats of the stomach appear much thickened, and of a green colour. Lewis's Mat. Med.

M. Navier has lately evinced the salutary effects of liver of sulphur, and particularly of liver of sulphur of Mars, as an antidote against the poison of verdigris.

Verdigris makes a blue-green colour in paint; but is generally used in yellow, which, by a proper mixture, renders it a true green. It is bright when good; but soon flies, when used in oil. When dissolved in vinegar, it is used in water painting, and is more durable; it may be also dissolved in the juice of rue, and thus produces a fine full green colour, equally fit for washing with that dissolved in vinegar.

Verdigris, with a decoction of logwood, strikes a deep black, which, when diluted, becomes a fine blue. See DYEING.

VERDELLO, in *Natural History*, the name of a green marble used in Italy as a touchstone, for the trying of gold, &c.

VERDEN, in *Geography*, a town of Germany, and capital of a principality of the same name, on the Aller, which divides itself here into two branches, the smaller of which lies near the town, and is at present only frequented by the ships going up and down the Aller. In the town are four churches, and a Latin school; 56 miles S.S.W. of Hamburgh. N. lat. 52° 58'. E. long. 9° 15'.

VERDEN, a principality of Germany, bounded on the north and west by the duchy of Bremen, and on the east and south by the duchy of Lunenburg; about twenty-four miles in length, and nearly as much in breadth. This principality consists for the most part of heath and dry land, as also of forests; but on the rivers Weser and Aller is good marsh-land. The Aller waters almost all the southerly, but the Weser a part only of the westerly boundaries of the country. Verden was formerly a bishopric, founded by Charlemagne. At the peace of Westphalia, in the year 1648, the crown of Sweden obtained the bishopric as a duchy. In 1712, the Danes invading the duchy of Bremen, the inhabitants of Brunswick-Lunenburg possessed themselves of it. In 1715, by virtue of the alliance concluded at Wismar, it was ceded, together with Bremen, by the king of Denmark, to the electoral house of Brunswick-Lunenburg; such cession being also made again, in the year 1719, by the crown of Sweden. This duchy has the same regency with the duchy of Bremen. The inhabitants are Lutherans.

VERDERER, or VERDERON, formed from *viridarius*, which Ulpian used in the like signification, a judicial officer

officer of the king's forest, whose business is to look to the vert, and see it well maintained.

He is sworn to keep the affizes of the forest; as also to view, receive, and enrol, the attachments and presentments of all manner of trespasses, relating to vert and venison therein.

VERDERONNE, or LA BOURLARDERIE, in *Geography*, a small island in the gulf of St. Laurence, near the east coast of Cape Breton.

VERDESE, a town of the island of Corsica, in the district of Cervionne.

VERDETER. See VERDITER.

VERDETUM, the name of a green substance, used as a colour in painting. It is a very pure kind of verdigris, being an ærugo of copper, produced by the vapour of vinegar.

VERDI, in *Geography*, a small island in the Indian sea, near the west coast of Madagascar. S. lat. 14° 35'. E. long. 47° 50'.

VERDICT, from *vere dictum*, q. d. *dictum veritatis*, the *dictate of truth*, is the answer of the jury given to the court, concerning the matter of fact, in any cause, civil or criminal, committed by the court to their trial and examination. See JURY.

A verdict is either *privy* or *public*: a *privy* verdict is when the judge hath left or adjourned the court; and the jury, being agreed, in order to be delivered from their confinement, obtain leave to give their verdict privily to the judge out of court; which is of no force, unless afterwards affirmed by a public verdict given openly in court, in which the jury may, if they please, vary from their privy verdict. If, indeed, the judge hath adjourned the court to his own lodgings, and there receives the verdict, it is a public and not a privy verdict. In a criminal case, no privy verdict is allowed.

But the only effectual and legal verdict is the *public* verdict; in which they openly declare to have found the issue for the plaintiff, or for the defendant; and if for the plaintiff, they assess the damages also sustained by the plaintiff, in consequence of the injury upon which the action is brought. This is either *general* or *special*.

VERDICT, *General*, is that which is brought into the court, in like general terms as the general issue: as in action of disseisin, the defendant pleads, *no wrong, no disseisin*. Then the issue is general, whether the fact be wrong, or not: which being committed to the jury, they, upon consideration of the evidence, come in and say, either for the plaintiff, *That it is a wrong disseisin*; or for the defendant, *That it is no wrong, no disseisin*: and in criminal cases, *Guilty*, or *Not guilty*.

VERDICT, *Special*, is when they say at large, that such and such a thing they found to be done by the defendant, or tenant; declaring the course of the fact, as in their opinion it is proved; and as to the law, upon the fact, praying the judgment of the court.

The special verdict, if it contains any ample declaration of the cause from the beginning to the end, is called a *verdict at large*. This is grounded on the stat. Westm. II. 13 Edw. I. cap. 30. in order to avoid the danger of an *attaint*; which see. After stating the facts, they conclude conditionally, that if upon the whole matter the court shall be of opinion that the plaintiff had cause of action, they then find for the plaintiff; if otherwise, then for the defendant. This is entered at length on the record, and afterwards argued and determined in the court at Westminster, from whence the issue came to be tried. Another method of finding a special verdict is when the jury find a verdict

generally for the plaintiff, but subject, nevertheless, to the opinion of the judge, or the court above, on a *special* case. This is attended with much less expence, and obtains a speedier decision than the other. But as nothing appears upon the record but the general verdict, the parties are precluded hereby from the benefit of a writ of error, if dissatisfied with the judgment of the court or judge upon the point of law. Blackst. Com. book iii. See JURY.

VERDICT, *Attainder* by. See ATTAINDER.

VERDICT, *Falfe*. See ATTAINT.

VERDIER, ANTONY DU, in *Biography*, lord of Vauprivas, was born at Montbrison in Forez in the year 1544, and distinguished himself not only by his writings, but by encouraging literature, for which purpose he granted to men of letters the use of his well-furnished library. He was advanced to the office of historiographer of France, and having occupied the rank of gentleman in ordinary to the king, died in the year 1600. Of his numerous writings, the only work that has been noticed by posterity is his "Bibliotheque des Auteurs François." It was first printed at Lyons in 1585, fol. and again published, under the title of "Bibliotheque de la Croix du Maine," by De Juvigni at Paris, in 5 vols. 4to. 1772-3, with notes and corrections.

VERDIER, CLAUDE DU, the son of Antony, though a man of learning, gained little reputation by his Latin and French publications. Having mismanaged a good estate transmitted to him from his father, he passed the latter part of his life in obscurity, and died in 1649, aged above 80. Moreri.

VERDISTAN, CAPE, in *Geography*. (See Cape BAR-DISTAN.) This cape is a land-mark which ships generally look out for in their passage up the Persian gulf. There is a dangerous shoal, which extends a considerable way to sea, and those are fortunate who pass by this place without meeting with a gale of wind. Here they manufacture an excellent kind of cloth, which is much worn by the Arabs. On this coast lies Congon or Kungoon, a large and populous town, which carries on a considerable trade with the gulf, and also with the inland country. The Portuguese had once a considerable settlement here. Between this and Tahire or Tahirea there is another town of some note, called Toombuch, and also the villages of Shilee (Sheeloo), Burg, and Ynat.

VERDITER, VERDETER, a kind of mineral substance sometimes used by the painters, &c. for a blue, but more usually mixed with a yellow for a green colour. See TERRE-VERTE.

Verditer, according to Savary, ought to be made of the lapis Armenus; or, at least, of an earthy substance much like it, brought from the mountains of Hungary, &c. only prepared by powdering it, and cleansing it by lotion.

But this stone and earth are very rare; and the verditer used is not a native, but a factitious substance, or blue pigment, obtained by adding chalk or whiting to the solution of copper in aquafortis. (See COPPER.) It is prepared by refiners of silver, who employ for this purpose the solution of copper, which they obtain in the process of parting, by precipitating silver from aquafortis with plates of copper. It is said, that a fine-coloured verditer cannot be obtained from a solution of copper prepared by dissolving directly that metal in aquafortis; and that the silver is necessary. According to Dr. Merret's account of the method of preparing it, a quantity of whiting is put into a tub, the copper solution poured on it, and the mixture stirred every day for some hours together, till the liquor loses its colour. The liquor is then poured off, and more of the solution

of copper added; and this is to be repeated till the matter appears of the proper colour; after which it is spread on large pieces of chalk, and laid in the sun to dry. Boyle observes, that the process often miscarried, and that heating the liquor, before it is poured on the whiting, has been found to contribute to its success. It is still, however, Dr. Lewis says, very apt to fail in the hands of the most skilful workmen; the preparation, instead of a fine blue, turning out of a dirty green.

From the liquor poured off in making verditer, Mr. Boyle says (*Works Abr.* vol. i. p. 169.), that the refiners obtain, by boiling, a kind of saltpetre, fit with the addition of vitriol to yield them a new aquafortis. Some have said that a deeper and brighter kind of verditer may be made by using a filtered solution of pearl-ashes instead of the chalk, in the above process.

Verditer, when good, is a cool full blue, but without the least transparency either in oil or water. In oil it is subject to turn greenish, and sometimes black; and in water it is not always found to hold. It is chiefly used for paper-hangings and coarse work, and in varnish.

VERDON, or FORDON, in *Geography*, a town of Prussian Pomerelia; 60 miles S. of Dantzic.

VERDON, a river of France, which runs into the Durance, at Pertuis, in the department of the Mouths of the Rhône.

VERDONE, in *Ichthyology*, the name of a fish of the turdus or wrasse kind, called by some authors *turdus viridis minor*. See TURDUS and LABRUS.

It is of a fine green colour in all parts of its body; the back, sides, and belly, have all plainly the same colour; but in different degrees: the back being of the deepest dye; the belly has something of yellowness with the green, and the sides are variegated with lines of a fine blue. It has only one long fin on the back, which has thirty rays or ribs, the eighteen foremost of which are rigid and prickly, the others soft and flexible. It is caught in the Mediterranean, and sold in the markets in Italy. *Salvian de Aquat.* p. 88.

VERDOY, in *Heraldry*, is applied to a bordure of a coat of arms, charged with any kinds or parts of flowers, fruits, seeds, plants, &c. Of these there are eight in number.

VERDUN, in *Geography*, a town of France, and principal place of a district, in the department of the Meuse. Before the revolution the capital of a province, called *Verdunois*, and the see of a bishop, suffragan of Treves. It is large, populous, and consists of three parts, the Upper, Lower, and New Town. Exclusive of its fortifications, this place is farther defended by a fine citadel. The bishop, before the city and district were annexed to the crown of France, was a prince of the empire, and afterwards styled himself such, as also earl of Verdun. Exclusive of the cathedral in this city, are one collegiate and nine parish churches, six abbeys, and one college. Verdun was formerly an imperial city; 33 miles N.W. of Toul. N. lat. 49° 9'. E. long. 5° 27'.—Also, a town of Spain, in Aragon; 15 miles W. of Jaca.—Also, a town of France, in the department of the Aude; 6 miles N.E. of Castelnaudary.

VERDUN-*sur-Garonne*, a town of France, in the department of the Upper Garonne; 12 miles S.S.E. of Castel-Sarasin.

VERDUN-*sur-Saône*, a town of France, in the department of the Saône and Loire, situated at the conflux of the Saône and the Doubs; 9 miles N.E. of Châlons-*sur-Saône*. N. lat. 46° 54'. E. long. 5° 7'.

VERDURE, the quality of greenness. The word is French, formed of *verd*, green.

VERE, Sir FRANCIS, in *Biography*, an English officer in the reign of queen Elizabeth, was a descendant from a branch of the De Veres, earls of Oxford, and born in 1554. Being sent with a body of troops, under the command of the earl of Leicester, to the assistance of the United Provinces in 1585, he distinguished himself first in the defence of Sluys, and in 1588 at Bergen-op-Zoom by resisting the arms of the duke of Parma. For his services on this occasion he obtained the honour of knighthood, and was employed on many subsequent occasions, in which he gained signal reputation, inasmuch that he was at length entrusted with the command of the English forces serving with the States. When these forces were withdrawn in the year 1592, Sir F. Vere was chosen representative for the borough of Leominster. In 1596 he successfully executed a commission with which he was entrusted to the States, and on his return obtained the command of a ship, with the rank of vice-admiral. In the expedition against Cadiz, he acquitted himself with skill and courage, and was principally instrumental in the capture of the town. On his return from an expedition with the earl of Essex to the Azores, he was appointed governor of Brill, one of the towns assigned to queen Elizabeth as security for money advanced to the States. At the battle of Nieuport, in 1600, his conduct, and the valour of the English whom he commanded, contributed very essentially to the success of the day, though the loss of lives was considerable, and Vere himself received a wound, which he concealed till victory was secured. The States, duly apprized of his merit, appointed him, in 1601, governor of Ostend, which was besieged by a powerful army under the command of archduke Albert. By means of artifices which some have thought incompatible with the character of a generous soldier, he prolonged the siege, and deferred a surrender by negotiation, till he obtained a reinforcement of troops, and then informed Albert that the treaty was at an end. The prince was indignant, nor were the States pleased with the fraud. This circumstance probably occasioned his resignation of the command at Ostend; but being solicited by the States to procure fresh supplies of men from his own country, he succeeded in obtaining them. His government of the Brill, which expired with the death of Elizabeth, was renewed by James I.; but his peace with Spain in 1604 terminated the occupation of military men. Sir Francis was also governor of Portsmouth, and remained at home till his death, in 1608, the 54th year of his age. A splendid monument was erected to his memory in Westminster Abbey by his widow. His exploits have been recorded by himself, in a work entitled "The Commentaries of Sir Francis Vere, being diverse Pieces of Service wherein he had Command, written by Himself in way of Commentary," published from his MSS. by William Dillingham, D.D. fol. Cambridge, 1657.

VERE, HORACE, baron of Tilbury, younger brother of the preceding, whom he accompanied in many of his actions in the Low Countries, and distinguished himself on several occasions. He succeeded his brother in the government of Brill, and held it till the year 1616, when it was restored to the States. Although he was entrusted, in 1620, by king James with a tardy and scanty aid to his son-in-law the king of Bohemia, he contributed for some time to preserve the Palatinate from being overrun by the Imperialists; and at last surrendered on honourable terms to Tilly at Manheim. On the accession of Charles I. he was the first peer created by the king, under the title of lord Vere of Tilbury. Retaining the post of general of the forces in

the service of the States-general, he was appointed master of the ordnance in 1629; but retired from public employment some short time before his death, which was occasioned in 1635, in the 70th year of his age, by an apoplectic fit. Lord Vere, no less skilful and brave than his brother as a commander, was of a milder and more modest temper. Biog. Brit.

VERE, in *Geography*, a river of England, in the county of Herts, which runs into the Coln, 2 miles S.E. of St. Albans.—Also, a county or parish on the south side of the island of Jamaica.

VERE, *Cape*, a cape on the W. coast of Calabria. N. lat. $39^{\circ} 20'$. E. long. $16^{\circ} 10'$.

VEREA, in *Botany*, for so it ought to be written, not *Vereia*, was thus named by Mr. Andrews, in compliment to James Vere, esq. F.L.S. of Kensington Gore, whose garden has long been celebrated among the richest, and best cultivated, in the neighbourhood of London.—Andr. Repof. t. 21. Willd. v. 2. 471.—We regret that this memorial of our amiable and liberal friend cannot be preserved. This supposed genus is merely a *Cotyledon*, with four-cleft octandrous flowers, of which several are known, (see *COTYLEDON*,) nor can they, on any sound principle, be separated therefrom.

The *Verea crenata* is *Cotyledon crenata*, Venten. Malmaif. t. 49. Ait. Hort. Kew. v. 3. 110. Leaves crossing each other in pairs, ovate, obtuse, crenate, fleshy. Flowers four-cleft, erect, in cymose panicles.—Native of Sierra Leone; kept in the dry stove or tan-bed, where it flowers in summer and autumn. The stem is shrubby. Leaves green, large and handsome, very juicy. Flowers an inch long, yellow, with a green tube and orange mouth.

VERELIUS, OLOF, in *Biography*, a Swedish antiquary and librarian in the academy of Upsal, was the son of a clergyman of East Gothland, where he was born in the year 1618. Having commenced his education in the gymnasium at Linköping, he pursued it for five years at the academy of Dorpt, and in 1638 removed to Upsal. Soon after he became tutor to some young Swedish gentlemen, whom he accompanied in their travels through various parts of Europe, and on his return in 1650, he was, by favour of the queen, appointed professor of eloquence at Dorpt in 1651, and in 1653 became treasurer to the academy of Upsal. In 1662 he was appointed professor of the antiquities of his native country, and in 1666 antiquary of the kingdom. He was in the same year nominated assessor in the college of antiquities, and died at Upsal in 1682. He was a good Latin scholar, and well skilled in Swedish antiquities, so that some of his countrymen honoured him with the appellation of “*Patris Eloquentiæ, et Filium Ariadnæum Antiquitatum Patriæ.*” He was a zealous advocate for the ancient origin of the Swedes, inasmuch as to contend that the Goths who took Rome issued from Sweden, and to assert, “that those who deny their antiquity ought to have their brains knocked out with Runic stones.” His dispute with professor Schæffer, concerning the former situation and name of the town and temple of Upsal, produced a number of publications. Among his other principal works are, “*Gothrici et Rolfi, Vestro-Gothiæ Regum, Historia lingua antiqua Gothica conscripta, quam è Manuscripto vetustissimo edidit, Versione et Notis illustravit.*” Upsal 1664, 8vo. and several publications relating to Gothic literature and Swedish history. Gen. Biog.

VERELLA, CAPE, in *Geography*, a cape on the E. coast of Cochinchina. N. lat. $12^{\circ} 55'$. E. long. $109^{\circ} 18'$.

VERELLA, *Cape, False*, a cape on the S.E. coast of Cochinchina. N. lat. $11^{\circ} 45'$. E. long. $109^{\circ} 4'$.

VERELST, SIMON, in *Biography*, was born at Antwerp

in 1604, and became an admirable painter of fruit and flowers. He came to England in the time of Charles II. and obtained very considerable practice; and not only in those matters for which his talents admirably qualified him, but also in portraits for which he was not qualified. His vanity was at least equal to his abilities as an artist, and having been employed and laughed at till he was 47 years of age, death then kindly removed him from any further opportunity of exposing himself.

VERERIA, in *Geography*, a town of Russia, in the government of Moscow; 56 miles W.S.W. of Moscow. N. lat. $55^{\circ} 18'$. E. long. $35^{\circ} 50'$.

VERES, a town of Russia, in the government of Archangel; 80 miles N.N.W. of Kola.

VERESMAN, a town of Hungary; 12 miles E. of Munkacz.

VERETUM, in *Ancient Geography*, a town of Italy, in Messapia, on the confines of the country of the Selentini, according to Strabo, who says that it was anciently called Baris.

VERFEIL, in *Geography*, a town of France, in the department of the Upper Garonne; 11 miles E.N.E. of Toulouse.

VERGA, CAPE, a cape on the W. coast of Africa. N. lat. $10^{\circ} 4'$. W. long. $13^{\circ} 40'$.

VERGADELLE, in *Ichthyology*, the name of a fish of the mullet kind, called by others the *chelon*, remarkable for the thickness of its lips.

VERGÆ, in *Ancient Geography*, a town of Italy, in Brutium.

VERGANTINAS, in *Geography*, a town of Spain, in Galicia; 20 miles S.W. of Corunna.

VERGARA, or VARGARA, a town of Spain, in Guipuscoa; 7 miles S. of Tolosa.

VERGAVILLE, a town of France, in the department of the Meurte; 4 miles N.W. of Dieuze.

VERGE, VIRGA, a rod, switch, or yard; particularly a stick or wand, which persons are admitted tenants by holding in their hand, and swearing fealty to the lord of the manor.

On this account, they are called *tenants by the verge*.

VERGE, among *Gardeners*, generally denotes the edge or outside of a border; but more particularly, is used for a slip of grass adjoining to gravel-walks, and dividing them from the borders in the parterre-garden.

VERGE, *Dented*. See DENTED.

VERGE is also used for the compass or extent of the king's court; within which is bounded the jurisdiction of the lord steward of the king's household.

It is thus called, from the verge or staff which the marshal bears. It was anciently denominated *pax regis*, or the king's peace.

The lord steward, by virtue of his office, without any commission, judges of all transgressions, as treasons, murders, felonies, bloodshed, &c. committed in the court, or within the verge of it; which extends, every way, by 13 Ric. II. stat. 1. cap. 3. (in affirmance of the common law) for twelve miles round the king's place of residence; only London, by charter, being exempted.

VERGE, *Court of*. See COURT.

VERGE of Land, *Virga Terre*. See YARD-Land.

VERGELLUS, in *Ancient Geography*, a torrent or river of Italy, in Apulia, near the place in which was fought the battle of Cannæ. This river was rendered famous by a bridge made here for the passage of the army.

VERGENNES, in *Geography*, a post-town of America, and one of the most flourishing commercial towns of Vermont,

mont, in Addison county, on Otter creek, about six miles from its mouth in lake Champlain. It contains a congregational church and a gaol, and 835 inhabitants. In its vicinity are several mills; 115 miles N. of Bennington, and 519 from Washington.

VERGENTUM, in *Ancient Geography*, a town of Spain, in Bœtica.

VERGER DE HAURANE, JOHN DU, abbot of St. Cyran, in *Biography*, was the descendant of a noble family, and born at Bayonne in 1581. After having enjoyed some inferior preferments he removed to Paris, and in 1620 became abbot of St. Cyran. He was distinguished as a zealous defender and propagator of Jansenism; and under this character gained a great number of partisans. But being suspected of holding several erroneous doctrines, and of contemning the authority of the church, he was denounced as a dangerous person to cardinal Richelieu, who caused him to be imprisoned at Vincennes in 1638, in which state of confinement he remained till the death of the cardinal; and soon after his liberation, he died at Paris in 1643, aged sixty-two. As a champion in the cause of the Jansenists against the Jesuits, the abbot wrote several works, which were evidences of his zeal and diligence rather than of his judgment and ability. Although these works were held at the time of their publication in high estimation, they are now forgotten, as well as the controversy that occasioned most of them; and it is therefore needless to enumerate them. Moreri.

VERGERIO, PIER-PAOLO, the elder, a reviver of literature, was born about the year 1349 at Justinopolis, now Capo d'Istria. Having studied at Padua and Florence, he passed some years in different towns of Italy, particularly at Padua, where he officiated as professor of dialectics; and he studied Greek at Venice, under the celebrated Emanuel Chrysoloras. At Padua he took the degree of doctor of laws in 1404, till which mature period of his life his condition bordered on that of indigence. From Padua, where he was attached to the interests of the princes of Carrara, he removed to Venice, and afterwards accompanied his friend Zabarella, when he became cardinal, to the council of Constance. Having lost this patron in 1417, he is said to have sunk into a state of mental derangement, and to have died in Hungary, about the time of the council of Basil, which commenced in 1431. His works caused him to be ranked among the most successful cultivators of literature at that period. His "History of the Princes of the House of Carrara, from its Origin to the Year 1355," composed in Latin that was deemed elegant in that age, has been published in Muratori's Collection of Italian Historians. His treatise "De ingenii Moribus et liberalibus Adolescentiæ studiis," addressed to one of the princes of Carrara, was very popular at the time of its publication. He also wrote "A Life of Petrarch," published in the "Petrarcha Redivivus" of Tommasini, and an eulogy of St. Jerom; and he left several manuscripts. Moreri.

VERGERIO, PIER-PAOLO, the younger, one of the few prelates converted from popery, belonging to the same family with the subject of the preceding article, was born about the beginning of the 16th century at Capo d'Istria; and having studied the law at Padua, and graduated, he became, in 1522, professor of the notary's art in that university. At Padua and at Venice he maintained the character of an able orator, as well as that of a man of good morals. The charges brought against him by an enemy, and particularly that of poisoning his wife, have been sufficiently refuted. From Venice, where he resided in 1530, he went to Rome, and being introduced to pope Clement VII., was sent by him as nuncio to Ferdinand, king of the Romans, pro-

bably about the close of the year 1532. On this occasion he used all his efforts in support of the papal see, and for the purpose of restraining the progress of Lutheranism. Paul III. recalled him from this embassy, but afterwards deputed him on the same mission, which gave him an opportunity of holding several conferences with Protestant princes, and of an interview with Luther himself at Wittenberg. In 1536 he was sent by the same pope to Charles V. in Naples, and for his services to the church he was made a bishop of his native city. From thence he returned to Germany, and was one of the commissioners who drew up the indictment of the council. At the close of the year 1540 he attended the conference at Worms, as a deputy from the king of France. However, before this time he was suspected by the court at Rome of a secret attachment to Lutheranism, but he still contrived to keep up appearances. Upon his subsequent retirement to his diocese, whilst, as it is said, he was preparing a confutation of the German Separatists, he became convinced that they were right; and having communicated his sentiments to his brother, bishop of Pola, he adopted the same opinions; and they both resolved to propagate them in their respective dioceses. The monks were alarmed, and reported them to the inquisition. Vergerio, after having in vain sought an asylum, determined in 1546 to justify himself before the council of Trent. The council referred his cause to the nuncio and patriarch of Venice. But the consideration of it being protracted to the year 1548, he was ordered not to return to his church; and he soon after withdrew to the country of the Grisons, where, as well as in the Valteline, he for some years exercised his ministry. His brother died before he left Italy. The younger Vergerio, having received an invitation to Tubingen from the duke of Wirtemberg, died there in 1565. His works, written in the Italian language, were numerous; and their principal object was to expose the impostures and absurdities of popery. Its advocates were of course much incensed, and circulated against the author many malignant, and probably unfounded, reports. Some Protestant writers have represented him as unsteady, and little acquainted with theological subjects. Bayle.

VERGERS, VIRGATORES, *Servientes*, are officers who carry white wands before the justices of either bench; called also, *porters of the verge*.

VERGERS of cathedral or collegiate Churches, are inferior officers, who go before the bishop, dean, &c. with a verge, or rod tipped with silver.

VERGES, in *Geography*, a town of Spain, in Catalonia; 10 miles E. of Gerona.

VERGIER, JAMES, in *Biography*, a French poet, was born at Lyons in 1657, and educated at Paris with a view to the ecclesiastical profession; but he soon laid aside the clerical habit and became a man of the world. He recommended himself to those whose society he frequented by his gaiety and polished manner, and in 1690 he obtained the post of secretary of marine, and afterwards that of president of the council of commerce at Dunkirk. But his love of pleasure, combined with indolence, prevented his acquiring the character of a man of business. His career of pleasure was terminated at Paris in 1720, by the pistol of a robber, at the age of 63. Rousseau characterises him as a *philosopher*, formed for society, without any mixture of gall or misanthropy, and extols the noble and elegant simplicity of his convivial songs, which entitles him to the appellation of the French Anacreon. In his other productions, such as odes, madrigals, sonnets, epigrams, tales, fables, epistles, &c. it is acknowledged that his style is negligent, and occasionally profane. "Vergier," says Voltaire, "is with regard

gard to La Fontaine, what Campiftron is with regard to Racine, a feeble but natural imitator." His poems were collected in 2 vols. 12mo. 1750. Moreri. Gen. Biog.

VERGILIA, MURCIA, in *Ancient Geography*, a town in the S.W. part of Hispania Citerior.

VERGILIÆ, a constellation, whose appearance denotes the approach of the spring.

According to the poets, the Vergiliæ were the daughters of Atlas; and by the Greeks, were called Pleiades: but the Romans named them Vergiliæ.

VERGILIO, POLYDORO, in *Biography*, an historian, was born at Urbino in the 15th century, and became first known to the learned by a Latin collection of proverbs, preceding that of Erasmus and the occasion of some bickering between them. It was first printed in 1498, and frequently republished. In the following year appeared his work "De Rerum Inventoribus," a very learned performance, but destitute of found criticism, and exhibiting many evidences of the credulity of the author. About the commencement of the following century, pope Alexander VI. deputed him on a commission to England, for the purpose of collecting the papal tribute called Peter-pence. As he was admired in this country for his learning and Latin style, he was promoted to the archdeaconry of Wells, and engaged by Henry VII. to write a history of England. This work was begun in 1505, and printed at Basil in 1548, with a dedication to Henry VIII. Enjoying in this country the preferments of prebend and archdeacon, he wished to continue it, notwithstanding the changes of religion that had occurred, and the cessation of his office as collector of a tax that no longer subsisted; more especially as he evinced himself, by his approbation of the marriage of the clergy and his condemnation of the worship of images, to be no strict Catholic. He had likewise introduced into his treatise "De Inventoribus," some passages which the Inquisition expunged, and reflected on the pride of the clergy, by suggesting that St. Peter would not suffer Cornelius the centurion to kiss his feet. He ventured, however, in 1550, being in advanced life, to return to his own country for the benefit of a warmer climate. His English benefices were continued till his death, which happened at Urbino about the year 1555. Of his history of England, contained in twenty-six books, and extending to the reign of Henry VIII. it is sufficient to observe, that its style is clear and elegant, but that the matter of it has been censured by various writers. Sir Henry Savile says, that as Polydore was an Italian, little acquainted with public business, possessing no great degree of genius or judgment, and for the most part taking falsehood instead of truth, he has left us a history full of errors, as well as poorly and jejune written. Our antiquaries also have severely treated him, on account of the contempt which he has expressed for the fables of Geoffrey of Monmouth, and other legendary narrations. He has been represented on the one hand as a columniator of our country and an enemy to its glory; whilst, on the other hand, the French and Scotch have accused him of partiality to England in those instances with regard to which their transactions have been blended with its history. Besides, it is said that he destroyed many MSS. with which he was intrusted, in order to prevent a detection of his errors; but Tiraboschi considers this as a tale which no man of sense can credit. By others it has been reported, that he sent off a whole ship-load of MSS. to Rome. Both these stories are destitute of proof. Polydore also published, in 1526, a book "De Prodigis," in which he strongly contends against the divinations of the ancients. Vossius. Tiraboschi. Nicolson's Hist. Lib. Gen. Biog.

VERGINE, in *Geography*, a mountain of Naples, in Lavora; 7 miles E. of Nola.

VERGIVIVS OCEANUS, in *Ancient Geography*, a name given by Ptolemy to that part of the sea which bathed the southern coast of Hibernia, and the western provinces of the isle of Albion. It is now called St. George's channel and the Irish sea.

VERGNE, LOUIS-ELIZABETH DE LA, Comte de Tressan, in *Biography*, a French miscellaneous writer, was born of a noble family at Mans in 1705. Introduced at Paris, when young, to an acquaintance with Fontenelle, Voltaire, and others, he imbibed a taste for polite literature. But devoted also to military service in common with other persons of his rank, he attended Louis XIV. in the campaigns of Flanders, on occasion of the war in 1741, and became his aid-de-camp at the battle of Fontenoy. Having risen to the rank of lieutenant-general, he withdrew upon the peace to the court of king Stanislaus at Luneville, which he contributed to adorn and enliven by his agreeable and sprightly talents. The king's Jesuit-confessor, dreading his influence, accused him of the crime of philosophy. When Stanislaus preferred this charge against him, he replied, "I request your majesty to recollect, that there were 3000 monks at the procession of the League, and not one philosopher." After the death of Stanislaus, the count lived in solitude, and employed himself as an author. In his youth he had penned some epigrams, which are thought to have prevented his obtaining admission into the French academy till his 75th year, an honour of which he was ambitious, and which gratified him much, though he did not long live to enjoy it; for he died of the gout, to which he had been much addicted, in the year 1782, at the age of 77. His love and talent for poetry were retained to the close of life. Several of his works, which were numerous, are romances, or compositions of that class, either original or altered from those of other authors. A posthumous work of different character is entitled "An Essay on the Electric Fluid, considered as an Universal Agent," in 2 vols. 8vo. A collection of his works was published in 1731, in 12 vols. 8vo. Nouv. Dict. Hist.

VERGOBRETS, a name given to magistrates in certain provinces of Gaul, who were like the archons of Athens, but only with an annual power.

VERGORAZ, in *Geography*, a town of Dalmatia, situated at the foot of some mountains which separate the dominions of Venice (now Italy) from those of the grand signior. It was formerly rich and flourishing, but is now a poor place; 20 miles E. of Narenta.

VERGUNNI, in *Ancient Geography*, a people of the Maritime Alps, S. of the Veamini.

VERGUTTUM, in *Geography*, a town of Hindooftan, in the circar of Cicacole; 20 miles N.N.W. of Cicacole.

VERGY, a town of France, in the department of the Côte d'Or; 10 miles S.S.W. of Dijon.

VERHEYEN, PHILIP, in *Biography*, an eminent anatomist and physician, was born in 1648 at Vesbrouck, in the country of Waes, and having been noticed by the rector of the parish, was instructed by him in the rudiments of Latin, and in his 24th year, sent to commence a course of classical education at Louvain. His diligence amply compensated for loss of time; and having assumed the clerical habit, he devoted himself to the study of theology. But his views were changed by an amputation of his leg, occasioned by an inflammation; and he substituted medical pursuits for those of divinity. These he followed at Louvain and Leyden, and taking his degrees at the former place, he there fixed his residence. In 1689 he was nominated professor of

anatomy in the university, to which was annexed that of surgery in 1693. His application was indefatigable, so that he attained to distinguished eminence, and attached to his school a great number of disciples. His celebrity was principally the result of a work, entitled "Anatomia Corporis Humani," published in 1693, frequently reprinted with corrections and additions, and enlarged in 1710 with a supplement, forming a second book. As a classical compendium of the science, it succeeded, for general use, that of Bartholine. Notwithstanding its imperfections and errors, it was entitled to the reputation which it acquired. Verheyen was also the author of a Compendium of the Theory and Practice of Medicine; of a Treatise on Fevers; and of the History of a miraculous Cure of a Jesuit by the Intercession of St. Francis Xavier, which latter work sufficiently evinces the superstitious credulity of the Netherland Catholics. Haller. Eloy.

VERIA, or BERIA, in *Geography*, a town of Spain, in Grenada, anciently Baria, near the coast of the Mediterranean; 16 miles E. of Motril.

VERIA, or *Cara Veria*, a town of European Turkey, in Macedonia; 48 miles W. of Salonichi. N. lat. $40^{\circ} 43'$. E. long. $21^{\circ} 58'$.

VERIFICATION, the act of proving, or making a thing appear true.

In the French law, *verifying* is used for the recording of the king's edicts and decrees by the parliament.

VERIFICATIONE RELICTA. See RELICTA.

VERIMUNGALUM, in *Geography*, a town of Hindoo-stan, in the province of Tinevelly; 20 miles S.S.E. of Palamcotta.

VERIN, a town of Spain, in Galicia; 20 miles S.E. of Orense.

VERISA, in *Ancient Geography*, a town of Asia, in the Lesser Armenia; situated on the route from Tavia to Sebasta, between Sebastapolis and Phiarasis. Anton. Itin.

VERISIMILITUDE. See PROBABILITY.

VERITH, in *Ichthyology*, a name given by Ifidore to the fish commonly called by authors *thrissa*; by us, the *shad*, or the mother of the herrings.

VERJUICE, a juice or liquor drawn from four grapes, or wild apples, unfit for wine, or cyder; or from sweet ones, while yet acid, or unripe.

Its chief use is in sauces, ragouts, &c. though it is also an ingredient in some medicinal compositions; and is used by the wax-chandlers to purify their wax. It is also very useful for forming poultices with, which are used in the swellings of animals, or for bathing the bruised and other parts of them with in different cases.

It has its name from a large sort of grape, called *verjus*, or *bourdela*; which is said never to grow perfectly ripe; or rather, which in its utmost maturity is too austere and sour to be used in wine; whence it is commonly turned into verjuice; though in France all unripe grapes are denominated *verjus*.

There is also tolerable verjuice made of crabs, gathered, and laid in an heap to sweat, the stalks, &c. separated; they are then stamped, or ground, and the crab mash put in a hair bag; the juice squeezed in a press, then barrelled up close, and set in a warm place to work for ten or twelve days.

Verjuice made for sale shall pay the same duty as cyder or perry.

VERIXA, in *Geography*, a town of Asiatic Turkey, in the government of Mosul; 15 miles N.W. of Naufa.

VERKENS VISCH, in *Ichthyology*, the Dutch name of a fish caught in the East Indies. It is about seven inches long, of a blackish-green colour, with fins and tail wholly black, and with yellow irises to the eyes. It is caught in fresh waters in the East Indies, and is a very delicate fish. It is very nearly related to the capriscus, or goat-fish, if not the same species.

VERLUCIO, in *Ancient Geography*, a place of Britain, in the fourteenth route of Antonine, between Aquæ Solis or Bath, and Cunelio or Marlborough. It is placed by Dr. Gale at Westbury, and by Dr. Stukeley at Hedington; but Mr. Horsley, following the route of the military way from Bath to Marlborough, and the distances from both these places, thinks it more probable that it was situated near Leckham, or at Silverfield near Lacock, where great quantities of Roman money have been found.

VERMAND, in *Geography*, a town of France, in the department of the Aisne. Before the revolution, the capital of a district in Picardy, called Vermandois; 6 miles W. of St. Quentin.

VERMANTES, a town of France, in the department of the Indre and Loire; 6 miles N.W. of Bourgeuil.

VERMANTON, a town of France, in the department of the Yonne; 12 miles N.W. of Avalon.

VERMANTREE, one of the smaller Shetland islands. N. lat. $60^{\circ} 27'$. W. long. $1^{\circ} 55'$.

VERMEJO, or RIO GRAND, a river of South America, which rises near Cafabindo, in the province of Tucuman, and runs into the Parana, near its union with the Paraguay, opposite Corrientes.

VERMEJO. See BERMEJO.

VERMELHO, in *Ichthyology*, the name of an American fish, more usually known by the name of the *puadiano*.
