Such an example is the most simple that can be conceived in interpolation, but simple as it is, it is all that is required in astronomy, even for the motion of the moon, which is the most irregular of all the planetary bodies; such at least is the assertion of Lalande in the article of the *Encyclopédie* above quoted.

Now knowing the above numbers, or observed longitudes, for every 12 hours, it will be easy, by means of the above rule, to find the same for every six hours; for since, in this case, the second differences ought to be only one-fourth of those above, that is 36, it will therefore only be necessary to construct a series of numbers beginning at 0, whose second differences are 36, and whose second term shall be 78;

therefore $\frac{78 - 36}{2} = 21$ is the first term of the first differences; and all the other terms will be found by adding successively to this, the constant second difference 36; thus

1st diff.	21,	57,	93,	129,	165,	201
Nos. or long.	0.21,	78,	171,	300,	465,	666.

But if, instead of interpolating one term between each of the given numbers, it had been required to interpolate two terms, then we must have taken a ninth part of the above second difference, viz. 16, and found from hence a series of numbers whose second difference should be 16, and the third term of the series = 78. Now in order to find this series, it will be sufficient to find the first term of the 1st differences, as all the rest that is required may be determined from this; suppose, then, this term to be x , which is also the first term of the required series, then the second will be $2x + 16$, and the third $3x + 48$; whence $3x + 48 = 78$, or $x = 10$; which gives for

the 1st diff.	10,	26,	42,	58,	74,	90,	106,	&c.
Nos. or long.	0.10,	36,	78,	136,	210,	300,	406,	&c.

and on similar principles may the interpolation in any other case be effected with the same degree of ease and accuracy; that is, generally, in order to interpolate any number of terms n , between any two given terms of a known series, we must divide the second difference of the given series by $(n + 1)$, in order to have the second difference of the new series; and then again in order to obtain the 1st differences, we have this formula; where $d = 1$ st term 1st diff. of the given series; and $d' = 2$ d difference new series,

$$1\text{st term } 1\text{st diff.} = \frac{d'}{n+1} \pm \frac{n d''}{2}$$

which may be more conveniently expressed in terms of the 1st and 2d differences of the given series as follows; $d = 1$ st difference, $d' = 2$ d difference of the given series, then the 1st term 1st diff. of the new series, becomes

$$= \frac{2d'(n+1) + nd''}{2(n+1)},$$

and this term being thus determined, all the others are readily obtained; and consequently also all the intermediate terms which were to be interpolated. The consideration of second differences, which render the interpolation so extremely easy, is, as we before observed, sufficiently exact for the greater part of astronomical calculations, particularly in the construction of tables; it was thus that Sharp in 1695 calculated his table of right ascension and declination for every degree of latitude and longitude; having first calculated *trigonometrically* the same for every fifth degree, the other intermediate degrees having been ascertained by means of the theory of interpolation. Mouton also, on similar principles, calculated the declination of the sun for every minute of

longitude in seconds and thirds, having first found *trigonometrically* the same for every degree. In general, whatever be the nature of the calculation, it will be sufficient to ascertain rigorously by trigonometry, or otherwise, terms at such a distance that their third differences may become zero, or so small that no sensible error will arise in considering them as such, and then all the intermediate terms may be supplied by the theory which has been investigated. Lalande has published in the "Connoissance des Temps for 1771," a very commodious table for abridging the kind of operations, and there is another still more extended in the "Recueil des Tables de Berlin."

The same theory of second differences may also be conveniently applied to correct calculations and observations, that is, by ascertaining the uniformity of the remainders or differences.

For example, a series of observations being submitted to this test, ought to have a certain order of their differences uniform, and if in any place such a uniformity is not observed, one difference being greater, or less, than another, it may be concluded with certainty, that some error has been committed in the corresponding observation; the correction of which may be readily made, without repeating the observation; Lalande has also given, in his memoirs above-mentioned, general formulae of correction, for all such cases, and which may be applied with the greatest facility, and the correction computed to the utmost possible accuracy.

On nearly the same principles as the foregoing, the extraction of roots, as the square root, cube root, &c. may be effected with great ease, by knowing certain equidistant roots. The application in this case being extremely simple, it may not be amiss to enter a little into the explanation of it.

Let then

$$(x^3 + 1)^3 = x^3 + \frac{1}{3}x^2 + \frac{1}{9}x + \frac{5}{81}x^3 + \frac{10}{243}x^3 + \&c.$$

$$(x^3)^3 = x^3$$

$$(x^3 - 1)^3 = x^3 - \frac{1}{3}x^2 + \frac{1}{9}x - \frac{5}{81}x^3 + \frac{10}{243}x^3 - \&c.$$

represent the cube roots of any three consecutive numbers, the differences of which are

$$1\text{st diff.} \left\{ \begin{array}{l} \frac{1}{3}x^2 + \frac{1}{9}x + \frac{5}{81}x^3 + \frac{10}{243}x^3 + \&c. \\ \frac{1}{3}x^2 - \frac{1}{9}x + \frac{5}{81}x^3 - \frac{10}{243}x^3 + \&c. \end{array} \right.$$

$$2\text{d diff.} \quad \frac{2}{9}x^2 + \frac{20}{243}x^3 + \&c.$$

In the same way, as it necessary, we might have found the third and fourth differences, and so on; but in the case we shall suppose, of $x^3 > 1000$, or $x > 10$, this second difference is sufficiently exact, and even the second term of this second difference is so small, that it may be omitted without affecting even the eleventh place of decimals, for

$$\text{taking } x = 10, \text{ we have } \frac{20}{243 x^3} = \frac{2}{243000000000}, \text{ which,}$$

when converted into a decimal, will not give an effective figure before the 11th place; we may, therefore, without any sensible error, call $\frac{2}{9x^2}$ the second difference, which will remain constant for several terms, while our extraction is not carried farther

INTERPOLATION.

farther than to eight decimal places. Supposing, therefore, the cube root of any two consecutive numbers greater than 1000 to be known, that is, $\sqrt[3]{x} = r$, and $\sqrt[3]{x+1} = r + d$; the first difference is ascertained by simple subtraction, and the second difference is found by the formula $\frac{2}{9x}$; and with these data, we may calculate eight or ten of the subsequent roots, when a new computation becomes necessary.

This is not, however, the simplest manner of employing the formulæ that have been deduced, because it requires the knowledge of two consecutive roots, whereas it will be sufficient to have the roots of numbers equidistant from each other, and by means of which the first and second differences may be readily obtained, and the successive extensions will thus become for many different checks upon each other. Suppose, for example, that we know the cube roots of 2000 and 2008; that is, $\sqrt[3]{2000} = a$, and $\sqrt[3]{2008} = b$; and it were required to find the roots of all the intermediate numbers; calling the first difference = d , and the second

difference = $\frac{2}{9a^3} = c$; then the cube roots will stand thus:

$$\begin{aligned} \sqrt[3]{2000} &= a \\ \sqrt[3]{2001} &= a + d \\ \sqrt[3]{2002} &= a + 2d - c \\ \sqrt[3]{2003} &= a + 3d - 3c \\ \sqrt[3]{2004} &= a + 4d - 6c \\ \sqrt[3]{2005} &= a + 5d - 10c \\ \sqrt[3]{2006} &= a + 6d - 15c \\ \sqrt[3]{2007} &= a + 7d - 21c \\ \sqrt[3]{2008} &= a + 8d - 28c = b. \end{aligned}$$

And since this last root ought to be equal to the known root b , we have a secure check upon all the preceding part of the operation; or more properly, this condition may be employed for finding the first difference d , and the check be made upon the subsequent difference; for since $a + 8d - 28c = b$,

we have $d = \frac{b - a + 28c}{8}$. This operation

will be better understood from the following work at length.

Given the cube root of 6280 = 18.449582727, and of 6288 = 18.45741356, to find all the intermediate roots between those numbers.

By logarithms we find $\frac{2}{9 \times 6280} = .00000105 = c$,

and hence $\frac{b - a + 28c}{8} = .00979222 = d$; hence, again,

the following operation.

$$\begin{aligned} \text{Cube root } 6280 &= 18.449582727 \\ &\quad \underline{979222} \text{ difference} \\ 6281 &= 18.450561949 \\ &\quad \underline{979117} \text{ difference} \\ 6282 &= 18.451541066 \\ &\quad \underline{979012} \text{ difference} \\ 6283 &= 18.452520078 \\ &\quad \underline{978907} \text{ difference} \end{aligned}$$

$$\begin{aligned} \text{Cube root } 6284 &= 18.453497985 \\ &\quad \underline{978802} \text{ difference} \\ 6285 &= 18.454477787 \\ &\quad \underline{978697} \text{ difference} \\ 6286 &= 18.455456484 \\ &\quad \underline{978592} \text{ difference} \\ 6287 &= 18.456435076 \\ &\quad \underline{978487} \text{ difference} \\ 6288 &= 18.457413563 \end{aligned}$$

And that may the extraction be carried on to pleasure, by simple addition and subtraction; the cube root of certain periodical terms being first known; it is unnecessary to observe that the above successive differences are found by subtracting always .00000105 from the first given one.

At present we have only considered the elementary principles on which the theory of interpolation is founded; it will be proper, however, before we conclude this article, to give some idea of the general formulæ and results obtained from these simple and obvious truths, by Newton in his "Methodus Differentialis;" and by Stirling, in his treatise entitled "Tractatus de Summatione et Interpolatione Serierum Limitarum," published in 1730, both of which works are worthy of their celebrated authors.

Let us imagine a right line given in position, on which let there be erected any number of ordinates parallel to one another, and at equidistances, which ordinates may be conceived to represent the terms of a regular series, continually increasing or decreasing; and one and the same curve will pass through all their extremities, the equation of which will be determined from the given equation to the series; that is, from the equation expressing generally the relation between any two or more successive ordinates: and if this equation be finite, the equation of the curve will also be finite, and consequently an absolute interpolation of the series may be effected; for this is nothing more than assigning to every particular abscissa, its corresponding ordinate, and this will always be the case if any order of the differences become equal to zero; thus, in all kinds of figurate numbers, as *triangulars, squares, pentagonals*, &c. the curve passing through their summits will be the common conical parabola. But if, as is frequently the case, no order of differences become zero, then the algebraic equation of the curve cannot be found, and consequently no interpolation can then be made, except by means of an infinite series, the quadrature of some curve, or some other approximation.

Let there be proposed, for example, the series 1, 8, 27, 64, &c. the general interpolation of which is required. This series is no other than that of the natural cubes, and therefore the method that we are about to follow is wholly unnecessary in this case, but the example is chosen in order to illustrate the general method, which is applicable in all cases, even when the terms of the series appear to follow no certain law. We first write the terms of the proposed series in one line, then the differences of these in the next, and then again the differences of these, and so on, till the last order of differences become all equal, or such that no sensible error will arise in considering them as such; then considering x as any abscissa, the first terms of these successive differences will be the co-efficients of the series of terms

$$1, x, \frac{x(x-1)}{1.2}, \frac{x(x-1)(x-2)}{1.2.3}, \&c.$$

O o which

INTERPOLATION.

which expression will then represent the corresponding ordinate to the absciss x ; and consequently the interpolation of the series may be made general. Thus in the example proposed,

Series	1	8	27	64
1st diff.		7	19	37
2d diff.			12	18
3d diff. const.				6

Therefore, considering y as the corresponding ordinate to the absciss x , we have

$$y = 1 + 7x + \frac{12 \cdot x(x-1)}{1 \cdot 2} + \frac{6 \cdot x(x-1)(x-2)}{1 \cdot 2 \cdot 3}, \text{ or}$$

$$y = 1 + 3x + 3x^2 + x^3,$$

as it ought to be, from the nature of the series. If, therefore, now we had to interpolate a term between each of the given ones, these terms would be $(1\frac{1}{2})^3$, $(2\frac{1}{2})^3$, $(3\frac{1}{2})^3$, $(4\frac{1}{2})^3$, &c.

And the same method is applicable in all cases, but it sometimes admits of abbreviation, if the law of the series can be determined, and therefore this should be the first consideration when the law is not evident.

Let there now be proposed the series

$$1, \frac{1}{2}, \frac{3}{8}, \frac{5}{16}, \frac{35}{256}, \&c.$$

where the law is not obvious, the interpolation of which is required.

Series	1	$\frac{1}{2}$	$\frac{3}{8}$	$\frac{5}{16}$	$\frac{35}{256}$	$\frac{63}{256}$ &c.
1st difference		$-\frac{1}{2}$	$-\frac{1}{8}$	$-\frac{1}{16}$	$-\frac{5}{128}$	$-\frac{7}{256}$ &c.
2d difference			$\frac{3}{8}$	$\frac{1}{16}$	$\frac{2}{128}$	$\frac{3}{256}$ &c.
3d difference				$-\frac{5}{16}$	$-\frac{3}{128}$	$-\frac{7}{256}$ &c.
4th difference					$\frac{35}{128}$	$\frac{7}{256}$ &c.
5th difference						$-\frac{63}{256}$ &c.

If hence assuming y for any ordinate corresponding to any proposed absciss x , the equation of the curve passing through the summits of the ordinates, will be

$$y = 1 - \frac{1}{2}x + \frac{3}{8} \cdot \frac{x(x-1)}{1 \cdot 2} - \frac{5}{16} \cdot \frac{x(x-1)(x-2)}{1 \cdot 2 \cdot 3} + \frac{35}{128} \cdot \frac{x(x-1)(x-2)(x-3)}{1 \cdot 2 \cdot 3 \cdot 4} - \frac{63}{256} \cdot \frac{x(x-1)(x-2)(x-3)(x-4)}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5}$$

But as the object of our inquiry is more particularly directed to the finding of the first interpolated term, represented above by x , we must make $x = \frac{1}{2}$; whence the above is reduced to

$$x = -\frac{1}{4}A + \frac{3}{16}B + \frac{15}{36}C + \frac{35}{64}D \&c.$$

in which series the order of formation of the co-efficients is obvious, A, B, C, D, &c. being representatives of the preceding terms; and hence, by the summation of the series, the value of x is found equal to 0.64052, and consequently

By a little attention it will be seen that the series is produced from the successive multiplication of the terms of the

series $\frac{1}{2}, \frac{3}{4}, \frac{5}{6}, \frac{7}{8}$; in which the order of formation is

manifest, and the interpolation of this, except for the term between 1 and $\frac{1}{2}$ is evident; the other interpolated terms

being $\frac{2}{3}, \frac{4}{5}, \frac{6}{7}$, &c.: let then the term between 1 and $\frac{1}{2}$ be x , then the series after interpolation will be

$$1, x, \frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{5}{6}, \frac{6}{7}, \&c.$$

and as the proposed series is generated from the continued

multiplication of the series $1, \frac{1}{2}, \frac{3}{4}, \frac{5}{6}$, &c.; so will the

interpolated terms required, be generated from the continued multiplication of the interpolated terms of this last series, which will therefore be

$$x, \frac{2}{3}x, \frac{2 \cdot 4}{3 \cdot 5}x, \frac{2 \cdot 4 \cdot 6}{3 \cdot 5 \cdot 7}x, \&c.$$

All, therefore, that is required, is to find the value of x , from which any interpolated term may be determined; and it may be further observed, that the term x of the above generating series must necessarily be the second term of the required series after interpolation, or that term which falls between 1 and $\frac{1}{2}$. Let therefore the differences be taken as follows, viz.

from what has been before observed, the interpolation of the proposed series is now complete, being as follows:

$$1, x, \frac{1}{2}, \frac{2}{3}x, \frac{1 \cdot 3}{2 \cdot 4}, \frac{2 \cdot 4}{3 \cdot 5}x, \frac{1 \cdot 3 \cdot 5}{2 \cdot 4 \cdot 6}, \frac{2 \cdot 4 \cdot 6}{3 \cdot 5 \cdot 7}x, \&c.$$

If it had been required to interpolate two terms between each of the given terms, it would have only been necessary to have assumed $x = \frac{1}{3}$, and $\frac{2}{3}$, as is evident; and therefore needs no illustration.

Hence we see that the general equation of any curve, made to pass through the summits of any number of equidistant ordinates, a, b, c, d, e, f , &c. will be

$$y = a + (b-a)x + (c-2b+a) \frac{x(x-1)}{1 \cdot 2} + (d-3c+3b-a) \frac{x \cdot (x-1)(x-2)}{1 \cdot 2 \cdot 3} \&c.$$

which is Newton's formula in his "Methodus Differentialis." The limits of our article will not admit of a farther development of the theory of interpolations, we must therefore refer the reader, who wishes for more complete information,

formation, to the work of Newton above quoted; to Stirling's "Tractatus de Summatione," &c. or to the translation of the same by Holliday, published in 1749; and to the other tracts mentioned in the preceding part of this article, by LaLande, Mayer, &c. See also SERIES.

INTERPOSED ARTICLE. See ARTICLE.

INTERPOSITION, the situation of a body between two others, so as to hide them, or prevent their action.

The eclipse of the sun is occasioned by an interposition of the moon between the sun and us; and that of the moon by the interposition of the earth between the sun and moon.

INTERPRETATION of *Laws* depends on more equitable and excellent principles than those which prevailed among the Romans, who, when any doubt arose upon the construction of their laws, stated the case to the emperor in writing, and took his opinion upon it. To interrogate the legislature, says judge Blackstone, to decide particular disputes, is not only endless, but affords great room for partiality and oppression. The fairest and most rational method to interpret the will of the legislator is by exploring his intentions at the time when the law was made, by signs the most natural and probable. These signs are either the words, the context, the subject-matter, the effects and consequence, or the spirit and reason of the law. *Words* are generally to be understood in their usual and most known signification. If words are dubious, their meaning may be established from the *context*. Thus the preamble often serves to aid the construction of an act of parliament; and the comparison of one law with other laws, made by the same legislator, and bearing some affinity or relation to the subject, will answer a similar purpose. As to the *subject-matter*, words are always to be understood as having a regard to it. With respect to the *effects and consequences*, the rule is, that where words bear either none, or a very absurd signification, if literally understood, we must a little deviate from the received sense of them. But after all, the most universal and effectual way of discovering the true meaning of a law, when the words are dubious, is by considering the *reason and spirit* of it; or the cause which moved the legislator to enact it. For when this reason ceases, the law itself ought likewise to cease with it. From this method of interpreting laws by the reason of them, arises what we call *equity*; which see.

INTERPRETER, a person who explains the thoughts, words, or writings, of some other, which before were unintelligible.

The word *interpres*, according to Isidore, is composed of the preposition *inter*, and *partes*, as signifying a person in the middle betwixt two parties, to make them mutually understand each other's thoughts. Others derive it from *inter*, and *pres*, i. e. *fulcrum*, q. d. a person who serves as security between two others, who do not understand one another.

There have been great debates about interpreting scripture. The Romanists contend, that it belongs absolutely to the church; adding, that where the is silent, reason may be consulted; but, where she speaks, reason is to be disregarded. The Protestants generally allow reason to be the sovereign judge, or interpreter, though some among them have a strong regard to synods, and others to the authority of the primitive fathers. Lastly, others have recourse to the spirit within every person to interpret for them; which is what Boehart calls *πνεῦμα τῆς συνέλευσεως*. It is, or at least ought to be, the fundamental principle of all Protestants, and indeed of all Christians, that every man should interpret scripture for himself, admitting no compulsory or

controlling authority, but at the same time availing himself of all the assistances which others may afford for directing his inquiries and determining his judgment. "Let every man," says scripture itself, "be fully persuaded in his own mind."

INTERREGNUM, the time during which a throne is vacant, or a kingdom without a head.

In hereditary kingdoms, as England, there are properly no interregnums. (See *Right of Crowns*.) In elective kingdoms, the interregnums are extremely liable to factions and disorders.

INTERREX, a magistrate who governs during an interregnum, or in the interval between the death of a monarch and the election or inauguration of his successor.

This magistracy was established in old Rome, and was almost as ancient as the city itself. After the death of Romulus there was an interregnum of a year, during which the senators were each interrex in their turn, five days a-piece.

After the establishment of consuls, and a commonwealth, though there were no kings, yet the name and function of interrex were still preserved; for when the magistrates were absent, or when there was any irregularity in their election, or they had abdicated, so that the comitia could not be held, provided they were unwilling to create a dictator, they made an interrex, whose office and authority were to last five days; after which they made another. To the interrex was delegated all the regal and consular authority, and he performed all their functions. He assembled the senate, held comitia, or courts, and took care the election of magistrates was according to the rules. Indeed, at first it was not the custom of the interrex to hold comitia; at least we have no instance of it in the ancient Roman history.

The patricians alone had the right of electing an interrex. This office fell with the republic, when the emperors made themselves masters of every thing.

INTERRMENT, INTERMENT, or *Entermment*, the act of *interring*, i. e. burying, or laying a deceased person in the ground. See BURIAL.

The excommunicated are not to be interred in holy, i. e. in consecrated ground. The ancients did not inter their dead; they burnt them, as the Indians do at this day. See BURNING.

The Abyssinians, in lieu of interring their dead, flut them up in the bodies of trees, dug hollow for this purpose.

Gardeners also inter, or earth up, celery, endive, and lettuce, to blanch, or whiten, and make them the tenderer.

To interr *wild flocks* in ditches, is what Columella calls *deponere semina scrobibus*. There are some seeds, as willows, olives, &c. which grow very well, by *interring* their truncheons, i. e. cutting a truncheon, or piece, off at both ends, and planting it in the ground; which is what the Latins call *inbunare taleas, talis ferere*.

INTERROGATE, a judiciary act, performed by a judge, or commissioner deputed to examine or question a party; who first gives his oath, that he will answer truly to every thing he is interrogated.

INTERROGATION, in *Rhetoric*. See EROTESIS.

As to the difference between *interrogation* and *exclamation*, (which see) we may observe, that interrogations are often employed with propriety in the course of no higher emotions than naturally arise in pursuing some close and earnest reasoning; whereas exclamations belong only to stronger emotions of the mind, as surprise, admiration, anger, joy, grief, and the like. Both interrogation and exclamation, and all passionate figures of speech, being natural signs of a moved

and agitated mind, when properly used, operate upon us by means of sympathy. Hence it follows, that the great rule with regard to such figures is, that the writer attend to the manner in which nature dictates to us to express any emotion or passion, and that he give his language that turn and no other; above all, that he never affect the style of a passion which he does not feel. Interrogations may be used with freedom; but nothing has a worse effect than the frequent and unseasonable use of exclamations to which raw and juvenile writers are addicted. They render compositions rigid to excess.

INTERROGATION, in *Grammar*, is a point which serves to distinguish such parts of a discourse, where the author speaks as if he were asking questions. Its form is this (?).

INTERROGATORIES, in *Law*, are particular questions demanded of witnesses brought in to be examined in a cause, especially in the court of chancery. And these interrogatories must be exhibited by the parties in suit on each side; which are either direct for the party that produces them, or counter on behalf of the adverse party; and generally both plaintiff and defendant may exhibit, direct, and counter or cross interrogatories. They are to be pertinent, and only to the points necessary; and either drawn or perused by counsel, and to be signed by them. See COMMISSION to examine witnesses, and EXAMINATION of witnesses. See also CONTEMPT.

INTERRUPTED SUTURE, in *Surgery*. See SUTURE.

INTERRUPTION, in *Matters of Proportion*, denotes the same with *disjunction*.

It is noted thus (::), and signifies the breaking off of the ratio in the middle of four disjoint or discrete proportionals: as A : B :: C : D; that is, as A is to B so is C to D. See RATIO, PROPORTION, &c.

INTERRUPTION is also a figure in *Rhetoric*, wherein a person breaks off his discourse suddenly, to show some passion.

INTERSCENDENT, in *Algebra*, is applied to quantities, when the exponents of their powers are radical quantities. Thus $x^{1/2}$, $x^{1/3}$, &c. are interscendent quantities. See FUNCTION.

INTERSECTION, in *Mathematics*, the cutting of one line or plane by another; or the point or line wherein two lines, or two planes, cut each other.

The mutual intersection of two planes is a right line. The centre of a circle is in the intersection of two diameters. The central point of a regular or irregular figure of four sides, is the point of intersection of the two diagonals.

The equinoxes happen when the sun is in the intersections of the equator and the ecliptic.

INTERSOILING, in *Husbandry*, the laying one kind of soil, or mould, upon another; as clay on sand, sand on earth, &c.

INTERSPERSUM VACUUM. See VACUUM.

INTERSPINALES, in *Anatomy*, are small muscles placed in the intervals of the spinous processes of the vertebrae, and distinguished as belonging to the neck, back, or loins.

Interspinales colli, interspiniens, epineux du cou, are arranged in pairs, as the processes, to which they are connected, are bifurcated. There are six pairs, of which the first is placed between the spinous processes of the second and third cervical vertebrae, the second between the third and fourth, and so on to the sixth, which is found between the last cervical and first dorsal vertebrae. Their surfaces are flattened, and they have some resemblance to lengthened squares; on the outside, they are in contact with the multi-

fidus spinee; on the inside, the two muscles composing the pair are in contact; their upper and lower edges are fixed to the spinous processes which bound the intervals containing them. With the exception of a few short aponeurotic fibres at their extremities, they are entirely fleshy. By approximating the spinous processes, they extend the cervical portion of the spine.

Interspinales dorsii, epineux du dos. Small muscles are sometimes placed between the spinous processes of the lower lumbar vertebrae; but they are more frequently absent.

Interspinales lumborum, epineux des lombes. These are six in number, seldom deficient, tendinous at their extremities, and attached above and below to the spinous processes of the lumbar vertebrae. They are covered at the sides by the multifidus spinee. The first is placed between the twelfth dorsal and first lumbar vertebrae; the sixth between the last lumbar and the sacrum. They produce in the loins the same effect as the corresponding muscles do in the neck.

INTERSTELLAR, a word used by some authors to express those parts of the universe that are without, and beyond, the limits of our solar system.

In the interstellar regions are supposed to be several other systems of planets moving round the fixed stars, as the centres of their respective motions; and if it be true, as it is not improbable, that each fixed star is thus a sun to some habitable orbs, that move round it, the interstellar world will be infinitely the greatest part of the universe.

INTERTIES, or INTERDUCES, in *Architecture*, those small pieces of timber which lie horizontally betwixt the summers, or betwixt them and the fell, or rafter plate.

INTERTRANSVERSI, in *Anatomy*, or *intertransversarii*, or *intertransversales*, are small muscles belonging to the spine, placed in the intervals of the transverse processes of the vertebrae, and distinguished in the different regions of the spine by the additional terms of colli, dorsii, and lumborum.

Intertransversarii colli, intertransversarii, petitis transversaires du col. These muscles are distinguished into anterior and posterior, as the transverse processes to which they are attached, are bifid at their ends. The anterior ones are six in number; the first is placed between the transverse processes of the first and second vertebrae, and the sixth between those of the sixth and seventh. They are flattened in their figure, and the first is longer than the succeeding ones. On the front, they are covered by the rectus capitis major anticus; behind, they are in contact with the anterior branches of the cervical nerves; their upper and lower margins are attached to the transverse processes.

The posterior intertransversi are five in number, the first being placed between the transverse processes of the second and third vertebrae, and the fifth between those of the sixth and seventh. They very much resemble the preceding muscles. They correspond in front to the anterior branches of the cervical nerves, and are covered behind by the splenius, transversarii colli, and sacrolumbalis. Their margins are fixed to the transverse processes. They are almost entirely fleshy. By drawing the transverse processes together, these muscles will inflect the neck laterally.

Intertransversarii dorsii, petitis transversaires du dos. These resemble in the back the corresponding muscles of the loins, but are smaller; they are placed between the points of the transverse processes. Some of the lower ones are of a conspicuous size; they become gradually more slender and tendinous, and, in the upper part of the back, appear more like thin tendons than muscles. In the latter situation they often do not exist. In front they lie on the intercostal muscles,

mufcles, and they are covered behind by the longiffimus dorsi and facrolumbalis; above and below they are fixed to the tranfverfe proceffes. They produce the lateral inflexions of the dorsal vertebrae.

Intertranfverfi lumborum, tranfverfares des lombes. These are fmall mufcular planes filling the intervals between the tranfverfe proceffes of the lumbar vertebrae. Their number is five, the firft being placed between the laft dorsal and the firft lumbar vertebra, and the laft between the fourth and fifth lumbar vertebra. They are thin, flattened, and quadrilateral. They correspond in front to the quadratus lumborum, and behind, to the facrolumbalis; their upper and lower edges are fixed to the tranfverfe proceffes. They are almost entirely fleshy. Their office is that of inclining the vertebral column towards one fide, or of reftoring it to the erect itate after it has been fo inclined.

INTERTRIGO, in *Medicina*, παρατριγμα of the Greeks, fignifies an erythematous affection of the fkin, a fmooth, fhining rednefs and tendernes of the part, chiefly from friction.

The *intertrigo* moft commonly arifes in thofe parts of the furface, which lie in contact with each other, and are liable therefore to confiderable attrition during motion; or in thofe which are fubject to friction and preffure from other caufes; and more efppecially when, at the fame time, any acrid fluid is prefent. Whence it is very frequent about the top of the thighs and the perineum of infants, when the cloths in which they are wrapped become wetted with the urine. Similar affections of the fkin are alfo liable to occur in perfons who take exercife on horfeback, or in the feet of thofe who have walked a confiderable diftance, efppecially in tight fhoes, and in the backs and fhoulders of fick perfons, long confined to bed. The firft of thefe varieties, which occur in the *pliee* or duplicatures of the fkin, or originate from the attrition of the bandages impregnated with urine, &c. Sauvages has called *Erythema intertrigo*; the latter from friction of the clothes, or bed, he denominates *Erythema paratrimma*. See his *Nofol. Method. Clafs. I. Genus II. fpec. 5 and 6.*

Dr. Willan alfo treats of the former varieties of the diforder under the fame head. When fpeaking of erythema, he fays, we may rank under the prefent article that fpecies of intertrigo which is produced in fome perfons by the attrition of contiguous furfaces, as beneath the breasts, round the *axilla*, in the groin, and at the upper part of the thighs, and is attended with a glary and fetid fecretion. The intertrigo is moft troublefome when it affects the thighs; it commences where they are in contact with the fcrotum, and extends upwards to the groin and *nates*, round the *fcrotum*, and down the hollow of the thigh. In places where the friction is ftrongeft, the rednefs is continuous, but it terminates at the edges in a mixed colour, fuch as characterizes efflorefcences generally. This complaint is moft frequent in very warm weather, and affects perfons of the fanguine temperament, efppecially thofe who are corpulent. It fometimes terminates in the *prurigo*, or *psoriasis ferotatis*. An appearance analogous to the intertrigo, is produced by acrimonious difcharges in perfons labouring under difentery, gonorrhoea, &c.; in females affected with fluor albus, or uterine furrows, and in infants, from the ftimulus of the urine, &c. with which their clothes are almoft continually wetted. (See Willan on Cutaneous Difeaes, p. 481.) He diftinguifhes two morbid itate of the fkin with excoriations, or fuperficial ulceration, as feveral writers both ancient and modern have done; and therefore excludes from the intertrigo thofe excoriations included in the 6th fpecies, or *Erythema paratrimma*, of Sauvages.

Frequent ablution with tepid water is neceffary to allay

the heat and uneafinefs which attend this complaint, to remove the vifcid fecretion from the furface, and to prevent excoriation. When the fkin is fretted by the difcharge of an acrimonious fluid, fome relief is obtained by the application of dry abforbent powders; in cafe of abraion and fiftures, the elder-ointment may be applied with much advantage.

INTERTWISTED SUTURE. See **SUTURE**.

INTERVAL, the diftance or fpace between two extremes, either in time or place.

The word comes from the Latin *intervalum*, which, according to Liddore, fignifies the fpace *inter fiffam et murum*, between the ditch and the wall: others note, that the flakes or piles, driven into the ground in the ancient Roman bulwarks, were called *valla*, and the interftices or vacancy between them *intervalla*.

INTERVAL, *Angle of*. See **ANGLE**.

INTERVAL, *Lucid*. See **LUCID**.

INTERVAL, in *Mufic*, the diftance between two founds, in refpect of acute and grave; or that imaginary fpace terminated with two founds differing in acutenefs or gravity. When two or more founds are compared in this relation, they are either equal or unequal in the degree of tone: fuch as are equal are called *unifons*, with regard to each other, as having one tone; the other, being at a diftance from each other, conftitute what we call an *interval* in mufic; which is properly the diftance in tone between two founds.

Intervals are diftinguifhed into *simple* and *compound*.

INTERVAL, *Simple*, is that without parts, or divifion: fuch are the octave, and all that are within it; as the fecond, third, fourth, fifth, fixth, and feventh, with their varieties.

INTERVAL, *Compound*, confifts of feveral leffer intervals: fuch are all thofe greater than the octave; as the ninth, tenth, eleventh, twelfth, &c. with their varieties. But this diftinction, it is to be obferved, regards practice only, becaufe there is really no fuch thing as a leaft interval. Befides, by a *simple* interval is not meant here the leaft practifed, but fuch as though it were equal to two or more leffer, which are in ufe, yet when we would make a found move fo far up or down we always pafs immediately from one of its terms to the other. What is meant then by a *compound* interval will be very plain: it is fuch, whose terms are in practice taken either in immediate fucceffion, or fuch where the found is made to rife and fall from the one to the other, by touching fome intermediate degree; fo that the whole becomes a compofition of all the intervals from one extreme to the other.

What we here call a *simple* interval, the ancients called a *diftem*, and the *compound* they call a *syftem*.

Each of thefe had its differences; even of the fimple there are fome greater, and others lefs: but they are always difcord; but of the compound, or *syftems*, fome are concord, others difcord. Unifons, it is plain, cannot poffibly have any variety; for where there is no difference, as in unifonance, which flows from a relation of equality, it is plain there can be no diftinction: unifons therefore muft all be con cords. But an interval depending on a difference of tone, or a relation of inequality, admits of variety: and fo the terms of every interval, according to their particular relation or difference, make either concord or difcord. Some indeed have retained the word *concord* to intervals, making it include a difference in time; but this is precarious; for as the word *concord* fignifies an agreement of founds, it is certainly applicable to founds in the firft degree. Intervals, it is plain, may differ in magnitude, and there may be an infinite variety, according to the poffible degree of tone; for there is no difference fo great or fo little, but a greater or a lefs

less may possibly be conceived. It is true, with regard to practice, there are limits, which are the greatest and least intervals our ears are judges of, and which may be actually produced by voice or instrument.

The degrees of tune are proportional to the number of vibrations of the sonorous body in a given time, or the velocity of their courses and recourses. Now these differences in tune constitute, as has been already said, the intervals in music; these therefore must be greater or less, as the differences are; and it is the quantity of these which is the subject of the mathematical part of music. Those intervals are measured, not in the simple differences, or in arithmetical ratios of the numbers expressing the lengths or vibrations, but in their geometric ratios; so that the same interval depends on the same geometrical ratio, and *vice versa*. It is, however, to be observed, that in comparing the equality of intervals, the ratios expressing them must be all of one species; otherwise this absurdity will follow, that the same two sounds may make different intervals. To describe the particular methods of measuring the inequality of intervals would be too tedious; this one rule may be observed, that, to determine in general which of two or more intervals are the greatest, take all the ratios as proper fractions, and the least fraction will be the greatest interval.

The ancients were extremely divided about the manner of measuring intervals. Pythagoras and his followers measured them by the ratios of numbers. They supposed the differences of gravity and acuteness to depend on the different velocities of the motion which causes sound; and therefore concluded, that they could only be accurately measured by the ratios of those velocities. Which ratios are said to have been first investigated by Pythagoras, on occasion of his passing by a smith's shop, and observing a concordance betwixt the sounds of hammers striking on the anvil.

Aristoxenus opposed this. He thought reason and mathematics had nothing to do in this case, and that sense was the only judge in the dispute; the other being too subtle to be of any use. He therefore determined the octave, fifth, and fourth, which are the most simple concords, by the ear; and by the difference of the fourth and fifth he found out the tone; which, once settled as an interval the ear could judge of, he pretended to measure every interval by various additions, and subtractions, made of these mentioned, one with another: but this method is very inaccurate.

Ptolemy keeps a middle course betwixt the two: he finds fault with the one for despising reason, and with the other for excluding sense; and shews how these two may mutually assist each other in this matter. Malcolm.

Intervals are founded on certain ratios or proportions expressible in numbers, which may all be analysed into the prime numbers 2, 3, and 5. And all intervals may be found from the octave, fifth, and third major, which respectively correspond to those numbers. These are the musician's elements, from the various combinations of which all the agreeable variety of relations of sounds results.

This is the modern system; and a late author assures us, it may be looked on as the standard of truth; and that every interval that occurs in music is good or bad, as it approaches to or deviates from what it ought to be, on these principles. He observes, that the doctrine of some of the ancients seems different. Ptolemy, for instance, introduces not only the primes 2, 3, 4, 5, but also 7 and 11, &c. Nay, he seems to think all fourths good, provided their component intervals may be expressed by super-particular ratios. But these are justly exploded conceits; and it seems not improbable, that the contradictions of different numerical hypotheses, even in the age of Aristoxenus, and their inconsistency with experience,

might lead him to reject numbers altogether. Dr. Papuse, ap. Phil. Trans. N. 481. p. 267, 268.

M. Euler defines an interval, the measure of the difference of an acute and grave found. Tentam. Nov. Theor. Musicæ, p. 72 and p. 103.

Suppose three sounds a , b , c , of which c is the acute, a the most grave, and b the intermediate found. From the preceding definition it appears, that the interval between the sounds a and c is the aggregate of the intervals between a and b , and between b and c . Therefore, if the interval between a and b be equal to that between b and c , which happens when $a : b :: c : d$, the interval between a and c will be double the interval a to b , or b to c . This being considered, it will appear that intervals ought to be expressed by the measures of the ratios constituting the sounds forming those intervals. But ratios are measured by the logarithms of fractions, the numerators of which denote the acute sounds, and the denominators the grave. Hence the interval between the sounds a and b will be expressed by the logarithm of the fraction $\frac{b}{a}$, which is usually denoted by $l \frac{b}{a}$, or, which

comes to the same, $lb - la$. The interval therefore of equal sounds, a to a , will be null, as $la - la = 0$. The interval called an octave, or diapason, will be expressed by the logarithm of 2; and the interval of the fifth or diapente, will be $l3 - l2$. From whence it appears that these intervals are incommensurable; so that no intervals, however small, can be an aliquot part, both of the octave and fifth. The like may be said of the intervals $l4$, and $l5$, and others whose logarithms are dissimilar. But intervals expounded by logarithms of numbers, which are powers of the same root, may be compared. Thus, the interval of the fourths $27 : 8$, will be to the interval of the fourths $9 : 4$, as 3 is to 2: For $l \frac{27}{8} = 3 l \frac{3}{2}$, and $3 l \frac{3}{2} = 2 l3$. Euler, *ibid.* p. 74.

But though the logarithms of numbers, which are not powers of the same root, be incommensurable, yet an approximating ratio of such may be found. Thus the measure of the octave is $l2 = 0.3010300$, and the measure of the fifth is $l3 - l2 = 0.1760913$. Hence the interval of the octave will be to that of the fifth, nearly as 3010300 to 1760913; which ratio being reduced to smaller terms, in the method explained under the head RATIO, will give us these simple expressions for the ratio of the octave and fifth: 2 : 1, 3 : 2, 5 : 3, 7 : 4, 12 : 7, 17 : 10, 29 : 17, 41 : 24, 53 : 31, which last is very near the truth. Euler, *ibid.* p. 75.

In like manner intervals may be divided into any number of equal parts: for this purpose we need only divide the logarithm of the proposed interval into the same number of parts, and then find its correspondent number by the tables. The ratio of the number so found, to unity, will give the required ratio of the divided interval to its proposed part. Thus let the third part of an octave be required; its logarithm will be $0.10033433 = \frac{1}{2} l2$. The ratio corresponding nearly to this will be 63 : 50, or less accurately, 29 : 23, or 5 : 4, which last expresses the third major; and this is by the less knowing taken for the third part of an octave, and seems to be such on our harpsichords and organs, where from C to E is a third, from E to G another, and from G to A another third. But the more intelligent know, that G to A ought not to be reputed the same found, since they differ by a diesis enharmonica, which is nearly equal to two commas.

M. Euler has inserted a table of intervals in his "Tentamen Nova Theoria Musicæ;" he supposes the logarithm or measure of the octave to be 1.000000, whence the logarithm

INTERVAL.

of the fifth will be 0.584962, and the logarithm of the third major will be 0.321928: from these the measures of all other intervals may be found. But as it has been customary for musicians to measure their intervals by commas, we shall here insert a table of intervals, with their measures in commas; where we suppose the logarithm or measure of the comma $\frac{2}{80}$ to be 1.00000: hence the logarithm of the octave $\frac{2}{1}$ will be 55.79763; that of the fifth 32.63952, and lastly, that of the third major 17.96282. From these all the other intervals may be found in the manner expressed in the table; where the first column shews the names of the several intervals; the second, the proportions of sounds forming these intervals; the third, the composition of these proportions from the primes 2, 3, and 5. The smaller figures marked above, and somewhat to the right of the larger, indicate the power to which the number expressed by the larger figures is raised. Thus $\frac{2^{17}3}{5^8}$ shews that the seventeenth power of 2 multiplied by 3, and divided by the eighth power of 5, will produce $\frac{3282216}{390625}$ in the second column, and that this is the proportion expressing the interval called *eschaton* in the first column. The fourth column of the table contains some simple signs of some of the intervals, as *b* for *hyperoche*, *d* for *diefis*, &c. and the fifth column shews how the intervals arise from others: thus over against *femitone major*, I find in the fourth column *S*, which is here only an arbitrary mark for this *femitone*; and in the fifth column I find $s + d = IV - III$, which signifies that the *femitone major* is equal to the sum of the *femitone minor* and *diefis*, or to the difference between the fourth and the third major. Observe, that the comma is marked by a dot (·); when this is placed over the letter or other symbol, it signifies that the interval

is supposed to be heightened by a comma; and on the contrary, when the point is placed below, it signifies that the interval must be diminished by a comma; thus $\dot{t} = T$ signifies that the tone minor increased by a comma is equal to a tone-major, and *vice versa*: $T = \dot{t}$ shews that the tone-major diminished by a comma is equal to the tone-minor. The signs +, -, =, are here taken in the same sense as in algebra, to signify addition, subtraction, and equality. So likewise the dot placed between two numbers, or between a number and the symbol of an interval, signifies that the interval is to be multiplied by the number. Thus 2. IV shews that the fourth is doubled; and thus $7 = VI - S = 2. IV = VIII - T$, shews, that the lesser flat seventh is equal to the sixth major and *femitone-major*, or also to two fourths, or to the octave when the tone-major has been taken from it. Lastly, the sixth column of the table shews the measures, or logarithms of the ratios in the second column. These are not the common logarithms of the tables where 1.0000000 is the logarithm of 10. But here 1.00000 is assumed as the logarithm of $\frac{2}{80}$, or of the comma, as before mentioned. These logarithms are easily derived from the common, of the large tables of Vlacq, or Briggs: thus the logarithm of 2, or the octave = 0.3010299957; the logarithm of $\frac{3}{2}$, or of the fifth = 0.1760912590; and lastly, the logarithm of $\frac{4}{3}$, or of the third major = 0.069100130. Now these logarithms being severally divided by the logarithm of $\frac{2}{80}$, or the comma = 0.0053950139; the quotients will give the number of commas in an octave = 55.79763; in a fifth = 32.63952; and in a third major = 17.96282. Hence all the rest may be found by addition and subtraction only. Here follows the Table.

The limma, apotome, trichord, ditonus, semidiatente, and trichord, mentioned in this table, by the names of limma, apotome, &c. of the Greek Scale, are such as are either mentioned by the ancients, or at least occur in their scale, where fourths are divided into two tones and a limma, and where the octave consisted of five tones and two limmas.

The term *redundant*, in the table, is applied to such intervals as exceed the truth by a comma; and such as fall short of the truth by a like quantity, are called *deficient*. Intervals that exceed true diatonic intervals, by a semitone

minor, are said to be *superfluous*; and those which fall short by the same quantity, are said to be *diminished*. Where an interval exceeds a true diatonic interval by the quantity of two semitones minor, we have called it an *extreme superfluous* interval: and if it falls short by the same quantity, the appellation of *extreme diminished* interval is given it. Thus, if from A to D ascending be a true fourth, and from D to a a true fifth, then if D be supposed raised by a comma, from A to D will be a redundant fourth, and from D to a a deficient fifth. From A to D \sharp will be a superfluous fourth,

and from D[♯] to a will be a diminished fifth. In like manner, from A to D[♯] will be a diminished fourth; and from D to a a superfluous fifth. From A to D^{♯♯} (D double sharp) will be an extreme superfluous fourth, and from A to D[♯] (D double flat) will be an extreme diminished fourth. In like manner from D^{♯♯♯} to a will be an extreme diminished, and from D[♯] to a an extreme superfluous fifth. Such intervals are not to be met with in the practice of music; but if the division of the octave into 31 parts were once established, as it ought for the perfection of music, such intervals as these here mentioned will necessarily occur in the scale. Vide Phil. Trans. N. 481. p. 275, 274. See GENUS.

This table, among other uses, will facilitate the examination of any proposed scale, or interval. Suppose, for instance, it were required to examine some of Ptolemy's divisions of the fourth, as his diatonicum molle, which he makes $\frac{1}{2} + \frac{1}{3} + \frac{1}{4} = \frac{13}{12}$. Take the logarithm of $\frac{13}{12}$ from the common tables, and divide it by the logarithm of $\frac{4}{3}$, the quotient will be 10.75, which gives the measure or number of commas, and its parts contained in an interval expressed by $\frac{13}{12}$. Look for the nearest measure of intervals to 10.75 in the table, it will be found to be 10.3958, which answers to the interval of two semitones major, or of the diminished third, as practitioners call it. But Ptolemy's exceeds this by 0.36, or about $\frac{1}{3}$ of a comma. The next interval in Ptolemy's division is $\frac{11}{8}$, which is a true tone minor. The third is $\frac{7}{4}$, which will be found to be 3.93 commas, that is, a semitone minor and 0.64 of a comma, or a semitone minor redundant by near $\frac{1}{3}$ of a comma. But this is much out of tune. In the common, and in Haygen's temperaments, the semitone minor is increased only by about $\frac{1}{4}$ th of a comma. Vide Ptolemy's Harmon. p. 92. apud Wallis Opera, tom. v.

INTERVALS, Concinuous. Discords are distinguished into *concinuous* and *inconcinuous* intervals: the *concinuous* are such as are fit for music, next to, and in combination with concords; being neither very agreeable nor disagreeable in themselves; but having a good effect, as by their opposition they heighten the more essential principles of pleasure; or as by their mixture and combination with them, they produce a variety necessary to our being better pleased. See CONCIINUOUS.

The other discords that are never used in music, are called *inconcinuous*.

INTERVAL, Diminished, is a defective interval, or an interval which is short of its just quantity by a lesser semitone. Thus from C ♯ to E being a third major, if E be lowered by a semitone minor, we shall have E ♭, and then from C ♯ to E ♭ is called a *diminished third*, in the language of practical musicians, and occurs frequently in their works. But, strictly speaking, in this case, the note E must be lowered more than a semitone minor.

INTERVAL, Harmonical, is an interval, or difference of two sounds which are agreeable to the ear, whether in consonance or succession.

Harmonical intervals, therefore, are the same with *concerds*; which see.

They are thus called, as being the only essential ingredients of harmony.

INTERVALS, in the New Method of Husbandry, denote the wide spaces, commonly about five feet, which are left between any two of the double, treble, or quadruple rows. See HUSBANDRY.

INTERVALS, in the Military Art, are the spaces left between each regiment in camp, and likewise between each tent.

INTESTATE, a person who dies without making a will. An heir *ab intestato*, is a person who inherits an estate by some other right than that of will or testament.

Heretofore, those who died intestate, were held infamous, and accursed; in regard, by the canons of several councils, every person was enjoined to bequeath a part of his estate (and Matthew Paris says it was at least to be a tenth part) to the church, for the safety of his soul; which a person who neglected to make a will, and to leave this legacy to the church, was judged to have abandoned. Several councils took on them to command the priests to forbid dying persons to be charitable to the church; and this they did so earnestly, that absolution and the viaticum were denied to those whom they could not prevail on; so that they made no difference between those intestates and self-murderers; and they were alike denied Christian burial. Du Cange adds, that all who died without absolution, without receiving the viaticum, and without having this to the church (even though they died suddenly), had their effects seized, and confiscated to the use of the church, bishop, &c. See ADMINISTRATION and TESTAMENT.

In the English law there are two kinds of intestates: the one *de facto*, which are those who make no will at all; the other *de jure*, called also *quasi intestati*, which are those who make a will; but such an one as is null and void, either from the executors refusing to act, or from some other cause: in which case they are judged to die as intestate, *quasi intestati*.

And the 22 & 23 Car. II. c. 10. commonly called the statute of distribution, appoints a distribution of intestates' estates, (except of femes covert, which are left as at common law, stat. 29 Car. II. c. 3. § 25.) after debts and funeral expences are paid among the wife and children of the deceased; or for want of such, among the next of kin, &c. and the act of parliament doth immediately upon the death of the intestate vest an interest in the persons entitled: so that if any one dies before the distribution, though within the year, his share shall go to his executors and administrators; and not to the survivors or next of kin to the intestate. (1 Lil. Abr. 487. See ADMINISTRATION.) By this statute the mother, as well as the father, succeeded to all the personal effects of their children who died intestate, and without wife or issue: in exclusion of the other sons and daughters, the brothers and sisters of the deceased. And so the law still remains with respect to the father; but by statute 1 Jac. II. c. 17, if the father is dead, and any of the children die intestate without wife or issue, in the life-time of the mother, she and each of the remaining children, or their representatives, shall divide his effects in equal portions. See CUSTOM of LONDON.

By the same statute it is enacted, that one-third part of the surplusage of the estate of any person dying intestate, shall be distributed to his widow, and the residue amongst his children by equal portions, or among such persons as legally represent his children, in case any of them be then dead, excepting such child or children (not being heir at law) who shall have any estate by the settlement of the intestate, or shall be advanced by the intestate in his life-time, by portion or portions equal to the share which shall by such distribution be allotted to the other children, and in case their portions have not been equal, they shall be made so as nearly as possible out of the same surplusage. But the heir at law is to have an equal part in the distribution with the rest of the children, without any consideration of the value of the land which he hath by descent or otherwise from the intestate. In case there be no children nor legal representatives, one moiety of the said estate shall be allotted to the widow of

the intestate, and the residue distributed equally to every of the next kindred of the intestate, who are in equal degree, and those who legally represent them; provided that there be no representatives admitted among collaterals, after brothers and sisters children: and if there be no widow, the said estate shall be wholly distributed in equal shares among the children, or if there be no child, to the next of kindred in equal degree, and their legal representatives. But no such distribution of the goods of an intestate should be made till after one year be fully expired after his death, and those to whom distribution is made, are required to give bonds with sufficient sureties, to refund in case of debts.

This statute of distributions bears a near resemblance to our ancient English law, "de rationabili parte bonorum," which Sir Edward Coke himself (2 Inst. 33.), though he doubted the generality of its restraint on the power of devising by will, held to be universally binding (in point of conscience at least) upon the administrator or executor, in the case of either a total or partial intestacy. It also bears some resemblance to the Roman law of succession "ab intestato;" which, and because the act was also penned by an eminent civilian (Sir Walter Walker), has occasioned a notion that the parliament of England copied it from the Roman prætor, though it is little more than a restoration, with some refinements and regulations, of our old constitutional law; which prevailed as an established right and custom from the time of King Canute downwards, many centuries before Justinian's laws were known or heard of in the western parts of Europe. Judge Blackstone observes, however, that the doctrine and limits of representation, laid down in the statute of distributions, seems to have been principally borrowed from the civil law; whereby it will sometimes happen that personal estates are divided "per capita," and sometimes "per stirpes;" whereas the common law knows no other rule of succession but that "per stirpes" only. Bl. Com. b. ii.

INTESTINA, in the *Linnaean System*, an order or division of worms (see **VERMES**); the characters of which are, that they are simple naked animals without limbs: some are pierced with a lateral hole or a kind of pore; and others are imperforated and have no lateral pore. The subordinate genera of this division of worms are the *ascaris*, *trichocephalus*, *uncinaria*, *tilaria*, *scoteles*, *ligula*, *linguata*, *strogylus*, *echinorhynchus*, *heruca*, *cucullanus*, *caryophyllus*, *fujicola*, *myxine*, *tenia*, *furia*, *gordius*, *birudo*, *lambricus*, *spunculus*, and *planaria*.

INTESTINE MOTION. See **MOTION**.

INTESTINE WAR. See **WAR**.

INTESTINES, in *Anatomy*, are portions of the membranous tube, in which the conversion of the food into chyle, and the expulsion of its residue in the form of feces is effected. They are two in number, and are distinguished by epithets derived from their relative size; the *small intestine* (*int. tenuis*) succeeds the stomach, and is immediately followed by the *large* (*int. crassa*). The use of the word in the plural, with either of these epithets, is incorrect; since each of these divisions of the alimentary canal is a single tube.

The changes which the food undergoes in the stomach and intestines, and the functions of these organs, have been fully discussed under the article **DIGESTION**: at present our object is merely anatomical, and consists in presenting to the reader the details concerning the forms, situation, connections, and structure of the intestines.

The small intestine is that part of the alimentary canal which extends from the pylorus to the valve of the colon. It is the longest division of the canal, and is supposed to be three or four times the length of the body. It is naturally divided into two parts: the first of these, placed between

the two layers of the transverse mesocolon, has a fixed situation in the abdominal cavity, and is called *duodenum*: the other floats loosely in the abdomen, and is distinguished by an ambiguous and arbitrary division into jejunum and ileum. It is generally, but not always, smaller in size than the large intestine; yet, when it is dilated with air or other contents, it exceeds the empty large intestine in diameter. The cells and folds of the latter give to its coats in the collapsed state a feel of greater thickness, although they are not actually thicker than some parts of the small intestines. A superficial view would lead us to describe it as a cylindrical tube; but more accurate examination and actual measurement will show that it is conical, largest at its commencement, smallest at its termination, and diminishing very gradually between these points. When distended, the outline of its section is circular: in the empty state its sides fall together, so that it represents an oblong oval.

The structure of the tube is the same, in all essential points, throughout its whole extent; and the distinctions of anatomy regard only points of situation and connection. The excretory tubes of the liver and pancreas open into the canal, near its beginning.

The *duodenum* is that part of the intestine included between the pylorus and the point at which the canal escapes from the transverse mesocolon. It is placed in the neighbourhood of the vertebral column, between the two layers of the mesocolon, which are connected to it by a loose cellular substance. The large end of the pancreas is very closely attached to it. From the pylorus it turns backwards, and to the right, under the neck of the gall-bladder, which touches it: hence it frequently has a yellow tint in the dead subject. This, which may be called the first portion of the duodenum, forms a distinct angle with the second, which descends almost perpendicularly behind the upper layer of the mesocolon connected to it by a loose cellular medium. Its posterior surface corresponds to the right side of the vertebral column, and to the front of the right kidney: its inner edge to the pancreas. The third part makes a turn at the lower end of the kidney, or about the third lumbar vertebra, passes from right to left across the vertebral column, in front of the aorta and vena cava, behind the superior mesenteric vessels, and below the pancreas. At the left side of the abdomen it again turns forwards and towards the right, escapes from behind the inferior layer of the mesocolon, and takes the name of jejunum. Thus this division of the intestinal canal forms a kind of half circle, of which the convexity is towards the right, and the concavity to the left: the pancreas is included within it.

The anterior surface of the intestine only is covered by peritonium; the posterior aspect being attached to the neighbouring organs by cellular substance. In the part near the pylorus, the covering membrane adheres closely to the muscular part of the intestine, as it does in the jejunum or ileum: but in the rest of its course, the adhesion is much more loose, and in the third portion the mesenteric vessels are interposed between the membrane and the intestine. A fold of membrane produced from the neighbourhood of the right kidney, and from the transverse fissure of the liver, is sometimes described as the ligamentum duodeni renale or hepaticum: the rest of the canal is included within the space left between the layers of the mesocolon.

Its length is about that of twelve fingers' breadths. The united pancreatic and biliary ducts have their opening on the posterior surface, at the angle formed between the first and second portions of the duodenum.

The peculiarities of the duodenum are its incomplete peritoneal covering; its circumscribed and fixed situation;

INTESTINES.

its connection to the pancreas, and receiving the secreted fluid of that gland and the liver. Its figure is perhaps less regularly cylindrical, and there are some differences in the mucous membrane.

The arteries of the duodenum are derived from the gastroduodenal branch of the hepatic, and from the superior mesenteric: the veins join some of the trunks, which contributed to the formation of the vena portarum. The absorbing vessels pass to the glands at the root of the mesentery. The nerves come from the cæliac ganglia.

Second Division of the small Intestines.—This part of the canal, which is very loose and moveable, forms numerous turns, and its convolutions fill up the space between the bladder and uterus below, and the large intestine above and at the sides: the latter part almost encircles the space in which this division of the canal lies. As the cæcum and the sigmoid flexures of the colon do not touch below, the small intestine descends in their interval, in greater or less quantity, into the pelvis. The umbilical and hypogastric regions of the abdomen are chiefly occupied by these convolutions: which accommodate themselves, by their perfect mobility, to the numerous changes produced in this space. A distended state of the stomach causes them to descend: when the bladder, rectum, and uterus are empty, much of the intestine is found in the pelvis; but when these organs, and particularly the latter, are distended, the intestine ascends: in a word, it passes into any space that remains open for it. The transverse arch of the colon bounds the space occupied by the small intestine above: the lumbar portions of the large intestine, fixed to the back of the abdomen, allow the convolutions to pass in front of them, and to correspond immediately to the abdominal parietes. The latter limit and confine it in front, and are separated from it only by the great omentum.

A broad fold of peritoneum, called the mesentery, connects it in its situation to the abdominal cavity; this consists of two layers, which receive the intestine between them, and give it a smooth external coat. This fold is attached to the back of the abdomen, in an oblique line, extending from the left lumbar to the right iliac regions: here it is about six inches broad. It expands so considerably as to be broad enough on the opposite or front margin, to be attached to the whole length of the jejunum and ileum. In consequence of this great breadth of the anterior part, the mesentery itself, in this situation, forms a vast number of longitudinal plaits. The flat surfaces of the mesentery are smooth, and contiguous to the intestinal convolutions. The depth of the mesentery, from its posterior or fixed, to its anterior or loose edge, is greatest in the middle, and gradually diminished towards either end. Its structure and attachments are such as to preserve the intestinal convolutions in a certain relative position, and at the same time to allow in the whole a considerable liberty of motion; it prevents the intestines also from becoming entangled in the motions of its individual parts.

It is composed of two membranous layers, produced from the peritoneum. The latter membrane, after lining the posterior and right portion of the abdomen, when it arrives at the root of the mesentery, is reflected from behind forwards, instead of being continued to the left side. That, which has lined the posterior and left division of the cavity, is also reflected from behind forwards, instead of passing in front of the vertebræ. These laminae, turned towards each other, form the two surfaces of the mesentery; they separate at the intestine, and leave a cylindrical tube, in which that canal is contained. They are connected by a layer of cellular membrane, containing more or less feet, and the ar-

teries, veins, and nerves of the jejunum and ileum, as well as the lacteal vessels and their glands.

The intestinal convolutions have no fixed situation, but are formed, destroyed, and renewed, carried upwards, downwards, &c. according to the general or particular motions of the canal: yet the concavity of each turn is always at the mesenteric edge, and its convexity at the loose margin of the gut. The very loose attachment to the sides of the cavity, and the apparently irregular order in which the convolutions of the intestines are disposed, seem at first sight to prevent us from assigning any particular direction to this part of the canal. But if we put out of the question the great mass of the turns, and examine the parts where it begins and ends, and consider at the same time the direction of the mesentery, we shall find that the canal altogether passes obliquely from above downwards, and from the left towards the right side. It begins in fact on the left side of the transverse mesocolon below the superior mesenteric vessels, and it terminates in the right iliac region, where it is fixed to the side of the cæcum.

A transverse section of the intestine presents an elliptical area; of which the smaller circle corresponds to the mesentery, and the larger to the loose edge of the intestine. Considered in its whole length, the mesenteric or attached edge is concave; the loose margin convex. The small trunks of the blood-vessels enter on the former; their minute ramifications, and the fine origins of the absorbents, are observed on the latter.

Sometimes small blind processes, or appendices, varying in length from a few lines to three or four inches, are connected to the small intestine. It is very uncommon to see more than one in a subject. They are cylindrical or conical towards the extremity, communicate freely with the rest of the canal, and completely agree with it in structure. There can be no doubt that they are originally formed parts, and not produced by any morbid extension of the intestinal parietes. They are often mentioned under the name of diverticula.

When moderately distended, the intestine measures more than an inch at its largest diameter, and less at the smallest. When it is completely distended, the figure is circular.

The coats are thinner than in the stomach or in the large intestine: they are thickest at the beginning, and grow gradually thinner to the end. They appear proportionally thicker, when the intestine is in a contracted state. It is more fleshy, elastic, and dark coloured; in a word, firmer and thicker in perfectly healthy men than in women or valedudinarians. When it is asserted that the canal is so many times the length of the body, we only mean to give a general notion of its extent: for there is no relation between the stature of individuals and the volume of their gastric viscera.

The distinction of the jejunum and ileum is quite arbitrary: there are no marks shewing the termination of one, and the beginning of the other: but the two ends of the canal differ obviously in several points. Winflow gives the former name to the upper two-fifths of the tube, and the latter to the lower three-fifths.

Organization of the small Intestine.—It consists, like the stomach, of three distinct strata or coats, connected by cellular substance: these are most clearly seen on the cut edge of the part, after a simple incision, when the difference of colour and density enables us to distinguish them easily. Boiling and maceration in proof spirit render the dissection of the intestinal coats more easy.

The first or external coat is a serous membrane, consisting

INTESTINES.

of a production of peritoneum. The two layers of the mesentery separate at the concave edge of the intestine, surround it, and are continued into each other at the convex side. It covers, therefore, the whole external surface, excepting the narrow strip where the two layers are separated.

This serous membrane is very thin, so as to be nearly transparent, and possesses no fibres: the muscular fibres and the blood-vessels can be seen through it. Its external surface is moist, and perfectly smooth; while the internal, connected to the subjacent fibres by cellular substance, has a rough appearance.

The muscular or second coat of the intestine consists of two strata of fibres. The external, which is thin and small, has a longitudinal direction, but their fibres can hardly be seen except at the convex edge of the gut. The internal is much more considerable; its fibres are more numerous, and they surround the intestine in a circular manner, so as to cut the former at right angles. These fibres are the most distinctly marked about the duodenum: they grow more slender, possess less colour, and are therefore hardly observable near the valve of the colon.

The third or internal covering is a mucous membrane, generally called by anatomists the villous coat of the intestine: it is always covered in a greater or less degree with a mucous fluid. This is connected to the muscular stratum by a very copious, white, and rather loose cellular substance, the *serpous* coat of many anatomists. The trunks of the blood-vessels and absorbents of the mucous surface are contained in this in great numbers, and give to it the appearance of considerable vascularity. It not only connects the mucous and muscular coverings together, but also unites the duplicatures of the former. Through the intervals of the muscular fibres it joins the cellular substance connecting the serous and muscular coats. When carefully separated, it has the appearance of a fine cotton on both surfaces: and this appearance may be still more strikingly produced by cutting off the mesentery close to the intestine, inverting the tube and inflating it forcibly, when the air will penetrate into the whole cellular structure of the organ. If the part be macerated, after separating by dissection the mucous and muscular coats, the water distends the cells and exhibits the structure very clearly.

The mucous membrane is much longer than the two other coats, and it is consequently collected, throughout the whole canal, into folds, by which the difference of length is compensated. These are not like the rugae of the stomach, formed only in the contracted, and disappearing in the distended state of the organ; but they belong to the essential structure of the part, and exist therefore under all circumstances. They are mostly transverse in their direction; that is, they cut the long axis of the gut at right angles; and they are called *valvulae conniventes*, although they have not, nor can possibly exert any thing like the action of a valve. They begin about an inch from the pylorus, are small, and longitudinally disposed in the duodenum. They then assume a more regular arrangement, are numerous and large, and nearly parallel; towards the end of the intestine they gradually become smaller and fewer, and have again in great part of the ileum a longitudinal disposition. Near the valve of the colon they are almost smooth.

The *valvulae conniventes* may occupy from one to three-fourths of the diameter of the canal, but rarely extend through the whole circle: they are often joined by small communicating folds, and frequently are bifurcated at their extremities. When short, they are narrow, and are broader in proportion as they are longer: they are broadest in the middle and narrowest at the extremities. Their breadth may

be from half a line to three lines. They are so completely unresisting, that they yield readily in either direction to any impelling force, and are applied against the surface of the canal. As they depend entirely on the cellular substance, they are destroyed by separating the mucous membrane and drawing it out: the surface then becomes smooth, and very much exceeds the length of the other coats.

The situation, length and breadth, direction, number and form of the *valvulae conniventes*, can be very well observed in a gut inflated and dried; but their natural appearance, their thickness, softness, &c. are best seen in an inverted intestine floating in water.

When the surface of the mucous membrane is attentively examined, it is found universally covered with very delicate and minute folds and projections, so as to give it a flocculent appearance; these are named villi. They are more numerous and large in the commencement of the canal, and decrease in number and size towards the opposite end. In some animals, as the dog, these villi are remarkably long and numerous, so that the surface of the mucous membrane completely resembles velvet.

When the blood-vessels have been successfully injected, microscopic examination discovers other irregularities on these villi, and shews us that the whole consists of a close net-work of vascular communications. Each villus contains moreover numerous absorbing vessels, so that they have been regarded as the great organs of absorption, containing the mouths by which the lacteals take up the chyle from the intestine. Anatomists have busied themselves much with attempts to detect the actual openings of the lacteals upon the villi. Lieberkühn thought that he could see, by the aid of the microscope, an opening into each villus leading into a small vascular cavity in the centre, which he called the ampulla. Hewson did not admit this structure, but conceived that the vessels begin by simple apertures, in the number of one or more on each villus. Mr. Cruikshank met with a subject, in which the lacteals and villi were remarkably loaded with chyle, and he examined these parts with the microscope. Many of the villi were so full that they seemed like white vesicles, without any distinction of particular vessels. "In some hundred villi," says he, "I saw a trunk of a lacteal, forming or beginning by radiated branches. The orifices of these radii were very distinct on the surface of the villus, as well as the radii themselves, seen through the external surface, passing into the trunk of the lacteal: they were full of a white fluid. There was but one of these trunks in each villus. The orifices on the villi of the jejunum, as doctor Hunter himself said, (when I asked him, as he viewed them in the microscope, how many he thought there might be,) were about fifteen or twenty on each villus: and in some I saw them still more numerous." *Anatomy of the Absorbing Vessels*, chap. 11, and plate 2.

It has been calculated, that the surface of this mucous membrane, when allowance is made for all its inequalities, exceeds that of the common integuments.

Numerous mucous glands are situated on the external surface of the mucous membrane of the small intestine: their ducts open on the internal surface of the organ. These parts are always small, and in many cases are not demonstrated without some difficulty. They are most advantageously examined by slitting up the gut, and holding it against the light; they are distinguished by their comparative opacity. Several exist in the duodenum; in the jejunum they are fewer, but they increase in number again in the ileum, are collected into considerable masses, and are particularly numerous towards the end of the intestine. They

vary

INTESTINES.

vary in size: some are rounded, others compressed; the larger are generally placed higher, the smaller are placed close together in collections of different extent. The openings of the excretory ducts of the larger ones on the mucous surface of the intestine are sufficiently conspicuous. They seem to possess a very firm structure; we can observe in them merely a network of minute vascular ramifications, which deposit their secreted mucus in a simple excretory tube.

According as these bodies are found single, or in collections, they have been called glandule *foliatis* or *agminatis*. Again, they have been named in different parts, after persons who first described them, glandule Peyroni and Brunneri.

The arteries of the jejunum and ileum are derived from the trunk of the superior mesenteric: the veins all end in the mesenteric root of the vena portarum. The blood in these veins has been observed to have white streaks in it; but this is not peculiar to the mesenteric vessels. Fluids injected into the mesenteric veins easily traverse on the mucous surface of the intestine.

The superficial absorbing vessels have their origin in the serous membrane, anastomose very frequently with each other, and with the deeper ones, pass through the mesentery in a superior and inferior set, and enter the mesenteric glands. The deeper-seated absorbents, arising from the villi of the mucous surface, are called the lacteal or chyloferous vessels; they are often dilated in a varicose manner to a considerable size: their trunks accompany those of the blood-vessels in the cellular substance on the surface of the mucous membrane, anastomose very frequently with each other, and with the superficial ones, both here and in the mesentery, so as to form a complete network, and then proceed to the glands. They are very numerous in the duodenum and jejunum; but are fewer in the rest of the canal; they form a plexus in the mesentery, proceed from gland to gland, becoming larger and larger, and still communicating together. Collected into large trunks, they arrive at the under and back surface of the pancreas, and are united with the absorbing vessels of the stomach, spleen, and liver in the glands and plexuses situated about this part. They then bend downwards, forming new plexuses, and arrive at the glands placed about the aorta, uniting with all the trunks from the other abdominal viscera, from the pelvis and lower extremities; they then ascend again to terminate in the thoracic duct.

The mesenteric glands, amounting in number to one hundred or more, even to one hundred and fifty, are chiefly placed on the superior mesenteric artery, either scattered and separated, or in a more close arrangement. They are fewer and smaller towards the lower part and right portion of the mesentery and intestine, than on the upper and left part. They are mostly flattened, with a round or oval circumference: and the larger are placed irregularly among the small ones. They have a brownish red colour, but are paler and smaller in adults than in infants. When full of chyle they are whiter.

The nerves of the small intestine are derived from the celiac ganglia; they form networks adhering very closely to the arteries. The animal sensibility of the intestines is probably very slight under ordinary circumstances; the functions of these parts are performed without our consciousness. Disease, however, develops a most acute animal sensibility. An ail contractility is entirely deficient: no exertion of the will can either accelerate or retard the action of the intestine. But the most striking phenomena of the intestinal functions are derived from their organic sensible con-

tractility, which resides in their muscular coat; these may be witnessed in living animals by exposing the abdomen, or in those recently dead, and sometimes in the intestines exposed by accident or surgical operations. The whole canal is observed to be in motion, and this is called *peristalsis*, which term signifies merely contracting. One part of the tube is seen to be contracted, while another is dilated; one ascends, while another descends; one is extended, another rendered shorter: thus a general twisting and creeping is produced, compared to the motion of worms, and hence called *vermicular*. Touch a part of the gut with a sharp instrument, or with any chemical stimulus, and it will be so contracted as to close the canal. A similar effect follows the application of stimuli, such as air, or other fluids, to the internal surface. This is not confined to the mere gut irritated, but the neighbouring parts partake of the affection. This sensibility continues some time after death, and is manifested even in the intestine when removed from the body.

The ordinary and natural stimuli, by which the organic contractility of the intestine is excited, are, the chyme or aliment as it comes from the stomach, the air mixed with and accompanying this, and the bile. The artificial and unusual ones are purgative medicines, worms, cold applied to the abdomen. Cold to the feet, and terror sometimes act sympathetically.

Physiologists have distinguished three kinds of motion in the intestine; the descending or regular one, proceeding from the stomach to the large intestine; the ascending or inverted, the reverse of the former; and the mixed, which partakes of both these.

The following phenomena may be observed in the motion of the intestine. Parts of the canal are alternately dilated and contracted; moved in various directions; rendered tense and loose to the touch; dilated with air or chyme; is incurvated or extended; appear longer or shorter according as the longitudinal or circular fibres act; are filled or emptied; in short, they are alternately at rest and in motion.

The longitudinal fibres shorten the canal lengthwise: the circular ones produce an opposite effect. The latter admit of dilatation, until the gut exceeds an inch in diameter; they contract it again to half a line, or even close the canal entirely.

The antiperistaltic action seems just sufficient in degree, in a healthy animal, to retain the chyle for the action of the absorbing vessels. In diseases, or when an insuperable obstacle exists to the natural passage of the aliment, this inverted motion is carried to a great degree, so that the contents of the small and even large intestine are conveyed into the stomach, and expelled by vomiting.

The *large intestine* is that portion of the alimentary canal, which extends from the end of the small intestine to the anus, and is so named because its diameter considerably exceeds that of the small. It is distinguished from the latter, not merely by its situation, connections, external form and functions, but also in its minute structure, so that a very small portion of it might be distinguished from a similar piece of the stomach or small intestine.

Its situation is more defined and constant than that of the small intestine. Beginning in the right iliac region, it rises in front of the right kidney, goes backwards under the liver, and then turns forwards and towards the left (the first or hepatic flexure of the colon). It continues in a transverse direction, from right to left, under the gall-bladder, the stomach, and the notch of the spleen below and behind, which it turns again, and forms a large angle (the second or splenic flexure). It descends on the left side of the abdomen, in front of the left kidney, forms in the left iliac region,

a large and loose fold, resembling in its form the letter S; passes over the left sacro-iliac symphysis into the pelvis, runs along the concave surface of the sacrum and os coccygis, and ends a little beyond the anterior extremity of that bone, at the anus.

We may distinguish six portions of the large intestine: 1, the *cæca*, which is commonly named simply the cæcum; 2, the vermiform, ordinarily called processus or appendix vermiformis cæci; 3, the *right part* of the colon, or the ascending portion; 4, the *transverse* part, or the arch; 5, the left part, including the descending colon and the sigmoid or iliac flexure of the gut; 6, the *rectum*. Very commonly the tube is divided into the three parts, cæcum, colon, and rectum. These different names, as in the small intestine, have led to the employment of the phrase large *intestines* in the plural, as if there were more than one tube.

We cannot assign any exact limits to these divisions, as the position of the intestine, on which they are founded, varies in its different states of distention or emptiness. The right colon descends lower, and appears longer when it is full than when empty. The transverse portion, when filled, may descend, from the looseness of its attachment, to the umbilicus or pelvis; if it be longer than usual, it forms an arch with the convexity upwards, or it may make one or two turns. When removed from the body, all distinction of particular divisions is lost, and the gut forms a straight uninterrupted tube. It is from three to five times shorter than the small intestine, and they are to each other nearly as five to twenty-five. In individuals of good proportions it measures about seven feet. The connections of the intestine are more firm in some situations, and more loose in others. In many parts the peritoneum does not entirely surround the tube, but covers its anterior portion only, leaving the posterior part to be affixed by cellular substance to the contiguous organs. The term mesocolon is applied generally to the peritoneum covering the large intestine.

The mesocolon dextrum passes from the under and back part of the liver, from the apex of the last rib, from the right quadratus lumborum, and iliacus internus, in front of the right colon and cæcum. Thus these parts, which are only covered on their anterior surface, are firmly bound to the iliac muscle, the kidney, liver, and duodenum, and constantly held in this situation. The appendix has its peculiar small and falciform mesentery.

The transverse mesocolon is a broad and loose fold, by which the transverse part of the intestine is uniformly covered, except just at the separation of its two laminae. The left mesocolon is inflected towards the right, nearly at a right angle, and is then continued behind and below the stomach and liver, in a transverse direction to the left kidney, under the name of mesocolon transversum. Together with the arch of the colon, it forms a kind of transverse partition or diaphragm, loose at the anterior edge, and separating the stomach, duodenum, spleen, and liver from the other abdominal contents. It is generally horizontal, as its name denotes; but it is sometimes so broad and long as to descend with the intestine into the pelvis. It is made up of two laminae of peritoneum, including between them, besides the blood-vessels, the absorbents with their glands, and the nerves of the intestine, connected and covered by more or less fat, the duodenum, and pancreas. The latter parts are placed quite at the root of the fold.

The upper lamina descends from the splenic fold of the peritoneum, the pancreas, the upper lumbar vertebrae, the external covering of the duodenum, and the neighbourhood of the kidney and vena cava. The inferior lamina, which is more simple and strong, comes on the left from the situa-

tion under the spleen, where it furrounds the duodenum by a kind of feminal fold; then from the right kidney, and from a fold placed between the liver and kidney.

The breadth of this mesocolon leaves the arch of the intestine quite moveable, so that its situation is by no means constant; the distended stomach pushes it downwards, and the repletion of the small intestine has the contrary effect. The great omentum covers the front of the transverse colon, and passes between this and the stomach; but does not tend at all to fix it.

The mesocolon finistrum is continued over the intestine, from the iliac vessels and psoas magnus to the left kidney; covering only the anterior surface. The back of the intestine is connected by cellular substance to the diaphragm, the psoas, and the kidney, so that its situation is very fixed. Sometimes, however, there is something like a mesentery belonging to this part of the tube.

The mesorectum is a duplicature, varying in breadth, produced from the side of the pelvis to the sigmoid flexure of the colon, and the commencement of the rectum. It is broadest above, where it is continuous with the mesocolon finistrum, and ends in an acute point below. It is made up, like the mesentery, of two laminae of peritoneum, including between them the blood-vessels, &c. of the intestine, and fat, and separating to cover the rectum. It allows the intestine a considerable liberty of motion. Below the termination of the mesorectum, the gut has no peritoneal coat; but is united by cellular substance to the surrounding organs: that is, to the sacrum and os coccygis, to the vagina in the female, to the bladder and prostate in the male. Its extremity is still further fixed by the attachment of the muscles of the anus, and by its continuity with the common integuments.

The diameter of the tube, when moderately distended, is about two inches or two and a half.

The ileum descends gently to the right iliacus internus muscle, and is inserted obliquely into the left and posterior side of the large intestine, between the cæcum and right colon, having its muscular and mucous coats continuous with those of the large intestine. This extremity of the small intestine forms an acute angle with the cæcum, and a right angle with the colon: its upper half is placed transversely, the lower ascends. On opening the large intestine, we find the communication to be of a valvular nature, and composed of two folds (*ala* or *labia*), a superior and an inferior one: it is prominent, soft, and of course moveable. Each of these folds is composed of a smaller internal lamina, which is the mucous lining of the small intestine, and an external larger one, composed by the corresponding coat of the large. These laminae, connected by cellular substance, and continuous with each other at the sides of the opening, form the valvula coli (valvula illi, or ileo-colica, or ileo-cæcalis). The superior fold, placed nearly transversely, is shorter and narrower than the inferior, which rises the highest of the two. A kind of stricture or fold of the large intestine bounds the valve on each side. Between the two folds composing this valve, the orifice of the small intestine opens transversely; its figure is an oblong oval, and its dimensions are much less than the diameter of the ileum. The length and breadth of the folds, and consequently the size of the interposed aperture, vary greatly. Sometimes the lower fold is very long and broad, the upper short and narrow, so that the intestine opens obliquely by a very small aperture. This structure admits of the opening being very completely closed. Sometimes both folds are but slightly prominent, and their distinction not clearly marked. Here the opening is more nearly circular, and cannot be so perfectly shut.

The external or peritoneal coat passes over the communica-

INTESTINES.

fluid. It seldom contains feces in the adult. Its length, size, figure, and direction vary greatly; it may be from one to six long, and from one to three lines broad. It very frequently adheres to the surrounding parts.

The rectum descends in an arched course, of which the convexity is turned downwards and backwards, from the last lumbar vertebra to the anus. Its curve is most clearly observed when the part is considered in a lateral view. In the infant, on account of the small size of the pelvis, it is continued for the greater part in the abdomen. Its external surface is uniform. The peritoneal covering is a partial one, and belongs only to the sides and anterior part of the intestine; behind it is connected to the pelvis by cellular substance. This membrane forms two lateral folds, continued, in the male sex, to the sides of the bladder; in the female to the vagina and the posterior surface of the broad ligaments of the uterus. From the anterior part of the intestine the peritoneum passes in men to the posterior and inferior part of the bladder, and in women to the under surface of the vagina. Beyond this point the intestine is continued, still in a curved course, with the convexity downwards, for an inch or more, united by cellular substance in the male subject to the vesiculae seminales, urinary bladder and prostate, in the female to the vagina. The serous coat has appendices epiploicae.

The muscular covering consists of a thick and strong layer of longitudinal fibres, and of a strong stratum of circular ones: the latter form an oval tumid ring at the end of the gut, called the sphincter ani internus.

The cellular substance is continued, at the end of the gut, into the general subcutaneous stratum; and the mucous lining is gradually, and in the European imperceptibly, lost in the common integuments. But in the negro the boundary is more clearly marked by the cessation of the black rete mucosum.

The mucous coat is marked with longitudinal serpentine folds, and covered with a copious viscid mucus: the latter is secreted by glands, whose ducts perforate the membrane, and the largest of which are near the termination of the gut.

The extremity of the intestine is provided with certain muscles concerned in the motions performed for the expulsion of the feces: these are the levatores ani, sphincter ani, transversus perinei, and coccygei.

The *levator ani* is a thin, broad, and flat muscular plane, of an irregularly quadrilateral figure, rather curved in its inner surface, and forming a septum, which closes the pelvis below, and completes the abdominal cavity. Its origin extends from the pubes to the spine of the ischium: it commences by short aponeurotic fibres, just behind the arch of the former bone, and continues its origin from a broad and thin aponeurosis which covers the obturator internus. The anterior fleshy fibres pass obliquely downwards, backwards, and inwards, and are lost on the prostate and sides of the rectum, where they are intermingled with the sphincter. The larger portion, which is behind these, passes downwards in the same direction, is partly united to the opposite muscle, by an aponeurotic expansion, between the rectum and coccyx, and partly fixed to the side of that bone. The external surface of the levator is in contact with the obturator internus, the gluteus magnus, the transversus perinei, and lower down with a large quantity of cellular and adipous tissue. The inner surface corresponds to the prostate, bladder, and rectum. For the description of the coccygeus, see COCCYGEUS.

The *sphincter ani* surrounds the termination of the intestine just under the integuments, and is commonly divided into

the sphincter cutaneous, or externus, and the internus. The latter, as we have already mentioned, is to be regarded rather as the termination of the circular muscular fibres of the gut, than as a distinct muscle. It is a pretty thick muscular ring, about half an inch in breadth. Externally, the longitudinal muscular fibres of the rectum cover it: on the inside it covers the mucous membrane of the intestine. The superior margin is continuous with the circular fibres of the gut; the inferior is placed between the opening of the external sphincter and the membrane of the intestine.

The sphincter externus, or cutaneous, is placed more superficially than the former, and extends from the apex of the coccyx to the posterior part of the perineum. It is flattened, elliptical, with its long axis inclined from behind forwards, and perforated in the middle. We distinguish in it a superior and an inferior surface, a right and left edge, and an anterior and posterior extremity. The thin skin surrounding the anus covers the under surface: the upper corresponds to the levator ani, being at first separated from it by cellular tissue, but having its fibres completely blended with those of that muscle on the rectum. The front end forms a sharp point, extending more or less under the back edge of the accelerator urinae, to which, as well as to the transversus perinei, it is closely connected. The posterior extremity is also pointed, and attached to the coccyx by a dense cellular matter approaching to the nature of ligament. The margins are partly covered by the skin, and partly by a mass of cellular and adipous substance.

The sphincter consists wholly of fleshy fibres, which describe concentric arcs of circles: those of the two sides are united at acute angles before and behind the anus.

The front end of the muscle is less elongated and acute in the female than in the male subject. In both its fibres are intimately blended with those of the internal sphincter.

The *transversus perinei* is situated towards the back part of the perineum, between the tuberosity and ramus of the ischium, and the middle of the space comprised between the bulb of the urethra and the anus. It is thin, flattened, and somewhat triangular. The anterior surface is inclined downwards, and corresponds to the erector penis and accelerator, and to the fat which fills the intervals between these. The posterior, inclined upwards, lies against the levator ani: cellular tissue, and the deepest branch of the internal pudic artery, separate them. The outer edge is attached to the inner surface of the tuberosity and ramus of the ischium, above the erector penis and the root of the crus penis. The inner edge is united to that of the opposite muscle, to the front of the sphincter ani, and to the back edge of the accelerator. The transversus is separated from the skin in front by a considerable quantity of fat: behind it is confounded with the reddish cellular tissue found in the angle between the bulb of the urethra, and the root of the corpus cavernosum. The origin is aponeurotic; and the termination is usually in a tendinous line.

The *transversus perinei alter* is not constantly found. It is a slender elongated fasciculus, running parallel to the ischium, on the inner edge of the erector penis. The origin is derived from the tuberosity of the bone, near to that of the erector; it terminates above in a thin aponeurosis connected to the bulb of the urethra, or corpus cavernosum.

Motions performed by these Muscles.—The muscular organs just described have two principal offices: 1. They move the whole pelvic viscera together. 2. They act on the rectum in particular. The levator and coccygeus are principally concerned in the former case. They represent an unicular plane capable of elevation and depression, and of moving

moving the organs which it supports in various directions. This plane is opposed in situation and action to that of the diaphragm: thus two strata, concave in opposite directions, and capable of contracting or enlarging, at the will of the animal, the perpendicular diameter of the abdomen, are placed at the opposite ends of this diameter. The most signal contraction is observed in the violent efforts employed for expelling the feces, urine, &c.: and the most marked enlargement in strong expirations, as in coughing, sneezing, &c. But these efforts are produced much more by the depression of the diaphragm contracting the abdomen from above downwards, than by the elevation of the other muscles. The latter support the parts, and enable them to resist the efforts of the former: the impulse may be felt very plainly by placing the hand on the perineum during any strong exertion of the abdominal parietes. The power of resistance is much less in these parts than in the sides of the abdomen, because the bony sides of the pelvis, and the contained viscera, support great part of the effort.

The action of the sphincter ani has the effect of contracting the opening of the rectum: it is constantly exerted for the purpose of maintaining the aperture permanently closed. Other openings furnished with sphincters, such as those of the mouth and eyelids, are often open for a considerable time, because there are various muscles which antagonise the sphincters; no such muscles exist about the anus. The only antagonist power is in the longitudinal fibres of the rectum, and in the contraction of the abdominal parietes; and these are only exerted when the feces are evacuated. An obvious advantage arises from the permanent contraction of the rectum, in preventing the escape of its contents: they are retained in the large intestine until their quantity produces irritation. When the sphincter is paralyzed, they escape involuntarily as they arrive in the rectum. This permanent action of the sphincter resembles that of parts belonging to the organic life, as it is completely independent of the will; yet we have the power, by means of volition, of constricting the opening more completely. The feces are evacuated in opposition to the resistance of the sphincter, which is overcome by an exertion of the abdominal parietes. The harder they are, the greater dilatation is required, and the greater difficulty is consequently experienced; and *vice versa*. When they are very fluid, they may escape in a slight degree by the longitudinal plants into which their contraction collects the firm of the anus.

The action of the longitudinal fibres of the rectum, and the pressure of the abdominal viscera, urged downwards by the respiratory muscles, occasion the intestine to descend slightly when the feces are voided. The levatores ani, coccygei, and transversi perinei, support the parts under this effort, limit the descent, and then restore them to their former situation. The levatores probably may be concerned in the functions of the generative organs by compressing the vesiculae seminales and prostates; and the transversi, by fixing the posterior end of the accelerator, may concur with that muscle in the expulsion of the semen.

The large intestine of the fetus is rounder and smaller than in the adult, hardly marked by any cells in young embryos, and not exceeding the small in diameter. The caecum is gradually diminished into the appendix vermiformis, which is considerably larger than in the adult, and disposed by its mesentery into a special arrangement. It is much more considerable in size compared to the caecum. This is the appearance of the part at birth, when it usually contains fecal matter. Soon after, the distinction between the caecum and appendix is more strongly marked: the

latter, instead of coming from the middle of the former, is produced from its left side; and as it is not increased while the caecum is growing in size, the proportions of the adult are gradually established.

After what we have observed concerning the action of the small intestine, the reader will immediately perceive how the muscular fibres of the large must act.

INTESTINES, *Inflammation of*. See ENTERITIS.

INTESTINES, *Protrusions of*. See HERNIA.

INTESTINES, *Wounds of*. See WOUNDS.

INTESTINES of Birds. See *Anatomy of BIRDS*.

INTESTINES of Fish. See FISH.

INTIRE TENACITY. See TENACITY.

INTONARE, to touch in the cathedral service a single key on the organ, to pitch for the priest, the choir, and the congregation, the responses.

INTONATION, in *cauto sermo*, implies an ecclesiastical tone or mode.

INTONAZIONE, *Ital.* intonation, a sound or tone. A vocal performer who sings in tune, is said to have a good intonation, the first of all vocal virtues. Singing out of tune, false intonations, the Italians call *intonazioni perfide*.

INTOUR, in *Geography*, a town of Hindoostan, in the circle of Cuddapa; 35 miles N.W. of Gandicotta.

INTOXICATION. See DRUNKENNESS.

INTRADA, INTRATA, or *Entrata*, *Ital.* an entry, introduction, prelude. In the 17th century, an overture in France was termed *entrée*.

INTRANSITIVE VERBS, in *Grammar*, such whose action does not (*transire*) pass on an object, or subject. See *VERB Neuter*.

INTRENCHMENT, in the *Art of War*, all sorts of works made to fortify a post against an enemy. See *RE-TRENCHMENT*.

They usually consist only of a bank of earth and a ditch, and are of two sorts; such as the trenches carried on in a siege, where the bank is between the ditch and the enemy or town; and where the earth is thrown up against the town; and such as serve to inclose a town or camp, secure a pass, cover the entrance into a country or other places, &c. In these the ditch is between the bank and the enemy. The first sort are usually called *trenches* or *approaches*; and the second are generally called *lines*.

It was a maxim amongst the Romans, that even in their most hasty marches they intrenched every night.

INTRESSIN, in *Geography*, a town of the duchy of Warsaw; 40 miles S. of Polen.

INTRIGUE, or *INTRAGUE*, an assemblage of events, or circumstances occurring in an affair, and perplexing the persons concerned in it.

The word is French, *intrigue*, formed from the Latin *intricare*; which, according to Nonius, comes from *trica*, *entanglements*; and that from the Greek $\tau\rho\iota\varsigma$, *hairs*: *quod pullos gallinacos involvant et impediunt capilli*. Which conjecture is adopted by Tripaud, who will have the word *intrigue* to be primarily and properly understood of chickens, which have the feet entangled in hair; and to be derived from the Greek $\nu\iota$, and $\epsilon\rho\gamma\epsilon$, *hair*.

INTRIGUE is more particularly used to signify the plot of a play, or romance; or that point wherein the principal characters are the most embarrassed, through the artifice and opposition of certain persons, or the unfortunate falling out of certain accidents and circumstances.

In a tragedy, comedy, or epic poem, there are always two designs; the first and principal is that of the hero of the piece; the second contains the designs of all those who oppose him. These opposite causes produce opposite effects.

to wit, the efforts of the hero for the execution of his design, and the efforts of those who thwart it. As those causes and designs are the beginning of the action, so those efforts are in the middle, and there form a knot or difficulty, which we call an intrigue, that makes the greatest part of the poem. It lasts as long as the mind of the reader or hearer is suspended about the event of those opposite efforts: the solution or catastrophe commences when the knot begins to unravel, and the difficulties and doubts begin to clear up.

The intrigue or plot of the *Iliad* is two-fold; the first comprehends the three days fighting in Achilles's absence, and consists, on the one side, in the resistance of Agamemnon and the Greeks, and on the other, in the inexorable temper of Achilles. The death of Patroclus unravels this intrigue, and makes the beginning of a second. Achilles resolves to be revenged, but Hector opposes his design; and this forms the second intrigue, which is the last day's battle. See *ILIAD*.

In the *Aeneid* there are also two intrigues: the first is taken up in the voyage and landing of Aeneas in Italy; the second in his establishment there. The opposition he met with from Juno, in both those undertakings, forms the intrigue. See *AENEID*.

As to the choice of the intrigue and the manner of unravelling it, it is certain they ought both to spring naturally from the ground and subject of the poem. Boissieu gives us three manners of forming the intrigue of a poem; the first is that already mentioned; the second is taken from the fable, and design of the poet; in the third, the intrigue is so laid, as that the solution follows from it of course.

INTRIGUE, in common language, is used to denote a plot; a private transaction in which several parties are engaged, and usually an affair of love. *Johnson*.

INTRINSIC, a term applied to the inner, real, and genuine values, properties, &c. of any thing; in opposition to their extrinsic, apparent, or popular values, &c. See **EXTRINSIC**.

INTROBIO, in *Geography*, a town of Italy, in the department of the *Montagna*; 7 miles N. of *Lecco*.

INTRODUCTION, in *Rhetoric*, is the first part of an oration or discourse, designed to prepare the minds of the hearers for the suitable reception of the succeeding parts; and for this purpose it is necessary that the orator gain the good opinion of his hearers, secure their attention, and give them some general notion of his subject. In order to gain the good opinion of his hearers, the orator, when he introduces the discourse with his own person, will be careful to do it with modesty, and seem rather to extenuate his virtues and abilities, than to magnify them: when he sets out with the persons of those to whom the discourse is addressed, it is not unusual to commend them for their virtues, and those especially which have a more immediate relation to the present subject. The other topics which are to be insisted upon for gaining esteem, are principally taken from the subject, as its justice, importance, advantage, or pleasure. In speaking of gaining the attention of the hearers, *Cicero* says, we shall be heard attentively by one of these three things; if we propose what is great, necessary, or for the interest of those to whom the discourse is addressed. Some account of the subject should always make a part of the introduction. As to the composition of this part of a discourse, it should appear easy and natural, and connected with the rest of the discourse: it should be suited to its length; the language of it should be just, easy, and pleasant: it ought neither to be wholly without passions, nor too violent and impetuous. It ought not to be too general. The introduction, however, is

not an essential part of a discourse, and is sometimes omitted by the best orators. *Ward's Or.* vol. i. lect. 12.

INTRODUCTOR, in *Antiquity*, was particularly used for an officer, who introduced the athlete to the stadium, or place where they were to contend.

INTROITUS, in the *Roman Ritual*, as settled by *St. Gregory*, is an introduction to high mass on great festivals, preceding the usual psalms.

INTROMISSION, in *Natural History*, is a term relating to the petrification of organic substances, in which mineral substitution takes place, during the removal of the organic particles, (the mineral being gradually introduced into the animal or vegetable body,) supplying the place, and taking the form of the matter lost. By this mode of petrification the internal fabric, as well as the external figure of the original is preserved. Petrified wood has usually partaken of this kind of change. See *W. Martin's Outlines*, p. 55. Petrifications formed by intromission, are sometimes said to be ingenerate. *Outl.* p. 67.

INTRONATI, the name of an academy at *Sienna*, in *Italy*.

The members of this academy contented themselves, at their first institution, with establishing the following six short laws: 1. To pray. 2. To study. 3. To be merry. 4. To offend nobody. 5. Not to credit too lightly. 6. To let the world talk.

INTRUSUSCEPTION, in *Surgery*. See **INTRUSUSCEPTION**.

INTRUSION, in the *Canon Law*, signifies the enjoyment of a benefice, or exercise of an office, without a good title to it.

The word is derived from *intrudere*, to thrust in, or enter by force.

Intrusion disqualifies the party from ever holding the benefice.

INTRUSION, *Information of*, in *Law*, is a method of suit, by information on behalf of the crown, filed in the exchequer by the king's attorney-general, for any trespass committed on the lands of the crown, as by entering thereon without title, holding over after a lease is determined, taking the profits, cutting down timber, or the like. See **INFORMATION**.

INTRUSION also denotes the entry of a stranger, after a particular estate of freehold is determined, before him in remainder or reversion. This entry and interposition of the stranger differ from an abatement in this; that an abatement is always to the prejudice of the heir, or immediate devisee; an intrusion is always to the prejudice of him in remainder or reversion. An intrusion is always immediately consequent upon the determination of a particular estate; an abatement is always consequent upon the descent or devise of an estate in fee-simple. And in either case the injury is equally great to him whose possession is defeated by this unlawful occupancy. See **OUSTED**.

INTRUSIONE, a writ brought against an intruder, by him that hath fee-simple, &c. See *Writ of ENTRY*.

INTUITION, among *Logicians*, the act whereby the mind perceives the agreement or disagreement of two ideas, immediately by themselves, without the intervention of any other: in which case the mind perceives the truth, as the eye doth the light, only by being directed toward it. Thus the mind perceives that white is not black, that three are more than two, and equal to one and two. See **IDEA**.

This part of knowledge, says *Mr. Locke*, is irresistible, and, like the sunshine, forces itself immediately to be perceived, as soon as the mind turns its view that way. It is on this intuition that all the certainty and evidence of our other

other knowledge depends: this certainty every one finds to be so great, that he cannot imagine, and therefore cannot require, a greater. See JUDGMENT, KNOWLEDGE, DEMONSTRATION, &c.

INTUITIVE EVIDENCE, is that which results from intuition. Dr. Campbell distinguishes different sorts of intuitive evidence: one resulting purely from intellect, or that faculty which others have called intuition; another kind arising from consciousness; and a third sort from that new-named faculty *commun sense*, which this ingenious writer, as well as several others, contend to be a distinct original source of knowledge; whilst others refer its supposed office to the intuitive power of the understanding. Campbell's Rhetoric, vol. 1. book 1. chap. 5.

INTURKI, in *Geography*, a town of Lithuania, in the palatinate of Wilna; 18 miles N. of Wilna.

INTURN, among *Wrestlers*, is when one puts his thigh between those of his adversary, and lifts up his thigh.

INTUSSUSCEPTION, or **INTROSUSCEPTION**, a term in *Surgery*, expressive of a very dangerous disease, which arises from the passage of one portion of an intestine into another. The word is derived from *intus*, within, and *susceptio*, to receive. The disorder is also frequently named a *volvulus*. It happens most commonly in the first fifteen years of life, older persons not being nearly so subject to the affliction.

When the upper part of an intestine passed into the lower, that is to say, when the intussusception was downwards (as generally happens), Mr. Hunter called the case *progressive*; but when the disease arose from the passage of a lower portion of bowel into an upper one, he named this example *retrograde*.

Intussusceptions are probably far more frequent cases than many suppose, and numerous infants and young subjects, no doubt, are victims to the disease, without its existence being in the least suspected. The affection may indeed be less severe; and we are informed, that the greatest part of three hundred children who died, either of worms, or during dentition, at the Hôpital de la Salpêtrière, and were examined by M. Louis, had two, three, four, and even more *volvulus*, without any inflammation of the parts, or any circumstances leading to a suspicion that these affections had been injurious during life. M. Louis thought such cases proved that an intussusception might be formed, and destroyed again, by the mere action of the bowels; an opinion which is confirmed by the observation of Dr. Baillie, that "in opening bodies, particularly of infants, an intussusception is not infrequently found, which had been attended with no mischief; the parts appear perfectly free from inflammation; and they would probably have been easily disentangled from each other by their natural peristaltic motion." See Mem. de l'Acad. de Chirurgie, 4to. edit. tom. iv. p. 222, and Baillie's Morbid Anatomy, 2d edit. p. 162.

Mr. Hunter thought that the manner in which an intussusception may be formed, is, by one portion of a loose intestine being contracted, and the part immediately below relaxed and dilated; under which circumstances the contracted portion slips a little way into that which is dilated. He supposed also, that this change was not the effect of any action in either portion of intestine, but might be the consequence of some additional weight in the upper part of the bowel. How far the peristaltic motion, by pushing the contents on to the contracted parts, might force these into the relaxed ones, Mr. Hunter was unable to determine, though he was inclined to think that nothing of the kind could happen.

Supposing the foregoing explanation to be true, an acci-

dental intussusception may take place either upwards or downwards; but if a continuance or an increase of the disease really arises from the action of the intestine, it can only be when the case is downwards. Yet this does not explain those instances in which a considerable portion of intestine is carried into the gut below. In order to understand these, the different parts which form the intussusception must be considered. We must recollect that every intussusception is composed of three folds of intestine; viz. the *inner*, which passes down, and being reflected upwards, forms the *second*, or *inverted* portion, which, being reflected down again, makes the *third*, or *containing* part. This latter is the outermost, and is alive in its natural position.

According to Mr. Hunter, the outward fold is the only one which is active, the inverted portion being perfectly passive, and squeezed down by the outer, which inverts more of itself, so that the angle of inversion, in the case, is always at the angle of reflection of the outer into the middle, or inverted fold, while the innermost is drawn in. Hence we may see how an intussusception, once begun, may have any length of gut drawn into it.

The external portion acting upon the other folds in the same way as upon any extraneous matter, will, by its peristaltic motion, urge them further; and if any extraneous substance is detained in the cavity of the inner portion, that part will become a fixed point for the outer, or containing intestine to act upon. Thus it will be squeezed on, till at last the mesentery, preventing more of the innermost part from being drawn in, will act as a kind of flay; yet, without entirely hindering the inverted outer fold from going still further. For since it is the middle fold which is acted upon by the outer, and this action continues after the inner portion becomes fixed, the gut is thrown into folds upon itself; so that a foot of intestine may not form an intussusception more than three inches long.

The outer portion of intestine is alone active in increasing the disease when once begun; but if the inner one were capable of equal action in its natural direction, the effect would be the same, viz. that of endeavouring to invert itself, as, indeed, happens in a prolapsus ani. The outer and inner portions would then tend to draw in more of the gut, while the intermediate part only would, by its action, have a contrary tendency.

Although capable of producing a prolapsus ani, the action of the abdominal muscles cannot assist, either in forming or continuing this disease, since the effect of it must be to make equal compression both above and below.

The manner in which the intestines are connected with the mesentery, would lead one to consider it impossible for any portion of the bowels to pass far within another, particularly as the increasing quantity of mesentery, that is drawn into the intussuscepted part, must render the further passage of intestine more and more difficult. The large intestines, being also more closely confined in their natural situations, would seem to be far less liable to the disease. One of the large intussusceptions ever known, however, was in the colon, as related by Mr. Whately in the Phil. Trans. vol. lxxvi. p. 305. The intussusception appeared to have begun at the insertion of the ileum into the colon, and to have carried in the cæcum with its appendix. The ileum passed on into the colon, till the whole of the ascending colon, the transverse arch, and descending colon, were carried into the sigmoid flexure and rectum. The valve of the colon being the leading part, it at last got as low as the anus; and when the person went to stool, he only ejected the ileum, for one-half of the large intestine being filled up by the other, the ileum alone, which passed through the centre, discharged its contents.

tents. The disease, when it thus begins at the termination of the small intestines in the large, is particularly apt to proceed to a considerable extent, and mostly proves fatal. Many instances of this kind are upon record. In the Edinburgh Medical and Surgical Journal, vol. iii. p. 263, Mr. Langstaff has published an interesting example. The case is that of a child three months old, where, upon examination after death, there was an extensive intussusception in the usual direction, together with a smaller one of the retrograde description, similar to what occurred in the instance related by Mr. Spry in the Med. and Physical Journal, No. 11.

Retrograde intussusceptions are much less common than such as are named progressive. In the Medical and Chirurgical Transactions, vol. i. Mr. Home has inserted the account of a retrograde intussusception, which happened in a cabin boy, who had previously swallowed arsenic. The case was also rendered remarkable by a small worm, which was found coiled up round the intussuscepted portion of the intestines.

A prolapsus ani is, in some respects, similar to an intussusception, and may possibly begin in the same way; but it is always continued by the action of the abdominal muscles, and never by that of the bowel itself. It differs from an intussusception in not being included in an intestine; for instead of having a containing bowel, inverting itself by its own action, there is an invaginated intestine protruded by the action of the abdominal muscles, while the passage of the feces through it, and the point of inversion, are at the extremity of the protrusion; and as it becomes inverted, it projects out of the body. Med. and Chir. Trans. vol. i. p. 112.

With regard to the symptoms of intussusception, they very much resemble those attendant on inflammation of the intestines, hernia, and any obstruction in the alimentary canal. In several of the cases upon record, the seat of the disease was plainly indicated by a hard tumour upon the left side of the abdomen. Sometimes it has been found impossible to inject more than a trivial quantity of fluid as a clyster; a circumstance which would strengthen the suspicion of what the disorder really is. It, also, (observes Mr. Langstaff,) the invaginated portion descended so low as to form a protrusion at the anus, and we could ascertain, that it was not an inversion of the rectum itself, the case might be considered as clear, and we should have no hesitation in delivering a prognosis, which, by preparing the friends for the fatal termination, would exonerate us from all blame on its occurrence.

Intussusception, like most other diseases, which are furthered from the reach of medical and surgical assistance, has been treated in a great number of different ways.

Former practitioners very commonly exhibited for its relief, a large quantity of crude mercury; a plan which certainly could never have accomplished the desirable object of disentangling the affected part of the bowels.

It has even been proposed to perform gastrotomy, and M. Hevin, in his "Recherches Historiques sur la Gastrotomie dans le Cas du Volvulus," has examined, with much ability, the question concerning the prudence and propriety of such a proceeding. After many interesting observations, he expresses his decided condemnation of the proposal. The operation, indeed, is rendered quite unwarrantable by the great uncertainty and obscurity which almost constantly prevail in regard to the actual nature of the case; but even were the existence of the disease positively known, the project would not be allowable. In the first place, cutting into the abdomen, with a view of disentangling a portion of the bowels, would be of itself a source of the most dangerous and pro-

bably fatal consequences. And in the second place, the scheme of disentangling the bowels would generally be altogether impracticable, by reason of the different folds of the intestine having become inseparably agglutinated to each other. This connection, in fact, is so strong, that the contained parts can hardly be withdrawn after death. In other instances, the friction on the intussuscepted part causes it to inflame and even mortify, in either of which states gastrotomy would be quite inadmissible.

The forcible injection of clysters was tried by Dr. Monro, without any beneficial effect.

Others have suggested the introduction of long bougies and pieces of whalebone within the anus, for the purpose of mechanically pushing back the intussuscepted portion of the bowels. But after it is known that adhesions are formed in the manner already described, what success can be expected from any plans of this kind? And what instrument could be invented, which would follow the windings of the bowels, a considerable way, without piercing their coats, and doing the most fatal mischief?

The manner in which the parts are agglutinated, explains why none of the methods hitherto devised for the relief of an intussusception, can be of any material service. Were a case to be submitted to some kind of treatment, before adhesions had taken place, perhaps the forcible injection of glysters, and the exhibition of vomits to invert the peristaltic action of the containing bowel, as proposed by Mr. Hunter, would be as rational steps as any which could be pursued.

We must reluctantly acknowledge, however, with Mr. Langstaff, that, in general, all the modes of treatment, hitherto proposed, will be found utterly inefficient. "Yet here, as in many other instances, the resources of nature are exhibited in a most wonderful and astonishing manner, while those of art completely fail. The invaginated portion of intestine sometimes sloughs, and is discharged *per anum*, while the agglutination of the parts preserves the continuity of the intestinal canal. The annals of medicine furnish numerous instances, where long pieces of gut have been discharged in this manner, and the patient has quite recovered. At the same time that we recognize the inefficiency of art, these cases will teach us to repose a just confidence in the powers of nature, and to retain some hope of a favourable event, under the most unpromising circumstances." Langstaff in Edin. Med. and Surgical Journal, vol. iii. p. 267, 268.

This gentleman has greatly enriched his paper by numerous references which will be deemed exceedingly valuable by any person desirous of being more particularly acquainted with the preceding subject.

INVADIATUS, in our *Old Writers*, a person accused of any crime, which not being fully proved, he was put *sub debita fidei jussione*, and called *invaditatus*.

INVALID, a person wounded, maimed, or disabled for action by age.

At Chelsea and Greenwich are magnificent hospitals, or rather colleges, built for the reception and accommodation of invalids, or soldiers and seamen worn out in the service. See HOSPITAL.

We have also several independent companies of invalids, dispersed in the several forts and garrisons.

Of these the 41st regiment was composed in 1719, but it has since been put upon the same footing with the other regiments of the line. In 1782 there were likewise 36 independent companies, forming the garrisons of Jersey, Guernsey, Scilly, Portsmouth, Plymouth, Chester, Hull, and other forts and castles; and there were also ten independent companies of invalids in Ireland. Invalids have been known in this kingdom ever since the restoration of Charles II. The invalids

invalids are armed like other regiments of infantry; their uniform red, faced with blue, and plain button holes.

At Paris is a college of the same kind, called *les Invalides*, which is accounted one of the finest buildings in that city.

INVASION, in *War*, the entrance or attack of an enemy in the dominions of another sovereign.

INVECTED, in *Herakles*, denotes a thing flated, or furrowed.

Invented is just the reverse of *engrained*, in which the points are turned outward to the field: whereas in invected they are turned inward to the ordinary.

INVECTIVE, in *Rhetoric*, differs from reproof, as the latter proceeds from a friend, and is intended for the good of the person reproofed; whereas invective is the work of an enemy, and entirely designed to vex and give uneasiness to the persons against whom it is directed.

INVENTION denotes the act of finding any thing new; or even the thing thus found.

Thus we say, the invention of gunpowder, of printing, &c. The alcove is a modern invention owing to the Moors.

The Doric, Ionic, and Corinthian orders are of Greek invention; the Tuscan and Composite of Latin invention.

Janfon ab Alne'oveen has written an Onomasticon of inventions, wherein are shewn, in an alphabetical order, the names of the inventors, and the time, place, &c. where they are made. Pauciroillus has a treatise of old inventions that are lost, and new ones that have been made; Polydore Virgil has also published eight books of the inventors of things. (*De Inventoribus Rerum.*) Beckman has also published a "History of Inventions and Discoveries."

INVENTION is also used for the discovery of any thing hidden.

The Romish church celebrates a feast on the fourth of May, under the title of "Invention of the Holy Cross."

INVENTION is also used for subtilty of mind, or somewhat peculiar to a man's genius, which leads him to a discovery of things new.

In which sense we say a man of invention: Wolfius has made some essays towards an art of invention.

INVENTION, in the *Arts of Design*, is that peculiar quality, which, being of all others the most rare, is also the most estimable in an artist. Without it the painter or sculptor rises not above the ordinary labouring mechanic, nor are his productions so useful to mankind.

Whether the power of invention be an immediate gift of God, or the offspring of cultivation, has been questioned by philosophers; and while some have traced its origin, or fancied they could, to a continued series of acquisitions, begun at an early age, and carefully stored in the mind, others have regarded it as not attainable by any exertions of man, and no other than a direct impulse imparted by the omnipotent Creator to his more favoured children.

Whichsoever of these abstruse opinions be correct, one thing none will be inclined to dispute, *viz.* that, be the power of imagination, which is the basis of invention, as vivid as possible in the mind of an artist, it must have materials to work upon; and if the power of combining ideas be originally given, they must first be collected: that power can never operate if the possessor does not lay by a store of observations upon the nature of things as they pass before his eyes. Invention is not creation, except as far as relates to the senses and perceptions of man. To him new combinations effectively create new objects; but in fact, it is only the power of combining, in new and previously unknown forms, things known individually before.

It grasps within its range whatever is possible, probable, or already certain; and the artist is at liberty to apply and combine whatever appertains to either of these qualities in any manner, which, producing novelty, still bears the appearance of truth, and does not wound the common perception of propriety; that is, the propriety which belongs to the nature of the subject treated of.

The exercise of invention will be more or less productive as the native vigour of fancy or imagination be accompanied by a constant and lively observation of nature, and a strong remembrance of her various productions under all the different circumstances in which they are found. A vivid imagination, being thus stored with images, requires but the slightest hint to call forth the most brilliant effects, and by contrast or combination produce new images. Sir Joshua Reynolds, in his 6th discourse, has observed, that "there can be no doubt, but that he who has the most materials has the greatest means of invention; and if he has not the power of using them, it must proceed from a feebleness of intellect, or from the confused manner in which they have been laid up in his mind;" and again, "it is vain for painters or poets to endeavour to invent without materials on which the mind may work, and from which inventions must originate. Nothing can come of nothing."

In the same lecture he remarks, that "the mind or genius has been compared to a spark of fire, which is smothered by a heap of fuel, and prevented from blazing into a flame. This simile, which is made use of by the younger Pliny, may be easily mistaken for argument or proof; but there is no danger of the mind's being over-burthened with knowledge, or the genius extinguished, by any addition of images. On the contrary, these acquisitions may as well, perhaps better, be compared, if comparisons signified any thing in reasoning, to the supply of living embers, which will contribute to strengthen the spark, that, without the association of more fuel, would have died. The truth is, he whose feebleness is such as to make other men's thoughts an incumbrance to him, can have no very great strength of mind or genius of his own to be destroyed."

These excellent remarks are made by Sir Joshua when treating of imitation; of the assistance an artist may acquire in his progress by studying the productions of other men; and to prove, that no source of information, either in nature or art, should be neglected by him who covets the title of a great inventor, or, as it is usually called, an original genius. He will find it requisite to be a constant observer of nature in all her steps, whether of the grand, the beautiful, the dreadful, expressive and interesting, or commonplace; the varieties of character among men, their modes of action, the powers of their passions, and the various ways in which they exhibit the impulse derived from them. In short, no object whatever should escape his eye without notice; no moral sentiment or feeling, his mind; and he will thus be best qualified to embody and illustrate whatever subject he may be called upon to represent.

This doctrine holds equally true of poetry, and indeed of all pursuits by which men are led, in which their necessities or their pleasures call for the exertion of their talents. But each art or science, having its peculiar end to answer, requires the observance of peculiar objects. In painting, invention requires the mind of the artist to be occupied in calling forth recollections of those circumstances he may have seen in nature, or in works of art, of a character consonant with that of the subject undertaken to be represented, and endeavouring to inspire every part of the composition with an union of effect. If, for instance, the subject be pathetic, the painter

will recall to his memory those scenes and varied actions and combinations of heads and figures, and that distribution and degree of light and shade which he may have observed in nature to be most affecting; and, placing them in situations proper for his purpose, he will endeavour to carry their effect to the highest point of perfection. His principal difficulty will be, as far as relates to the invention, to clear his work of whatever is not necessary to display its character effectively; to seize upon the most just and powerfully descriptive moment in the occurrence, and, collecting together only what justly belongs to it, impart to those materials he selects the utmost degree of interest possible within the boundary of his art.

He who tells his story in the most natural, and at the same time, dignified method; who brings forth images at once intelligent and correct; and, combining them in an agreeable manner, impresses the mind of an observer with the full scope of his intention, without evidently exhibiting the art he has employed, is certainly entitled to the praise of the greatest inventor: not he, who, to be striking and imposing, composes attitudes for passions, instead of allowing feeling and nature to govern him; and fancies, when he has surprised by strong contrast or brilliant colouring, that he has effected the purposes of art.

Sometimes, indeed, the painter is called upon, like the poet, to tread in fairy ground, and illustrate his subject by images of beings found only in the regions of imagination; but he is not at liberty to indulge his fancy so freely as the poet. Forms described do not make so strong impressions on the sense as those presented to the eye by lines and colours; and many a high-flown indulgence of the inventive faculty which passes current, nay, is even allowable in poetry, would dwindle into pure grotesque if laid upon canvas, or wrought in sculpture; and would more disgust and disappoint, than gratify a sensible mind. Such is Milton's description of Death. The obscurity of the language in which this description of the all-subduing son and paramour of Sin is enveloped, alone renders it effective in the poem. In painting, it is idle waste of time to attempt it.

—————"The other shape,

If shape it might be called that shape had none
Distinguishable in member, joint or limb,
Or substance might be called, that shadow seemed,
For each seemed either,"

is language sublimely effective of the intention of the poet, and conveys in its no meaning (when strictly examined) an indistinct and vague idea of the nature of the monster, just as the description itself is contradictory and indistinct. Still the mind of the reader is filled with figure and idea sufficient for the poet's purpose, and the degree of interest excited by the appalling tremendous circumstances of the moment and in succession, draws off his attention from dwelling long enough to discover the illusion. But once embody the idea it is made to convey in a picture, where every image remains for examination, and meets the eye, not vaguely, for then it would be no image, but apart and distinct, and it becomes absurd; the shadow, substantial, or sublimity is overpowered by obscurity.

The inventor is at liberty to combine all that is possible or probable with all that is real; or dwell in possibilities or probabilities alone. There is a limit, however, to his exertions, which is, that whatever be the nature of his subject, it should have such a degree of union with our ideas of existence, convey such an air of real semblance, or be so compounded in its parts, as not to shock us with an apparent violation of the laws of nature, or the appearance of total

impossibility. Mr. Opie, in his Discourse on Invention delivered in the Royal Academy, lays upon the same point, "that in the exercise of invention in the imitative arts, all possible licence may be granted, and any degree of the extraordinary be indulged, which does not incur the censure of being extravagant; provided that the trains of ideas be perfectly connected, and the whole consistent with itself; that there be nothing suffered to intermix which checks the progress of the imagination, exposes the contrivance or illusions, and recalls a different set of principles to the mind." To the verge of this limit the artist may indulge his fancy, and exert his powers. When he goes beyond it, and launches forth into a world of mere fanciful imagery, he may flatter himself that he is working wonders, but in fact he will be regarded as a dealer in legerdemain, as one falsifying his intellectual powers; and will only excite ridicule and mere surprise, instead of that admiration which men of found sense can alone enjoy. The true inventor will seek only for the most natural and direct means of disclosing his ideas, of imparting that information he wishes to convey, be it of what nature it may. Thus Hogarth ranks with the very first among the possessors of this almost god-like quality; notwithstanding his subjects were of a low and frequently vulgar cast. How admirably simple, and yet how completely effective, is his figure of a Woman setting fire to the Map of the World in the Bagno Scene in the Rake's Progress! He evidently meant to convey the idea of the mischievous power of female beauty when the possessor of it is fordid, selfish, treacherous, and base! Can words convey it more explicitly? It would be almost endless, and certainly needless, to point out the numerous instances with which his works abound of the same effective simplicity and truth of imagery, which render them so admirably attractive and useful. Sir Joshua Reynolds, in his picture of the death of cardinal Beaufort, has been equally successful. Shakspeare informs us that he died in the utmost agonies of conscience without any trust in God, any hope of salvation; the tortures of his mind convulsing him more than the agonies of body. The painter would only represent a man writhing with violent pain; and therefore, to give another character and sentiment to the representation, having effected the appearance of suffering, he introduced the fiend, "grinning horribly a ghastly smile," which at once informs the observers of the agency under which the dying man is tortured. Without this figure, which has been so loudly reprobated by many who probably regarded beauty rather than sentiment, the work would have been merely a representation of a sick man dying in pain, and an assemblage of beautiful colours. The fiend decidedly stamps its character with his own; and perhaps by a similar figure alone, can we be informed of the nature of the torments the cardinal endured, without resorting to the original Gothic mode, of introducing a label from the mouth or over the head of the figure.

In every branch of the art invention is demanded, and without it, tameness and insipidity will be the result of the artist's labours. In drawing, in colouring, and in chiaro-scuro, selection, or that ideal beauty of form, force and effect on which all lovers of the arts alone delight to dwell, is entirely an effort of invention. To it we owe the beautiful and sublime forms of the statues of the heathen gods, and the grand style of design of which Michael Angelo and Lionardo da Vinci are the parents: the rich, deep, and harmonious style of colouring of Titian, Giorgione, and Rubens; the magic sweetness of effect, or chiaro-scuro, in Correggio, and the force and brilliancy of it in Rembrandt. To Raphael, however, it is that the art is indebted for the noblest use of invention. His object always appears to have been the

illustration of his subject, not the exhibition of his art. Of this none ever appear to have been so capable, none saw so fully the whole force of it, entered so immediately into the very heart, and throwing all trifling or indifferent occurrences aside, applied his force to strengthen what was useful, or feeling what was wanting, was fertile in expedients to supply its deficiency. We have mentioned one instance under the article *ENERGY*, in *Painting*, which exhibits strongly the native vigour of the mind of Raphael, *viz.* the Cartoon of Ananias struck dead: wherein we have shewn his invention not only to have been capable of delineating the fact, but also of informing us in some measure of the preceding and subsequent circumstances connected with it. The same power may be pointed out in others of his works, particularly in the cartoon of the sacrifice to St. Paul and Barnabas at Lystra. The great perfection of the inventive faculty in the mind of this extraordinary man is exhibited in the purity, simplicity, and truth of the images he selects. It is very seldom indeed that his ideas require explanation, he never appears to have wandered from the subject of his work in search of something abstruse or rare, but trusts to the growth of ideas which appear naturally to have sprung up in his mind upon consideration of the nature and object of it. Yet so well stored was he with nature and art, that he is rarely insipid or deficient of illustration, either as relates to beauty, elegance, and grace of composition, or expression and sentiment.

Invention in the works of Michael Angelo Buonarroti is exhibited in a very different mode. Instead of treading in the beaten path of common life, or adopting the labours of others, he, breathing the spirit of the epic poet, invents his subject; and clothes it with the ideal grandeur which breadth of form, flowing lines, and bold and difficult actions can give it. Taking his own conception of the generic character of the human body for his model, he perfected, if not invented, a style of design entirely new, of a sublime and dignified nature, though bordering upon the extravagant, and rendered truly so by most of his imitators. Of this style Lionardo da Vinci is perhaps properly the parent, but he had not the full force of M. Angelo, and his invention in art was engaged in a middle way between those of the two great men we have mentioned.

In Titian we find the same faculty operating in a manner totally different. To him it was most grateful to seek after and develop the power of colours in brilliancy, depth, and clearness: and maintaining their full powers, to unite them by arrangement or contrast, in a manner harmonious and agreeable to the eye. Add to this application of his invention, a very extraordinary degree of perception of grandeur and dignity in design and effect, and he will be found to have extended the boundaries of art in no inferior degree.

To this talent in Correggio and Parmegiano we are indebted for whatever is grateful, soft, and amiable in the art of painting; and to Rembrandt for bold vivid effects of the chiaro-scuro: whilst Rubens, endowed by providence with almost super-human powers, revelled in the utmost luxury of imagination, and produced works representative of almost all the varied objects of creation, with a gaiety of action and a splendour of colouring and effect unknown, in so extensive a combination, to any artist before or after him.

It is only by a constant study of the works of nature and of art that a mind possessed with the power of invention can ever be enabled to exert itself either extensively or usefully. The impressions made upon it by the common intercourse of life, without a precise direction of study, would be soon exhausted; and one poorly gifted by nature with the fire of imagination, but anxiously and steadily pursuing the studies

recommended, would soon surpass the former, he he never so richly endowed if he neglected the necessary cultivation.

INVENTION, in *Musick*. Having no objects, melody, or harmony in nature to copy, except the common chord arising from the divisions of a string or sounding body into its harmonics, a musician has more to invent than the professor of any other art. Every passage, every combination, every motive or subject, that has not been used before, is invention. There is so little invention in some compositions, that whoever has heard or seen much music, could point out the prototype of every bar. There is, on the contrary, such an ambition in some authors of being new, that the ear is teased and disappointed by the constant struggle and labour to be unnatural. Haydn's invention, which is so unbounded, is never sufficient to such excess. There is in his most original and capricious movements and passages, a mixture of natural, graceful, ingenious or spirited connecting traits, which relieve the hand of the player, and the attention of the hearer.

There is no infallible receipt for invention; all a master can do is to recommend to his disciples to avoid excesses of every kind: too easy and common, too hard and uncommon; complaints of pieces being too long are more frequently made than of their being too short, which would be more flattering to a composer. When fertility is wanting, passages are frequently repeated *alla tonta Rosalia*, to a degree which now cannot escape remark and censure. A master cannot, nor ought if he could, tell his pupil in composition what to adopt; he can only tell him what to avoid. See *COMPOSITION*, and *COUNTERPOINT*, to which this article may serve as a supplement.

INVENTION, in *Poetry*, is applied to whatever the poet adds to the history of the subject he has chosen; as well as to the new turn he gives it.

INVENTION, in *Rhetoric*, signifies the finding out, and choosing of certain arguments which the orator is to use for the proving or illustrating his point, moving the passions, or conciliating the minds of his hearers.

Invention, according to Cicero, is the principal part of oratory: he wrote four books *De Inventionibus*, of which we have but two remaining.

This invention of the orators cannot, according to lord Bacon, be properly called invention: to invent, is to discover things not yet known, not to recollect those that are; whereas the use and office of this rhetorical invention are only, out of the stock of knowledge laid up in the mind, to select such articles as make for the purpose.

The same author divides this faculty of invention into two parts, the one *topical*, the other *promptuary*: the first points out the way in which we are to pursue the argument; the latter only lays up and disposes things, for which we have frequent occasion, in the mind.

Invention furnishes the orator with those different kinds of arguments and motives which are adapted to the various purposes he has in view. The helps of invention are a lively imagination and readiness of thought, great learning and extensive knowledge, previous consideration, and clear enlarged apprehensions of the subject. See *ARGUMENTS*, *COMMON PLACES*, and *TOPICS*, &c.

INVENTORY, in *Law*, a catalogue, or schedule orderly made of all a deceased person's goods and chattels, at the time of his death, with their value appraised by indifferent persons, which every executor or administrator is obliged to exhibit to the ordinary upon oath, if thereunto lawfully required.

By 21 Hen. VIII. c. 5. executors and administrators are to deliver in upon oath to the ordinary, intended inventories;

one part of which is to remain with the ordinary, and the other part with the executor or administrator: this is required for the benefit of the creditors and legatees, that the executor or administrator may not conceal any part of the personal estate from them. The statute ordains that the inventory shall be exhibited within three months after the person's decease; yet it may be done afterwards, for the ordinary may dispense with the time, and even with its being ever exhibited, as in cases where the creditors are paid, and the will is executed.

The use of the inventory is borrowed from the civil law: for whereas by the law of the ancient Romans the heir was obliged to answer all the testator's debts; by which means, inheritance sometimes became rather prejudicial than profitable; to obviate this inconvenience, Justinian ordained, that if the heir would first exhibit a true inventory of all the testator's effects, he should be no farther charged than to the value of the inventory.

In the British army, when any commissioned officer happens to die, or is killed on service, it is directed by the articles of war, that the major of the regiment, or the officer doing the major's duty in his absence, shall immediately secure all his effects or equipage then in camp or quarters; and shall before the next regimental court-martial make an inventory thereof, and forthwith transmit the same to the office of our secretary at war, to the end, that the executors of such officer may, after payment of his regimental debts and quarters, and the expences attending his interment, receive the overplus, if any be, to his or their use.

When any non-commissioned officer, or private soldier, happens to die, or is killed on service, the then commanding officer of the troop or company, shall, in the presence of two other commissioned officers, take an account of whatever effects he dies possessed of, above his regimental cloathing, arms and accoutrements, and transmit the same to the office of the secretary at war. These effects are to be accounted for and paid to the representative of such deceased non-commissioned officer or soldier; and in case any of the officers, so authorized to take care of the effects of dead officers and soldiers, should, before they have accounted to their representatives for the same, have occasion to leave the regiment by preferment or otherwise, they are ordered, before they be permitted to quit the same, to deposit in the hands of the commanding officer, or of the agent of the regiment, all the effects of such deceased non-commissioned officers and soldiers, in order that the same may be secured for, and paid to, their respective representatives. See *Articles of War*, section XIX.

INVENTORY, in *Trade*, is a list, or particular valuation of goods, &c. See *VALUE, APPRAISEMENT, &c.*

INVER, in *Geography*, a small river of the county of Donegal, Ireland, which is discharged into a small bay, to which it gives name. Inver bay may be considered as a part of Donegal bay, and has good anchorage. The parish is also called Inver, and there was formerly an abbey there. There is also a village called Inver in the county of Mayo, on the east side of Broadhaven, and in the wild barony of Erris.

INVERARY, a royal borough, and the county town of Argyleshire, Scotland, is situated on the southern bank of Loch Fyne, where the river Aray, or Aoridh, falls into the sea. It consists chiefly of one row of commodious houses, built with great uniformity, and covered with slate. The old town was situated on the north side of the bay. It seems probable, that, prior to the fourteenth century, Inverary was little more than a small village for fishermen, who subsisted by their occupation, and erected their huts

here. About that period, the family of Argyle fixed on this site as their place of residence; and as the hereditary jurisdictions of judicary and sheriff were vested in them, Inverary became the seat of the courts and the county town. The circuit court of judicary is held here twice a year for the trial of offences in the counties of Argyle and Bute, and the minor courts are those of the sheriff, magistrates, and justices of the peace. It was created a royal borough by charter from king Charles I., and is governed by a provost, two bailiffs, and a council, nominated by the duke of Argyle. Its only revenue, about 30*l.* sterling annually, arises from the petty customs and the rent of a common, which, on the creation of the borough, was bestowed on it by the Argyle family. About the middle of the last century, Archibald, duke of Argyle, seeing how inadequate this revenue was to the occasions of the borough, added to it a perpetual annuity of 20*l.* secured on his estate.

Inverary is so situated in the Highlands, that as many of the inhabitants speak English as Gaelic, and two ministers officiate in these dialects. For which purpose, two new churches, under one roof, have been recently built, from a design by Mr. Milne. Inverary seems tolerably well situated for manufactures, yet none are carried on to any great extent. About the year 1748, duke Archibald introduced the linen manufacture, which has been attended with beneficial consequences. The late duke established a woollen manufacture; and erected proper buildings and machinery, which he gave to the town; but the business has not been conducted with any adequate advantage.

Inverary derives its chief source of profit from the herring fishery in Loch Fyne. This lake, which extends more than 30 miles from the Western ocean into the country, has been, from time immemorial, noted for its herrings, which are said to be superior in quality to any found in the Western seas. The fishery generally commences in July, and sometimes continues till the end of the year. During this season, the lake is frequented by innumerable shoals. The country people expel the quantities of herrings abounding here, in very strong language: "At these seasons," say they, "the lake contains one part of water and two parts of fish." In this single bay five or six hundred boats are sometimes employed in the fishery; and it is estimated, that in some seasons, upwards of 20,000 barrels of herrings have been caught and cured; each barrel containing, at a medium, seven hundred fish. Part of each boat is covered with a kind of sail-cloth, to shelter the four men who compose the crew, and who seldom quit their boat during the whole season. The inhabitants of Inverary, and of the banks of the loch, do indeed spend Sunday at home; but as many of the boats come from more distant parts, the crews take up their abode entirely in them, subsisting chiefly on herrings. The night is the time of fishing; the day is employed in gutting the fish, in sleep, or in singing Celtic songs to the sound of the bagpipe. Each boat clears, on an average, from 40 to 50*l.*, and, in very productive seasons, 100*l.* The parish of Inverary extends about 18 miles in length, and about three in breadth, on an average. The number of houses in the late return to parliament was 275, of inhabitants 2045.

At a small distance from the town, is the house, or castle, of Inverary, the principal seat of the duke of Argyle, and the chief ornament of the Western Highlands. It is situated on a gentle rise, on the western side of Loch Fyne; and is surrounded by an amphitheatre of mountains, some of which are rugged and broken, and others entirely

covered with wood. The loch from this place appears like a large bay, round which are royal plantations, covering the ground to a vast extent, from the lake to the summit of the highest mountains. The castle, rearing its towers above the woods, has a very picturesque effect; to the south-east of which, close to the bay, appears the town of Inverary in its uniform line of handsome buildings. On the right is a fine view of Dunfries, a steep hill, 700 feet in height, covered with wood almost to the summit. Inverary House, though by no means an old structure, is built in the form of a castle, upon the plan of the mansions of some of the German nobility. The hall, which is very spacious, is hung round with arms and other ornaments adapted to the style of a Highland castle. In the election of a representative to parliament, Inverary is classed with Ayr, Irvine, Rosfay, and Campb.-town. Sinclair's Statistical Account of Scotland, vol. v.

INVERKEITHING, a royal borough and sea-port town in Fifehire, Scotland, is situated on an eminence at the head of the bay which bears its name on the north coast of the Frith of Forth. It consists of one principal street of considerable length, with a smaller one branching from the middle of the former, and a few lanes. The houses have an ancient appearance, and almost every one has a piece of garden ground annexed to it. The return to parliament in the year 1801, stated the number of houses to be 350; of inhabitants 2228. The borough received its first charter from king William, furnished the Lion; since whose time several kings of Scotland have granted other charters, all which were ratified and confirmed by king James VI. in a writ bearing date May 4th 1598. The civil government is vested in a provost, two bailiffs, a dean of guild, and a treasurer, all of whom are annually elected by the counsellors and deacons of trades. The latter, five in number, are also elected yearly: but the counsellors hold their office during life and residence; these must not be fewer than twenty, but are not limited to any number. The town-house, a neat structure, built in 1770, contains a prison, and rooms for the town-clerk, and for public meetings and entertainments. The bay of Inverkeithing is large and safe, and affords anchorage to vessels of any burthen in all winds. Here ships of war from the Leith roads seek shelter from the winter storms, and merchant ships from the Mediterranean used to perform quarantine. The harbour itself is a small bay; at the mouth of which, on the west side, lies a large Dutch built vessel as a lazaretto; where, instead of detaining ships from foreign parts, the particular goods supposed to be infected are immediately received, aired under the inspection of a proper officer, and delivered within a limited time to the owners. At the head of the bay is the quay, the place for landing and receiving goods; the depth of water at spring-tides is thirteen and sometimes fifteen feet. The chief employment of the vessels arises from the exportation of coal and salt. The coal is brought to the shore by a waggon road three miles in length; and 25,000 tons are annually shipped on an average: the demand is greater than can be answered; and vessels, to the number of forty or fifty, are sometimes obliged to wait several weeks for their cargo. The quantity of salt annually made is from twelve to fifteen thousand bushels. Inverkeithing was a royal residence in the time of king David I.; vestiges of his house were visible within the last fifty years. This borough joins with those of Culros, Queensferry, Stirling, and Dumfriess, in sending a member to parliament.

On the top of Lethen-hill, near the town, are several upright stones, placed in a circular form, said to have been a druidical temple: and in the northern part of the parish is a

stone ten feet high, called the Standing stone, on which are basso relievos of several rude figures of men and horses. Within the parish is also the castle of Rosfyt, a ruinous edifice, built upon a rock, and at high water entirely surrounded by the sea; it was one of the seats of the Stuart family, and is now the property of the earl of Hopetoun. The celebrated admiral Greig, commander in chief of the Russian navy, was a native of this parish. Sinclair's Statistical Account of Scotland, vol. x.

INVERNESS, a royal borough, and the county town of Invernesshire, Scotland, is situated on the shore of Moray-Frith, and is divided into two unequal parts by the river Nefs, over which is a stone bridge of seven arches. It is a borough of great antiquity; and according to the best authority obtained its first charter from king Malcolm Canmore. In ancient times the townsmen maintained many desperate conflicts with the neighbouring rebellious chieftains and their clans. Traces of this state of hostility are still extant, on the west side, where irruptions were commonly made. At a small distance from the town, is a place called *Pallfair*, that is, "the Watch-Town;" also a hill, named *Tumnaifair*, "the Watch-Hill;" and a large stone, called *Glacinaifair*, "the Watch-Stone." The last charter in favour of the borough was granted by king James VI. From that period to the revolution, the inhabitants were an industrious and thriving people; carried on a considerable commerce in corn and skins; and brought the malt-ing trade to great extent; a considerable part of the town consisting of kilns and granaries. From the revolution to the year 1746, the borough suffered a gradual decline; so that, at that period, and for several years after, the town appeared little better than the ruins of its former state. In the rebellion in 1745, which commenced among the chiefs in the western part of this county, Inverness became the centre of all the military operations, and other works carried on by government. Hence it began to revive, and commerce was gradually restored. The principal manufactures now are those of hemp and flax. The first has been established about forty years; and at present employs above a thousand persons in spinning, dressing, and weaving. The raw material is imported from the Baltic, and manufactured into sail-cloth and sacking; which are sent to various parts of Britain, and the East and West Indies. A white thread manufactory has been established nearly twenty years; and employs in its various branches of heckling, spinning, twisting, bleaching, and dyeing, not less than ten thousand individuals in the town and surrounding country. The company have, in this and the neighbouring countries, several agents for the management of the spinning departments. The flax is also chiefly imported from the Baltic, and the greatest part of the thread sent to London, whence it is dispersed to different parts of the world. The cotton manufactory has been introduced here with success. Inverness possesses peculiar advantages for manufactures; the raw material being easily imported, and the manufactured goods readily exported. Dearness of fuel is the greatest obstacle, coal being imported from England. The situation of the town is highly favourable. Ships of four or five hundred tons can ride at anchor within a mile of it; and at spring tides vessels of half that burthen can come up to the quay close to the town. The principal part of the vessels belonging to Inverness, is employed in conveying to London the produce of the manufactory, also the fish caught in the river Nefs, and the skins of otters, rat-bits, hares, foxes, goats, roes, &c. In return, materials are brought back both for use and luxury; particularly hardware and haberdashery; with which the traders of this town supply the extensive fur-

rounding district. A spacious harbour or basin has been constructed here for vessels sailing across the island by the Caledonian canal.

Inverness is a large and well-built town; many of the houses are lofty, and assume an elegant appearance. It may be considered as the capital of the Highlands; being the only town of any importance north of Aberdeen. It was returned, under the act of 1801, as containing 1431 houses, and 8732 inhabitants. Nearly in the centre of the town stands the Court-house, connected with the Tolbooth, a handsome modern building, with a tower terminated by a spire. An academy, on a very liberal and extensive plan, was established here in the year 1790, and is supported by voluntary subscription. A piece of ground, containing about three acres, was purchased, and an appropriate building erected, consisting of a large public hall and six spacious apartments, for the accommodation of the different classes, for a library, and for philosophical apparatus. The seminary is conducted by a rector and four tutors; the number of students is generally between two and three hundred; who are divided into five classes. In the first, the English language is taught; in the second, Latin and Greek; in the third, arithmetic and book-keeping; in the fourth, geometry, trigonometry, measurement of planes and solids; geography, navigation, and practical astronomy; naval, civil, and military architecture; gunnery, perspective and drawing; in the fifth, or highest, under the immediate care of the rector, are taught civil and natural history, experimental philosophy, and chemistry. The rector has a small house and a small salary; the tutors have still less salaries; so that their chief dependence is on the fees of their several classes, which is an incitement to attention and industry.

The civil government of the town is vested in a provost, four bailiffs, and a dean of guild, assisted by a council of twenty-one members, called the town council. The members of the new council are elected every year by the old previous to their recession from office: and the former elect from among themselves the provost, bailiffs, dean of guild, and a treasurer. There are six corporations of craftsmen, besides several crafts not incorporated. The edifices for public worship are, three national or Presbyterian churches, and one of Episcopalian, with chapels for dissenting congregations.

About half a mile from the town, on the western side, is Tmona-heurich, the "Hill of Fairies," a beautiful insulated hill covered with trees. It is of a singular form, nearly resembling a ship with the keel uppermost: its base is a parallelogram, in length 1084 feet, in breadth 176; from which it rises above 250 feet above the level of the river. About a mile farther from the town is another hill, called Crai Plathic, rugged and steep, and much higher than the former; the elevation of its highest part being 1150 feet above the bed of the river: the summit is flat, and has been surrounded by a wall eighty yards long by thirty broad. The most remarkable circumstance attending it is, that the stones are all firmly cemented together by a vitrified matter like lava, or resembling the slag or scorie of an iron foundery; and even the stones, in many places, seem to have been softened and vitrified. The circuit court of judicary for the northern district, comprehending the counties of Inverness, Ross, Caithness, Orkney, and Sutherland, is held at this place. Sinclair's Statistical Account of Scotland, vol. ix.

INVERNESS, *New*, a town of America, in the state of Georgia, situated on the river Altamaha, and built by a company of emigrants from the Hebrides of Scotland, 130 of whom were taken over by Gen. Oglethorpe in 1734. It is about 20 miles from Frederica.

INVERNESS and *Fort William Canal*, was the parliamentary name first given, in the act of 1793, to an important line of canal for the passage of large ships across Scotland, principally in Invernesshire, of the designs for which we gave a full account, under that head, in our article CANAL, and have since added, under the topographical articles CLACHMACHARRY and CORPACH, villages at the extremities of the line, such particulars as had occurred to the time of putting these articles to the press, respecting the progress of the works: in the present article we shall have the pleasure of stating the further and successful progress, to the present time, of this very large and important undertaking, now more commonly known by the name of the Caledonian Canal. Seven annual reports have now been made by the commissioners appointed to manage this great national work, and printed by order of the house of commons; which reports contain the greatest body of minute information, satisfactorily arranged, by John Rickman, esq. the secretary to the commissioners, which has, perhaps, ever been given to the public, and shew strongly the merit which is due to Messrs. William Jessop and Thomas Telford the engineers, for the correctness of their original designs and estimates, and to the latter gentleman in particular, for carrying the whole into effect by himself and his resident assistants. From the last of these reports (ordered to be printed the 31st of May 1810), it appears, that about six miles in length at the Clachmacharry, north-eastern, or Inverness end of the line, were in hand or finished; and about the same length, at the Corpach, western or Fort-William end, were also in progress, except some particular parts, presenting no material difficulties. We shall first mention those important and expensive works, the entrance sea-locks in Loch Beaulay, and in Loch Eil.

At Clachmacharry two sea-mounds, or parallel banks for inclosing the canal, have been extended more than 360 yards into the sea beyond high water-mark, and have been secured by a wall of puddled earth carried up from the bottom: and as the shore here is found to consist of wet muddy sands, capable of considerable compression by the weight of these artificial banks, the same have been extended higher than would otherwise have been necessary, and at the further extremity they have been joined into a solid mass, by filling up the space in which the sea-lock is to be constructed, and allowing time for this great weight of earth to act, in compressing the soft bottom, before the digging therein for the lock is commenced; by which the great expence and risk of a coffer-dam is to be avoided. The sea-mounds of earth, three hundred and fifty yards beyond high-water mark, and the coffer-dam for the sea-lock at Corpach, had been some months made and erected and stood firm, and at the time of making the 7th report the steam-engine and drains thereto from the site of the lock were completed ready for commencing the excavation. The second lock at the fourth-cast end of Clachmacharry village had been completed, except the gates, ever since 1806; the masonry of the four connected locks (Nos. 3, 4, 5, 6,) at Muirtown, N. of Inverness, were also completed, and their joints pointed with Parker's cement, prepared from the Ludus helmontia, or clay-balls of the London clay strata. The two locks at the N.W. end of Corpach village were long finished, all but their gates, and the masonry of the six lowest of the principal chain of eight locks near Corpach-moss were about completed. In the next most important head, that of aqueduct bridges, road arches, and culverts under the canal, only a small culvert, had been found necessary in the Clachmacharry district, and was finished in the hands of Kinnylics: in the Corpach district, five considerable aqueducts had been completed a

INVERNESS.

long time, viz. at Lower Banavie, Upper Banavie, Shangan, Muirfearnich, and Loy, all of which had their arches enlarged and paved at the bottom, or side arches constructed, in order to serve as road arches under the canal, and supercede the expence and great inconvenience of as many communication swing bridges over the canal: for which they have been found very complete substitutes. A large job of mason's work had also been completed in walling the intended wharfs, 113 yards in length, at the south-east end of the large basin intended for holding the ships which trade to Inverness, such wharfs being situate within less than a mile of the town. In the Clachnasharry district the masonry of the road bridge at Muirtown had been completed, and a temporary timber bridge laid upon it; the masonry of Bught bridge was very nearly completed, and a temporary wooden bridge had been laid over the middle of the eight Corpach-mofs locks, for the road to Lochie-ferry and Fort-William, where the masonry for a swing bridge had been prepared.

Of the earth works, the stupendous embankments for the sea-locks at the extremities of the canal have been mentioned: in Kinmylies lands, W. of Inverness, a considerable embankment, across some low ground, had been very nearly completed: a more considerable and difficult embankment along the whole course of the Ness river, extends near half a mile in length, under the steep bank of Torvaine; a new channel for the river being formed fourth of this, and the new canal bank effectually faced with loose rubble stone to protect it from the floods: at Molindour a similar embankment along the bed of the old Ness, and the making of a new channel for it for a quarter of a mile in length, has been completed, under Torremore, a steep bank. In the lands of Doughgarroch, near the Smithy, another embankment for the canal across a loop of the river, and enlarging its channel on the further side of a gravel island were in hand. In the Corpach district, embankments of earth have been completed over each of the five aqueduct bridges mentioned above, and many smaller ones, particularly in the rugged tract between Upper Banavie and Shangan aqueducts. The principal extra cutting, or removing of earth, has been on the S.E. of Clachnasharry, where a basin of 20 acres extent, being more than one-third of a mile long, has been completed; the principal deep-cutting, partly executed in this district, being nine feet deep, for about half a mile in length, through the lands of Doughgarroch. The principal work of extra cutting in the Corpach division, has been the basin next the sea-lock, great part of which is hard rock-cutting, and was partly completed, waiting for the steam-engine to drain it: considerable deep cuttings occur on each side of the rivulet of Moy, and near several others of the aqueducts for straightening the course of the canal, and finding stuff for adjacent embankments, all of which were completed. Having thus enumerated all the principal works which had been entered on or completed, we shall present an account of the total expenditure from the commencement on the 20th of October 1803, to the third of May 1810, viz.

	£.	s.	d.
Drought over	141,629	5	4½
Labour and workmanship paid by the day or tide, letting out and trying the ground, whiffkey for the men working in the water, &c. - - - - -	5,711	10	11½
Quarries and masonry work, and for bricks, lime, and cement - - - - -	70,971	14	1¼
Timber, viz. foreign fir and carriage - - - - -	9,310	12	7¼
Native timber, purchased in the neighbourhood, felling, carriage, &c. - - - - -	11,795	15	5½
-----	21,106	8	1¼
Machinery, including four steam-engines, a saw-mill, dredging-machine, iron rails for all the temporary rail-ways, various tools and utensils, and repairing of the same, carriage, &c. - - - - -	29,869	15	5½
Shipping; building and rigging four floops and barges, repairs, stores, seamen's wages, shore dues, &c. in fetching part of the stone from the distant quarries to the works - - - - -	5,573	18	10½
Purchase and hire of horses and provender, farriery, &c. for extra and irregular works, the superintendent's nag, &c. - - - - -	811	18	0
Houses, completing-houses, sheds, stables, and other temporary buildings for the use of the superintendants, and the work - - - - -	2,345	3	9
Stationery, portage, carriage of parcels, feeds for the canal banks, &c. - - - - -	434	11	6½
Expences of management, viz. expences of surveys and obtaining the act, surveys and valuations of land, juries, and conveyancing: the secretary's, engineer's, and superintendent's salaries, keeping and copying accounts, reports, &c., reducing and engraving maps, &c. and travelling expences - - - - -	10,998	12	2¾
Total - - - - -	£.289,452	18	5½

The British public are but little used, we are persuaded, to see such effectual checks established on the expenditure of their money, more real economy exercised, or more minute and satisfactory accounts produced, than the series of valuable reports furnish, from which we have principally extracted our accounts of this truly great national undertaking. From a careful re-estimate of what remained to be done by Mr. Jeffon and Mr. Telford, a well-grounded hope is held out that the whole undertaking will be entirely completed, when the sum of 553,000*l.* is expended, except, perhaps, some purchases of land in the middle district, where no works had yet been commenced. Our inquiries further enable us to state, that at the present time (April, 1811) the excavation in hard rock for the Corpach sea-lock has been completed to 20 feet beneath high-water of neap tides, and a great proportion of the masonry of the tide-lock completed; the masonry of the great chain of eight locks near Corpach-mofs is completed, and the regulating lock near Loch Lochie began; that plan, adopted for avoiding a coffer-dam to the tide lock at Clachnasharry has succeeded, a part of the space for it had been excavated, and the water which sprang in, easily commanded by a six-horse engine; and the regulating lock near Loch Ness is in hand; the number of men at present

	£.	s.	d.
Purchase of lands and buildings, and payments on account of damage for the canal-works, roads, quarries, &c. - - - - -	16,442	8	6
Labour and workmanship paid by measurement, or per job, in excavating, puddling, banking, forming temporary rail-roads, sawing, and carpenters' work - - - - -	125,186	16	10¾
Carry over	141,629	5	4½

INVERNESS-SHIRE.

sent employed exceeding 1200. Mr. John Telford, the brother of the engineer, resided and superintended the works with great ability and integrity until his death, in June 1804; since which the works have been superintended by Mr. Matthew Davidson.

INVERNESS-SHIRE, one of the largest counties of Scotland, is situated on the western side of that part of the kingdom, having numerous bays of the Atlantic ocean to the west, the counties of Perth and Argyle on the south, Roxburgh and part of Moray Frith on the north, and the shires of Moray, Elgin, and Aberdeen on the east. The area thus inclosed comprizes a variety of districts, respectively named Badenoch, Lochabar, Glenelg, Glengary, Glen-Morrison, Glenhiel, &c. These are again divided into 31 parishes, and comprehended, in the year 1801, a population of 74,292 persons. A considerable proportion of the Hebrides or Western isles is also annexed to it; particularly the isles of Sky, Harris, North and South Uist, Benbecula, Barra, and Eigg, and the smaller islets which are situated on its coasts. The mainland, excluding the isles, extends in length, from the point of Arisaig on the west to that of Arderfer on the east, where Fort George is built, about ninety-two miles, and its greatest breadth is nearly fifty. The county is divided into two almost equal parts by a valley running from south-west to north-east, parallel to the Grampians. This valley is called Glen-more-na-h'Alabin, or the "Great Glen of Albion;" and appears to be a deep fissure between the chains of enormous mountains which run in the same direction. The glen is, in the greater part of its length, filled with water; or is rather a long chain of lakes succeeding each other, and rising but little above the level of the sea; a circumstance which has suggested the propriety of taking advantage of this valley to form the canal which is now executing across the island, *viz.* the Caledonian canal. The fresh water lakes which form the chain from Inverness on the Moray Frith to the Sound of Mull below Fort William, are Loch Ness, Loch Oich, and Loch Lochie. The distance, in a direct line, is little more than fifty miles, of which nearly thirty-six are occupied by these three lakes. The salt-water lochs, or arms of the sea, which occupy the two extremities of the valley, are the Linne Loch, which advances from the fount of Mull, on the west, to Fort William at the mouth of the Lochie, and the Moray Frith on the east. The dimensions of the canal are, in depth 20 feet, in width, at the bottom, 50 feet, at the top 110; the locks are 20 feet deep, 170 long, and 40 broad; frigates of 32 guns may be admitted.

Loch Lochie, the most western of the fresh water lakes, is a fine piece of water, in length about fourteen miles, and from one to two in breadth. The mountains on each side are very steep, and in some parts covered with wood. The waters of this loch are chiefly derived from another to the northward, called Loch Archaig, which runs in a northern direction, six or seven miles in length, and one in breadth. From it flows the river Archaig, which after running about a mile, falls into the north end of Loch Lochie. The river Lochie, which takes its rise from the loch, runs westward, and falls into the sea at Fort William; its length being about ten miles, and its medium breadth about two hundred feet. It is navigable by small boats. Next to Loch Lochie, on the eastward, is Loch Oich, in length about three miles; its banks form a number of small bays, and include some beautiful little islands. It gives rise to the river Oich, which flows eastward, and soon falls into Loch Ness. This lake is twenty-two miles long, and from one to two and a half broad; its depth in the middle being from sixty to one hundred and thirty five fathoms. It sometimes, especially after

long-continued rains, rises eight or ten feet perpendicularly above low-water mark. The water possesses a peculiar quality; it never freezes in the severest winter, and in frosty weather is covered with a thick mist, which has the appearance of smoke. At the time of the great earthquake at Lisbon, Nov. 1, 1755, the water of Loch Ness was agitated in an extraordinary manner. It rose rapidly, and flowed up the lake from east to west with amazing impetuosity; the waves being carried more than two hundred yards up the river Oich, breaking on its banks five feet above the level of the river. It continued ebbing and flowing for about an hour; when a wave, much greater than the preceding, terminated the commotion, overflowing the north bank of the lake to the extent of thirty feet. From the eastern extremity of Loch Ness, rises the river of that name, which, running in an easterly direction for six miles, falls into the Moray Frith at the town of Inverness, of which its estuary forms the harbour. This chain of rivers and lakes was made the track of a series of forts, when the English government was endeavouring to subdue the aristocracy of the Highlands, and to reduce this mountainous territory under the dominion of law. The waters which fall into the eastern part of the chain of lakes, that is, below the head of Loch Oich, come chiefly from the south; the Tariff, the Errick, and the Foyers, and a variety of other torrents, which descend from the mountains, where great numbers of lakes are found. The Foyers is remarkable for its celebrated falls. This river takes its rise among the lofty mountains of Boleiskine and Abertarf, and pouring through the vale of Floyers, falls into Loch Ness nearly mid-way between the eastern and western extremities of that lake. The falls of Floyers are accurately described by Dr. Garnet in his Tour through Scotland. Respecting the upper fall, he states that "from the arch of the bridge to the surface of the water, after the lowest part of the fall, is 200 feet. Height of the fall 70 feet." Of the lower fall, distant from the former nearly half a mile, he says, "its height, in one continued stream, is 207 feet. Down this precipice the river rushes, with a noise like thunder, into the abyss below, forming an unbroken stream as white as snow. Burns has given a beautiful description of this fall. It is undoubtedly one of the highest in the world, and the quantity of water is sufficient to give it consequence. The scene is awfully grand; the celebrated cascade of Niagara in North America is not much more than half the height of this." The waters which fall into the eastern part of the lakes from the north, are chiefly the Garry, the Morrison, the Enneric, and Collic. The lakes may be considered as two rivers, which receive the waters of the greatest part of Invernesshire, and convey them to the eastern and western oceans. It is said that pikes are not found in those lochs in the Highlands whose waters descend into the Atlantic; whereas they are found in those lakes whose waters flow eastward into the German ocean. The other principal rivers in this county are the Beaulie on the north, and the Spey on the south. The first, which is chiefly composed of three lesser streams, runs about eight miles before it enters the Frith of Beaulie. The river Spey rises towards the fourth-western part of the county out of a small lake of the same name. It receives in its course a great variety of mountain torrents; and passes through the great fir-woods of Glenmore and Strathpey; the trees of which are conveyed to the ocean by means of its waters. To the fourth of Loch Spey is Loch Laggan, which is fifteen miles in length, and, with its environs, forms a large district in Badenoch. On the fourth side is the Coill More, or Great Wood, the most considerable remnant of the great Caledonian forest. Several arms of the sea advance into the western shore of In-

vernesshire;

INVERNESS-SHIRE.

vernessshire; such as the founth of Sky, on which are the barracks of Bernera; Loch Houra, Loch Nevish, Loch Morven, Loch Avlert, Loch Shail, and Loch Eil; the two last form part of the boundary between this county and Argyleshire. Our limits will not admit a particular description of the scenery to be met with in this extensive county; consisting, as the whole surface of it does, of lofty mountains, which, especially towards the west, are piled above each other in towering magnificence; and between which are deep glens of a boundless variety of forms, each of which has its stream and its lake, and many of which abound in woods. In this county stands the celebrated Ben Nevis, the highest mountain in the island of Great Britain; the altitude being no less than 4370 feet. The summit of this mountain affords a wide extent of view, from the horizon of the sea at the Moray Frith on the north-east to the island of Colonsa on the south-west. (See BEN-NEVIS.) In the eastern part of the parish of Kilmanavag a singular curiosity appears, viz. the remarkable parallel roads of Glenroy, which are to be seen on the declivities of lofty mountains extending for seven or eight miles on each side of the water of Roy. Dr. Anderson, in his View of the Agriculture of Aberdeen, says, "these roads are carried forward along the sides of the hills in a direction every where perfectly horizontal. Wherever they come to a vacancy in the hill, there they bend inwards till they find the natural level; and where they come to a river, instead of sinking down to the level of its bottom, or requiring to have a bridge directly across it, to raise the ground to its proper level, they turn up the bank of the river, keeping still their horizontal direction, till they thus gradually reach the bottom of the stream, when, crossing it, and altering their direction once more, they pursue the course of the stream on the opposite bank till they reach the strath, when they proceed forward in the same horizontal direction as before." These parallel terraces, however, are not works of art, but natural phenomena, as suggested by Mr. Jamieson, professor of natural history in the university of Edinburgh, in his Account of the Mineralogy of Dumfriesshire. Glenroy muft, at a former period, have been a lake, the surface of whose waters stood some fathoms above the highest of the parallel roads. When the river was in flood, great quantities of mud came down to the lake, but chiefly at the sides, where the current was slower than in the middle. At the lower part of the glen, however, the lake, after a lapse of ages, muft have built its barriers, so as to reduce the surface of the waters to the level of some fathoms above the second terrace. The mud formerly deposited would now become the uppermost terrace. This operation muft have been thrice repeated, to produce the three parallel roads or terraces; and at last the river has burst for itself the channel which it now occupies, and has converted this ancient lake into a glen or deep valley. About eight miles from the mouth of the river Nevis is a remarkable cavern, known by the name of Haigh-'t-Hovile, or "Samuel's Cave;" that being the patronymic of the family of Glenewis. This cave is in the heart of a rock, which appears to be about 70 feet high, and nearly as broad, leaning to the side of a mount south of the river, and not far distant from it. The cave appears to have been formed by one part of the rock inclining towards the other, and forming between them an arched, irregular, shapely kind of grotto, from six to twelve or fourteen feet in height, thirty in length, and eleven in breadth. Opposite the rock in which the cave is formed, on the other side of the river, is a beautiful cascade, falling by a gradual slope from Ben-Nevis, upwards of half a mile before it reaches the bottom of

the valley, where it unites its streams with those of the Nevis. About two miles farther up the Nevis, on the cave side, is another cascade, which, after forcing its way through hills and rocks, has a fall 500 feet perpendicular. The whole vicinity, as may be expected from the number of mountains, abounds with cascades, which produce variety of picturesque scenery.

Such is the rude wildness of the mountains, rocks, and glens, that it is not wonderful the mountain chiefs and inhabitants of this country so long retained their independence. Not more than twenty years ago, a formidable banditti infested Invernessshire. They conspired of deserters and robbers, leagued together for the annoyance of the country; but the military from the forts on the lakes being sent against them, the leaders were taken, the association was broken, and tranquility restored.

The north-eastern corner of this county, adjacent to the Moray frith, is to be considered as a part of the Lowlands of Scotland; but all the rest of the county belongs to the Highlands. The low country contiguous to Inverness is, upon the whole, well cultivated. The rest of the eastern coast enjoys a drier climate than is to be found in the west. Considerable quantities of wheat are sown here, together with barley, oats, and peas. Potatoes are raised in great abundance, and constitute the principal food of the poorer class of inhabitants. Some rye is sown, generally mixed with oats, which gives a softness to the oat-bread of this country. In the upper parts, and in every quarter where possessions remain on the ancient small scale, agriculture is in a miserable state. In the remotest districts, the harness of a horse still consists of a bridle made of the twisted twigs of birch; with a stick put under the horse's tail, and tied with twigs, for a crupper; the saddle is a pad made of coarse sack, fastened with twisted birch twigs, or hair ropes. The mountains and forests are inhabited by immense herds of red and roe deer, which roam in safety, in recesses almost impenetrable to man: the alpine and common hare, and other game, are also abundant. The fir woods in Glenmore and Strathspey, the property of the duke of Gordon and sir James Grant, are supposed to be more extensive than all the other natural woods in Scotland together. Indeed, in every quarter are considerable forests; and there are natural plantations of great extent near the seats of the different proprietors, on the sea-coast or lakes. In the parish of Kilmalie alone, near Fort William, the wood-lands are estimated at about 14,000 acres. The trees that grow naturally are oak, fir, birch, ash, mountain-ash, holly, elm, wild green, hazel, and the Scottish poplar: those planted are larch, spruce, silver fir, beech, plane, and fruit trees. Limestone, approaching to the nature of marble, is found in every district of the county. In Lochaber, near the farm-houses of Ballachulish, is a lime-stone or marble rock of an ashen-grey colour, and of a fine regular grain or texture, capable of being raised in blocks or slabs of any size, and susceptible of a fine polish. This singular rock is sprinkled throughout with grains and specks of bright mundic or pyrites, and of lead-ore of a fine texture, which appears to be rich in silver. In the farm of Blarrafuillach, belonging to the duke of Gordon, about three miles to the south of Fort William, in the bed of a river, is a very peculiar kind of marble, consisting of a black ground, flowered with white. This stone is of a fine close grain, but not very hard; the flowering is light and elegant, like fine needle-work. Many of the mountains are composed of reddish granite. In the parish of Kingurie a rich vein of silver was discovered, but could never be successfully wrought; and in other places, veins of lead,

lead, with silver intermixed, have been found. Iron ore has also been discovered, but not in sufficient quantity to make it an object of manufacture.

This county contains many vestiges of antiquity. In various parts are to be seen remains of Druidical temples. At Corymony, in the northern part of the county, is one in which the middle of the circle is occupied by a cairn of loose stones, on the summit of which is one very large stone. Such temples are also found in the southern parts. Sometimes each great standing stone is supported by two other large stones buried under ground; so that where there is a single circle above, there is a double one beneath.

In the parish of Kilmanavaig is the ruined castle of Inverlochy. There was, at one time, a thriving borough of the same name adjacent to this building, which some of the old Scottish historians call the emporium of the west of Scotland; but of this borough there are no other indications than some pavement in different places, which were probably the streets of it. The castle has survived the borough, and now stands alone, a monument of ancient magnificence. It is a quadrangular building, with round towers at the angles, measuring thirty yards every way within the walls. The towers and ramparts are built of stone and lime, nine feet thick at the bottom, and eight feet above. It was surrounded by a ditch, from thirty to forty feet in breadth, which was supplied with water from the river. The whole building, including the towers, covers about 1600 square yards; and within the outside of the ditch are contained nearly 7000 square yards. At the great gate, between the fourth and east towers, are some remains of a draw-bridge.

This gate is nine feet wide, and arched to the same height, with abutments of fourteen feet at each side. Directly opposite was another gate, of nearly the same size, which probably was designed as a water gate. Besides these two principal entries, three of the towers were provided with fally ports; one from each, well contrived, and close to the arrow-holes, which also flanked and defended them. There is a tradition that this castle was once a royal residence; and that the league betwixt Charles the Great of France and Achaus king of the Scots was signed there on the part of the Scottish monarch, about the end of the eighth century.

Within sight of Inverlochy castle stood that of Dundhairdghall, on the summit of a hill about 400 yards in height. The traces of the building are still visible; and the part now remaining runs round the whole top of the hill, the compass of which is 150 yards. The part of the hall that now remains is no more than from two to four feet high, and is vitrified all round. On the northern banks of the river Lochie are the remains of an ancient castle, which, before the invention of fire-arms, was certainly a very strong place. It stands on the brink of a frightful precipice, at the bottom of which the river forces its passage through rocks, and has been secured on the land-side by a ditch and draw-bridge. The traces of the ditch are still visible. The castle of Urquhart, now fallen to decay, stands on a rocky promontory, on the west side of Loch Neis, of which it commands a view from one end to the other. The loch washes the east side of the building, and the other three sides were fortified with a strong rampart, a ditch, and a draw-bridge. Within the walls were accommodations for five or six hundred men. This castle was a royal fort, and was granted by king James IV. in 1509, with the estate and lordship of Urquhart, to the laird of Grant, in whose family they still continue. Along the chain of lochs are three forts, or military stations, designed to keep the Highlanders in subjection, Fort George, Fort Augustus, and Fort

William. The first is placed at the eastern extremity of the lakes, and prevents all entrance up the Moray frith: it is a regular fortification, and covers ten Scottish acres. Fort Augustus is situated in the middle of the chain: it has four bastions, and barracks for the accommodation of four hundred soldiers, with proper lodgings for the officers. On the west, to check any attempts from that quarter, stands Fort William, which is of a triangular form, with two bastions: this has fifteen twelve-pounders, some mortars, and a considerable armoury. It was built during the usurpation of Cromwell, under the direction of general Monk; and was then more extensive than at present, as it contained two thousand effective troops.

The remains of old watch-towers, or very small fortresses, are to be seen on the summits of many of the mountains. In the parish of Laggan is a rock, upwards of an hundred yards perpendicular height, and of very difficult access; yet on the very summit are considerable remains of a fortification. The area is about 500 feet by 253; the wall is upwards of fifteen feet in thickness. In the middle of Coil-More, the great wood on the south side of Loch Erich, is a place called Ailt-Merigie, or "the height on which a standard was wont to be erected." It appears to have been held sacred from the most remote antiquity, and is said to be the burial-place of seven kings of the ancient Caledonians. On a moor in Badenoch, are the remains of a square encampment; which has suggested the idea that the Romans advanced into this mountainous district: in clearing some adjacent ground some years ago, an urn was found full of ashes; also a Roman tripod.

In the parish of Kilmorack, are the ruins of the ancient priory of Beaulieu, which was founded in the year 1230, by James Bisset, of Lovat. In the parish of Petty are two circular earthen mounds; one close by the church-yard, the other about 200 yards west from it. These are evidently artificial, the outside being sod or turf, inclosing sand or light earth. The tradition concerning them is, that they were places for the admintiration of justice, as their name imports, being called Tom-in-he'it, "The Court-Hill." In the same parish are the ruins of the Castle Stewart, a large old house, belonging to the earl of Moray. In the eastern corner of the county, near the Moray Frith, is Culloden-Moor, the scene of the memorable battle which terminated the rebellion in 1745.

The modern buildings of this county worthy of observation are but few, and chiefly to be found in the north-eastern corner. The most distinguished residence in the county is Castle Grant, the seat of Sir James Grant, bart. It is situated on an eminence in the parish of Cromdale, on the north side of the Spey: the apartments contain a great variety of portraits and other paintings.

The islands of Barra, Benbecula, Egg, Harris, St. Kilda, Sky, North and South Uist, which are annexed to, or connected with, this county, will be found described under their respective names. Beauties of Scotland.

INVERSE, is applied to a manner of working the rule of three, or proportion, which seems to go backward, or contrarily to the order of the common and direct rule.

In the rule of three direct, the first term is to the second as the third is to the fourth; that is, if the second be greater than the third, or less than the first, in any proportion, the fourth is less than the third in the same proportion. But in the inverse rule the fourth term is as much greater than the third, as the second is less than the first.

In the inverse rule, therefore, the proportion is not as the first is to the second so is the third to the fourth; but as the

Fourth is to the first, so is the second to the third. For instance, in the direct rule we say, if three yards of tapestry cost twenty pounds, how much will fix cost? The answer is, forty. In the inverse rule we say, if twenty working men make ten yards in four days, in how many days will forty do it? The answer to this, is in two days. See RULE of Three.

Inverse Method of Fluxions. See FLUXIONS.

Inverse Planting. See PLANTING.

Inverse Proportion. See PROPORTION.

INVERSION, the act whereby any thing is inverted, or turned backwards.

Problems in geometry and arithmetic are often proved by inversion: that is, by a contrary rule, or operation.

INVERSION, in *Grammar*, is where the words of a phrase are ranged in a manner not so natural as they might be. For an instance: "Of all vices, the most abominable, and that which least becomes a man, is impurity." Here is an inversion; the natural order being this: impurity is the most abominable of all vices, and that which least becomes a man.

An inversion is not always disagreeable, but sometimes has a good effect.

INVERSION, in *Music*, is often applied to the complements or supplements of intervals to the major eighth or octave; thus the major sixth is the inversion of the minor third, the minor sixth the inversion of the major third, &c. Intervals which are the inversion of each other, always have one term of their ratios common to each, and the other terms, are one the double of the other: thus $\frac{3}{2}$ and $\frac{2}{3}$, $\frac{4}{3}$ and $\frac{3}{4}$, are inversions of each other.

INVERSION, in *Rhetoric*, is a method of confutation, by which the orator shews that the reasons offered by the opposite party make for him. So when Cæcilius urged that the province of accusing Verres ought to be granted to him, and not to Cicero, because he had been his treasurer in Sicily, at the time when those crimes were committed with which he was charged, and consequently knew most of that affair; Cicero turns the argument upon him, and shews, that for that very reason, he was the most unfit of any man to be intrusted with his prosecution; since having been concerned with him in his crimes, he would certainly do all in his power to conceal or lessen them (See Cæcil. c. 18.) Again, sometimes the charge is acknowledged, but the crime shifted off to another. Thus when Sextius was accused of sedition, because he had got together a body of gladiators, and brought them into the forum, where a warm engagement happened between them and Clodius's faction; Cicero owns the fact, but charges the crime of sedition upon Clodius's party in being the aggressors. (Pao Sext. c. 36.) Another method made use of for the same purpose is to alleviate the charge, and take off the force of it by shewing, that the thing was not done with that intention, which the adversary insinuates. Thus Cicero in his defence of king Dejotarus (cap. 8.) owns that he had raised some forces, though not to invade the Roman territories, as had been alleged, but only to defend his own borders, and send aid to the Roman generals. See CONFUTATION.

Inversion of the Uterus. See PROLAPSE Uteri.

INVERTED ARCH, in *Engineering*, is an arch of stone or brick, with the crown downwards, turned in the bottoms of the locks of canals, and in the bottoms of tunnels, and of aqueducts and other bridges whenever the bottom is soft or liable to give way or tear up, for securing the side walls; in locks and tunnels, the inverted arch should never be omitted. See the account of constructing these in our article CANAL.

VOL. XIX.

INVERTED Crescent, Point, Voh. See the substantives.

INVERTED, in *Natural History*, is a term applied to such reliqua or extraneous fossils as have a nucleus of stony matter inverted or covered by the reliquium.

INVERURY, in *Geography*, an ancient royal borough in Aberdeenshire, Scotland, is situated on the point of land formed by the confluence of the rivers Don and Ury. It is said to have been made a royal borough by king Robert Bruce, on occasion of a victory obtained by him, in this vicinity, over the English forces under Comyn, earl of Buchan. The oldest charter, however, extant, is one granted by queen Mary; the preamble of which states, that "Inverury had been a royal borough time immemorial, but the charter of its erection had been lost during the civil wars." The town is small, and its increase and improvement have been retarded by the peculiarity of its situation; it being inaccessible, excepting one side, with boats, and even that mode not always practicable. The spirited exertions of the earl of Kintore and the provost, Dr. Thom, have, in a great measure, removed this obstacle, by promoting a public subscription for building an elegant bridge over the Don, at the expence of 2000*l*: this was completed in 1791. The borough is governed by a provost, three bailiffs, a dean of guild, a treasurer, and thirteen councillors. The return to parliament in the year 1801, stated the number of houses to be 194, inhabited by 783 persons, of whom 641 were employed in agriculture. Inverury does not appear ever to have been a place of trade.

INVESTIGATION properly denotes the searching or finding any thing out, by the tracts, or prints of the feet.

Hence, mathematicians, schoolmen, and grammarians, came to use them in their respective researches.

INVESTIGATION of a Theme, is the art, method, or manner of finding the themes of verbs, that is, the primitive tense, mood, and person, of any verb, far removed from its source. To understand a Greek author, it is absolutely necessary to be well acquainted with the method of investigating a theme. This theme, in the Greek tongue, is the present tense of the indicative mood.

Clenard was the first who introduced this term into grammar: he gives the title *investigatio thematicæ* to that part where he teaches the manner of finding whence any person, or tense, or verb, proceeds, and of reducing it to its primitive word, or finding its indicative.

INVESTING, the act of conferring on any one the right or property of a fee, dignity, or office, or of ratifying and confirming what has been obtained elsewhere.

The emperors pretend to a right of investing several princes both in Germany and Italy. There was formerly a particular ceremony for the investing of bishops. After the election of a knight of the Garter, he is invested by the sovereign with two principal ensigns of the order, the Garter and George. Before his installation he is also invested with the habit of the order.

INVESTING, in the *Military Art*, signifies the opening a siege, and the encamping of an army round the place; to block up its avenues, and prevent all ingress and egress. In order to do this effectually, the general in chief of the approaching army must detach a large body of cavalry, together with the different corps of dragoons, under the command of a lieutenant-general, for the purpose of regularly investing the place. Sometimes a place is partially invested, for the sole purpose of diverting the enemy's attention from the real object, and of inducing him to weaken the garrison by detaching it to different quarters.

INVESTING, in *Common Law*, signifies the putting in possession

possession. A tenant is invested by giving him a verge, or rod, into his hands, and administering an oath.

Others define it thus: *investire est in suum jus aliquem introducere, to give livery of seisin, or possession.* See LIVERY and SEISIN. See also FEOFFMENT.

INVESTITURE, is used both for the right, and the act, of investing a tenant, or vassal; that is, of receiving the faith and homage by which a vassal becomes seised, and possessed of a fee, by his lord. See FEE.

Investitures, in their original sense, were probably intended to demonstrate in conquered countries the actual possession of the lord; and that he did not grant a bare litigious right, which the foldier was ill qualified to prosecute, but a peaceable and firm possession. And at a time, when writing was seldom practised, a mere oral gift, at a distance from the spot that was given, was not likely to be either long or accurately retained in the memory of bystanders, who were very little interested in the grant. Afterwards they were retained as a public and notorious act, that the country might take notice of and testify the transfer of the estate, and that such as claimed title by other means, might know against whom to bring their actions.

Investiture was anciently performed by rehearsing a formula of words; afterwards by the delivery of such things as had the nearest resemblance to what was transferred. Thus, land passed by the delivery of a turf: and to shew the trees were transferred at the same time, a bough was cut and delivered along with it.

In after-times, the things by which investitures were made were not so strictly observed. Many were invested by the delivery of a staff, a glove, a knife, a piece of a cloak, of a strap, and a girdle: or by pricking the thumb, by giving the keys, a spit, a blow, a ring, a turf, a bough, a straw, &c. The investiture of a kingdom or lordship, was performed by a standard, a banner, a cap, a sword, a bow, arrows, spurs, &c.

The symbols were sometimes preferred in the repositories of the houses, and were annexed to the titles.

INVESTITURES were also used with respect to spiritual benefices. These were frequently performed by delivering the crozier and pastoral ring.

The kings of England and France, the emperor of Germany, &c. had formerly this right; so that on the death of a prelate, his clergy sent the crozier, &c. to their sovereign, to be used at the ceremony of investing his successor. It is not certain when this custom began; Cardinal Humbert places the commencement of it in the reign of Otho the Great: and it appears, that in the ninth century, the greater part of the European princes made no opposition to the right of electing the bishops, which was both claimed and exercised by the clergy and the people. The first who disputed this privilege with the emperors and sovereign princes, was Gregory VII.; he excommunicated the emperor Henry IV. and forbade all ecclesiastics, under pain of excommunication, to receive investiture at the hands of secular princes. This occasioned a long and bloody war; the civil and ecclesiastical powers being divided into two great factions, of which one maintained the rights of the emperor, while the other seconded the ambitious views of the pontiff. The laws of Gregory for the abolition of investitures were confirmed and renewed by Victor III. and Urban II. the last of whom not only confirmed the laws and anathemas of Gregory, in a council assembled at Placentia in the year 1095; but published also a prohibitory law in the council of Clermont, forbidding the bishops and the rest of the clergy to take the oath of allegiance to their respective sovereigns. Pascal II. in a council assembled at Rome, A.D.

1102, renewed the decrees of his predecessors against investitures and the excommunications they had thundered out against Henry IV. Pascal, however, was obliged, in 1117, to confirm Henry V. in the right of giving investitures; but repenting what he had done, he assembled a council in the church at Lateran, in 1122, which solemnly annulled his treaty with the emperor, who was excommunicated in many synods and councils, both in France and Germany. At length, however, Calixtus II. engaged him to renounce investiture on certain conditions, and peace was concluded between the emperor and the pope's legates, at a general diet held at Worms, A.D. 1122. This convention was confirmed the following year in the general council of Lateran, and remains still in force.

INVISCIATIO, a sticking of the eye-lids together.

INULA, in *Botany*, so named by Pliny. This appellation is contracted or corrupted, says professor Martyn, from *Helenium*, Dict. *Novus*; fabled to have sprung from the tears of Helen. Linn. Gen. 126. Schreb. 577. Willd. Sp. Pl. v. 3. 2089. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. Soc. Ait. Hort. Kew. v. 3. 222. Juss. 181. Lamarck Dict. v. 3. 253. Illustr. t. 680. Gertn. t. 170. (Enula; Cæfalp. and Magnol.—*Helenium*; Gerard. em. 793. Vaill. Mem. Acad. Paris. 1720.) Class and order, *Syngenesia Polygamia Superflua*. Nat. Ord. *Compositæ Discoidæ*, Linn. *Corymbiferae*, Juss.

Gen. Ch. *Comm. calyx* imbricated; scales loose, spreading, the exterior ones larger, of equal length. *Cor.* compound, radiated, broad; *florets* of the disk all perfect, equal, very numerous, funnel-shaped, with a five cleft straightish limb; those of the radius female, ligulate, numerous, crowded together, linear, entire. *Stam.* (in the tubular florets) Filaments five, thread-shaped, short; anthers cylindrical, composed of five smaller, linear, conjoined ones; each ending below in two straight bristles, the length of the filaments. *Pist.* (in the tubular florets) Germen long; style thread-shaped, the length of the filaments; stigma bifid, somewhat erect. The female or ligulate florets differ in having the style cloven but half way down, and the stigma quite erect. *Peric.* none, except the unchanged calyx. *Seeds* in the florets of the disk as well as the radius, foliary, linear, quadrangular. *Down* capillary, the length of the seeds. *Recept.* almost naked, flat.

Eff. Ch. Receptacle nearly naked. Down simple. Calyx imbricated. Florets of the radius very numerous, linear, anthers with two bristles at the base.

Obs. This genus differs not only from *Aster*, but from most others, in having the anthers terminated below by ten bristles, though this character is not apparent in all the species. *Inula* is an extensive genus, Willdenow having enumerated thirty-five species, from which number we select for description the only four which are natives of this country: these are,

1. *I. Helenium*, Elecampane. Linn. Sp. Pl. 1236. Engl. Bot. t. 1546. Woodv. Med. Bot. v. 2. t. 108.—“Leaves clasping the stem, ovate, rugged, downy beneath. Scales of the calyx ovate.”—Found in moist rich pastures and meadows in various parts of Britain, but not common, flowering in July and August. *Stems* about four feet high, leafy, downy, branched in the upper part. *Leaves* ovate, slight: serrated, veiny, downy beneath. *Flowers* large, terminal, of a fine golden yellow.

The ancients entertained a very high opinion of the virtues of this plant, and “in gardens it is still cultivated occasionally, for the sake of its root, which is perennial, large and fleshy, abounding with mucilage, combined with an aromatic,

matic, bitter flavour, and some acrimony. These qualities render it useful to promote expectation.

Horace was acquainted with its fame, for we find it celebrated by that poet in two of the satires in his second book.

————— cum rapula plenus
Atque acidas mavult inulas. Sat. 2. v. 44.

And also in sat. S. v. 51.

Erucas virides, inulas ego primus amaras
Monstravi incoquere. —

2. *I. dytiscica*. Common Fleabane. Linn. Sp. Pl. 1237. Engl. Bot. t. 1115. Curt. Lond. fasc. 3. t. 56. — "Leaves oblong, clasping the stem with their heart-shaped base, downy. St. in woolly, panicked. Calyx-seales bristle-shaped, hairy." — Native of clear ditches and moist places, flowering in August. — Root creeping and perennial. Stem branched in a panicked or corymbose manner. Leaves waved and slightly toothed at their margin; their under side densely clothed with hoary down. Flowers numerous, terminal, of a full bright yellow. The herb is viscid to the touch, exhaling a peculiar sharpish aromatic scent, not unlike that of a peach.

Mr. R. Han mentions a variety of this species with very short rays, and Linnæus, in the *Flora Suecica*, observes that the Russians were cured of the bloody flux by this plant, in their expedition against the Persians, whence its specific name.

3. *I. pulicaria*. Small Fleabane. Linn. Sp. Pl. 1238. Engl. Bot. t. 1166. Curt. Lond. fasc. 3. t. 57. — "Leaves clasping the stem, waved. Stem much branched, hairy. Flowers hemispherical, with a very short radius." — Found on moist sandy heaths and commons, where water has stagnated, and flowering late in autumn. — Root annual, tapering and branched. Stem generally erect, sometimes spreading or decumbent, zigzag, angular. Leaves lanceolate or oblong, hairy on both sides. Flowers solitary, of a pale dull yellow. There is a variety of this which has scarcely any flowers of the radius.

4. *I. crithmoides*. Samphire-leaved Fleabane. Linn. Sp. Pl. 1240. Engl. Bot. t. 68. — "Leaves linear, fleshy, generally three-pointed. Calyx smooth." — This is a maritime plant, which thrives in a muddy soil, and is rather scarce. It flowers in August. — Root perennial, fibrous. Leaves alternate, smooth and succulent, salt to the taste, those about the centre of the stem generally furnished with a tooth on each side of the tip. Flower solitary, very handsome, having yellow rays and an orange disk. Down tough, bluish-coloured.

The remaining species are *I. odora*, *Oculus Christi*, *britannica*, *indica*, *arabica*, *spiræifolia*, *japonica*, *squarrosa*, *viscosa*, *falcina*, *grandiflora*, *glandulosa*, *bubonium*, *hirta*, *suaevolens*, *Vaillantii*, *mariana*, *dubia*, *orientalis*, *germanica*, *ensifolia*, *provincialis*, *montana*, *astuani*, *bifrons*, *cerulea*, *aromatica*, *faturçoides*, *pinifolia*, *setida*.

INULA, in *Gardening*, comprehends plants of the herbaceous and shrubby kinds; of which the species principally cultivated are the common inula or elecampane (*I. helenium*); the creeping-rooted inula (*I. britannica*); the willow-leaved inula (*I. falcina*); the canary inula (*I. canariensis*); the favory-leaved inula (*I. fatureioides*); and the shrubby inula (*I. fruticosa*.)

There are some other sorts that may likewise be cultivated.

Method of Culture. — The first of the five sorts may be propagated by seeds sown in autumn, soon after they are

ripe, on a warm, loamy, rather moist border. The plants should be transplanted to the places where they are to grow in the following autumn.

But the common practice is to increase it by offsets, which, when taken from the old roots carefully, with a bud or eye to each, take root easily: the best season is the autumn, as soon as the leaves begin to decay; planting them in rows about a foot asunder, and nine or ten inches distance in the rows. The following spring the ground should be kept clean from weeds, and be slightly dug over in the autumn following. The roots will be fit for use after two years growth, but will abide many years if permitted to stand.

The two following sorts may be increased by parting the roots, and planting them in the autumn, in the borders or other places where they are to remain. They should not be removed oftener than every three years.

The fourth and fifth sorts may be raised by planting cuttings of the branches, in the summer season, in pots of light earth, in shady borders. They must be removed into shelter in autumn, but should have as much free air as possible at all times, when the weather is mild. In cold weather the first should have but very little water, as the stalks and leaves, being succulent, are very apt to rot. In summer they should be placed abroad with other hardy exotic plants, in a sheltered situation.

The last sort is propagated by seeds procured from places where it grows naturally. These must be sown in pots, or upon a hot-bed, and when the plants are fit to remove, be each put into a small pot filled with light earth, and plunged into a fresh hot-bed; treating them in the same manner as other similar tender plants. It requires to be kept constantly in the stove.

The first sort may be cultivated for the medicinal use of the roots, or for ornament, in large borders.

The two following sorts may have places in the same way.

The fourth and fifth kinds afford variety among other potted green-house plants, and the last among stove-plants.

INULA Helenium, in the *Materia Medica*. See *ELECAM-PANE*.

INVOCATION, in *Theology*, an act whereby we adore God, and call on him for his assistance.

The Romanists also practise invocation of saints, begging them to intercede with God in their behalf. This is one of the grand articles of dispute between the Romanists and the Reformed.

INVOCATION, in *Poetry*, an address at the beginning of a poem, wherein the poet calls for the assistance of some god, particularly of his Muse, or the deity of poetry. See *MUSES*.

This part is absolutely necessary in an epic poem, because the poet relates things which he could not be supposed to know, unless some deity inspired him. Besides, this serves his readers as an example of piety and devotion, which ought to be the foundation of this whole work. To these it may be added, that the gods themselves are to have a part in the action; and it is not decent he should set them to work, without first asking them leave.

Indeed, in the course of an epic poem, there are usually several invocations; particularly where any thing extraordinary, or miraculous, comes to be related; as that when Virgil describes the metamorphosis of Æneas's fleet into sea nymphs: but the first invocation is always the most considerable.

In the invocation *Bosiu* considers two things: the first is what the poet requests; the second, to what deity he addresses his request. As to the first, Homer has joined the

invocation so closely to the proposition, that he seems to invoke his Muse for the whole work. But Virgil, on the contrary, only requests his Muse to furnish him with a part of his subject; and even mentions what particular part it is he desires. After proposing his matter in all its extent, he begs the Muse to acquaint him with the cause of it. See PROPOSITION.

As to the deity invoked, the same author observes, that it must always be, either the divinity that presides over poetry in general, or that which presides over the particular subject of the work. Ovid's invocation, in the *Metamorphoses*, is of the latter kind; and so is that of Lucretius; those of Homer and Virgil are of the former kind; they only invoke the Muses; and thus they distinguish between the divinities who preside over poetry, and those who preside over the actions of the poem, and have parts in it.

By the way, it may be observed, that the deities invoked are not looked on, even by the poets themselves, as divine personages from whom they expect any real assistance. Under the name of Muse they wish for the genius of poetry, and for all the qualities necessary for the execution of their design. These are mere allegories, or manners of expressing themselves poetically; just as when they personify and make gods of sleep, of rest, fame, and other natural and moral things. And thus the Muses come to be of all ages, countries, and religions; there are Pagan, Christian, Greek, Latin, and English Muses.

INVOICE, or INVOCICE, a list, or account of commodities, with their value, customs, provision, charges, &c. sent by a merchant to his factor, or correspondent, in another country.

INVOICE, Book of. See BOOK.

INVOLUCELLUM, in *Botany*. See the following article.

INVOLUCRUM, a term adopted by Linnaeus, at the suggestion of Artedi, for the row of small leaves found at the base of the umbels in most umbelliferous plants. That of the general umbel is termed the *General Involucrum*; that of each partial one a *Partial Involucrum*, in Latin *Involucellum*. The same word is used for what might be more properly called *Bracteas* in *Euphorbia* and other genera, and Linnaeus has probably erred in reckoning the *involucrum* a species of calyx in any instance. In ferns, however, we retain this appellation for the membranous covering of their fructification, in preference to a newly invented term *indigium*.

INVOLUNTARY Discharge of Urine. See INCONTINENCE of Urine.

INVOLUNTARY Motion. See MOTION.

INVOLUTE CURVE, in the *Higher Geometry*. See EVOLUTE.

INVOLUTION, in *Algebra*, the raising any quantity from its root to any height, or power, assigned. See POWER.

Any quantity multiplied by itself, the product is the square of that quantity; the square being again multiplied by the quantity, produces its cube. See SQUARE and CUBE.

Thus if $a + b$ were to be raised to its second power, it will produce $a^2 + 2ab + b^2$.

And if it be involved again, or if that square be multiplied by the root, the cube or third power will be produced; viz. $a^3 + 3a^2b + 3ab^2 + b^3$, &c. so that the involution of any compound quantity is performed by a continual multiplication of it by itself: if the powers of $a - b$ are required, they will be found the same as those of $a + b$,

except that the terms in which the exponent of b is an odd number will be negative, because an odd number of multiplications of a negative produce a negative; or, in general, the terms of any power of $a - b$ are positive and negative by turns. See BINOMIAL Theorem.

If a quantity, consisting of three or more terms, is to be involved, it may be distinguished into two parts, which are to be raised to any power in the same manner as a binomial; and then by the same rules, the value of these compound parts may be substituted in their stead; thus,

$$\overline{a + b + c}^2 = \overline{a + b + c} = \overline{a + b}^2 + 2c \times \overline{a + b} + c^2 \\ = a^2 + 2ab + b^2 + 2ac + 2bc + c^2.$$

$$\text{And } \overline{a + b + c}^3 = \overline{a + b}^3 + 3c \times \overline{a + b}^2 + 3c^2 \times \overline{a + b} \\ + c^3 = a^3 + 3a^2b + 3ab^2 + b^3 + 3a^2c + 6abc + 3b^2c + 3ac^2 + 3bc^2 + c^3. \text{ The reverse of involution is called evolution. See EXTRACTION of ROOTS, and ROOT.}$$

INWARD Flanking Angle, in Fortification. See ANGLE.

IOACHIM, in *Biography*, a celebrated Italian monk, was born at Celico, near Colenza, in the beginning of the 12th century. After he had received a common education, he rather obtained for him a post at the court of Naples, in which he served some time. After this he took the resolution of visiting the holy places in Palestine, left Naples, without communicating his design to his father, and reached Constantinople, where he made a short stay. While in this city he was so alarmed at the extraordinary mortality produced by a pestilential disorder, that he made a vow to renounce the world, and, having assumed the habit of a hermit, proceeded barefoot on his journey. On his return he entered into the order of Cistercians, and founded several monasteries, which he governed with great discretion. He was regarded by many of his contemporaries as a prophet, and several of his predictions were printed, in a book entitled "The Everlasting Gospel." He was author of other works, particularly of "A Harmony of the Old and New Testament." He died in the year 1202, at the age of 90. His followers wished to persuade the world that miracles were wrought at his tomb, and applied to the pope to canonize him, but this was rejected on account of the numerous errors contained in his works. Moreri. See JOACHIMITES.

JOACHIM, GEORGE, a celebrated mathematician and astronomer in the 16th century, was born, in 1514, at Feldkirch, in the Tyrol. He was educated at Zurich, where he soon discovered a strong inclination for mathematical pursuits, in the elements of which he was initiated at that place. Afterwards he went to Wittemberg, where he prosecuted his studies with ardour and success. In the year 1555 he was admitted to the degree of M. A., and in two years afterwards he was appointed joint professor of the mathematics with Reinhold. He was a zealous and able defender of the Copernican system of the world; went into Prussia, where he placed himself under the tuition of Copernicus himself, and became the editor of his great work, entitled "De Revolutionibus." While Joachim continued in Prussia, to render astronomical calculations more ready and accurate, he began an elaborate canon of sines, tangents, and secants, to fifteen places of figures, and to every ten seconds of the quadrant. He did not live to accomplish this great work, but the canon of sines for every ten seconds, and for every single second in the first and last degree of the quadrant, computed by him, was published at Frankfort in 1613, by Pitiscus; the larger work was perfected and published after his death in 1596, by his disciple Valentine Otho. Joachim

returned

returned from Prussia in 1543, and was again admitted to his professorship of mathematics at Wittenburg; he afterwards was elected to fill the mathematical chair at Leipsic. He died in 1576, in the sixty-second year of his age, leaving behind him "Narratio de Libris Revolutionum Copernici;" first published at Dantzic in 1540. He also composed and published "Ephemerides;" according to the doctrine of Copernicus, till the year 1551. Moreri. Hutton.

JOACHIM, *St.*, in *Geography*, a town of South America, in the kingdom of Granada, on the Mata; 240 miles E. of Santa Fé de Bogota.—Also, a town of South America, in the province of Mexico; 150 miles N.N.E. of Trinidad.—Also, a town of Canada, on the river St. Lawrence. N. lat. 47° 5'. W. long. 70° 45'.

JOACHIM de Omaguas, *St.*, a town of South America, in the audience of Quito, on the river Amazons; 400 miles S. E. of Quito. S. lat. 4° 40'. W. long. 72° 30'.

JOACHIMITES, in *Ecclesiastical History*, the name of a sect, the followers of one Joachim, abbot of Flora, in Calabria, who was esteemed a prophet while he lived, and left, at his death, several books of prophecies, contained in his Everlasting Gospel, commonly called the book of Joachim, besides other works; which were condemned, in 1215, by the council of Lateran; and by the council of Arles, in 1266.

One of the spiritual friars, named Gerhard, belonging to the order of Franciscans, undertook to explain the Everlasting Gospel of Joachim, in a book published in 1250, entitled "The Introduction to the Everlasting Gospel." In this work St. Francis is declared to be the angel mentioned in the Revelation, xiv. 6, who had promulgated the true and everlasting gospel of God; it is also asserted, that the gospel of Christ was to be abrogated in 1260, and this new gospel to be published in its room; and that the ministers of this signal reformation were to be humble and barefooted friars, destitute of all worldly employment. This absurd book was suppressed by order of pope Alexander IV. in 1255, and at length publicly committed to the flames.

The Joachimites were particularly fond of certain ternaries: the Father, said they, operated from the beginning till the coming of the Son; the Son from that time to theirs, viz. the year 1260; and the Holy Spirit then took it up, and was to operate in his turn. Hence they divided every thing that related to men, time, doctrine, and manner of living, into three classes, or states, according to the three persons in the Trinity; every one of which states either had already, or was hereafter to succeed in its turn; and hence they called the divisions ternaries.

The explication given by Joachim, of the Trinity, in opposition to Peter Lombard, which was considered by many as differing little from the Arian system, procured the damnable sentence of his doctrine by Innocent III. in the council of Lateran; but notwithstanding this papal sentence Joachim has still a considerable number of adherents and defenders, more especially among those of the Franciscans, who are called Observants, or Friars observant.

JOACHIMSTHAL, in *Geography*, a town of Bohemia, in the circle of Elbogen, celebrated for its silver mines, which were discovered in the year 1516, and which yielded from the year 1586, to the year 1601, 305,790 marks of silver; 52 miles S.S.E. of Dresden. N. lat. 50° 20'. E. long. 12° 53'.—Also, a town of Brandenburg, in the Uecker Mark; 31 miles N.N.E. of Berlin. N. lat. 53° 5'. E. long. 13° 55'.

JOAG, a town of Africa, in the country of Kujang; which Mr. Park supposes to have contained about 2000 inhabitants. It is surrounded by a high wall, in which is a

number of port holes, from which muskets may be fired in case of an attack; and every man's possession is likewise surrounded by a wall. To the westward of the town is a small river, on the banks of which are cultivated considerable quantities of tobacco and onions. N. lat. 14° 25'. W. long. 9° 38'.

JOAL, a town of Africa, in the kingdom of Sin, situated on the sea-coast, with a good road and anchorage; where the French had a factory for slaves, skins, ivory, and wax.

JOAN I., in *Biography*, queen of Naples, eldest daughter of Charles duke of Calabria, son of Robert king of Naples, was born about the year 1326. Her father died while she was very young, and Robert immediately betrothed her to Andrew, second son of Charles king of Hungary, who was her cousin, and who was then sent to Naples to be educated. On the death of Robert in 1643, Joan was proclaimed queen. She had already conceived a great aversion from her husband, which was increased by the idle tales of her attendants, and was now determined to hold all power in her own hands; but the pope, who was in his interest, granted a bull for the coronation of Andrew, as king in his own right. Joan was suspected of barbouring an attachment for Lewis, prince of Tarento; and she was accused of being privy to the murder of Andrew, who was taken off at the instigation of the princes of the blood, to prevent, as they thought, the kingdom from falling into the hands of the Hungarians.

The king of Hungary determined to revenge himself upon the perpetrators of his brother's assassination, and advanced with a large army into Naples; the queen, who had already married the prince of Tarento, fled into Provence, and all Naples fell under the dominion of Lewis the Hungarian monarch. Joan went to Avignon, and was received with great respect by pope Clement VI. and the cardinals, before whom she underwent a formal trial on account of her husband's death. She pleaded her cause with eloquence, and was declared not only innocent, but free from all suspicion. With this decision the king of Hungary seems to have been satisfied, and immediately returned to his own dominions. Joan was now invited by the Neapolitan barons to resume her crown; she accordingly fitted out a fleet, and re-entered Naples with general acclamations in 1348. She was next engaged in a contest with the king of Hungary, which proved so much against her, that she was obliged to seek a cessation of arms, which was granted by the king, on the condition that she should abide the event of another trial before the papal court. Upon the issue of this was to be determined the possession of the kingdom of Naples. Joan now had recourse to a different kind of defence, and she pleaded in excuse that she was under the influence of witchcraft at the time, which rendered her averfe from her husband, and encouraged others to conspire against him. This plea served her purpose, and she was declared blameless of all actions committed subsequent to the supposed fascination. She was left in the peaceable possession of her throne, and was again crowned, with her husband Lewis, in the city of Naples. Lewis died in 1362, and in the course of a few months she married James of Aragon, called the Infant of Majorca, whom she did not allow to assume a higher title than duke of Calabria. This prince died in 1375, and in the following year she took a fourth husband, viz. Otho, of the house of Brunswick, an accomplished soldier and handsome man, on whom she conferred the title of duke of Tarento, with a large estate. Having no children, the one by Andrew being dead, she adopted as a successor her relation Charles de Duras, who revolted against her at the instigation of the king of Hungary. She then adopted for her heir Lewis of France, duke of Anjou, which produced a bloody war. Charles, however, was a native prince, and

being more agreeable to the wishes of the Neopolitans than a foreigner, he marched to Naples, and being joined by the bishop, he found little or no difficulty in getting possession of the kingdom. The queen was obliged to capitulate, she was imprisoned, and after a few months was put to death. This event occurred in 1522, in the thirty-ninth year of her reign. She was a woman of great accomplishments, and possessed many good qualities, though sullied by early dissoluteness. She was the friend and patron of men of learning. Univer. Hist. Bayle.

JOAN D'ARC. See ARC.

JOAN, *Pop.*: a short notice must be taken of this character, as being frequently referred to, though it is now generally regarded as merely fictitious. It is said, that about the middle of the ninth century, a woman named Joan, born at Metz, and who had received an excellent education, conceiving a violent passion for a young monk named Fulda, resolved to desert her family and friends to assume the male habit, and gain admittance into the monastery. The plan succeeded, and having long indulged in their amours undisturbed and unsuspected; they eloped together, and travelled into most of the countries of Europe, availing themselves of every opportunity for increasing their knowledge, by engaging the assistance of the best masters in the different cities through which they passed. On the death of her lover, Jean repaired to Rome, still in the dress of a man; her address, and engaging manners raised her into notice; she commenced the duties of professor, and persons of the highest rank and most considerable talents enlisted in the number of her disciples. At length, on the death of pope Leo X. in 875, she was unanimously elected his successor to the pontifical throne. So prudently did the conduct herself, and with so much ability did she perform the duties of her station, that the people had reason to congratulate themselves on their choice. At length she confided her secret to a domestic whom she took to her bed, the consequence of which was her pregnancy, and she was taken in labour at one of the most solemn processions, delivered of a child in the street, and died on the spot. It is likewise said, that to perpetuate the memory of such an extraordinary adventure, a statue was erected on the place where it happened; that in abhorrence of the crime, the pope and clergy in their subsequent annual processions from the Vatican to the Lateran have turned off from that street; and that to prevent a similar imposition, a custom was introduced of examining each pope previously to his consecration, in order to ascertain his sex. Such are the particulars of a story that seems not to have been called in question till the time of Luther, but which the best informed historians usually abandon as fictitious. "Till the reformation," says Gibbon, "the tale was repeated and believed without offence, and Joan's female statue long occupied her place among the popes in the cathedral of Sienna. She has been annihilated by two learned Protestants, Blondel and Bayle, but their brethren were scandalized by this equitable and generous criticism. Spanheim and L'Enfant attempted to save this poor engine of controversy; and even Mosheim condescends to cherish some doubt and suspicion."

JOAN D'ALBERT, queen of Navarre, daughter of Henry d'Alart, and Margaret of Valois, was born in 1528. In 1548, she married Antony of Bourbon, duke of Vendome, by whom she had, as a third son, the afterwards celebrated Henry IV. of France. At the decease of her father, in 1555, she became queen of Navarre, and her husband took the title of king. They were both favourable to the principles of the reformation, and would probably have openly professed it had they not feared the resentment of the king of France, but after his death they declared their conversion

to Calvinism, of which Joan was ever after the zealous protector. Antony, on the other hand, was sickle and weak, renounced his new faith, and was a principal commander in the civil war against the Protestants, in which he lost his life at the siege of Rouen, in 1562. Joan not only established the Protestant religion in her states, but abolished popery, and seized the property of the ecclesiastics, which she applied to the maintenance of the reformed clergy and the schools. In 1563, she quitted her states to join the chiefs of the French Protestants, and at Cognac had an interview with the prince of Condé, to whom she presented her son, then of the age of fifteen, with her jewels, as devoted to the service of the cause. She next withdrew to Rochelle, whence she wrote a pathetic letter to queen Elizabeth of England, describing the calamities and oppressions which had induced the Protestants to take up arms. She died in 1572, at Paris, whither she had come to make preparations for the marriage of her son with the sister of Charles IX. Her death was not without suspicion of poison, though the fact was never ascertained.

JOANA, in *Geography*, a town on the north coast of the island of Java, situated on a river of the same name, which is the largest and most navigable along this coast. It is here more than 20 feet deep, and about 200 feet broad. It flows out of a large inland lake, into which several small streams discharge themselves, and falls into the sea about four leagues to the westward of Rembang. The town consists of two rows of houses built along the river, about a quarter of a Dutch mile in length. The fort of Joana is a redoubt, with four demi-bastions, in which are the rice warehouses, the barracks for the soldiery, and some buildings which serve for a kitchen and other offices for the resident. The emoluments of this residency amount to 16,000 rix-dollars, or about 3500l. sterling. This town yields rice and timber, a little indigo and cotton.

JOANNA, JOHANNAS, or *Hinsuan*, one of the Comora islands, about 30 miles long and 15 broad. The Abbé Raynal describes this island in terms of high commendation. Hills, he says, that are ever green, and valleys that are always gay, every where present a variety of delightful landscapes. Thirty thousand inhabitants, distributed into 73 villages, share its productions. They speak a corrupt dialect of the Arabic language, and their religion is a corrupt kind of Mahometanism; their moral principles are more refined than they usually are in this part of the globe. Accustomed to the plain diet of milk and vegetables, they are averse from labour. Among persons of distinction, who indulge themselves in ease and indolence, the nails of the fingers are suffered to grow to an immoderate length, and in order to give this effect of negligence the appearance of beauty, they tinge their nails with a yellow red, which they obtain from a shrub called *Alaana*, which see. Sir William Jones, who touched at this island, in his voyage to India, was much pleased with the beautiful scenery which its verdant hills and mountains, covered with elegant palms and other trees, presented to his view. He particularly mentions the town of Matlamado, distinguished at a distance by the tower of the principal mosque, and another small town called Bantani. For an account of his rambles through part of the island, and his intercourse with some of the principal inhabitants, we must refer to his "Remarks" on this island, in the second volume of the Asiatic Researches. Other voyagers who have visited this island, say, that the hills are steep, covered with wood, and difficult of access, and that the valleys exhibit a few irregular plantations of cocoa-nuts. The original natives, stated at about 7000 in number, occupy the hills in the interior of the island; and they are generally at war with the Arabian interlopers, who have established themselves by con-
quest

quest on the sea-coast, and are said to be in number about 3000. These latter are described as poor miserable beings, who, not being able to carry on any extensive cultivation, on account of being exposed to the depredations of the mountain-people natives, subsist chiefly by supplying the Indian ships which touch there for refreshment, with a few cattle and tropical fruits. Of their ability to accommodate strangers on shore, those who have touched at the island speak in very degrading terms, as their huts or hovels are filthy and badly constructed. The huts of the poorer people are formed of twigs, interwoven with and covered by a strong coat of galls, and the roof is protected by a kind of mat, made of the leaves of the cocoa trees. People of superior rank have houses built of stone, cemented with tempered clay. The king, as he is called, or chief of the island, resides about nine miles from the town of Joanna, which contains about 200 houses, many of which are built of stone and occupied by persons of principal distinction in the island: but they are low and inconmodious: the palace of the king excepted, which is high and spacious. This chief possesses an unlimited power over his subjects, in all concerns, religious as well as temporal: he seldom visits the town except on the arrival of European vessels, when he is accompanied by a numerous equipage, and received with great attention and respect by the commanders of the ships. Every captain finds it his interest to treat him in this manner, as his permission must be obtained before any traffic can be opened with the inhabitants; and with this view he receives a small present of European manufactures. The principal domestic animals in the island are cattle, sheep, and hogs; there are several species of fowl, and different kinds of game. The sea abounds with a variety of excellent fish; and particularly with a sort of electrical fish, seven inches long, $2\frac{1}{2}$ inches broad, with a long projecting mouth, a head of a dark brown colour, the belly of sea-green, the sides yellow, and the fins and tail of a sandy-green; the body interperfed with red, green, and white spots; the eyes large, and the iris red, having its outer edges tinged with yellow. The sea-coast is wholly composed of coral rocks, which are in many places hollowed by the sea; and in those cavities several of the electrical fishes were found. See a description and drawing in the Phil. Trans. vol. lxxvi. p. 352. The natives of the island are, in general, tall, robust, and well-made; the women are inferior to the men; they have all long black hair, piercing eyes, and colour between olive and black. People of lower rank have no other covering besides a piece of cloth tied round their loins, and on their heads a cap of any stuff which they can procure. Those of higher rank wear a shirt with large sleeves, hanging down upon a pair of drawers and covering a stuff waistcoat; those of still higher orders wear turbans; and they generally have large knives attached to a belt, which pass round their middle. The women are clothed in a kind of jacket and petticoat, with a loose robe, and when they go abroad, they cover the face with a veil: they are very attentive to ornaments for their legs, arms, and ears. Their children, both male and female, are suckled to be naked till the age of seven or eight years. The inhabitants in general are commended for their simplicity, obliging disposition, and hospitality. Polygamy is allowed; so that each person has two or three wives, and as many concubines as he can maintain. S. lat. $12^{\circ} 13'$. E. long. $44^{\circ} 15'$.

JOAO, *St.*, a small island near the coast of Brazil. S. lat. 22° . W. long. $46^{\circ} 26'$.

JOAO FUSTADO, a town of Brazil, in the island of Marajo; 20 miles S. S. W. of Engenho-real.

JOAO DE FUNDOS, *St.*, a town of Portugal, in Estremadura; 32 miles N. E. of Thomar.

JOAO DE FURTADO, *St.*, a town of Brazil, in the government of Para, on the Guanapu; 75 miles S. W. of Para.

JOAO MARTINO, a small island in the Indian sea. S. lat. 10° S. W. long. $42^{\circ} 54'$.

JOAO DE MONTE, *St.*, a town of Portugal, in the province of Beira; 12 miles W. S. W. of St. Viseu.

JOAO DE NOVA, a small island in the channel of Mozambique. S. lat. $16^{\circ} 58'$. E. long. $40^{\circ} 34'$.—Also, two small islands in the Indian sea. S. lat. $9^{\circ} 30'$. E. long. $39^{\circ} 14'$.

JOAO DE PEQUENEA, *St.*, a town of Portugal, in the province of Beira, on the Duero; containing two parish churches, and about 600 inhabitants; near it is a cataract on the Duero, which prevents the navigation of this river; 21 miles E. S. E. of Lamego. N. lat. $41^{\circ} 1'$. W. long. $7^{\circ} 1'$.

JOAO DE PO, *St.*, a town of Portugal, in the province of Beira; seven miles N. E. of Braganza Nova.

JOAO DEL REY, *St.*, a town of Brazil, in the government of Minas Geraes; 80 miles S. W. of Villarica.

JOAR, a town of Africa, in the kingdom of Burfali, surrounded with palisades as a defence from wild beasts; 10 miles S. of Kower.

JOARTAM, a town and kingdom of the island of Java, in the N. E. part of the island.

JOARYA, a town of Bengal; 55 miles S. of Islamabad.

JOB, or the Book of Job, a canonical book of the Old Testament, containing the narrative of a series of misfortunes, which happened to a man, whose name was Job, an inhabitant of the land of Uz, supposed to be that part of Arabia Petraea which is called Idumaea, as a trial of his virtue and patience; together with the conferences he had with his cruel friends on the subject of his misfortunes; and the manner in which he was restored to ease and happiness. This book is filled with those noble, bold, and figurative expressions, which constitute the very foul of poetry.

Many of the Jewish rabbins pretend that this relation is altogether a fiction; others think it a simple narrative of a matter of fact, just as it happened; while a third class of critics own the ground-work of the story to be true, but that it is wrote in a poetical strain, and decorated with peculiar circumstances, to render the narration more profitable and entertaining. Others, again, suppose that, like some of our Saviour's parables, it is a fabulous narration designed to convey important and useful sentiments respecting the superintending providence of God, in a manner more forcible and impressive than in the form of abstract rules and precepts.

See an express dissertation on the book of Job, in the bishop of Gloucester's "Divine Legation of Moses," vol. ii. The bishop is of opinion that this book is a dramatic poem written by Ezra, some time between the return of the Jews from the captivity of Babylon, and their thorough settlement in their own country, and adapted to the circumstances of these times, by being made allegorical as well as dramatic: thus, Job, who is supposed to have been a real person, that lived a generation or two before Moses, is designed to personate the Jewish people; his three friends the three great enemies of the Jews, Sanballat, Tobiah, and Geshem, who upon their return from captivity, vexed and obstructed them in rebuilding their city and temple; Job's wife was intended by the poet to represent the idolatrous wives which many of the Jews had taken, contrary to the L. W. and for which they are reproved by the prophet Nehemiah.

In order to prove the composition of this book to be dramatic, the learned bishop alleges its style, which, excepting the introduction and conclusion, is in measure; its sentiments, which are delivered not only in verse but in a kind of poetry, animated by all the sublimity of figure and boldness of description, whence he concludes the whole to be a work of imagination; and the whole form of its composition. The bishop's

Lishop's proof that the book of Job is no older than the time of Ezra, rests chiefly upon these two points, *viz.* his notion of an equal providence under the Mosaic dispensation, and that of the book's being an allegorical dramatic poem. The former point, which he conceives to have been the grand question discussed in this book, could be no question, in his opinion, any where out of the land of Judea; nor there neither, in any period of the Jewish nation, either before or after that in which he places it. The question he supposes to be this, whether God admixtures his government over men here with an equal providence, so as that the good are always prosperous, and the bad unhappy; or whether, on the contrary, there be not such apparent inequalities, as that prosperity and adversity often happen indifferently to good and bad. Job, says our author, maintains the latter part of the question, and his three friends the former. They argue these points through the whole dispute, and each party firmly adheres to his first opinion. After giving some account of the distressed condition of the Jews upon their return from the captivity, he thus proceeds: "Could any thing be conceived more reasonable and necessary at this time than such a work as the book of Job? In which, on a traditional story of great fame and reputation all over the East, a good man was represented as afflicted for the trial of his virtue, and rewarded for his afflictions; and in which their doubts about God's providence were piously resolved into his almighty power. For to quiet all their anxieties, and to comfort them under their present distresses, was I suppose, the reason of one of their prophets composing the book of Job at this very period. But if such was the end of writing this poetic story, we cannot but suppose every thing in it would be fitted to the circumstances of those times. But this could not be done without making the poem *allegorical* as well as dramatic; that is, representing the real persons of that age under the persons of the drama." That this poem is wholly allegorical the bishop argues from the divers circumstances that are added to each character, which can, by no means, belong to the persons representing; and therefore others were meant under those characters, as persons represented. This statement he endeavours to justify and confirm by examining each character, in its reference to the person represented, beginning with Job, who represents the Jewish people; and proceeding to shew how his wife portrayed the idolatrous wives of the Jews, and how his three friends represented the three capital enemies of the Jews, above-mentioned.

The next person in this allegorical drama is the devil himself, or Satan, the author and contriver of all the mischief. This assault of Satan upon Job, says the bishop, was that which, as the prophet Zachariah tells us, (chap. ii. ver. 13. chap. iii. ver. 1, &c.) he made, at this time, on the people; "The only difference is, that, in the prophecy, Joshua the high priest stands for the people, and in this poem, Job; in all the rest, the identity is so strongly supported, that this single circumstance is alone sufficient to confirm the truth of our whole representation."—"The finding of Satan in the scene is a certain proof (says our author) that the work was composed in the age we assign to it. This evil being was little known to the people till about this time." The last person in this allegorical drama is Elihu; and Elihu, according to the bishop's statement, was Ezra, or the sacred writer himself. Such are the general outlines of the learned bishop's hypothesis, in which, it must be allowed, he has manifested a considerable degree of ingenuity, and, as we conceive, no small display of fancy. This hypothesis has been examined, and in our judgment, satisfactorily refuted in Mr. Peters' "Critical Dissertation on the Book of Job."

Le Clerc supposes that the book of Job, which, in his opinion, was a history treated in a poetical manner, or a history treated in the form of a parable, was written after the Jews were carried into Babylon, and urges, in proof of this, the frequent chaldaisms that occur in it.

The learned Grotius apprehends that this book contains a true history, treated in a poetical manner; and he was probably led to adopt this opinion from adverting to the supernatural and surprising incidents that occur in it; such as that of the sons of God presenting themselves before Jehovah, and the divine interposition at the conclusion. But as he supposed the book to be written at the distance of about a thousand years from the date of the subject of which it treats, he could scarcely imagine that there was much of true history in it. Would not a considerable difficulty in settling the time, when this book was written, be obviated, by supposing that the introductory part in the two first chapters, in which Satan makes so conspicuous a figure, (and perhaps the conclusion,) were written after the Babylonish captivity, by some writer, Ezra or another person; for, as bishop Warburton allows, Satan became more known among the Jews after their return from Babylon? Grotius further supposes, that the events recorded in this poetical history happened in Arabia, whilst the Hebrews wandered in the desert; and that the writer, who was a Hebrew, lived before the time of Ezekiel, as he infers from that passage in his prophecy, where Job is mentioned; but after David and Solomon, from whose writings, as he conceives, some sentences and forms of speech are transferred hither; and that it was written for the use of the Edomites, transported to Babylon, to confirm them in the worship of the true God, and to teach them patience in adversity.

The learned writer whose sentiments we are now detailing, acknowledges that there is no mention in this book of any law but such as was traditional; nor of any point of history, besides those of the more ancient times, *viz.* before the giving of the Mosaic law; that the length of Job's life which extended to 200 years, agrees with those times; and that though the writer is unknown, it appears credible from a passage in Ezekiel, that he lived before the time of that prophet. David and Solomon might have borrowed forms of speech from the book of Job; which is no less probable than the supposition of Grotius already mentioned; and if the book was written before the time of Ezekiel, the author could not have borrowed from Daniel, Ezra, and the Chaldee paraphrasts, as Grotius seems to intimate.

Schultens ascribes the poetical, or dialogue part of this book, the style of which, he says, has all the marks of the most venerable and remote antiquity, to Job himself; the rest he supposes to be the work of some Hebrew collector. As for Le Clerc's chaldaisms, such as the termination *in for im*, in the plural, he says they are true Hebrew and Arabic, of the most ancient stamp. See also Grey's Job, p. 12. of the preface. Most of the Jewish doctors believe that Moses was the writer of this book; and M. Huet, with whom professor Michaelis concurs, supposes that it was written by Moses in his exile in the land of Midian; where he resided 40 years. Some have supposed that it was either written by him, or translated by him from the original Syriac, or Arabic, and that it was designed to prepare the Israelites for their exodus from Egypt, and the hardships of their future peregrination. All those learned men, who suppose this book to have been written by Moses, or Elihu, as Lightfoot imagines, or some person near the time of Job, must of course be persuaded that there is nothing in the style, which is not very consistent with this remote antiquity; and that the phrases which others take for imitations of passages in the Psalms or Proverbs, Daniel or Ezra, are rather originals

originals to theft, and that these last are really the imitations. It is certain, whence was the author of this book, that the style has a mixture of the Arabic. And those who have made the happiest conjectures for the solution of difficulties and the explication of particular passages, have been more indebted to the Arabic than to the Chaldee; so that the language in which it was written might have been spoken in Arabia in the days of Job. And this is the more probable, if the sons of Abraham by Keturah (from whom Job himself is supposed to be descended) were those who peopled this part of the world; for then, without doubt, they carried the language of Abraham along with them.

Mr. Peters concurs in opinion with those who believe this book to be the oldest in the world; that it was written, probably, by Job himself; and that it contains, in the main, a true history.

The eminently learned and ingenious critic, bishop Lowth, has devoted three lectures of his "Praelæciones, &c." to the examination of the book of Job. The scene of this book is laid in Idumæa; the history of an inhabitant of that country is the basis of the narrative; the characters who speak are Idumæans, or at least Arabians of the adjacent country, all originally of the race of Abraham. The language is pure Hebrew, although the author appears to be an Idumæan; for it is not improbable that all the posterity of Abraham, Israelites, Idumæans, and Arabians, whether of the family of Keturah or Ishmael, spoke for a considerable time one common language. Our learned author, discarding the fictions of those who ascribe this book to Elihu, proceeds to examine the claims of Moses, to whom it has been more generally ascribed. This hypothesis he represents as very futile, since it is impossible to trace, throughout the whole book, the slightest allusion to the manners, customs, ceremonies, or history of the Israelites. The style of Job appears, also, to be materially different from the poetical style of Moses; being much more compact, concise, or condensed, more accurate in the poetical conformation of the sentences. He therefore avows himself inclined to favour the opinion of those, who suppose Job himself, or some contemporary, to be the author of this poem, which is the most ancient of all the sacred books, as is manifest from the subject, the language, the general character, and even from the obscurity of the work. The style of the poem favours so much of the antique, that in the judgment of the learned prelate, whoever would suppose it writt'n after the Babylonish captivity would fall little short of the error of Hardouin, who ascribed the golden verses of Virgil, Horace, &c. to the "iron age" of nonkish pedantry and ignorance.

As to the time in which Job lived, the length of his life evinces that he was before Moses, and probably contemporary with the patriarchs. That he lived at a period prior to the promulgation of the law is very probable, from the nature of the sacrifice which he institutes, conformably to the command of God, namely, seven oxen and seven rams; a respect being paid in these countries, and at that period, to that number, from the traditional accounts which were still preserved among them of the seven days of creation. The poem is founded in fact, as far as concerns the general subject of the narrative; though the whole dialogue, and probably some other parts, have partaken largely of the embellishments of poetry: but this has not by any means extended so far as to convert the whole into an allegory. The exordium and conclusion, indeed, are distinct from the poem itself, and stand in the place of an argument or illustration; but our author conceives, that they are coeval with the poetical part, and the work of the same author beauti-

they are indispensably necessary to the unravelling of the plot, which is not developed in the body of the poem. Michaelis, who considers the subject of the poem as altogether fabulous, and who apprehends that it is more instructive as a fable than it possibly could be if it were a true history, cannot but regard the exordium, in which Satan appears as the accuser of Job, rather in the light of a fable than of a true narrative. It is surely incredible that such a conversation ever took place between the Almighty and Satan, who is supposed to return with *ætas* from the terrestrial regions. There are, it is true, says the learned prelate, phrases extant in the exordium, in which some critics have pretended to discover the hand of a later writer; but he is not convinced by the arguments which they produce. The principal object held forth to our contemplation in this production is the example of a good man, eminent for his piety, and of approved integrity, suddenly precipitated from the very summit of prosperity into the lowest depths of misery and ruin; who having been first bereaved of his wealth, his possessions, and his children, is afterwards afflicted with the most excruciating anguish of a loathsome disease, which entirely covers his body. He sustains all, however, with the mildest submission, and the most complete resignation to the will of Providence. "In all this," says the historian, "Job sinned not, nor charged God foolishly." And after the second trial, "In all this did not Job sin with his lips." The author of the history remarks upon this circumstance a second time, in order to excite the observation of the reader, and to render him more attentive to what follows, which properly constitutes the true subject of the poem: namely, the conduct of Job with respect to his reverence for the Almighty, and the changes which accumulating misery might produce in his temper and behaviour. Accordingly we find that another still more exquisite trial of his patience yet awaits him, and which indeed, as the writer seems to intimate, he scarcely appears to have sustained with equal firmness, namely, the unjust suspicions, the bitter reproaches, and the violent altercations of his friends, who had visited him on the pretence of affording consolation. Here commences the plot or action of the poem: for when, after a long silence of all parties, the grief of Job breaks forth into passionate exclamations, and a vehement execration on the day of his birth; the minds of his friends are suddenly exasperated, their intentions are changed, and their consolation, if indeed they originally intended any, is converted into contumely and reproaches. The first of these three singular comforters reproves his impatience; calls in question his integrity, by indirectly insinuating that God does not inflict such punishments upon the righteous; and finally admonishes him, that the chastisement of God is not to be despised. The next of them, not less intemperate in his reproofs, takes it for granted, that the children of Job had only received the reward due to their offences; and with regard to himself, intimates, that if he be innocent, and will apply with proper humility to the divine mercy, he may be restored. The third upbraids him with arrogance, with vanity, and even with falsehood, because he has presumed to defend himself against the unjust accusations of his companions; and exhorts him to a sounder mode of reasoning and a more holy life. They all, with a manifest, though indirect allusion to Job, discourse very copiously concerning the divine judgments which are always openly displayed against the wicked, and of the certain destruction of hypocritical pretenders to virtue and religion. In reply to this, Job enumerates his sufferings, and complains bitterly of the inhumanity of his friends, and of the severity which he has experienced from the hand of God; he calls to witness both God and man, and

that he is unjustly oppressed; he intimates, that he is weak in comparison with God, that the contention is consequently unequal, and that he has cause ever to righteous he cannot hope to prevail. He expostulates with God himself still more vehemently, and with greater freedom, affirming, that he does not discriminate characters, but equally afflicts the just and the unjust. The expostulations of Job serve only to irritate still more the resentment of his pretended friends; they reproach him in severer terms with pride, impiety, passion, and madness: they repeat the same arguments respecting the justice of God, the punishment of the wicked, and their certain destruction after a short period of apparent prosperity. This sentiment they confidently pronounce to be confirmed both by their experience and by that of their fathers; and they maliciously exaggerate the ungrateful topic, by the most splendid imagery and the most forcible language. On the part of Job, the general scope of the argument is much the same as before, but the expression is considerably heightened; it consists of appeals to the Almighty, affirmations of his own innocence, earnest expostulations, complaints of the cruelty of his friends, melancholy reflections on the vanity of human life, and upon his own severe misfortunes, ending in grief and desperation: he affirms, however, that he places his ultimate hope and confidence in God; and the more vehemently his adversaries urge, that the wicked only are objects of the divine wrath, and obnoxious to punishment, so much the more resolutely does Job assert their perpetual impunity, prosperity, and happiness even to the end of their existence. The first of his opponents, Eliphaz, incensed by this assertion, descends directly to open crimination and contumely; he accuses the most upright of men of the most atrocious crimes, of injustice, rapine, and oppression; inveighs against him as an impious pretender to virtue and religion, and with a kind of sarcastic benevolence exhorts him to penitence. Vehemently affected with this reproach, Job, in a still more animated and confident strain, appeals to the tribunal of All-seeing Justice; and wishes it were only permitted him to plead his cause in the presence of God himself. He complains still more intemperately of the unequal treatment of Providence; exalts in his own integrity, and then more tenaciously maintains his former opinion concerning the impunity of the wicked. To this another of the triumvirate, Bildad, replies, by a masterly, though concise, dissertation on the majesty and sanctity of the Divine Being, indirectly rebuking the presumption of Job, who has dared to question his decrees. In reply to Bildad, Job demonstrates himself no less expert at wielding the weapons of satire and ridicule, than those of reason and argument; and reverting to a more serious tone, he displays the infinite power and wisdom of God more copiously, and more poetically than the former speaker. The third of the friends making no return, and the others remaining silent, Job at length opens the true sentiments of his heart concerning the fate of the wicked; he allows that their prosperity is unstable, and that they and their descendants shall at his experience on a sudden, that God is the avenger of iniquity. In all this, however, he contends that the divine council is do not admit of human investigation; but that the chief wisdom of man consists in the fear of God. He then solemnly descends upon his former prosperity; and exhibits a striking contrast between it and his present affliction and lamentation. Lastly, in answer to the crimination of Eliphaz, and the imputations of the others, he relates the general transactions of his past life; he asserts his integrity as displayed in all the duties of life, and in the sight of God and man; and then appeals to the justice and omniscience of God in attestation of his veracity.

When Job's three friends have ceased to dispute with Job, "because he seetheth just in his own eyes," that is, because he has uniformly contended, that there was no wickedness in himself which could call down the heavy vengeance of God; Elihu comes forward jolly offended with both parties; with Job, because "he justified himself in preference to God," that is, because he defended so vehemently the justice of his own cause, that he seemed in some measure to arraign the justice of God; against the three friends, because, "though they were unable to answer Job, they ceased not to condemn him," that is, they concluded in their own minds that Job was impious and wicked, while, nevertheless, they had nothing specific to object against his assertions of his own innocence, or upon which they might safely ground their accusation.

The conduct of Elihu evidently corresponds with this state of the controversy: he professes, after a slight prefatory mention of himself, to reason with Job, unbiased equally by favour or resentment. He therefore reproves Job from his own mouth, because he had attributed too much to himself; because he had affirmed himself to be altogether free from guilt and depravity; because he had presumed to contend with God, and had not scrupled to insinuate that the Deity was hostile to him. He asserts, that it is not necessary for God to explain and develop his counsels to men; that he nevertheless takes many occasions of admonishing them, not only by visions and revelations, but even by the visitations of his Providence, by sending calamities and diseases upon them, to repress their arrogance and reform their obduracy. He next rebukes Job, because he had pronounced himself upright, and affirmed that God had acted inimically, if not unjustly towards him, which he proves to be no less improper than indecent. In the third place, he objects to Job, that from the miseries of the good, and the prosperity of the wicked, he has falsely and perversely concluded that there was no advantage to be derived from the practice of virtue. On the contrary he affirms, that when the afflictions of the just continue, it is because they do not place a proper confidence in God, seek relief at his hands, patiently expect it, nor demean themselves before him with becoming humility and submission. This observation alone, he adds very properly, is at once a sufficient proof of the contumacy of Job, and a full refutation of the unjust suspicions of his friends. Lastly, he explains the purposes of the Deity in challenging men, which are in general to prove and to amend them, to repress their arrogance, to afford him an opportunity of exemplifying his justice upon the obstinate and rebellious, and of showing favour to the humble and obedient. He supposes God to have acted in this manner towards Job; so that account he exhorts him to humble himself before his righteous Judge, to beware of appearing obstinate or contumacious in his sight, and of relapsing into a repetition of his sin. He intreats him, from the contemplation of the divine power and majesty, to endeavour to retain a proper reverence for the Almighty. To these frequently intermitted and often repeated admonitions of Elihu, Job makes no return.

The speech of Elihu is followed by the address of God himself: at the close of which, Job humbly submits to the will of Providence, acknowledges his own ignorance and imbecility, and "repents in dust and ashes."

On a due consideration of all these circumstances, the principal object of the poem seems to be to strip a distant trial of Job, from the injustice and unkindness of his accusing friends. The consequence of which is, in the first place, the anger, indignation, and contumacy of Job, and afterwards his compulsion, submission, and penitence. The

design of the poem is, therefore, to teach men, that having a due respect to the corruption, infirmity, and weakness of human nature, as well as to the infinite wisdom and nobility of God, they are to reject all confidence in their own strength, in their own righteousness, and to persevere on all occasions in an unwavering and unshaken faith, and to submit with becoming reverence to his decrees.

The whole history detailed in the book of Job, taken together, contains an example of patience, together with its reward.

Our author next proceeds to inquire whether the poem of Job be possessed of the peculiar properties of the Greek drama: and after considering a variety of circumstances, he affirms without hesitation, that the poem of Job contains no plot or action whatever, not even of the most simple kind: it uniformly exhibits one constant state of things, without the smallest change of feature from the beginning to the end; and contains nearly a representation of those manners, passions, and sentiments, which might actually be expected in such a situation. The very nature of the subject excludes even the possibility of a plot or action. Upon the whole, our author concludes, that the poem of Job cannot properly be brought into comparison with any of the Greek tragedies. But though it has no claim to the merit of a perfect drama, our author does not wish to derogate from its merits. That censure will rather apply to those who, by criticising it according to foreign and improper rules, would make that composition appear lame and imperfect, which, on the contrary, is in its kind most beautiful and perfect. If indeed the extreme antiquity of this poem, the obscurity and the difficulty that necessarily ensue from that circumstance be considered; and if allowance be made for the total want of plot and action, we shall have cause to wonder at the elegance and interest which we find in its form, conduct, and economy. The arrangement is perfectly regular, and every part is admirably adapted to its end and design. The antiquary or the critic, who has been at the pains to trace the history of the Grecian drama from its first weak and imperfect efforts, and has carefully observed its tardy progress to perfection, will scarcely, without astonishment, contemplate a poem produced so many ages before, so elegant in its design, so regular in its structure, so animated, so affecting, so near to the true dramatic model: while, on the contrary, the united wisdom of Greece, after ages of study, was not able to produce any thing approaching to perfection in this walk of poetry before the time of Æschylus. But however this be—whatever rank may be assigned to Job, in a comparison with the poets of Greece, to whom we must at least allow the merit of art and method; amongst the Hebrews, it must certainly be allowed, in this respect, to be unrivalled. It is of little consequence whether it be esteemed a didactic or an ethic, a pathetic or dramatic poem; only let it be assigned a distinct and conspicuous station in the highest rank of the Hebrew poetry.

The most splendid examples, says our author, of every beauty and elegance of sentiment, of imagery, and of diction, meet the eye of the attentive reader in every part of the poem. Let it suffice to say, that the dignity of the style is answerable to that of the subject; its force and energy to the greatness of those passions which it describes; and as this production excels all the other remains of the Hebrew poetry in economy and arrangement, so it yields to none in sublimity of style, and in every grace and excellence of composition. Among the principal of these may be accounted the accurate and perfectly poetical conformation of the sentences, which is indeed generally most observable in the most ancient of the poetical compositions of the He-

brews. Here, however, as is natural and proper in a poem of so great length and sublimity, the writer's skill is displayed in the proper adjustment of the period, and in the accurate distribution of the members, rather than in the variety of words, or in any laboured adaptation of the particularities.

"The poetry of the book of Job," says Dr. Blair, "is not only equal to that of any other of the sacred writings, but is superior to them all, except those of Isaiah alone. As Isaiah is the most sublime, David the most pleasing and tender, so Job is the most descriptive of all the inspired poets. A peculiar glow of fancy, and strength of description, characterize this author. No writer whatever abounds so much in metaphors. He may be said, not to describe, but to render visible, whatever he treats of. Instance, every where occur; particularly in the 18th and 20th chapters, in which he paints the condition of the wicked." Schlutens and Le Clerc's *Præf. ad Comment. in Job.* Lowth de Sac. Poet. *Prælectiones* 32—34. Gregory's *Transl. with Michaelis's Notes.* Peter's *Crit. Dissert.* Dupin. Heath, Scott, and Grey on Job. Blair's *Lect.* vol. iii. Dr. Stock, bishop of Killala, in his translation and notes, concurs with those who refer this book to a late period; not earlier than the Babylonish captivity.

Job's Tears, in Botany. See COIX.

Job, Str., in Geography, a town of Hungary, near which are a celebrated abbey, and an old castle; 24 miles S.E. of Debreczin.

JOBBAK, a town of Hindoostan, in the Gurry Mundeah; 30 miles S. of Gurrha.

JOBBER, a person who undertakes jobs, or small pieces of work.

In some statutes, jobber is used for a person who buys and sells cattle for others. See BROKER.

JOBGING, in Stock, denotes the practice of trafficking in the public funds, or of buying and selling stock, with a view to its rise or fall. The term is commonly applied to the illegal practice of buying and selling stock for time, or of accounting for the differences in the rise or fall of any particular stock for a stipulated time; whether the buyer or seller be possessed of any such stock or not. See *Stock Brokers.*

JOBBING, in Rural Economy, a term used by farmers for a petty kind of buying and selling, or dealing in cattle, or any other sort of farming-stock. Men of this kind are also frequently employed by the larger dealers. It has been observed, that "if a midland farmer goes to a fair, he is ashamed to return without having done some business; he must either buy or sell, or he loses his credit as a market man. Hence, probably, the quantity of business done at the midland fairs, compared with those of other districts, where one-third, or perhaps half, the stock is frequently unsold, is very considerable, while here, the whole fair may be said to be generally transferred."

JOBBENT NAILS. See NAILS.

JOBERT, LEWIS, in Biography, a French Jesuit, distinguished as well by his antiquarian knowledge, as by his pulpit talents and eloquence, was born at Paris in the year 1637. He was a teacher of the several branches of polite literature, and performed the duties of his station with distinguished ability. He died in 1719, leaving behind him many works, but the most important was an elaborate treatise on "Medals," which was published in two volumes, 12mo., in the year 1692. This work possesses great merit, and met with a very favourable reception. It has gone through many editions at Paris, Amsterdam, Leipzig, and Nuremberg. The most correct is said to be that of Paris in 1739, with additions by M. Joseph Binard de la Balfie. *Moreri,*

JOBBE, in *Geography*, an island in the Pacific ocean, at the entrance of a great bay on the coast of New Guinea; 110 miles long from E. to W., and from 6 to 20 broad. S. lat. 1° 36' to 3°. E. long. 135° 50' to 137° 36'.

JOCALLA, a town of Peru, in the diocese of La Paz; 9 miles N. of Potosi.

JOCHEP, CHRISTIAN GOTTLIEB, in *Biography*, doctor of theology, public professor of history at Leipzig, and librarian to the academy, was born in that city in 1694. Having received the elements of an excellent education at different schools, he devoted himself to the study of theology, and obtained his degrees at Leipzig. He soon became a disciple of Leibnitz and Wolf, and was the first person who gave lectures on the system of Wolf. He soon attracted a numerous concourse of pupils, and was most assiduous in his instructions. To render his lectures as useful as possible, he studied incessantly, so as to injure his health. In 1720 his father died in distressed circumstances, which obliged the son to exert all his powers for his support: he became the editor of the German "Acta Eruditorum," which he conducted with great spirit till the year 1739. In 1730 he was appointed professor of philosophy, then of history, and in 1742 he obtained the office of librarian to the university. He died in 1758, much esteemed as a man of letters and a good teacher. He possessed an extensive knowledge in the various branches of literature and science, and was acquainted with the best writers on the several subjects. His principal work was "A Compendious Dictionary of learned Men," arranged alphabetically. This went through four editions in the author's life time, of which the last was extended to four volumes quarto. Two supplementary volumes, which go as far as I, have been since published by Adelung, entitled "A Continuation of, and Supplement to Joche's General Dictionary of learned Men." Gen. Biog.

JOCKEY, in the management of horses; the person who trims up, and rides about horses for sale.

JOCKGRIM, in *Geography*, a town of France, in the department of the Lower Rhine, situated on an eminence near the Rhine; 9 miles S.E. of Landau.

JCKLET, or **YOKLET**, a term used in some parts of Kent for a little farm which requires but one yoke of oxen to till it.

JOCKMOCKI, in *Geography*, a town of Sweden, in the lapmark of Lulea; 90 miles N.N.W. of Lulea.

JOCKO, in *Zoology*. See *SIMIA SATYRUS*.

JOCRONS, in *Geography*, a town of Hindoostan, in Mysore; 20 miles N.N.E. of Chittledroog.

JODELLE, STEPHEN, in *Biography*, a nearly French poet, was born at Paris in 1532, of a family of some rank. He was a man of various talents, skilled in the ancient languages, and conversant in the arts of painting, sculpture, and architecture, as well as dextrous in the use of arms; but his chief excellence was in poetry. He is said to have made five hundred Latin verses in one night. He was the first person who introduced tragedy and comedy in the ancient form into French poetry. His Cleopatra is the earliest of French tragedies, and was acted with great applause before Henry II. and all the great men of France. It is simple in its plan, and provided with a perpetual chorus in imitation of the ancient style. The comedies of this writer are said to be superior to his tragedies; he was undoubtedly popular in his day, but was, notwithstanding, suffered to fall into indigence, to which his carelessness and love of pleasure contributed. He died in 1573, at the age of 41, and upon his death-bed he dictated a sonnet to Charles IX., containing severe reproaches for deserting him in necessity. His works have been published collectively at Paris and Lyons.

JODO, in *Geography*, a town of Japan, in the island of Niphon; 5 miles S. of Meaco.

JODOIGNE, a town of France, in the department of Dyle, and chief place of a canton, in the district of Nivelles; the place contains 2012, and the canton 14,434 inhabitants, on a territory of 165 kilometres, in 28 communes.

JOEL, or the *Prophecy of Joel*, a canonical book of the Old Testament. Joel was the son of Pethuel, and the second of the twelve lesser prophets. The style of this prophet is elegant, perspicuous, copious, and fluent; he is also sublime, animated, and energetic. In the 1st and 2d chapters he displays the full force of the prophetic poetry, and shews how naturally it inclines to the use of metaphors, allegories, and comparisons. Nor is the connection of the matter less clear and eminent than the complexion of the style. But after allowing him perspicuity both in language and arrangement, it cannot be denied, that there is sometimes great obscurity in his subjects, and particularly in the latter part of his prophecy. About the beginning of the last century, Herman Von der Hardt, the Hardouin of Germany, attempted to reduce Joel's allegories, as he calls them, to laudic verse. Joel upbraids the Idracites for their idolatry, and foretels the calamities they should suffer as the punishment of that sin: but he endeavours to support them with the comfort that their miseries should have an end upon their reformation and repentance. Some writers, inferring the order of time in which the minor prophets lived from the order in which they are placed in the Hebrew copies, conclude that Joel prophesied before Amos, who was contemporary with Uzziah, king of Judah. Archbishop Usher makes this inference from Joel's foretelling that drought, chap. i. which Amos mentions as having happened, chap. iv. 7, 8, 9. If we consider the main design of Joel's prophecy, we shall be apt to conclude, that it was uttered after the captivity of the ten tribes; for he directs his discourse only to Judah, and speaks distinctly of the sacrifices and oblations that were daily made in the temple.

Bishop Newcome, adopting the conjecture of Drusius, supposes that he lived under the long reign of Manasse, and before his conversion; that is, some time from 697 to 660 B. C. Lowth's Com. Lowth's Præf. xxi. Newcome's Attempt towards an improved Version, &c. of the Twelve Minor Prophets.

JOGHIS, a sect of heathen religious in the East Indies, who never marry, nor hold any thing in private property; but live on alms, and practise strange severities on themselves.

They are subject to a general, who sends them from one country to another to preach: they are, properly, a kind of penitent pilgrims; and are supposed to be a branch of the ancient Gymnosophists.

They frequent, principally, such places as are consecrated by the devotion of the people, and pretend to live several days together without eating or drinking. After having gone through a course of discipline for a certain time, they look upon themselves as impeccable, and privileged to do any thing; or on which they give a loose to their passions, and run into all manner of debauchery.

JOGHY-COOPA, in *Geography*, a town of Affam; 90 miles N.W. of Gerghongoe.

JOGUES, or **YOGUES**, certain ages, eras, or periods, of extraordinary length, in the chronology of the Hindoos. They are four in number; of which the following is an account, extracted from Halhed's Preface to the Code of Gentoo Laws, p. 36.

1. The *Subtle Yogue* (or age of purity), is said to have lasted three million two hundred thousand years; and they hold

hold that the life of man was extended in that age to one hundred thousand years, and that his stature was twenty-one cubits.

2. The *Tritab Jogue* (in which one-third of mankind was corrupted), they suppose to have consisted of two million four hundred thousand years, and that men lived to the age of ten thousand years.

3. The *Dwapaar Jogue* (in which half of the human race became depraved), endured one million six hundred thousand years, and the life of man was then reduced to a thousand years.

4. The *Collee Jogue* (in which all mankind are corrupted, or rather lessened, for that is the true meaning of *Collee*), is the present era, which they supposed ordained to subsist four hundred thousand years, of which near five thousand are already past; and the life of man in that period is limited to one hundred years. See **HINDOOS**.

We shall here subjoin Dr. Robertson's observations on the above periods, from the Notes to his *Historical Dissertation concerning India*.

"If (says he, p. 365) we suppose the computation of time in the Indian chronology to be made by solar, or even by lunar years, nothing can be more extravagant in itself, or more repugnant to our mode of calculating the duration of the world, founded on sacred and infallible authority. From one circumstance, however, which merits attention, we may conclude that the information which we have hitherto received concerning the chronology of the Hindoos is very incorrect. We have, as far as I know, only five original accounts of the different jogues, or eras of the Hindoos. The first is given by M. Rogers, who received it from the Brahmins on the Coromandel coast. According to it, the Sutttee Jogue is a period of one million seven hundred and twenty-eight thousand years; the Tirthah Jogue is one million two hundred and ninety-six thousand years; the Dwapaar Jogue is eight hundred and sixty-four thousand. The duration of the Collee Jogue he does not specify. (Porte Ouverte, p. 179.) The next is that of M. Bernier, who received it from the Brahmins of Benares. According to him the duration of the Sutttee Jogue, was two million five hundred thousand years; that of the Tirthah Jogue, one million two hundred thousand years; that of the Dwapaar Jogue is eight hundred and sixty-four thousand years. Concerning the period of the Collee Jogue, he likewise is silent. (Voyages, tom. ii. p. 160.) The third is that of colonel Dow; according to which the Sutttee Jogue is a period of fourteen million of years; the Tirthah Jogue one million eighty thousand; the Dwapaar Jogue seventy-two thousand; and the Collee Jogue thirty-six thousand years. (Hist. of Hindost. vol. i. p. 2.) The fourth account is that of M. le Gentil, who received it from the Brahmins of the Coromandel coast; and as his information was acquired in the same part of India, and derived from the same source with that of M. Rogers, it agrees with his in every particular. (Mem. de l'Academie des Sciences, pour 1772 tom. ii. part. i. p. 176.) The fifth is the account of Mr. Halhed, which has been already given. From this differ any, not only of the total numbers, but of many of the articles in the different accounts, it is manifest that our information concerning Indian chronology is hitherto as uncertain as the whole system of it is wild and fabulous. To me it appears highly probable, that when we understand more thoroughly the principles upon which the fabulous eras or jogues of the Hindoos have been formed, we may be more able to reconcile their chronology to the true mode of computing time, founded on the authority of the Old Testament; and may likewise find reason to conclude, that the account given by their astronomers of the

situation of the heavenly bodies at the beginning of the Collee Jogue, is not established by actual observation, but the result of a retrospective calculation."

JOHADING, in *Geography*, a town of Bengal; 32 miles N.E. of Calcutta.

JOHAN, ST., a town of France, in the department of the Sarre, on the Sarre, communicating by a bridge with Saarbruck.—Also, thre towns in the duchy of Stiria.—Also, a town of the archbishopric of Salzburg; 30 miles S.S.E. of Salzburg.

JOHAN-GEORGEN-STADT, a town of Saxony, in the circle of Erzgebirg, founded in 1654 by the Protestant miners, who were driven from Platten in Bohemia, and so named after John George I. The corn, cultivated near the town, is inconsiderable, but the breed of cattle is good. The men are employed in mining, and the women in weaving lace. Ores of tin and silver have been formerly found near this place. Copper ore, cobalt, emery, and other minerals are now found; 24 miles S. of Chemnitz. N. lat. 50° 23'. E. long. 12° 40'.

JOHANNES, a small island in the Pacific ocean, discovered in 1767. N. lat. 6° 50'. E. long. 132° 18'.

JOHANNESBERG, or **BUCHHOFFSBERG**, a town of Germany, famous for its wine; 16 miles W. of Mentz.

JOHANNESBURG, a town of Prussia, in the province of Natangen, near the Spirding lake; 96 miles S.S.E. of Konigsberg. N. lat. 53° 22'. E. long. 22° 2'.

JOHANN, ST., a town of Austria; 11 miles S.S.E. of Glaggnitz.—Also, a town of Austria; 8 miles E. of Bavarian Waidhoehn.

JOHANSTHAL, a town of Moravia, in the circle of Prerau, situated in Silefia; 12 miles N.N.W. of Jagendorf.

JOHN the BAPTIST, in *Scripture Biography*, was the son of Zacharias, a priest of the course of Abia, and of Elizabeth, cousin to Mary, the mother of our Saviour. He was announced before his birth to Zacharias, who received instructions to call him John, and who was apprized of the high and honourable character which he was to sustain, as the forerunner of the Messiah. See the account of his birth and office in the first chapter of St. Luke's Gospel. Having withdrawn himself from society, in order to prepare, by exercises of devotion, and strictness of manners, for the duties of the office which was assigned him, he was called to commence his ministry when he was about thirty years of age; and, like the ancient prophets, he quitted his solitude in a garment of camel's hair, and distinguished himself by abstinence and self-denial, and severity of morals. His commission was to proclaim the approaching advent and kingdom of the Messiah, and to qualify men, by repentance and reformation, for becoming partakers of the blessings which the great teacher and saviour was empowered to bestow. The success of his preaching was such, that multitudes resorted to hear him, and to be baptised by him in the waters of Jordan. His reputation was such among the people, that many began to debate among themselves, whether he was not the Messiah; and when the Jewish Sanhedrim, hearing of his fame, sent scribes and pharisees from Jerusalem to examine his pretensions, John thought it sufficient honour to be commissioned as the forerunner of the Messiah, and therefore explicitly declared that he was not the Messiah himself. At the appointed time Jesus came to him from Nazareth, and after some hesitation, first from ignorance of his person and character, and afterwards, from humility and diffidence, John performed for him the religious rite of baptism, according

to his request. As soon as this service was concluded, John had ample evidence presented to him of the dignity and real character of Jesus; for a lambent flame descended upon him with a kind of hovering dove-like motion, and a voice from heaven accompanied it, proclaiming "This is my beloved Son, in whom I am well pleased." John, being thoroughly satisfied that Jesus was the promised and expected Messiah, eagerly embraced every opportunity that occurred of announcing him to the multitude, which attended his ministry, under this character. The disciples of John became jealous of the increasing fame of Jesus; and fearful that the reputation and influence of their master would decline: but John corrected their misapprehensions, acknowledged his inferiority to Jesus, and directed the people to transfer their views and regard from him, who was merely the forerunner of the Messiah and Saviour, to the person who really sustained this high character, and to whom these honourable appellations belonged. In the course of John's ministry his fame commanded the attention of Herod, tetrarch of Galilee, and induced him to send for the preacher to his court; for some time his instruction and counsel seemed to impress the tetrarch's mind, and to give him pleasure. But the fidelity of John would not permit Herod to form an incestuous connection with Herodias, his brother's wife, without seasonable animadversion and severe reproof. The tetrarch resented the faithful reprehension of John, and committed him to prison. During the interval of his confinement, Herodias was plotting his death: but Herod, for some time, partly from reverence for John, and partly from a dread of the people, who believed him to be a prophet, resisted the machinations of Herodias. An opportunity at length occurred, upon the birth-day of Herod, for the execution of the cruel purpose which this wicked woman had formed against John. Her daughter, by her former husband, danced before the assembly that was convened in honour of his nativity, so much to the satisfaction of Herod, that he promised with an oath to grant her whatsoever she requested, even though it should be to the value of half his kingdom. The princess, instructed by her mother, requested that the head of John the Baptist should be delivered to her in a charger, or large dish. Herod was for some time reluctant; but upon her persisting in her request, Herod complied, and ordered John to be beheaded in the prison. The death of John the Baptist is mentioned by Josephus in a passage, the genuineness of which is generally admitted by learned men. A dispute had arisen between Aretas, king of Petra, the father of his first wife, whom he had put away for the sake of Herodias, which was partly owing to this conduct, and partly to some difference that took place between them about the limits of their respective territories. In a contest between them Herod's whole army was defeated; and this defeat, says Josephus, was considered by some of the Jews as a just punishment providentially inflicted on Herod, for the death of John, called the Baptist. For Herod, continues the Jewish writer, had killed a man who was a just man, and had called upon the Jews to be baptized, and to practise virtue, exercising both justice towards men, and piety towards God; for to would baptism be acceptable to God, if they made use of it, not for the expiation of their sins, but for the purity of the body; the mind being first purified by right conduct. And many coming to him, for they were wonderfully taken with his discourses, Herod was seized with apprehensions, lest, by his continuance, they should be led into sedition against him, for they seemed capable of doing anything by his direction, &c. (Antiq. l. xviii. c. 5. § 11, 2.) It has been said by some persons, that this paragraph contradicts our evangelists: for, according to them, it was at the solicitation of Her-

odias and her daughter that John was beheaded. But here it is said, that Herod put John to death because he feared that he might be the cause of a sedition. But the two accounts are by no means inconsistent: for Herod might have apprehensions from John's popularity, and be disposed, on that account, to take him off. See Lardner's Works, vol. vii. p. 117. The festival of the nativity of John the Baptist was appointed to be observed in the Christian church on the 24th of June: the date of the first appointment is not known: but that it is to be placed before the end of the fourth century, appears from the sermons of St. Augustine, adapted to the day.

JOHN Baptist, Hermit of. See HERMITS.

JOHN, Saint, an apostle and evangelist, was the son of Zebedee, a fisherman, of the town of Bethsaida, on the sea of Galilee, the younger brother of James the elder, (see JAMES,) and commonly reckoned the youngest of all Christ's disciples. His mother's name was Salome. Zebedee, though a fisherman, was not poor, and therefore we have no reason to imagine that his children were altogether illiterate, which some have imagined to have been the case, from a misinterpretation of Acts, iv. 13, in which the terms *αρχιμαθηται* and *διδασκαλοι* denote persons that were neither doctors nor magistrates, but men of private stations, who had not been educated in the schools of the Rabbies. (Grot. in loc.) See DIDOT. They were, without doubt, well acquainted with the scriptures of the Old Testament; having not only read them, but having heard them publicly read and explained in the synagogues. In common with other Jews, they entertained the expectation of the Messiah, and had heard John the Baptist preach, though they were not enlisted in the number of his disciples. Before John was called to be an apostle, it cannot be questioned that he had seen and heard our blessed Lord, and had been witness of some of his miracles, particularly that at the wedding of Cana in Galilee. (See John, ii. 1—11.) His call to attend upon Jesus steadily is related Matt. iv. 21, 22. Mark, i. 19, 20. Luke, v. 1—10. From this time he and his brother James were the constant attendants on Christ; they heard his discourses, and saw his miracles; and after previous instruction, both public and private, they were honoured with a selection and appointment to be of the number of the twelve apostles. What was his age at this time, his history does not precisely ascertain. Some have supposed that he was then 22 years old: others conjecture that he was about 25 or 26; and others again think, that he was about the same age with our Saviour. Dr. Lardner is of opinion, that none of the apostles of Christ were much under the age of 30, when they were appointed to this important office. However it be, John seems to have been the youngest of the twelve, and to have been distinguished by a temper singularly mild, amiable, and affectionate. He was eminently the object of our Lord's regard and confidence, and admitted, on various occasions, to free and intimate intercourse with him; so that he was characterized as "the disciple whom Jesus loved." The evangelical history recites many instances which evince the intimacy that subsisted between him and his master, and the high opinion which our blessed Lord entertained of his disposition and character. His failings, however, did not escape notice; and he was reprehended for them by our Lord. Notwithstanding his affectionate attachment to Christ, and the numerous instances of kind and condescending attention with which he had been honoured, he, in common with the other apostles, betrayed a culpable timidity in forsaking him during his last conflict; though he afterwards recovered his firmness, and attended the crucifixion: and, indeed, he seems to have been the only apostle who thus har-

zarded his own safety. On this occasion he was distinguished by the notice of his master, and by the recommendation of his mother to the future protection of this apostle. He was also a witness of the circumstances that ascertained our Lord's death and burial. After his resurrection John was the first who entertained the belief that he was really risen from the dead. On subsequent occasions, when Jesus manifested himself to his disciples, and thus evinced the reality of his resurrection, John was one of the number. In one of these interviews, when Peter, having received information of the manner of his own death, inquired with a reprehensible curiosity concerning the fate of John, our Lord replied, "what if he tarry till I come," thus intimating either that he would sur vive the destruction of Jerusalem, or that his life would be prolonged till it was terminated in the course of nature. After the ascension of Christ, and the effusion of the Spirit on the day of pentecost, John became one of the chief apostles of the circumcision, and exercised his ministry at and about Jerusalem, in the manner and with the success related in the book of Acts: he was present at the council of this city held in the year 49 or 50. (See Acts, xv.) Until this time he probably remained in the land of Israel, and had not travelled into any foreign countries. During his stay in Judæa, it appears that he wrought many miracles. From the book of Revelation (chap. i. 9.) we learn, that St. John was for some time in the island of Patmos, where he was favoured with visions and revelations. He is supposed to have been banished thither in the 11th year of Domitian, and to have returned in the beginning of the reign of Nerva; so that his exile could not have lasted more than two years, or perhaps not above a year. From ecclesiastical history we learn that he lived to a great age, and that in the latter part of his life he resided in Asia, particularly at Ephesus, the chief city of that country. His settlement in Asia seems, from several circumstances, to have taken place about the time when the war broke out in Judæa, in the year 66, or a short time before, when probably St. Peter and Paul had been previously crowned with martyrdom. According to Irenæus, this apostle lived in Asia till the time of Trajan, who succeeded Nerva, A. D. 98. From other accounts it appears that he died at Ephesus, and was buried near that city, about 68 years after our Lord's passion. Supposing our Lord to have been crucified in the year 32 of the vulgar era, which seems to have been Jerom's opinion; 68 years will extend to the year 100, or the third of Trajan; at which year of that emperor the death of St. John is placed by Jerom in his chronicle. At the time of his death it is not incredible, nor unlikely, that he was about 100 years of age. Some other particulars have been recorded concerning this apostle, which the most impartial critics have reckoned fabulous. It is related of him, that going to bathe at Ephesus, and perceiving that Cerintus, or, as others say, Ebion, was in the bath, he came out hastily without bathing, saying to those that were with him, "Let us fly hence, lest the bath should fall while Cerintus, the enemy of the truth is within." It is also said, that by order of the emperor Domitian, St. John was cast into a caldron of boiling oil at Rome, and came out again without being hurt. The following account, given by Jerom, of St. John's method of preaching when he was far advanced in years, and not able to make a long discourse, is more worthy of credit. "The blessed apostle John, living at Ephesus to extreme old age, and being with difficulty carried to church in the arms of the disciples, and being unable to make a long discourse every time they assembled, was wont to say nothing but this: 'Little children, love one

another.'" At length the disciples and brethren who attended, tired with hearing so often the same thing, said, "Sir, why do you always say this?" who then made this answer, worthy of himself: "Because," says he, "it is the Lord's command; and if that alone be done, it is sufficient."

The writings which are generally ascribed to St. John, and received as his, are a gospel, three epistles, and the book of Revelation.

The gospel of St. John has been universally received as genuine; and, as it is generally allowed that he had seen the other three gospels, it may be considered as a kind of supplement to these, containing several things that occur in them, and many others which they have omitted. In the account of our Saviour's persecution, death, and resurrection, all four gospels coincide in many particulars; though here St. John has various things peculiar to himself. In his gospel many things recorded by the other evangelists are omitted. He has given us no account of our Saviour's nativity, nor of his baptism by John. He takes no notice of our Saviour's temptation in the wilderness; nor of the call, or names of the 12 apostles; nor of their mission in the time of our Saviour's life; nor of our Lord's parables, or other discourses of his, recorded by them; nor of our Saviour's journeys, of which they give an account; nor of any of those predictions relating to the desolations of Jerusalem, which are found in the gospels of Matthew, Mark, and Luke; nor has he repeated any miracles recorded by them, excepting only that of the multiplication of small provision for feeding 5000, with the extraordinary circumstances of the return to Capernaum from the country, where that miracle had been wrought. But he mentions several incidents which the other evangelists have not noticed. St. John gives an account of our Lord's cleansing the temple, at his first passover, when he went to Jerusalem; but all the other evangelists give a like account of his cleansing the temple at the last passover. These two acts are, however, different. He gives an account of the acts of Christ before the imprisonment of John the Baptist; of the wedding at Cana; of Nicodemus; of the woman of Samaria; of the cure of the man blind from his birth; of the resurrection of Lazarus; of the indignation of Judas at the woman who anointed the Lord with ointment; of the Greeks that came to Jesus; of Christ washing the feet of his disciples; and of the consolatory instructions, which he delivered to his apostles previously to his death, &c. St. John's gospel contains also many plain and frequent assertions, that Jesus is the Son of God, and the Christ, the Son of God, or that, as our prophet, that should come into the world; whereas the other gospels, by peculiar expressions, to his present and only, though others talk of a future mission to him.

Writers are not agreed on the time when this gospel was written. St. John, according to Mill, Fabricius, and Le Clerc, wrote his gospel at Ephesus, after his return from the island of Patmos, A. D. 97, at the desire of the Christians of Asia. Others thought that this gospel might be written about the year 72 after our Lord's ascension. Bingham and Lardner suppose that it was written before the destruction of Jerusalem; Dr. Lardner adopts this opinion, and assigns the date of it to the year of Christ 68. This period brings it nearer to that of the three other gospels, which was about the year 64 or 65, and the gospel itself, the leading design of which was to show how inexcusable the Jews were in not receiving Jesus to be Christ, and to vindicate the providence of God in the calamities already befallen, or now coming upon them, was suitable to the circumstances of the Jews at this period. It is observed by Dr. Lardner, as an evidence

dence that it was one great design of St. John, in writing this gospel, to shew the unreasonableness and great guilt of the Jews in rejecting Jesus, that in his gospel are inserted more instances of their attempts upon our Lord's life than in the other gospels. Chryl-stom was of opinion, that St. John did not write his gospel till after the destruction of Jerusalem. John, he says, writes not any of the things that occur in Matt. xxiv., lest it should be thought that he took an advantage from the event: for he was living a good while after the destruction of Jerusalem. But the other evangelists, who died before the destruction of Jerusalem, and saw none of these things, record these predictions. But John, if he wrote at the time above specified, viz. when the event was near, might omit these predictions, as they were sufficiently recorded already, and as it is not his manner to repeat what had been related before. He gives, however, several intimations of the miseries that were coming upon the Jewish people, (Ch. iii. 36. iii. 18, 19. viii. 12. 21. 24. ix. 39—41. xii. 35, 36.) Mr. Whitton, observing that St. John uses the Roman or Julian beginning of the day in his gospel, and reckons the hours from midnight and noon, urges this as an argument for the gospel having been written after the destruction of Jerusalem, and the period of the Jewish polity, at Ephesus, a place remote from Judea, and under the Roman government. To this it is replied, that St. John does not compute the hours of the day after the Roman, but rather after the Jewish manner; and, supposing St. John to have used the Roman method of computation, it does not follow that he wrote after the destruction of Jerusalem, &c. As the gospel was written at Ephesus, at a distance from Judea, he might, if he thought fit, have used the Roman way of reckoning, especially when the period of the Jewish commonwealth was near, though not quite accomplished. The late date of the gospel has been also argued, from what some have alleged, to have been the object or end of the writer. Accordingly, many ancient and some modern writers say, that this gospel was written with a design to remove the errors of the Cerinthians, Ebionites, and other sects, which cannot be supposed to have appeared before the destruction of Jerusalem, and the overthrow of the Jewish people. But Mr. Lampe and Dr. Lardner have urged several reasons to shew that St. John did not write against Cerinthus, or any other heretics in his gospel; and that it was written before the rise of those heresies, which are said to be confuted by it. Lardner thinks that it would have been below an evangelist to write against heretics in the history of his Lord and master; and that none of the evangelists have entered into a particular account of things after our Lord's ascension. Nothing of this kind, says this writer, occurs in the rest of St. John's gospel; and, therefore, why should we imagine that there is any such thing in the introduction; the design of which is to shew, that Jesus came and acted by the authority of God, the Creator of the world, the God and supreme Lawgiver of the Jewish people. Some have thought, and particularly Grotius, that St. John concluded his gospel with the words, which are at the end of the 20th chapter; and that which is in the 21st chapter was added after St. John's death by the church of Ephesus. But this opinion is contradicted by the general, or even universal, consent of manuscripts and versions: to which it may be added, that none of the ancient Christian writers ever made a question, whether this chapter was composed by St. John or another. Moreover, the style is St. John's. Lardner's Suppl. to the Credibility, or Works, vol. vi. chap. 9.

Besides the gospel, St. John wrote three epistles, which are generally received in these parts of the world. The

genuineness of the first epistle does not seem to have been ever questioned. It is referred to by Papias, and the martyrs of Lyons, and quoted by Papias. The first and second epistles are cited by Irenæus, and received by Clement of Alexandria. Origen mentions three epistles, though he says that the second and third were not allowed by all to be genuine. Dionysius of Alexandria receives the first epistle, calling it the "Catholic epistle," and he assigns the other two as ascribed to St. John. The first epistle was received by Cyprian, and probably the other two. The second epistle is quoted by Alexander, bishop of Alexandria. Eusebius says, "that besides the gospel, his first epistle is universally acknowledged by those of the present time, and by the ancients; but the other two are contradicted," i. e. doubted of by some. All the three epistles were received by Athanasius, by Cyril of Jerusalem, by the council of Laodicea, and by Epiphanius. All three were received by Jerom: and the two last were doubted of by some in his time. All three were received by Rufinus, by the third council of Carthage, by Augustine, and by all those authors who received the same canon of the New Testament with ours. All three are in the Alexandrian MS. and also in the catalogues of Gregory Nazianzen and of Amphilochius. The Syrian churches, however, received only one; nor were any more received by Chryl-stom. Upon the whole we may observe, that one epistle was received by all as certainly genuine; and it is not of any importance to contend about the other two, as they are so very short, and resemble the first in sentiment, phrase, and manner of writing. The second epistle consists of only thirteen of our verses; and of these eight may be found in the first, either in sense or expression. See CAXON.

As to the time when these epistles were written, critics and commentators have entertained different opinions. Grotius, Hamm ond, and Whitby, suppose the first to have been written before the destruction of Jerusalem, and the former thinks the place of writing it was Patmos. Dr. Beaufobre inclines to date it in the year of our Lord 68. Mill and Le Clerc refer it to the year 91 or 92; Beaufobre to the year 98, and Baronius to 99. Beaufobre and Lantier refer it to the end of the first century, when the apostle was far advanced in age. Whitton thought that this, and the two other epistles of St. John, were written not long after each other, about the year of Christ 82 or 83. Lampe supposes the first epistle to have been written after the Jewish war, before St. John's exile in Patmos, and, probably, some considerable time before it: so that he nearly agrees about the time of the epistle with Whitton. Dr. Lardner, considering that there are no expressions in the epistle declaring the time of it, or clearly referring to the calamities attending the downfall of the Jewish state, thinks it probable, that it was not written till a good while after that event, about the year of Christ 80, or later. Some have thought that the first epistle was written to Jewish believers in Parthia; and others are of opinion, that it was addressed to the Jewish Christians in Judea and Galilee. Others think it more probable, that it was directed to all believers, Gentiles as well as Jews; though Jewish believers are especially regarded. The second epistle is inscribed "The elder to the elect lady, and her children." By the "elect lady" some have understood the Christian church in general, and others understand the appellation as designed to express some particular church. Others again have supposed, that it was addressed to a female of the name of "Electa," or "Eclesta;" and some have rendered the inscription "to the elect Kyria." Others again understand the inscription agreeably to our own translation; and this has been the common

common opinion, supported by the authorities of Beza, Mill, Wolfius, Wall, Le Clerc, and others.

The third epistle of St. John is inscribed, "The elder to the beloved Gaius." There were two persons of this name, mentioned in the Acts (ix. 29.), and in St. Paul's epistles (1 Cor. i. 14. Rom. xvi. 23.). He seems to have been an eminent Christian, who lived in some city of Asia, not far from Ephesus, where St. John chiefly resided, after his leaving Judea. Concerning the case to which St. John refers in this epistle, there have been various sentiments of learned men. Grotius supposed that the strangers he spoken of were believing Jews, whom Diotrophes, a gentile, and bishop of Pergamos, would not receive, because they were Jews, or because they were for blending the rites of the law with Christianity. Others think, that Diotrophes was a Jew, and zealous for the law, and that he would not admit these strangers, converts from among the Gentiles, because they did not consent to the observance of the rites and ceremonies of the law of Moses. Learned men have lately been of opinion that St. John here speaks of some, particularly Jews, who had gone out into the world, to propagate the Christian religion, without receiving any pecuniary recompense from those whom they had converted to the Christian faith: and they think, that Gaius or Gaius is commended by St. John for encouraging such teachers, whilst he blamed Diotrophes for not receiving and helping them. But this opinion is rejected by Lardner as unfounded, and he sees nothing that should lead us to think preachers here spoken of, but only strangers in want. Some have supposed, that Diotrophes excommunicated, or cast out of the church, the "brethren," members of it, who were for receiving these strangers. Others suppose that the persons, whom Diotrophes cast out of the church were these strangers, not members of the church. It is supposed, that Diotrophes had the disposal of the revenues of the church; and that he opposed the distribution of the common stock to these strangers, partly Jews and partly Gentiles, who needed relief, and discouraged such as were willing to assist them out of their own property. Concerning the time of writing these two epistles, nothing can be said with certainty. Mill places them about the same time with the first, in 91 or 92. Whiston supposes, that all three were written about the year 82 or 83. Dr. Lardner conceives, that St. John was somewhat advanced in age, and that he had resided a good while in Asia, before he wrote any of these epistles. Hence he concludes, that these two were not written sooner than the first; and if the first was written about the year 80, these two may be reckoned to have been written between the years 80 and 90. See EPISTLE. Lardner's Works, vol. vi. chap. 20.

The book of Revelation has been also ascribed to St. John. See REVELATION.

JOHN, *St.*, *Christians of.* See CHRISTIANS.

JOHN, *surnamed Mark.* See MARK.

JOHN I. emperor of the East, surnamed *Zimisceus*, was an Armenian noble, who served with distinction in the armies of Romanus the younger. After the death of that emperor, he assisted Nicephorus Phocas in his elevation to the empire and his marriage of the imperial widow, Theophano. Zimisceus became an object of suspicion to Nicephorus, who deprived him of the post of general of the East, in which he had been generally victorious, and banished him from court. The hero was resolved to be revenged for the indignities insisted on him, and having insinuated himself into the good graces of the empress, he contrived a plot to take away her husband's life. The plan succeeded, Nicephorus was slain,

and John was immediately declared emperor, A. D. 969. Before the patriarch would consecrate him he was told he must, by public penance, expiate the crime of which he had been guilty. John threw the blame of the deed on his companions, and readily agreed to separate himself from them. Theophano parted in a paroxysm of rage, and was immediately shut up in a monastery of Armenia. The reign of John was chiefly spent in military transactions, in which his valour and good fortune were equally conspicuous. He obtained many victories over the Russians, Bulgarians, and Saracens; and is supposed to have fallen a sacrifice to the eunuch Basil, whom he had offended, after a reign of six years. John Zimisceus, though arriving at the crown by an act of treason, wore it with glory, and seemed to merit it by his public and private virtues. His piety is extolled by writers of the time, and he is recorded as the first emperor who caused the effigy of Christ to be stamped upon the coin, with the legend, "Jesus Christ, the King of Kings."

JOHN II. emperor of the East, was born in 1088, and succeeded his father Alexius in 1118. Soon after his accession a conspiracy was excited against him by his sister, the celebrated Anna Comnena, to depose him in favour of her husband Bryennius. The conspiracy was discovered in time to prevent the evils that would otherwise have resulted from it. This was the only domestic trouble by which his reign was disturbed, and he had the happiness of being able, during an administration of twenty-five years, to banish capital punishments from the whole empire, not excepting the case of those persons who had engaged with his sister to take away his life. Against the public enemies of his country he was active and successful, and he entertained the ambitious project of extending the eastern empire to its former limits, and recovering Antioch from the dominion of the Latins. He not only planned the enterprise but actually set out on the business, accompanied by his two sons. They were carried off by a premature death, and he himself died shortly after, in 1143, of a wound from one of his own poisoned arrows. He was called the "Handsome," an appellation which has been thought to have been applied ironically: but whatever the qualities of his body were, his soul was formed in the mould of moral beauty, and few possessors of a throne have graced it with purer manners and more humane principles.

JOHN III., DUCAS, surnamed *Vataces*, emperor of the East, was born in 1193, and succeeded, by virtue of his marriage with the daughter of Theodor Lascaris, to the throne at the death of that prince. Constantinople, the capital of the empire, was, at this period, in the hands of the Latins, as was likewise a considerable part of the empire. John, however, was a prince of great virtue, and recovered all the other places which had been taken by the Latins, and reduced under his dominion the European territories almost to the gates of Constantinople, and nearly the whole of Lesser Asia. He fought and gained many battles, defeating the Scythians, Tartars, and Bulgarians, and extended his empire on all sides. While he was thus distinguished in war, he was equally illustrious in the internal administration of his affairs, by which he restored prosperity to the harassed subjects of the eastern empire. He encouraged agriculture, and the useful arts, and promoted simplicity and regularity of manners. He died in 1258, after a glorious reign of 33 years.

JOHN IV., LASCARIS, son of Theodore the younger, whom he succeeded in 1259, at the age of six years, but ere he had sat on the throne a single year, he was deprived of his eyes, and imprisoned for life, by the despot Michael Palaeologus.

JOHN V., CANTACUZENUS, emperor of the East, descended from the Paladins of France, was one of the principal confidants of the younger Andronicus, at the time of his revolt from his grandfather, and acted with great fidelity in the service of the young prince, in whose reign he held the office of great domestic, by virtue of which he ruled both the emperor and the empire. At the death of Andronicus in 1341, Cantacuzenus was left guardian to the eldest of his sons, then but nine years of age, and was made regent of the empire. His administration was disturbed by the ambition of the great duke Apocaeus, who encouraged the empress dowager to assert a maternal right to the tutelage of her son, and by the patriarch John, who laid claim himself to the office of guardian. In self-defence, therefore, Cantacuzenus caused himself to be made emperor in 1342, which produced a civil war, in which he was, at first, so far unsuccessful, that he was obliged to quit his country and take refuge in Servia. After a series of misfortunes he was at length, in 1347, received as a conqueror into Constantinople. He now associated himself with his ward in the empire, but the union was soon interrupted by intestine divisions, which, in 1355, he put an end to by a voluntary abdication, when he took the religious habit in a monastery of mount Athos. Here he employed himself in composing a history of the transactions to which he had been witness; and this work, comprising a period of forty years, from the revolt of the younger Andronicus to his own abdication, is one of the most elegant productions of the modern Greeks. He likewise engaged in a religious controversy, and composed four books against the Jews and Mahometans. This work was published at Basil in 1543; and of his History there is a Louvre edition in three volumes, fol. 1655. He is said to have died in 1411: a letter to him from pope Gregory XI., in 1375, is still extant. These are the only emperors of the name of John that require any notice in this work. Gibbon. Universal History.

JOHN, king of France, succeeded his father, Philip of Valois, in 1350, being, at the time, forty years of age. One of his first acts was to put to death, without the form of trial, the constable, count d'Eu, who was suspected of being in the interest of Edward III., king of England. This arbitrary act occasioned much discontent among his nobles, whom he attempted to appease by the institution of the order of the star, in imitation of Edward's order of the Garter, but being too lavish of the new honour, it was brought into contempt. A war broke out between England and France, and John summoned the states-general for the purpose of raising the necessary supplies. In the assembly of these states it was agreed that no proposition should be admitted without the unanimous consent of the three orders, which gave to the third estate an authority and independence which assimilated them to the commons of England. John made considerable concessions, and was enabled thereby to raise a powerful army. It was in this contest that the king of France was opposed to the Black Prince of England: at Mauvertuis, near Poitiers, they met; the former with an army of sixty thousand men, the latter could scarcely enumerate twelve thousand effective soldiers. Edward, feeling the disadvantageous ground on which he stood, offered to resign his prisoners, and the booty which he had already made, and to sign a truce for seven years, provided he might be permitted to return to his own country in security, but John, confident of success, required him to surrender himself a prisoner, with the principal officers of his army. This demand brought on the famous battle of Poitiers, on the 19th of September, 1356, in

which John was made prisoner, and many of the French nobility lost their lives. The captive monarch, though respectfully treated, was brought to England to grace the triumph of the conqueror; the peace, in 1360, put an end to his captivity, but to obtain his liberty he made over many of the most valuable provinces of his kingdom to the king of England, and agreed to pay a ransom of three millions of gold crowns. The disasters to which he had already been subject, had so little effect in teaching him political wisdom, that at the persuasion of pope Urban V. he took the cross, and seriously resolved upon an expedition into the Holy Land. The execution of this project was prevented by the dishonourable escape of his son Lewis, count of Anjou, from England, where he was detained as a hostage. The king's sense of justice and honour determined him instantly to return to England in the stead of his son. He landed in 1364, and was received by Edward with great magnificence; but he was shortly after attacked with a disease, of which he died at the palace at the Savoy in April, in the 56th year of his age, and the 14th of his reign. John was possessed of many noble qualities, but he was not gifted with very superior talents: he was author of the maxim, "That if justice and good faith were banished from the rest of the world, they ought to find refuge in the hearts of princes." Univer. Hist. Hume.

JOHN, king of England, born in 1166, was the youngest son of Henry II. by queen Eleanor of Guienne. He was his father's favourite, nevertheless he joined his brother Richard in those projects against Henry, which induced the unhappy king, on his death-bed, to pronounce a curse upon his children. He was left without any particular provision, which circumstance gave him the name of "Lack-land." Richard, upon his accession to the throne, behaved with the utmost liberality to John, but his generosity could not attach him to his interest. During his absence in the Holy Land, he formed secret intrigues with Richard's rival and inveterate foe, Philip king of France. These broke out into open rebellion, but being unsuccessful, he threw himself upon his brother's mercy. With a knowledge of his character, Richard said to his intercessor, queen Eleanor, "I forgive him, and hope I shall as easily forget his ingratitude and injuries, as he will my pardon." John, who was utterly void of all sense of honour and generosity, proved the baseness of his nature by the act with which he purchased forgiveness. He invited the officers of Philip's garrison of Evreux to an entertainment, caused them to be all massacred, put the soldiers to the sword, and delivered up the town to his brother. He ascended the throne at the death of Richard in 1199, but he did not obtain an undisputed succession. War was excited in favour of Arthur of Brittany, in which the young prince fell into the hands of his uncle John: he was at first confined in the castle of Falaise, and his uncle in vain endeavoured to procure his assassination. At length he was conducted to the castle of Rouen, where John resided, and he was never after heard of. The manner of his death was uncertain, but it is generally believed that the king stabbed him with his own hands. From this period John became the object of universal detestation, and all his foreign subjects prepared to throw off the yoke. The pope also excommunicated him, and absolved his subjects from their allegiance. He for some time resisted the papal authority, but in 1213 he made his submission. The pope, now regarding England as his own, and jealous of the aggrandizement of Philip of France, sent a message to that prince, acquainting him with John's return to his duty towards the church, and requiring him to desist from hostilities against a country now under the protection

protection of the holy see. Philip had, however, made preparations for war, and was not to be put off from his plans by the mere order of the holy pontiff. A battle ensued, in which the fleet of England triumphed over that of France, and John even thought of regaining his former possessions; but the attempt was unsuccessful, and he was obliged to return in disgrace. His own barons, who had suffered by his controul, determined now to assert their privileges, and laid a statement of their grievances before the king, which he attempted to elude. To second their efforts they chose a general, and immediately proceeded to warlike operations. They were received into London with open arms, which so intimidated the king, that he was obliged to submit to such articles of agreement as they thought fit to dictate. At Runnymede, John signed the famous Magna Charta, the basis of English liberty, which not only protected the nobles against the crown, but secured many important rights and privileges to every order of freemen. It was stipulated that London should remain in the hands of the barons, and the Tower in the custody of the primate, till the articles of the charter were executed. The king made another attempt to retrieve his affairs by insisting under his banners foreign troops, but most of his projects failed, and he died partly of disease, and partly of chagrin, at Newark, in October 1216. The character of this prince is transmitted to us in very black colours: perhaps his vices have been exaggerated. Ingratitude, perfidy, and cruelty were certainly the ruling principles of his conduct. His private life was stained with licentiousness, and he seems to have paid no regard to the forms of religion. The best part of his conduct as a sovereign, was the attention which he paid to commerce and maritime affairs. In his reign London received the gift of its popular constitution of the corporation. Hume. Henry.

JOHN I., king of Portugal, natural son of Peter the Severe, was born about the year 1350, and raised to the throne in 1383, to the prejudice of John of Castile, who claimed in right of his wife Beatrix, daughter of Ferdinand. Soon after his accession, the king of Castile invaded Portugal with a powerful army, but victory, which decided in favour of John, permanently fixed him on the throne. In 1387 he married Philippa, daughter of John of Gaunt, duke of Lancaster. It was not till the year 1400, that a peace was finally settled between the two countries, which remained inviolate during the rest of the reign. John employed the season of public tranquillity in improving the police, and promoting the prosperity of his kingdom. Mindful of his former condition, he behaved with great condescension and familiarity to his subjects, and bestowed his favours liberally. Though his bounty kept him poor, he moderated his imposts, and found resources in his frugality with respect to the ordinary amusements of a court. He was accustomed to say that conversation was the cheapest of all pleasures, as well as the most improving, and he promoted a taste for letters among the nobility. He was, however, inflexible in the punishment of crimes, and by his severity in this respect, he rooted out the bands of bravos kept by the nobility to execute private revenge. In 1414, he fitted out a formidable expedition against the Moors, in which he was successful, and he entrusted to his son Henry, duke of Viseo, the chief management of affairs in Africa, which gave occasion to that course of maritime discovery by which he became so much distinguished. (See HENRY.) The concluding cares of this sovereign were occupied in the settlement of his family, in which he was very successful. He died in 1433, after a long and prosperous reign, leaving behind him the character of one of the ablest and best of the Portu-

guese sovereigns, under the title of "the father of his country." He is regarded as the founder of a new royal family.

JOHN II., king of Portugal, son of Alphonso V. was born in the year 1455. In 1476, he was appointed regent, and, in 1481, he assumed the whole power of king on the death of his father. Finding that the administration of justice was become exceedingly corrupt, he appointed a commission to enquire into abuses, and to reform whatever was wrong. He watched over the conduct of the judges, forewarning them of his displeasure if they proved backward in the equitable discharge of their duties. "Take care," said he, to one of them, "I hear you keep your hands open and your doors shut" this timely warning sufficed for his reformation. A conspiracy was shortly formed against his life, at the head of which was the duke of Viseo, a very young man and the queen's brother. The king, on being informed of it, sent for the duke to court, and taking him aside, charged him with his treasonable purpose. What particularly passed on this occasion is not known, but the result was, that the king drew his dagger, and laid the duke dead at his feet. Several of the other conspirators were apprehended, some were executed, and others went into voluntary exile. John, willing to shew that he was not unnecessarily severe, restored the forfeited estates of the duke of Viseo to his brother, whom he likewise raised to high dignity in the state. It is to the honour of this prince that he was the patron of commerce, particularly of that opened to the Portuguese by their settlements on the coast of Guinea. Being told by Cano, the discoverer of Congo, that the natives concealed their gold-mines, "Never look for them," said the king, "carry them what they want, and you will get their gold without digging for it." He did much towards the discovery of the passage by the Cape of Good Hope; but he had the mortification of reflecting, that by his refusal of the proposals of Columbus, he missed the opportunity of adding the western world to his dominions. About the year 1490, he was grievously affected by the death of his only son, who was killed by a fall from his horse at a race. He endeavoured, after this, to introduce his natural son George into the succession, but the great opposition which he met with in this scheme induced him to lay aside the project. He died in October 1495. The chief object of his reign seems to have been, to depress the nobility, to raise the inferior orders, and to promote the commercial prosperity of his kingdom.

JOHN III., king of Portugal, was born in 1502, and succeeded to the crown in 1521. The events of this reign are in many respects important, and attach to them very serious consequences. In the time of this prince the execrable inquisition was introduced into Portugal, of which it was the cradle nearly three hundred years, and has only been abolished within these few months, at the suggestion or demand of the British court. John sent missionaries into the East Indies, of whom the celebrated Xavier was one. The new settlement of Brazil was brought into a flourishing state in this reign, and particular attention was paid to the conversion of the natives. The king was attentive to what he believed would conduce to the happiness of his subjects; he was economical with regard to himself, and unwilling to burden his subjects with new taxes. From his own resources he founded hospitals, constructed fortifications, highways, and aqueducts, restored the university of Coimbra, and executed other projects of utility and splendour. John died of an apoplexy in 1557, at the age of fifty-five, after a reign of thirty-five years. He was succeeded by his grandson Sebastian, a minor.

JOHN IV., king of Portugal, born in March 1604, was son of Theodolius, duke of Braganza, of the royal line. He succeeded his father in that dukedom in 1630, for, at that time, the Spaniards had taken possession of the Portuguese government, and annexed the country to the crown of Spain. It was become, in the reign of Philip IV., a domain of Castile, intended for the enriching of favourites. The oppressions and indignities suffered by the Portuguese had inflamed their discontents to the highest pitch, and they were only waiting for a leader, to break forth into a general revolt which they meditated. They fixed on the duke of Braganza, and offered him the crown of Portugal, if he would stand forth in their cause, and merit the high honour by his proofs. The Spanish court, aware of their intentions, practised a variety of arts to get the duke into its power. The highest honours were offered him, in hopes of alienating him from the Portuguese cause; when these proved ineffectual, he was invited, or rather ordered, to come to Madrid to confer on state affairs, and the impossibility of excusing himself from this step, hastened his final determination. The leaders of the conspiracy pressed him again to accept of the crown; he hesitated, but on consulting the duchess, she confirmed him, with this heroic address, "My lord, a violent death awaits you with certainty at Madrid, perhaps at Lisbon; at the former place you must die as a wretched prisoner; here, covered with glory, and a king. Let us confide in the love of the people, your just claim, and the protection of heaven." He accordingly acquiesced, a revolution was effected in his favour in December 1640, and he was instantly proclaimed John IV. The new sovereign was acknowledged by all the powers of Europe, not immediately under the influence of the house of Austria, a conspiracy was however formed against his life and throne, but it was discovered and suppressed, and a treaty with France and the United Provinces assailed Portugal in foiling the attempts of Spain to recover its sovereignty. The reign, nevertheless, was passed in perpetual hostilities, though carried on with little vigour on either side. John died in 1656, leaving behind him two sons and two daughters. His reign, though far from brilliant, was useful; he was ever desirous of promoting the good of his people, and very unwillingly imposed any burthens on them. He recovered from the Dutch, and secured the valuable settlement of the Brazils, but lost the island of Ceylon.

JOHN V., king of Portugal, born in 1689, succeeded his father Peter II., in December 1706. The nation was at this time engaged in the Spanish succession war, as one of the allies against the house of Bourbon; the new king was faithful to the cause, but little either of success or honour attended his arms. The peace of Utrecht was favourable to Portugal, and from that time the king's attention was occupied in rendering his country flourishing. His government was wise and moderate, his character generous and patriotic. He died in 1750. For farther particulars relating to the kings of Portugal, the reader is referred to the Modern Universal History.

JOHN, king of Denmark, born in 1455, succeeded his father Christiern I. in 1481. He had been acknowledged king of Denmark and Norway in his father's life-time. He expected to have been chosen king of Sweden, but was disappointed by the intrigues of the administrator of that kingdom, and it was not till 1497 that he was crowned the king. At the coronation-feast, one of the king's German officers hinting that it would be a politic act to cut off the heads of those who had been leaders in the opposition to him, John replied with a manly indignation, that he would rather see all his evil counsellors on a gibbet

than incur the flame and infamy of so savage a deed. "God forbid," said the virtuous monarch, "that I should ever deny to any free people the right of chusing their own governors." For some time he acted conformably to this sentiment, and exhibited a mind intent upon the public good, which produced a general satisfaction with his government. John, however, did not always act upon the principle of equity, which the maxim above quoted should have inculcated. The people of Dithmarsh accordingly vindicated, at the point of the sword, their independence; and their success was the forerunner of an open revolt in Sweden, where discontents had been gradually accumulating against the king's administration, owing to the facility with which he had conferred offices and grants on his favourites, to the prejudice of the natives. The former regent headed the malcontents, and renounced his allegiance to John. The queen, Christina, who was left at Stockholm, was obliged to capitulate; and a revolution was effected in 1502. After this many changes in the government took place, several of which led John to hope for a restoration to the crown; and a treaty for that purpose was concluded a short time before his death, which happened in February 1513, in consequence of a fall from his horse. He possessed many estimable qualities, and would have been a really good king, but that he suffered himself to be swayed too much by his favourites.

JOHN III. king of Sweden, born in 1537, was second son of Gustavus Vasa, who settled upon him the dukedom of Finland. In 1560 he was sent to the court of England to forward the proposed union between his elder brother Eric and queen Elizabeth. Not long after this Eric succeeded to the crown, and John became the object of his suspicion. He was arrested, brought to trial, and condemned; but his life was spared, and the sentence exchanged for perpetual imprisonment. Several times it was determined to destroy him, but the tyrant as often relented, till at length, finding it necessary to strengthen his government, he liberated John in 1567, to the great joy of the Swedish nation. In the following year he took up arms against Eric, whom he deposed, and ascended the throne in his stead. He found the nation involved in a war with Denmark and Russia, and almost struggling for its existence. He concluded peace with the former power, but hostilities continued with the latter till they were suspended by a truce in 1573. By the influence of the queen, John abjured the Protestant religion, and embraced that of the church of Rome. In consequence of this dereliction of principle he made many enemies; and although numbers of the clergy were gained over by views of ambition and emolument, yet a formidable party, attached to the reformation, with the king's brother, Charles, duke of Sudermania, at their head, made such an opposition as nearly to involve the kingdom in a civil war. By the death of the queen, John found it expedient to lessen his zeal with regard to the establishment of the Roman religion, though he retained the desire of making it the religion of the state. He accordingly published a liturgy conformable to it, the use of which he enjoined to the clergy under the severest penalties. The flame of religious discord was hereby re-kindled; and the duke Charles again stood forth as the defender of the Protestant church. In 1590 John married Christina, daughter of the duke of Holstein. The war with Russia was renewed, and Sweden lost several fortresses. In this state of affairs John died in 1592, after a reign of 24 years. Mod. Univ. Hist.

JOHN SOBIESKI, king of Poland, born in 1624, was son of a brave and able statesman of the same name. He received

ceived a very liberal education, and visited the politest courts in Europe. He ascended, through the several gradations, to the highest post in the army, and signalized himself in many important actions. In the battle of Chociezim, in 1673, after three days fighting, he gave the Turks a total and bloody defeat. In the following year, after many difficulties, and struggling through much opposition, he succeeded to the crown of Poland, and immediately applied his resources in the prosecution of the Turkish war, and by a series of brilliant successes soon induced the Porte to agree to a treaty, which completely revoked the dishonourable terms of a former one. His coronation followed the restoration of peace, and he employed the interval of tranquillity in the re-establishment of the finances of the kingdom, and in preparations for a future war, which his own martial disposition rendered no distant event. In 1683, he made an alliance, offensive and defensive, with the court of Vienna, and without hesitation expended the treasures which he had accumulated in levying troops, and putting his army into the best possible state. The Turks having laid siege to Vienna, and reduced it to great straits, he marched to its relief. Forming a junction with the imperial general, the duke of Lorraine, they attacked the Turkish camp on September 11th, 1683, entirely routed the Grand Visir, took possession of all his cannon, warlike stores, &c. and broke up the siege. The people of Vienna regarded John as their saviour, and all Europe has rendered him the homage due to his heroism on this important occasion; but the pride of the emperor Leopold produced from him a cold and ungracious acknowledgment of the service. Between this and the year 1686 he performed many other noble deeds of valour; but from that period he passed life without glory, in projects for the advancement of his family by alliances, and especially for securing the crown to his son, by which he was involved in many domestic inquietudes, and civil dissensions. He died in 1696, less regretted than might have been expected; but he had been accused, in his latter years, of consulting the interests of his own power and ambition, rather than those of his country. It was, however, universally admitted that he was not only a brave warrior and consummate commander, but possessed all the accomplishments that are fitted to adorn a throne. As a literary man, he was eloquent and well informed on most subjects. He was a good Latin scholar, conversant in several modern languages, and acquainted with science beyond most of his countrymen. *Mod. Univ. Hist.*

John of Gaunt, or Ghent, duke of Lancaster, was the third son of Edward III. king of England, and born at Ghent in 1340. He married Constance, a natural daughter of Peter the Cruel, king of Castile and Leon; and on the death of that monarch he laid claim to the throne in right of his wife, in opposition to Henry of Transtamare, but without success. He served with considerable glory in France with his brother the Black Prince, and on his death the management of public affairs was committed to the care of John during the life of his father. On the accession of Richard II. he retired; but the envy of the courtiers, particularly the ecclesiastics, who hated him for protecting Wickliffe, followed him with false accusations of a design to usurp the throne, from which, however, he satisfactorily vindicated himself. In 1386 his only daughter was married to the heir apparent of the king of Castile, and John renounced his claim to that crown in consideration of a very large sum of money and pension. John took for his third wife Catherine Swinford, sister to the wife of his friend Chaucer the poet. He died in 1399, leaving a high character for valour, prudence, and generosity. His son afterwards

became king, under the title of Henry IV. See Hume's *Hist.* and Godwin's *Life of Chaucer*.

John of Austria, Don, the natural son of the emperor Charles V. was born at Ratibon in 1547. He first appeared as a public character in 1569, during the revolt of the Moors of Granada, when he was appointed captain-general of the Spanish galleys, and was sent to Cartagena to take the command. He assisted in the operations of the war, which was brought to a happy termination the following year. The holy league against the Turks for the protection of the Venetians, being formed between the king of Spain, the pope, and the Italian states, don John was nominated, in 1571, general in chief, and assembled the united fleet at Corin. In October he engaged with the Turkish fleet in the gulph of Lepanto, and obtained that victory which stands conspicuous in the series of actions between the Christian and Mahometan powers. Don John, in person, fought with and took the Turkish admiral's galley, and the battle terminated in the loss, on the part of the Turks, of 130 galleys taken, 55 destroyed, 25,000 men killed, and 10,000 made prisoners, besides achieving the liberty of 15,000 Christian slaves. Divisions arose as to the future operations of the war: the advice of John was over-ruled, and the advantages obtained by this splendid victory by no means equalled the public expectation. In 1576 he was appointed governor of the Low Countries. The Catholic provinces had united with Holland and Zealand against the Spaniards, and don John was directed openly to concur in this convention, and cause the Spanish troops to leave the country. Shortly after this don John took possession of Namur, Charlemont, and Marienburg, contrary to the interests of the states, who, in 1577, resumed their arms, deposed don John, and declared the archduke Matthias their governor. A war commenced, and John gave the army of the Netherlands a very signal defeat, and made himself master of many strong places. He was proceeding in his military career, when, in October 1578, he was taken off, after a short illness, in his camp at Namur, in the 32d year of his age. He resembled his father in person, whom he equalled in activity and enterprise, and whom he greatly surpassed in generosity and humanity.

John I. pope, was a native of Tuscany, and ascended the papal chair on the death of Hormisdas, in the year 523. His pontificate was short and wretched, owing to the intemperate zeal of the emperor Justin for the extirpation of all the sects who would not conform to the Catholic faith: he even attempted to extirpate the Arians, of which party Theodoric, king of the Goths, avowed himself a defender. This prince wrote to the emperor most pressing letters in favour of his persecuted subjects, and when he found that no regard was paid to these, knowing the influence which the pope had at the imperial court, he ordered John to attend him at Ravenna: from thence he went in quality of ambassador to Constantinople, where he was very honourably received, but the main object of his embassy was conducted in a way which gave his employer very little satisfaction; and on his return Theodoric caused him to be conducted from the palace to a prison. He died in confinement in the year 526, after a pontificate of little more than two years and a half.

John II. was elevated to the papal throne in 533, upon the death of pope Boniface II. In the following year the dispute, "whether one of the persons of the Trinity suffered in the flesh," was carried on with great bitterness. In this dispute the emperor Justinian took a part; he not only maintained the affirmative side of the question, but declared all those who dissented from him to be heretics. He also

wrote

wrote to John, sending him his own creed, assuring him that it was the faith of the whole eastern church, and intreated him to pronounce a judgment in its favour. The emperor's letter was accompanied with rich presents, and the pope, without much hesitation, decided in favour of Justinian's confession. He died in 535, after a pontificate of two years and five months. Six letters bear his name in the Collect. Council, of which the first is generally rejected as spurious.

JOHN III. pope, surnamed *Catalane*, a native of Rome, was son of Anastasius, a person of considerable distinction. He was elevated to the popedom on the death of Pelagius in 560, and after holding it about thirteen years he died.

JOHN IV. pope, surnamed *Scholasticus*, was elected to the pontifical dignity upon the death of pope Severinus, in the year 642. He engaged deeply in the controversy of the MONOTHELITES (which see), and involved himself in some difficulties on that account. He employed the wealth of the church in humanely redeeming vast numbers of Christians, whom the Saracens had carried off captives in their irruptions into the empire during the reign of Heraclius. The reign of this pontiff did not extend to a single year. Three of his letters are inserted in the fifth volume of the Collect. Council.

JOHN V. pope, a native of Antioch in Syria, was, while only a deacon in the church, appointed by pope Agatho one of three legates, whom he chose to be his representatives at the sixth general council, and it was by him that the Greek copy of the letters of Honorius to Sergius, produced and read in the council, was compared, and found entirely to agree with the Latin original, deposited in the library of the patriarch. In 685, upon the death of Benedict II., John was elected his successor, an honour which he retained something more than a year. He died, after a long and tedious illness, in the year 686.

JOHN VI. pope, was elected to the papal throne in the year 702: the reigning emperor, Tiberius Apthamarus, objected to the election, and ordered him to be driven from the apostolic see; but the soldiers took part with John, and established him on his throne. He displayed great generosity by redeeming many captives, whom the duke of Benevento had taken in an irruption into the territories of the empire of Italy, and at length prevailed upon that prince to put an end to his hostilities against the subjects of the empire. He held a council at Rome, in which Wilfrid, who had been driven from the see of York, and banished England, was declared innocent of the crimes laid to his charge. John died in 705, after a reign of little more than three years.

JOHN VII. pope, was raised to the pontifical dignity on the death of John VI. Immediately on his elevation to the throne, the emperor Justinian demanded of him his opinion with regard to certain canons; but John was too wary to be thus drawn into a trap, and declined giving any judgment, lest, by so doing, he might incur the emperor's displeasure. He died after a pontificate of two years and seven months, in the year 707. A single letter of this pope is to be found in the sixth volume of the Collect. Council.

JOHN VIII. pope, was, on the death of Adrian II., elected to fill the papal see. This was in the year 872; and in the following year the emperor Lewis II. came to Rome, where he held an assembly of the states of Italy subject to his empire, at which the pope assisted. In that assembly the pope absolved Lewis from an oath which he had taken not to interfere with the government of the dukedom of Benevento, under the pretence that it had been extorted by force, and also that it was inconsistent with the welfare of the empire. In 875 he crowned the emperor Charles the Bald, and three years after went to France, where he held a council at Troyes.

In his pontificate Italy was greatly ravaged by the Saracens, who obliged the pope to pay tribute. He corresponded with Photius, patriarch of Constantinople, who had driven Ignatius from his seat, and usurped for himself the dignity. At first the pope refused to acknowledge him; but Photius, by rich presents, rendered his holiness propitious, who not only consented to absolve him from the excommunications which had been repeatedly thundered out against him, but readily received him as his brother and colleague. In a council held at Constantinople, in the year 879, at which the papal legates and Photius conjointly presided, the latter was declared lawful patriarch of the imperial city, and the legates, won over by his presents, ventured so far to depart from their instructions, that they pronounced an anathema against all who should receive any of the councils which had condemned him. Upon their return to Rome, conscious of having gone beyond their instructions, they endeavoured to conceal this circumstance from the pope; but he was soon apprised of it, and exasperated, as well at their treachery, as at the dissimulation of Photius, declared all their proceedings null and void, and assembled another council in 881, at which he caused the patriarch to be a second time condemned. After this he made an offer of the imperial crown to Charles the Great, and urged him by all means to come to Rome to receive it. As soon as the state of his affairs would permit him, Charles proceeded to that city, and was crowned by the pope in St. Peter's church. John, however, could not prevail with the new emperor to lend him any assistance against the Saracens; he, therefore, endeavoured to gain over such of the Italian princes as had entered into an alliance with them. He even went to Naples, to try whether he could persuade Athanasius to turn his arms against them. That prelate promised to support the pope, and was supplied with money to enable him to levy the requisite forces, but with the coolest treachery he turned those forces against the pope himself. John instantly excommunicated him, and refused him absolution but upon such conditions as he could not comply with. This pope died in the year 882, after a pontificate of little more than ten years. More than three hundred of his letters are to be found in the ninth volume of the Collect. Council, some of which are said to throw considerable light on the ecclesiastical and civil affairs of the time in which he flourished. He left also a sermon pronounced in council on the confirmation of the election of Charles the Bald.

JOHN IX. pope, a native and deacon of Tivoli, was raised to the papal dignity on the death of Theodore II., in 898. At this period Italy was divided by the factions of different pretenders to the empire: John at first refused to take any part in these contentions; but owing to the violence of Berenger, king of Lombardy, he was induced, apparently, to espouse his cause, and to crown him emperor. He had, however, no sooner left the city, than the pope assembled a council, in which he declared the coronation of Berenger null and void, as having been extorted by force, and acknowledged Lambert, who had also been crowned king of Italy, as the only lawful emperor. In the same year John convened a council to meet at Ravenna, which confirmed the acts of the council of Rome, and approved of the coronation of Lambert, who was present in person. This pope died in the year 900, after having filled the papal chair about two years. Four of his letters are extant in the ninth volume of the Collect. Council.

JOHN X. pope, rose in the church by degrees, from the rank of deacon to that of archbishop of Ravenna. He was indebted, for this last promotion, to a celebrated prostitute Theodora, with whom he had long been intimate notwithstanding

standing his elevated station in the church. In 914, Theodora, by her intrigues and interest, got her favourite and friend preferred to the pontifical chair. Under this pope, Rome and Italy were indebted for deliverance from the barbarous and oppressive Saracens. In 916 he crowned anew Berenger, who readily assisted him in his ambitious projects. The pope resolved to take the field himself as generalissimo of all the forces, and under him the Saracen power was completely annihilated, which, during the space of forty years, had been the terror of the whole of Italy. In the following year the pope began to feel some compunctions of conscience on account of his former conduct, and accordingly sent a legate, as his proxy, on a pilgrimage to the tomb of St. James, of Compostella, in the kingdom of Leon, hoping, at least wishing, others to believe, that he should atone for his vices by offering rich presents at the shrine of a departed saint. In the year 925 John shewed how little regard he paid to the canons of the church by confirming the nomination of Hugh, a child only five years old, and son of count Herbert, in the archbishopric of Rheims. As John was indebted for his rank and elevation in the church to the intrigues of one infamous woman, so he lost his dignity and life through those of another. This was Marozia, the daughter of his former mistress Theodora. Marozia, exasperated that she did not succeed her mother in the confidence of the pope, resolved to destroy him and his brother Peter, who at this time was in habits of the strictest intimacy with him. She communicated the bloody design to her husband, and prevailed on him not only to approve, but to be the instrument of carrying it into execution. Accordingly this wretch, on a certain day, when the pope and his brother were together in the Lateran palace, broke into it at the head of a band of ruffians, killed Peter before his brother's face, and then, seizing the pope, dragged him to prison, where he soon afterwards died. This tragical event happened in the year 928, after John had been seated on the papal throne more than fourteen years. Three of the letters of this pope are to be found in the ninth volume of the Collect. Concil.

JOHN XI. pope, was supposed to be the natural son of pope Sergius III. by the infamous Marozia, but according to others he was the son of Alberic, duke of Spoletta. It is certain he attained the dignity of pope through the influence of Marozia, and her husband Guy, marquis of Tuscany, in the year 931, upon the death of Stephen VII. Guy did not long survive the promotion of John, and immediately upon his death, Marozia sent word to his brother Hugh, king of Lombardy, that he would make him master of Rome, upon the condition of marrying her. To this the prince readily acceded, and took possession of his bride, and the castle of St. Angelo at the same time. Hugh rendered himself hateful to the Romans, and excited the resentment of Alberic, a son of Marozia by her first husband, who put himself at the head of the discontented, attacked the castle of St. Angelo, and made himself master of the fortress. In the confusion Hugh made his escape, but Marozia and pope John fell into Alberic's hands, who kept them both in close confinement during the remainder of their lives. John died in 936, after a pontificate of nearly five years.

JOHN XII. pope, whose original name was Octavian, was son of the Alberic referred to in the last article. On the death of his father in 954, Octavian succeeded to his dignities, and not satisfied with his temporal power, he aspired to the papal throne when it became vacant in the year 956, and secured the possession of it to himself. On this

occasion he assumed the name of John XII. and thus introduced the custom which was afterwards adopted by his successors of changing their usual names for others, upon their accession to the pontificate. At this time Berenger tyrannized over Italy, and the pope implored the assistance of Otho I., who delivered the country. John crowned Otho at Rome, and promised him fidelity, which however was of very short duration, for he united with the son of Berenger against his deliverer. Otho returned to Rome in 953, and called a council, in which the pope was accused of adultery, sacrilege, and other crimes, which were satisfactorily proved against him, and he was deposed. When the sentence of his deposition had been pronounced, the council, clergy, nobility, and people, unanimously elected Leo VIII. to fill his place. After this, John several times conspired against the life of the new pope, and was as frequently pardoned, till at length he contrived to set himself again on the papal throne. John instantly assembled a council of prelates and cardinals, who condemned the council that had deposed him, and passed different sentences of condemnation on all those who had been accessory to the elevation of his rival. John did not long survive the holding of this council, for having engaged in a criminal connection with a married woman, the injured husband who caught him in the act put an end to his holiness's life and debaucheries by some violent blows which he gave him on his temples. His death is supposed to have taken place in 964, after he had filled the papal throne about eight years. A single letter of his is inserted in the ninth vol. of the Collect. Concil.

JOHN XIII. pope, was one of the principal accusers of the pope whose history has been just given. By the part which he took on this occasion, he recommended himself to the favour of the emperor Otho, who, after the death of John, returned with his army to Rome, and held a council there, in which a decree was passed, conferring on the emperor and his successors for ever the power of nominating the pope, and of granting investiture to bishops. After the death of Leo VIII., in the year 965, John was recommended by the emperor as his successor to the holy see, which was decidedly contrary to the inclination of the Roman people, who conspired against him and drove him from his throne. The emperor determined to take ample revenge for this insult, and marching his army, he restored the pope, and severely punished those who had taken part against him. He next went to Ravenna, accompanied by the pope, where he held a council in the year 967. Upon the breaking up of the council the pope returned to Rome, where he spent the remainder of his life in the unmeditated possession of his high dignity. In 968 he crowned, in St. Peter's church, the young Otho, king of Germany, whom his father had taken for his partner in the empire, and in the year 971 he crowned as empress Theophania, daughter of the late eastern emperor Reminus, who was married to Otho the younger. John died at Rome in 972, after having presided in the Roman see nearly seven years. In his pontificate the Poles were first converted to the Christian religion, and he is said by some writers to have been the person who introduced the practice of blessing or consecrating church bells. Four letters of this pope may be found in the ninth vol. of the Collect. Concil.

JOHN XIV. pope, succeeded to the papal chair on the death of Benedict VII. in the year 985, an honour which he enjoyed but eight months. Boniface VII. who is classed among the anti-popes, undertook the expulsion of John. He prevailed, seized his rival, confined him in the castle of St. Angelo, and there either starved him to death, or

more

more humanely dispatched him with poison. Boniface himself did not long survive the victim of his cruelty, being carried off in the same year by a sudden death. Upon this event, John, a native of Rome, and the son of one Robert, was elected pope, and governed the church during the space of about four months, but for some cause or other, not sufficiently explained, he is not reckoned among the popes.

JOHN XV. was elected to the papal dignity in the year 985, on the death of John, the son of Robert, who has been just mentioned. Soon after the commencement of his pontificate, Crescentius, a man of great power at Rome, aspired at the sovereignty of the city, seized the castle of St. Angelo, and assumed the title of consul. The pope, conceiving that he was in danger, implored the assistance of the emperor Otho III., who promised him, that, if necessary, he would come with his whole army, and support the apostolic see with the same zeal which his father and grandfather had displayed. John informed Crescentius of the imperial determination; he submitted, and sent some of the chiefs of his party to invite his holiness back to Rome, with the strongest assurances of safety, and of that respect which was due to the successor of St. Peter. John complied, and was permitted to live unmolested till towards the close of his pontificate. In the year 993, at a council held at the Lateran palace, the pope, after hearing read an account of the life and supposed miracles of Ulderic, bishop of Angulla, declared, with the approbation of his bishops, that from thenceforth Ulderic might be worshipped and invoked as a saint in heaven reigning with Christ. This is the first instance on record of the solemn canonization of a pretended meritorious character, a practice which soon contributed to crowd the Roman calendar with saints, and loaded the church with wealth, by the rich offerings with which the superstitious multitude was encouraged to propitiate the favour of these new mediators between God and man. About this period the pope became engaged in a quarrel with the French clergy, over whom he obtained a complete victory; he had, however, more trouble with Crescentius who began to resume his ambitious projects at Rome. John applied again for assistance to Otho, who marched an army to his assistance, but in the midst of these warlike preparations the pope died in the year 996, and in the eleventh year of his pontificate. Three of his letters are extant in the ninth vol. of the Collect. Concl.

JOHN XVI. pope, was a native of Rossano, in Calabria, of mean extraction, but a person of considerable abilities and address. He was employed by the emperors Otho II. and III. in affairs of considerable moment; and from the latter he obtained possession of the see of Placentia, and held it till he heard that Gregory V. was driven from Rome by Crescentius in the year 997, when he bargained for, and purchased the popedom of that usurper, and then assumed the title of John XVI. He was excommunicated by several councils held in Italy, France, and Germany, and at length the emperor Otho brought against him a powerful army. The pope, or, as he is sometimes called, the antipope, endeavoured to make his escape from the city, but falling into the hands of some of Gregory's friends, they barbarously deprived him of his sight, and cut off his nose and ears. To complete the climax of their cruelty, they mounted the unhappy wretch on an ass, led him through the streets of the city, and forced him to exclaim "Whoever shall dare to dispossess a pope, let him be served like me."

JOHN XVII. pope, was elected to the holy office on the death of Silvester II. in the year 1003, in which year he also died, after he had presided over the church about five months. It has been asserted, that from this time, the peo-

ple were deprived of voting at elections of the sovereign pontiffs, which was afterwards confined to the clergy. He was succeeded by

JOHN XVIII. pope, who held the office to which he was elected in 1003, between five and six years, but few of his acts have come down to us, except his sending St. Bruno to preach Christianity to the Russians, and his putting an end to the schism which existed between the eastern and western churches.

JOHN XIX. pope, was son of Gregory, count of Tusculum, and brother of Benedict VIII. Upon the death of the latter in the year 1024, the influence and wealth of Gregory procured the election of his other son, who was then a layman. It was at this moment that he thought it advisable to assume the name of John XIX. Early in this pontificate an attempt was made, by the emperor Basilius, to allow the patriarch of Constantinople the title of Universal bishop of the East, but John sent back the ambassadors with a refusal, telling them that the title of universal bishop became none but the successors of St. Peter in the apostolic see. In the year 1026, Conrad, king of Germany, having entered Italy with an army, and having reduced all the towns which had shaken off the imperial yoke, went to Rome, where the pope crowned him emperor, and his queen empress, with the usual solemnities. On this occasion, Rudolph, king of Burgundy, and Canute, king of England, who were on a pilgrimage to Rome, were present. John died in 1033. Three of his letters are inserted in the ninth volume of the Collect. Concl.

JOHN XX. or XXI. pope, a Portuguese, son of one Julian, a physician, became eminent for his acquaintance with the sciences, particularly with that of medicine, the practice of which he followed for some time with great reputation. He afterwards devoted himself to the church, and advanced by degrees to high preferment. He was made cardinal by Gregory X., and on the death of Adrian V., in 1276, he was elected to the pontifical dignity, when he took the name of John XX. or XXI. The first act of his pontificate was to revoke the famous constitution of Gregory X. which ordered that the cardinals should be shut up in the conclave during the vacancy of the papal see. He did all in his power to assist the Christians in the East. He was ignorant of the world, and became attached to the pretended principles of judicial astrology; from these he thought he had many years to live, and began to devise schemes for the future. He was, however, carried off in eight months after his elevation to the holy see. He was author of several tracts on logic, one on physiognomy, and some medical treatises. One of his letters to Edward I. king of England, is in the tenth volume of the Collect. Concl. and some others in the second volume of Widdings' "Annal. Minor."

JOHN XXI. or XXII. pope, a Frenchman by nation, and by descent, according to different writers, the son of a noble, a tavern-keeper, or a cobbler. In early life he was appointed to some considerable offices in the state, the duties of which he performed with so much credit to himself, as to manifest very superior talents for public business. On the death of Clement V., in 1314, the most violent disputes occurred in the election of a successor to the holy see. These were carried on for two years, after which the cardinals unanimously elected James de Ossa, the subject of this article, who assumed the name of John XXI. or XXII. During his pontificate he founded several abbeys and bishoprics; but he was not only the witness to, but the perpetrator of, many cruelties with respect to the Franciscans; some of whom were, by his order, actually stayed alive, as preparatory to their being bound to the stake for burning, which
favage

avage sentence was carried into execution without mercy. The cruelty of John was condemned by his warmest adherents, who did not scruple to declare that by it he had rendered himself utterly unworthy of the papal dignity, and that his deeds proved him to be the predicted anti-christ. They even revered these victims as martyrs to the truth, paying religious veneration to their bones and ashes. He was next involved in the dispute whether Christ and his apostles ever possessed any property or dominion, either in common or personally. The discussions on this question were violent and bitter, and those who maintained the negative side of the question paid for their temerity by the most excruciating sufferings inflicted on them. John was next engaged in a dispute with Lewis of Bavaria, who, as the reward of his victory over Frederic of Austria, claimed the Imperial crown as his right. John, alarmed at his assurance, instantly excommunicated him, and forbade all the subjects of the empire, on penalty of the same sentence, to acknowledge him for king, or obey him as such. From this sentence the monarch appealed to a general council, and published a manifesto against his holiness, describing him as one who trampled on all laws, human and divine, to gratify his ambition or avarice; as a ravenous wolf, fleeing and devouring the flock committed to his care; and, as an avowed heretic, in condemning as heresy the doctrine concerning the poverty of Christ. John died after a most turbulent pontificate, in the year 1334, at the great age of ninety years. Notwithstanding his various acts, which have been but merely referred to, he found biographers to praise his good deeds, forgetting those which were of a contrary description. They said he was a man of learning, and an encourager of the learned. The historian has held him up as ambitious, arrogant, cruel, and avaricious. He is supposed to have been the person who invented the "Annates," obliging every clergyman, preferred to a benefice, to pay into the apostolic chamber one year's income before he took possession of it. He died immensely rich, and was known in the literary world as author of several treatises: one "On the Contempt of the World;" one "On the Transmutation of Metals," and twenty-two Constitutions which he ordered to be called "Extravagantes." Many of his bulls and letters are likewise extant. He is said also to have been author of several treatises on medicine, which led some of his biographers to say he was better fitted for a physician than a pope. He is said by Walther to have written, among other things, a treatise on music, *Cine Rëtitum*; but no such treatise is enumerated in the list of his works by Baronius or Fabricius. This pontiff, however, seems to have interested himself very much about ecclesiastical music. The attempts at dissent, or extemporaneous counterpoint, were thought so licentious in his time, that he prohibited the use of it in the church by a bull in 1322. There is, however, at the end of it this favourable clause: "It is not our intention wholly to prevent the use of concords in the sacred service, particularly on great festivals, provided the ecclesiastical chant or plain-song be carefully preserved. The Abbé Lebeuf observes, that those who drew up this bull, which is inserted in the body of canon laws, erroneously confined dissent to fourths, fifths, and eighths, from the perusal of ancient authors on the subject of music, particularly Cassiodorus, where they had found the following definition: "Symphonia est temperamentum sonitus gravis ad acutum, vel acuti ad gravem, modulamen efficiens, live in voce, five in percussione, five in statu. Symphonia sunt sex: prima, diatessaron; secunda, diapente; tertia, diapason. Quarta, diapason et diatessaron; quinta, diapason et diapente; sexta, diapason et diapason."—"Symphony, or music in con-

nance, is the mixing grave sounds with acute, or acute with grave, either in singing or playing upon stringed or wind instruments. Symphonic concords are six: the fourth, fifth, and eighth, with their octaves. It is hardly possible to read this passage, and not give up the content concerning ancient counterpoint, or at least reduce it to the meagre kind of which Padre Martini has framed an example in his *Storia Musica*.

JOHN XXII. or XXIII. pope, formerly known by the name of Balthasar-Cossa, was a native of Naples, and being descended from a noble and wealthy family, he enjoyed the advantages of an excellent education at Bologna, where he took his degrees, and from thence he set out to Rome, anticipating the honours that seemed to be reserved for him, for on being asked by some of his friends whether he was going, he replied "to the popedom." Scarcely had he arrived at this great city, when he was made chamberlain to pope Boniface IX. who, in 1402, promoted him to the purple. He took an active part in the deposition of Gregory XII. and exerted all his talents, influence, and property to secure the election of Alexander V. Soon after that pontiff's election the plague obliged him to quit Pisa, and he was prevailed upon by cardinal Cossa to pay a visit to Bologna. Here he found means to detain the pope, under various pretences, till his holiness fell dangerously ill, and his complaints proved fatal to him. The subject of our present article has lain under the heavy charge of causing him to be poisoned by his physicians: he was, however, elected his successor, and from the title of cardinal Cossa he assumed the name of John XXIII. On the very day that he was raised to this high dignity in the church, he wrote to all Christian princes, acquainting them of his promotion, and exhorting them to support his claims against the pretensions of those who had been condemned and deposed by the church universal. One of the earliest objects of John's administration was to raise a fund to support the claims of his friend Lewis of Anjou, in opposition to those of his inveterate enemy, Ladislaus, to the possession of the kingdom of Naples. In his progress he solemnly excommunicated Ladislaus, and then ordered a crusade to be preached against him all over Christendom. By the bull issued on this occasion, all were exhorted to take the cross and engage in this holy war; and to all who should embark in it, the same indulgences were granted as to those who went to the conquest of the Holy Land. In a short time peace was restored; this was effected by John's taking off the excommunication from Ladislaus, who, in return, agreed to abandon the cause of Gregory, whom he had hitherto vindicated as the true pope. After the restoration of tranquillity, John made a promotion of fourteen cardinals, and summoned all the prelates of the church to attend a general council at Rome. At this council few bishops were present, its proceedings were, probably, unimportant, except in this, that it condemned the doctrine of Wickliff, and ordered his works to be committed to the flames. Ladislaus took the first opportunity of attacking pope John: the pontiff appealed to all Christian princes, exhorting them to appoint a general council to put a stop to the reigning evils, and to unite the whole church under one head. The choice of the place was left to the emperor, who fixed on Constance. Here the council was opened on the 1st of November 1414. After many sessions a list of accusations against the pope was read, containing seventy articles, some of which, however, were too scandalous even to be gone into: the others related to the pope's simony and tyranny; and to the means which he took of amassing immense riches. After these articles, and the depolitions in support of them, were read and examined, the

council declared them to be fully proved, and then unani- mously passed a sentence of suspension against the pope. This sentence was communicated to him by a deputation from the council. After this, viz. on the 29th of May 1415, the council proceeded a step further, and unanimously passed the definitive sentence of John's deposition, and ordered his seals to be broken. He was then committed to the care of Lewis, duke of Bavaria, and count palatine of the Rhine, who kept him prisoner, but treated him with civility and respect. At the expiration of about four years he obtained his liberty, and made such concessions to the existing pope Martin V. that he created him cardinal bishop of Tusculum, and dean of the sacred college: he also ordained that he should always sit next to the pope, and that his seat should be elevated a little above those of the other cardinals. He did not live many months to enjoy these honours. His character has already been described: he was unquestionably vicious and destitute of good principles, and merited that fall which he experienced. He was author of a poem "De Varietate Fortunæ," which is said to be distinguished by genius and taste. His bull for assembling the council of Constance; the form of his resignation, and some of his letters, are still extant. For farther particulars relating to the popes John, the reader is referred to Bower's History.

JOHN of Bayeux, known also by the name of John of Avranches, an illustrious Gallican prelate in the eleventh century, the first of all the bishops of Avranches, and afterwards promoted to the archiepiscopal see of Rouen. He held a provincial council in the year 1074, at which several statutes were passed for the regulation of ecclesiastical discipline, which provoked the resentment of the lax and dissipated clergy, who obliged him to seek for safety in flight. Other persecutions obliged him to resign his preferment, and retire to his country house: here he was attacked by the monks of the abbey of St. Owen, who killed him on the spot. He was author of a work "On the Duties of Ecclesiastics," which was first published with notes, by John le Prevost, canon of Rouen. Moreri.

JOHN DAMASCENUS, or St. John of Damascus, who lived in the eighth century, is celebrated by the writers of his life, and by ecclesiastical historians, as the compiler and reformer of chants in the Greek church, in the same manner as St. Gregory in the Roman. And Leo Allatius, under the title of *Orobanchus*, tells us they were composed by John Damascenus. Zar'no goes still farther, and informs us that in the first ages of Christianity the ancient Greek notation by letters having been thrown aside, John Damascenus invented new characters, which he accommodated to the Greek ecclesiastical tones; and that these characters did not, like ours, merely express single sounds, but all the intervals used in melody: as a semitone, tone, third minor, third major, &c. ascending and descending with their different duration.

This resembles, in many particulars, the notation in ancient Roman missals, before the time-table and characters in present use were invented, or even the Gregorian notes generally received.

JOHN DE MURIS. See MURIS.

JOHN of Salisbury, a learned Englishman of the 12th century, was elected bishop of Chartres in France in the year 1177, an office which he held about four years when he died. He wrote the life of Thomas à Becket and several other works. This learned prelate seems to have been much offended and scandalized at the licentiousness of the singers in performing the sacred rites. We should suppose, by his censures, that the choral band was outrageously addicted to flourishing, and that many of them sung in falsetto. What

the complaints of the good bishop of Chartres were, the following passage from his Poliricaticus will shew.

"Musica cultum religionis incusat, quod ante conspectum Domini, in ipsis penetraibus sanctuariorum, lascivientis vocis luxu, quadam ostentatione sui, muliebribus modis notularum articulo- rumque casuris, stupentes animulas emollire nituntur. Cum præcænitium, et fuculentium, cauentium, et decenentium, intercentium, et occientium, præmolles modula- tiones audieris, Sineaurum concitus credas esse, non homi- nam, et de vocum facilitate miraberis, quibus philomela vel pſittacus, aut si quid foris est, modos suos nequeunt cœ- quare. Ea siquidem ætate ascendendi descendendique facilis; ea sectio vel geminatio notularum, ea replicatio articulo- rum, singulorumque consolidatio; sic acuta vel acutissima, gravi- bus et subgravis temperantur, ut auribus sui iudicii fere subtrahatur autoritas." Poliricaticus, sive de Nugis Curia- lium, lib. i. c. 6.

"The rites of religion," says he, "are now profaned by music: and it seems as if no other use were made of it than to corrupt the mind by wanton modulations, effeminate in- flections, and frittered notes and periods, even in the *Pen- tæstia*, or awful sanctuary itself. The stupid crowd, deli- ghted with all these vagaries, imagine they hear a concert of sirens, in which the performers strive to imitate the notes of nightingales and parrots, not those of men; sometimes descending to the bottom of the scale, sometimes mounting to the summit; now softening and now enforcing the tones, repeating passages, mixing in such a manner the grave sounds with the more grave, and the acute with the most acute, that the astonished and bewildered ear is unable to distinguish one voice from another."

JOHN of Ragusa, a learned Catholic prelate, who flourished in the fifteenth century, was born in the city whence he de- rived his surname. While young he entered himself among the preaching friars, and applied with such diligence to his studies, that he became one of the most learned men of his time. He was particularly celebrated for his deep acquaintance with the Oriental languages. In 1426 he was appointed attorney-general of his order at the court of Rome, and was nominated by pope Martin V. one of his divines at the council of Basil. At this assembly he was the principal disputant against the doctrines promulgated by John Hufis. After this he was sent on different legations to Constantinople, with a design of bringing about an union between the eastern and western churches, but his exertions were not at- tended with success. On his return to Italy he was nomi- nated to the see of Argos in the Peloponnus. It has been asserted by some authors that he was made a cardinal. His works are "A Discourse against the Hufites;" Acts of his Legation to Constantinople; and "An Account of his Travels in the East." Moreri.

JOHN, Prester. See PRESTER.

St. JOHN'S Bread, in Botany. See CERATONIA.

JOHN'S Sweet See PINK.

St. JOHN'S Wort. See HYPERICUM.

St. JOHN'S Wort, Hypericum perforatum, in the *Materia Medica*, a species of hypericum which grows, commonly to the height of a foot and a half, in woods and uncultivated grounds, and flowers in July. This plant has a bitterish, sub-astringent taste, and a sweetish smell. Among the an- cients it was in great repute; and they prescribed it in hy- teria, hypochondriasis, and mania: they also imagined that it had the peculiar power of curing demones, and it thence obtained the name of "fuga demonum." It was also re- commended internally for wounds, bruises, ulcers, hæmop- toyes, mictus cruentus, gravel, dysentery, agues, worms; and outwardly as an anodyne, and as a discutient and de- tergent.

tergent. However, it is now very rarely used. The flowers only are directed for use, as containing the greatest proportion of the resinous oily matter, in which the medical efficacy of the plant is supposed to reside. The dark puncta of the petals and the capsules afford this essential oil, which is contained in minute vesicles, or glands, and gives a red colour to rectified spirit, and to expressed oils: the latter has been long known in the shops by the name of "oleum hyperici." The colouring matter is said to give a good dye to wool. Woodville's Med Bot.

JOHN'S, *St.*, College, in America. See COLLEGE.

JOHN'S DE FRONTERA, *St.*, in Geography. See JUAN DE LA FRONTERA.

JOHN'S HAVEN, a small sea-port town in the parish of Benholme, and shire of Kincardine, Scotland, was formerly one of the most considerable fishing towns on the southern coast of Scotland. At present, however, it is much reduced, its trade declined, and population diminished. A company of sail-cloth manufacturers have established works here, and thus given employment to the inhabitants. The population of the parish, in the year 1703, was calculated at 1019. This place is 9 miles north of Montrose.

JOHN'S ISLANDS, islands of America, near the coast of South Carolina, S.W. of Charlestown harbour, divided from James's island by the river Stono, which forms a convenient and safe port.

JOHN'S ISLAND, an island in the bay of Quita, Upper Canada, opposite the Mohawk settlement, west of Richmond.

JOHN, *St.*, a town of the island of May, one of the cape Verd islands.—Also, one of the Virgin islands, in the West Indies; 12 leagues E. of Porto Rico; about five miles long, and one broad; said to be the best watered of all the Virgin isles, though it has little good land, and its exportations are few. Its harbour, called "Craw bay," is reckoned better than that of St. Thomas, and is accounted the best to the leeward of Antigua. N. lat. 18° 1'. W. long. 64° 32'.—Also, a sea-port town well built, on the west coast of the island of Antigua. It is situated in a parish of the same name, on Loblolly bay. It is the capital of the island, and a port of entry. Its harbour is excellent and well fortified. This town is the residence of the governor-general of the leeward Charaibe islands; here the assembly is held; and its port carries on a great trade. This town was nearly destroyed by fire in August 1769; upwards of 260 houses being consumed, besides wharfs, cranes, &c. N. lat. 17° 4'. W. long. 62° 4'.—Also, an island, called also Prince EDWARD'S ISLAND (which see), in the gulf of St. Lawrence, situated at a small distance to the west of the island of Cape Breton, and to the north of Nova Scotia, to which it is attached. Its coasts on the north and south are much intersected with bays; it is well watered by rivers, and its soil is for the most part rich and fertile. It formerly belonged to the French, who improved it to such advantage, that it was deemed the granary of Canada, which it supplied with plenty of corn, as well as beef and pork. On the conquest of Cape Breton in 1755, the inhabitants quietly submitted to the British arms. Its capital is Charlotte's town, which is the residence of the lieutenant-governor, who is the chief officer in the island: its other towns are George town, Prince's town, Hillborough town, Pownal town, Maryborough town, &c. Its length from N.E. to S.W. is reckoned about 100 (Pinkerton says 60) miles, and its mean breadth is 30 miles. The whole island is divided into three counties, viz. King's, Queen's, and Prince's counties, which are subdivided into 14 parishes, consisting of 27 townships, and comprehending in all 1,363,400 acres. The

number of inhabitants is estimated at about 5000. N. lat. 46° 20'. W. long. 63°.—Also, a small island in the Pacific ocean, east of New Ireland, so called by Schouten, and by Bougainville Bourmand. S. lat. 4°. E. long. 153° 50'.—Also, a small island in the Red sea.—Also, a small island in the West Indies, north of St. Croix, and south of Tortola; noted for its fine harbour, which, it is said, is sufficient to contain the whole British navy.—Also, a bay and island on the west coast of Newfoundland, in the gulf of St. Lawrence, at the S.W. end of the straits of Bellefleur.—Also, a town on the east coast of Newfoundland. N. lat. 47° 35'. W. long. 52° 20'.—Also, a town of America, being the north-westernmost in Sullix county, Delaware, situated at the head of Nanticoke river, about 22 miles S.W. of Dover. N. lat. 38° 48'. W. long. 75° 40'.—Also, a town and fort in Lower Canada, on the west bank of Sorel river, at the north end of lake Champlain, 28 miles south of Montreal. This town has been established as the sole port of entry and clearance for all goods imported from the interior of the United States into Canada, by the executive council of Lower Canada, in July 1796. N. lat. 45° 9'. W. long. 72° 18'.—Also, a sea-port on the S.E. coast of the island of Tinos. N. lat. 37° 32'. E. long. 25° 15'.—Also, a river of America, in East Florida, which rises in a swamp in the interior of the province, and pursues a northern course, in a broad navigable stream, spreading frequently into spacious bays or lakes, of which lake George is the chief. At its mouth is a shifting bar; 10½ leagues north of St. Augustine.—Also, a river, called Little St. John's, which rises in a swamp called Ouaquephenogaw, and after a winding course of about 200 miles, falls into Apalache bay, about 10 miles east of Apalache river. It is said to be the purest and clearest of any in America, receiving, as the Indians say, no tributary streams, but being fed by springs which gush through its banks, and is about 200 yards broad, and about 15 or 20 feet deep at the town of Talahachete.—Also, a river which is the largest in the British province of New Brunswick. From its mouth on the north side of the bay of Fundy to its main source it is computed to be 350 miles; the tide flows 80 or 90 miles up this river; and it is navigable for floops of 50 to 60 miles, and for boats 200. Its general course from its origin is E.S.E. It is the common route to Quebec. It furnishes the greatest plenty of salmon, bass, and sturgeon. This river is fed by many tributary streams, and in its various branches it waters and enriches a large tract of excellent country, which is settled and under improvement. The uplands are, in general, covered with fine timber, such as pine and spruce, hemlock and hard wood, principally beech, birch, maple, and ash. The pines on this river are the largest in British America, and afford a considerable supply of masts for the British navy.—Also, a river of Africa, which runs into the Indian sea, S. lat. 31° 20'. and another of Africa, which runs into the Atlantic, N. lat. 19° 20'.—Also, a lake in Lower Canada, which receives rivers almost in every direction, and discharges its waters through Saguenai river into the St. Lawrence, at Tadoussac. It is about 25 miles in diameter.

JOHNNY Groat's HOUSE, the most northerly dwelling of Scotland, in the county of Caithness; one mile W. of Duncansby Head.

JOHNSBURY, a township of America, in Ca'edonia county, Vermont, bounded S.W. by Danville; containing 663 inhabitants.

JOHNSON, JOHN, in Biography, a learned divine of the church of England, was born at Friendsbury, near Rochester, in Kent, in the year 1662. He received the elements of a good education at King's school, Canterbury, and from

thence he was sent, when he was about 15 years of age, to Magdalen college, Cambridge. Here he took his degrees and entered into deacon's orders, and shortly after obtained a curacy near Canterbury. In 1686, he was ordained priest, and collated by archbishop Sancroft to the vicarages of Bocton and Hearne-Hill. After the revolution he complied with the new order of things, and became an able advocate in its defence, which gained him the friendship and patronage of archbishop Tension, from whom he received several influences of church preferment, and in 1707, was collated to the vicarage of Cranbrook. Here he seems to have completely abandoned his friends and his principles, and to have advanced from step to step till he even denied the king's supremacy, and refused to read the prayers enjoined on the accession of George I. Notwithstanding this dereliction of principle, he was twice chosen proctor in convocation for the diocese of Canterbury. He died in 1725, having been several times under prosecution, from the effects of which he was relieved by submission to the higher powers: had his fortitude been equal to his zeal, he would have suffered in defence of the most arbitrary and indefensible opinions, that can well be broached by a man of sense. Johnson was unquestionably a man of sound learning; his morals were exemplary and his piety unaffected. He was diligent in the discharge of the several duties belonging to the pastoral office, but his temper was bad, and during the latter years of his life, he shewed so much bigotry and intolerance against those who thought as he himself had formerly thought, as detracted from the value of his good qualities. His principal works are "The Clergyman's Vade Mecum;" "A Collection of Ecclesiastical Laws, Canons, &c.;" "The unbloody Sacrifice and Altar unveiled and supported;" and "A Paraphrase on the Psalms in the Liturgy." After his death his surviving daughter published two volumes of his posthumous sermons and discourses. *Biog. Brit.*

JOHNSON, SAMUEL, an English divine, was born in the year 1649, in the county of Stafford, though others have named Warwickshire as his birth-place. He was educated at St. Paul's school, London, whence he was removed to Trinity college, Cambridge. After he had taken orders, he was presented to the rectory of Corringham, in the hundreds of Essex, but the place not agreeing with his health, he removed to London, and took an active part in the political discussions of the times. He was introduced to lord Russell, who immediately made him his domestic chaplain. He now became a formidable writer in the cause of liberty, and was called on during the reign of Charles II. to bear his testimony to the truth by severe imprisonment. But his sufferings were brought to the acme by a paper which he drew up in the year 1686, when the army was encamped upon Hounslow Heath, entitled, "An humble and hearty Address to all English Protestants in the present Army." For this he was brought to trial, and condemned to stand in the pillory at three places, to pay a fine of 500 marks, and to be publicly whipped from Newgate to Tyburn. Before they executed this savage sentence they intended to degrade and deprive him of his orders, but fortunately for the sufferer, the prelates Crew, Sprat, and White, too eager, probably, to perform the commands of the tyrant, forgot to strip off his cask. This informality was fatal to their plans, and they found it impossible to take away his living. Notwithstanding the laceration of his body, his heart was unbroken, and he continued to employ his pen in the same cause, till the revolution changed his situation. Parliament now declared that the proceedings against him were illegal, and the house of lords addressed king William to confer upon him some preferment. Johnson was ambitious of a

bishopric, but he was offered a deanery; this he did not accept, but received a pension of 300*l.* per annum during his own and his son's life, a present of 1000*l.*, and a place of 100*l.* per annum for his son. A tract, which he afterwards published, was the cause of so much personal violence as nearly to have cost him his life: the piece was entitled "An Argument proving that the Abrogation of King James by the People of England from the Royal Throne, and the Promotion of the Prince of Orange in his stead, was according to the Constitution of the English Government, and prescribed by it." It was, unquestionably, on account of this pamphlet that seven ruffians broke into his house early in the morning, assembled round his bed, gave him a wound on the head with a sword, and otherwise ill-treated him. They threatened to take his life, but shrinking from so foul a deed, they left him wounded, and did no injury to his house or effects. Notwithstanding his general attachment to the new government, he did not spare its defects; he complained grievously of the duration of parliaments, which he maintained ought to be continued for one year each only. On some occasions his opposition was carried so far as to lead his best friends to suspect he was about to abandon his original principles. He died in 1731, and his works were collected and printed in one volume folio. *Biog. Brit.*

JOHNSON, SAMUEL, a celebrated English writer, was born at Litchfield, in the year 1709, in which city his father carried on the book-selling business on a very small scale. He was educated partly at the free-school of his native city, and partly at Stourbridge, in Worcestershire. He was probably intended for trade, but having acquired a reputation for learning, his father very willingly complied with the proposal of Mr. Corbet, of maintaining Samuel at Oxford, as companion to his son. He accordingly was entered a commoner of Pembroke college, in the year 1728, when he was in the nineteenth year of his age. Johnson was careless of his character with respect to the discipline and the studies of the place, yet he obtained credit by some of his compositions, of which the most distinguished was a translation into Latin of Pope's *Messiah*, written with great spirit and vigour. He remained at Oxford but three years, during a part of which he had to struggle with the griping hand of penury. Soon after his return home, his father died in very narrow circumstances, and about this time it appears, from his own account, that he was first led to think in earnest of religion, by the perusal of Law's "Serious Call to the Unconverted." He engaged himself as usher to the grammar school of Market Bosworth, Leicestershire, but the treatment which he met with at this place ill accorded with his feelings, and he quitted the school, and passed some time with a friend at Birmingham. Here he wrote some literary essays, and translated and abridged from the French the account of the voyage to Abyssinia, by father Lobo. This was published without the translator's name, at London, in 1735. Returning to Litchfield, he issued proposals for publishing by subscription, the Latin poem of Politian, but they did not meet with encouragement, and the design was abandoned. He now made a bold effort to improve his situation, married the widow of Mr. Porter, a mercer of Birmingham, and opened a school. He had received 800*l.* with his lady, and depending on his own learning and powers, he took a large house, and advertised for scholars to be boarded and instructed in the Greek and Latin languages. His plan did not succeed; not more than three scholars offered, among these was the celebrated David Garrick. After a year's trial he abandoned his school, and resolved to become a literary adventurer in the metropolis. He accordingly set out, taking his scholar

Garrick as his companion, being furnished with recommendatory letters by Mr. Gilbert Walmfley, a gentleman who had been before the friend and benefactor of Johnson. Johnson and his friend arrived in London in March 1737; his first and principal engagement was with Cave, the proprietor of the *Gentleman's Magazine*, and at the desire of this gentleman he undertook a translation of Father Paul's *History of the Council of Trent*, which was partly printed and then the scheme was given up. At this period Johnson became acquainted with Savage, in whose misfortunes he sympathized, and in whose company he was a spectator of the vices and disorders of the metropolis, and probably a sharer in the hardships which he endured, and in the irregularities which he committed, but whatever stain the morals of Johnson might receive from this connection, it was obliterated by the permanent influence of the principles of piety and virtue. The literary piece which brought him into public notice, was entitled "London, a Poem;" written in imitation of Juvenal's *Third Satire*. For this he received of Dodsley the sum of 10*l*. It was printed without any name, but it was said by Pope, then in the height of his popularity, that the author of so good a satire could not remain long concealed. Johnson, at this period, wanted something more substantial than mere praise, and offered himself as a candidate for the mastership of a free-school in the country. This he was unable to attain, because it was necessary that the master should have taken his degree of M. A. This he had neglected to do while he was at Oxford, and now he had applied for the honour to the university of Dublin, through the medium of lord Gower, who, in writing to his friend on the subject, says, "he is not afraid of the strictest examination, though he is of so long a journey; and yet he will venture it, if the dean (Swift) thinks it necessary, choosing rather to die on the road, than to be starved to death in translating for the booksellers, which has been his only subsistence for some time past." This application produced no effect, and he was obliged to content himself with the patronage of the London booksellers, particularly with the employment which he obtained in the *Gentleman's Magazine*. In this work were given the parliamentary debates, under the fiction of "Debate in the Senate of Liitput;" and the speakers were disguised under feigned names. Guthrie, for a time, composed these speeches from such hints as he could bring away in his memory. Johnson first assisted in this department, and then entirely filled it, and the public was highly gratified with the eloquence displayed in these compositions. In 1739 he published a humorous pamphlet, entitled "*Marmor Nortolcienfe*," consisting of a supposed ancient prophecy in Latin monkish rhymes, with an explanation. He composed, about the same period, several biographical articles for the *Gentleman's Magazine*, of which the principal was the life of Savage, which was afterwards published separately, and has been universally admired both as a most interesting and curious portrait, and as containing many admirable reflections on life and manners. In the year 1747 he published the plan of his *English Dictionary*, addressed to the earl of Chelsterfield, whom he would gladly have recognized as his patron in this arduous task. But his lordship concerned himself very little about the author or his work. No two men could be more opposite in their manners than Johnson and lord Chelsterfield, and a very slight intercourse on this occasion terminated in their mutual aversion, so that the author in his preface informed the public, that "the *English Dictionary* was written with little assistance of the learned, and without any patronage of the great; not in the soft obscurities of retirement, or under the shelter of academic

bowers, but amidst inconvenience and distraction, in sickness and in sorrow." From the booksellers, Johnson received fifteen hundred guineas for his labour, which was not completed till the year 1755. The intervals of this compilation were sufficient to allow of various literary avocations. In 1747 he wrote a prologue on the opening of Drury-lane theatre. In 1749 he produced another imitation of Juvenal, entitled "*The Vanity of Human Wishes*;" and his tragedy of "*Irene*." He next commenced his periodical work, entitled "*The Rambler*," which came out in papers at the rate of two in a week, from the month of March 1750, till the same month in 1752. He was the author of the whole of this work, with the exception of about ten papers only, and in it he appears the warm and steadfast friend of religion and morality. The serious style of the *Rambler* prevented it at first from attaining a very extensive circulation, but after it was collected into volumes, it rose in the public estimation, and the author saw the publication of the tenth edition. Soon after the close of this paper he had the misfortune to lose his wife, a circumstance which he never ceased to deplore. Not long afterwards he took into his house, as an inmate, Mrs. Anne Williams, the daughter of a physician in South Wales, who had consumed his time and fortune in pursuit of the longitude. Her deplorable condition, aggravated by blindness, with her talents for writing and conversation, recommended her to the benevolence of Mr. Johnson. In the "*Adventurer*," conducted by Dr. Hawkworth, he interested himself, supplied it with several papers of his own, and obtained for it the contributions of Mr. Warton. Previously to the publication of his dictionary, the degree of M. A. was conferred on him by the university of Oxford, and about the same time the earl of Chelsterfield wrote two letters in its favour in "*The World*." This civility was regarded, by Johnson, as an advance from that nobleman for the purpose of obtaining from him a dedication as patron of the work, but he now rejected the patronage which he would before have gladly accepted, and wrote a letter to the noble lord, in which he employed all the force of pointed sarcasm and manly disdain to make him ashamed of his former conduct. The dictionary was received by the public with general applause, and its author was immediately ranked among the greatest benefactors of his native tongue. The publication of this great work did not relieve him from his embarrassments, for the price of the labour had been consumed in the progress of its compilation. He was still entirely dependent upon the exertions of the day for its support, and so low was he reduced, though now regarded as an honour to his country, that in the following year he was put under an arrest for the trifling sum of five or six pounds. In 1758 he began "*The Idler*," a periodical paper, which was published in a weekly newspaper. On the death of his mother in 1759, he wrote the romance of "*Rasselas*," to defray the expences of her funeral, and to pay her debts. This, though written in a very hasty manner, is reckoned one of his most splendid performances: it is elegant in language, rich in imagery, and weighty in sentiment. It has been translated into several modern languages. Such, however, was the depressed state of his finances, that he was obliged to break up house-keeping and retire to chambers. From this situation he was rescued by the grant of a pension of 300*l. per annum*, in 1762, without any stipulation with respect to his literary exertions. In 1765 he had the honour of an interview with his majesty in the royal library, when the sovereign asked if he intended to publish any more works? To this he replied, that he thought he had written enough, on which the

king said, "I should have thought so too, if you had not written to well." In this year he published his edition of Shakspeare's Works, which was sent into the world with a preface, written with all the powers of his masterly pen, and which is reckoned among the most valuable of his critical disquisitions. About this period he instituted a literary club, consisting of several of the most celebrated men of the age, among whom were some who occupied very elevated situations in society. In 1770 he appeared an advocate for the measures of government, and published, first, "The False Alarm," occasioned by the expulsion of Mr. Wilkes from the house of commons. This was followed by "Thoughts on the late Transactions respecting Falkland's Island," designed to shew the unreasonableness of going to war on account of the conduct of Spain relative to that barren possession. His next publication on political subjects was entitled "The Patriot," which was composed on the eve of a general election in order to indispose the people against the measures of the opposition. In 1775 he published, "Taxation no Tyranny," which was written in defence of the right of the mother country taxing the colonies at pleasure. These pamphlets, which were probably written on principle, did but little service to the cause which he vindicated. In 1773 he went on a tour with Mr. Boswell to the western islands of Scotland, of which journey he published an account under the title of "A Journey to the Western Islands of Scotland." In this he gave a most decisive opinion against the authenticity of the poems ascribed to Ossian, which occasioned a difference between him and the translator, Mr. Macpherson. In 1775, the university of Oxford conferred on him, through the interest of the minister, the degree of doctor of laws, which he highly valued. The same honour had been given him some years before by the university of Dublin, of which he had made no use. When the unhappy Dr. Dodd lay under sentence of death, in Newgate, Johnson, moved either by compassion for the man, or by a desire of rescuing the cloth from public disgrace, wrote two petitions to his majesty in his name, and supplied him with a speech at the bar, and a sermon to be preached to his fellow convicts. (See DODD.) In the year 1779, Dr. Johnson began his last literary undertaking, "The Lives of the English Poets," which, notwithstanding the strong prejudices of the author, may be regarded as a most valuable treasure of sound criticism, and a model of literary biography. This work was completed in 1781: it is not only attached to his edition of the English poets, but has been re-printed a great many times in a separate form. The concluding portion of Dr. Johnson's life was clouded over by the loss of several highly respected friends, by a progressive decline of health, and by the prospect of approaching dissolution, which neither his religion nor his philosophy taught him to bear with even decent composure. At last, however, his mind became calm, composed, and truly resigned: he died December 13th, 1785, in the 75th year of his age. His remains, attended by a respectable concourse of friends, were interred in Westminster abbey; and a monumental statue has been erected to his memory in St. Paul's cathedral. His works, with a life of the author, were published collectively in 11 volumes, 8vo. by Sir John Hawkins, in 1787; and in 1792, a new edition of them in 12 volumes, with a life by Mr. Murphy, was given to the public. Mr. Boswell and Mrs. Piozzi have likewise given ample accounts of their friend: perhaps there is no instance of a private man of letters, in this country, whose decease was marked by the appearance of so many laudatory and biographical tributes to his public reputation. As a writer, Dr. Johnson did much service to his country, by fixing its language and regulating

its morality. In his person he was large, robust, and unwieldy; in his dress he was singular and flowery; in conversation he was positive, and impatient of all contradiction. But with these deductions, he was an excellent character; he had a heart full of tenderness and compassion, and all his actions were the result of principle. He was a zealous advocate for what he regarded as the truth. He was high in his religious and political principles, and at one period of his life he was friendly to the views of the house of Stuart. He had a noble independence of mind, and would never stoop to any man however exalted, nor disguise his sentiments to flatter another. His judgment was uncommonly acute, his imagination quick, his memory tenacious, and his conversation, though very dictatorial, was often brilliant, and always instructive. For farther particulars, the reader is referred to the works above mentioned.

JOHNSON, in *Geography*, a county of America, in North Carolina and Newbern district, containing 6201 inhabitants, of whom 1763 are slaves. It is 30 miles square, and watered by several streams. The greatest part of the county is level, and its principal produce is corn. Its chief town is Smithfield.

JOHNSONIA, in *Botany*, so named by Mr. R. Brown in memory of Dr. Thomas Johnson, author of some little botanical works, published in the form of travels between 1629 and 1641, and editor of the second edition of Gerard's Herbal in 1635. Wood says he was killed, while fighting in the royal cause, in September 1644. Brown. Prodr. N. v. Holl. v. 1. 287. Clafs and order, *Triandria Monogynia*. Nat. Ord. *Apollidei*, Juss.

Ess. Ch. Perianth (rather corolla) in six deep equal segments, withering, deciduous. Filaments dilated and united at their base, inserted into the base of the inner segments of the corolla. Style thread-shaped. Stigma obtuse. Capsule superior, of three cells and three valves, with partitions from the middle of the valves. Seeds two in each cell, inserted into the central column, one of them pendulous. Scar crested.

1. *J. lupulina*. Native of the fourth coast of New Holland. Root fibrous, perennial. Leaves four-ranked, twisted, linear, dilated, and half sheathing at the base. Stalk radical, simple, bearing near its top a solitary, oblong, hop-like spike of small sessile flowers, with coloured imbricated bracts, the lowermost of which are small and barren.

JOHNSTON, JOHN, in *Biography*, an eminent naturalist, was born at Sambter, in Great Poland, in the year 1603; he received the greater part of his education in his own country; but in 1622, he came to England, and from thence he went to Scotland, where he studied with great diligence in the university of St. Andrews till the year 1625. He afterwards studied at Leyden and Cambridge. He undertook the education of the two sons of the count de Kurlzbach, and accompanied them to Holland. While he resided with his pupils at Leyden, he took his degree as doctor of physic; and when he went a third time to England, the same honour was conferred on him by the university of Cambridge. He died in June 1675, in the 72d year of his age. He is known in the literary world by a number of works in the different departments of natural history. Gen. Biog.

JOHNSTON, in *Geography*, a township of America, in Providence county, Rhode island, west of the town of Providence; containing 1364 inhabitants.—Also, a township in Franklin county, Vermont; having 135 inhabitants.

JOHNSTONE, GEORGE, in *Biography*, a naval commander, son of a Scotch baronet, devoted himself to the sea service at an early period of life. After passing through the subordinate

subordinate stations, he was, in the year 1760, made master and commander; and in two years after, he was raised to the rank of post captain. At the peace, he was appointed governor of West Florida; and on his return to England, he took an active part in the affairs of the East India company, particularly in opposition to lord Clive. In 1771 he wrote a work, entitled, "Thoughts on our Acquisitions in the East Indies, particularly respecting Bengal." He sat twice in parliament: first for Cockermouth, and afterwards for Appleby. He had a duel with lord George Germaine, on account of some reflections which fell from him in the house respecting his lordship. He was one of the commissioners sent to treat with the Americans. He died in 1787.

JOHNSTONE'S Straits, in *Geography*, a channel of the Pacific ocean, between the island of Quadre and Vancouver, and the west coast of North America. This channel branches off from the northern part of the gulf of Georgia, from point Clatham to the west, bearing a little north for about 60 miles in length, the breadth being from two to four. N. lat. 50 20 to 50 35'. E. long. 233 to 234 46.

JOHNS-TOWN, a post-town of America, and capital of Montgomery county, in the state of New York, situated on the north bank of Mohawk river, 24 miles west of Schenectady. The town contains about 70 houses, a Presbyterian and an Episcopal church, a court-house, and a gaol. In the township are 3932 inhabitants. — Also, a town in the township of Edwardburgh, Upper Canada, situated upon the river St. Lawrence, above the uppermost rapids, in ascending to lake Ontario. From this town vessels may be navigated with safety to Queenstown, and at the ports of lake Ontario.

JOHNSTOWN, New, a town in the township of Cornwall, Upper Canada, situated upon the river St. Lawrence, below the long Saal, to the northward of Grand Isle St. Regis; and is now called Cornwall.

JOHNSTONS, the name of several villages in Ireland. One of these, in the county of Kilkenny, has been lately made a post-town. It contains a number of neat houses, built for the accommodation of those who frequent the neighbouring chalybeate Spa of Ballyspellan. It is on the mail-coach road from Dublin to Cork, through Cashel, and is 60 miles S.W. from Dublin. Another Johnstown, in the county of Kildare, is about 13 miles from Dublin, on the Great Southern road; and in consequence of a good inn, is frequently made a stage by those who travel post. — Two others, called St. Johnstown, were formerly boroughs represented in parliament: one of them in the county of Donegal, on the river Foyle, which is here of considerable breadth, 87 miles N. by W. from Strabane, and 108 N. by W. from Dublin; the other in the county of Longford, 6 miles W. from Granard. There is also a small town called Johnstown Bridge, in the county of Kildare, on the borders of Moath, situated on the river Blawater, 21 miles from Dublin.

JOHOR, a town of the peninsula of Malacca, near the south coast, and capital of a kingdom of the same name. N. lat. 1 40. E. long. 103 54.

JOIGNY, a town of France, and principal place of a district, in the department of the Yonne, near the river Yonne. The place contains 5219, and the canton 13,137 inhabitants, on a territory of 267 kilometres, in 17 communes; 14 miles N.W. of Auxerre. N. lat. 47 59. E. long. 3 29.

JOIN-GUR. See JEENAGUR.

JOINDER, or **JOINDER**, is the coupling, or joining,

two persons in one action, or suit, against another. See DEMURREUR.

JOINERY is a branch in *Civil Architecture*, and consists of the art of framing or joining wood together, for internal and external finishings of houses; as the coverings and linings of room walls, or the coverings of rough timbers, and of the construction of doors, windows, and stairs.

Hence joinery requires much more accurate and nice workmanship than carpentry, which consists only of rough timber, used in supporting the various parts of an edifice: joinery is therefore used by way of decoration only, and being always near to the eye, and consequently liable to inspection, requires that the joints should be fitted together with the utmost care, and the surfaces made smooth.

The wood used is called fluff, and is previously formed by the pit-saw into rectangular prisms, which are denominated boards, battens, or planks, according to their breadth. Battens run from two to seven inches wide, boards from seven to nine inches wide, and planks from nine inches to any greater breadth that can be cut out of a piece of wood.

The operations of joinery consist of forming surfaces of various kinds, also of grooving, rebating, and moulding, and of mortising and tenoning, and lastly, of joining two or several pieces together, so as to form a frame or solid mass.

Surfaces, in joinery, are either plane or curved, but most frequently plane.

All kinds of surfaces are first formed in the rough, and finally brought to exact forms by means of tools adapted thereto.

Grooving consists in taking away a part of a rectangular section from a piece of wood, so as to form a channel of equal breadth throughout, with three surfaces, one being parallel, and the other two perpendicular to the surface of the wood from which the channel is recessed: the channel thus formed is called a groove.

Rebating consists in taking away a part from a piece of wood of a rectangular section, so as to leave only two sides, each of a parallel breadth, the one side being perpendicular to the surface of the wood, and the other parallel thereto: the cavity thus formed is called a rebate. From this definition it is manifest, that a rebate can only be formed by rebating the piece of wood to be rebated at the angle itself, and may therefore be looked upon as a half groove.

A mortise is a cavity recessed within the surface of a piece of wood, with four sides perpendicular to that surface, and likewise to each other: the act of making a mortise is called mortising.

A tenon is a projection formed on the end of a piece of wood with four plane sides, at right angles to each other, and to a plane, from which it projects; and this plane is called the shoulder of the tenon.

In the following, all pieces of wood whatever are supposed to be rectangular prisms, and the length in a direction of the fibres; two of the sides of every mortise to be perpendicular, and the other two sides parallel to the fibres; the four sides of every tenon in the direction of the fibres, unless otherwise asserted: likewise, if two of the surfaces of a piece of wood be of greater breadth than the other two, these are called the edges and those the sides, and each line of concurrence, formed by two adjacent sides, is called an arris.

Moulding consists in forming the surface of a piece by curve or plane surfaces, or by both, in such a manner, that

JOINERY.

all parallel sections will be similar figures, that is, their boundaries may be made all to coincide.

The first thing to be done in joinery is to select the fluff or boards, which ought to be well seasoned for every purpose in joinery, and then line it out; and if the fluff is not already at the size, as is most frequently the case, it must be ripped out with the ripping saw, or crofs cut with the hand saw, or both, as may be wanted. The next thing is the planing of the fluff first upon a side, then the edge squared, and then gaged to a breadth and thickness, should either or both be found necessary.

Two or more pieces of fluff may be fastened together in various ways by pins of wood or by nails, but in work prepared by the joiner for the use of building, pieces are more frequently joined together by making their surfaces coincide, and then plastering them over with a hot tenacious liquid called glue, then rubbing the surfaces until the glue has been almost rubbed out, and the one piece brought to its situation with respect to the other. The best work is always joined by this method.

When boards are required of a greater breadth than common, several common boards must be fastened together edge to edge, either by nailing them to pieces extending across the breadth, or gluing them edge to edge, or by joining pieces transversely together with small boards, tongued and grooved into the interstices.

Two pieces of fluff are joined together at right or oblique angles by mortise and tenon adapted to each other, and fastened together with glue. When a frame, consisting of several pieces, is required, the mortises and tenons are fitted together, and the joints glued all at one time, then entered to their places, and forced together by means of an instrument called a cramp.

The operation of forming a given surface, by taking away the superfluous wood, is called planing, and the tools themselves planes.

The first tools used by joiners are bench planes, which generally consist of a jack plane, for taking away the rough of the saw and the superfluous wood, only leaving so much as is sufficient to smooth the surface; the trying plane to smooth or reduce the ridges left by the jack plane, and to straighten or regulate the surface, whether it be plane or convex; the long plane when the surface is required to be very straight; and the smoothing plane in smoothing, as its name implies, and giving the last finish to the work.

Besides the bench planes there are others for forming any kind of prismatic surfaces whatever, as rebating planes, grooving planes, and moulding planes: but for a more particular description of these and the bench planes, we shall refer to the article PLANE.

The tools employed in boring cylindrical holes are a flock with bits of various descriptions and sizes, gimblets and brad awls of several diameters.

The tools used in paring the wood obliquely, or across the fibres, and for cutting rectangular prismatic cavities, are in general denominated chisels: those for paring the wood across the fibres are called firmer, or paring chisels, and those for cutting rectangular prismatic cavities, are called mortise chisels, the rectangular cavities themselves being called mortises when made to receive a projection of the same form and size, and by this means to fasten two pieces of wood together at any angle. The sides of all chisels, in a direction of their length, are straight, and the side of a chisel which contains the cutting edge at the end is steel. The best paring chisels are made entirely of cast steel. Chisels for paring concave surfaces are denominated gouges.

Dividing wood, by cutting away a very thin portion of the material of equal thickness throughout, to any required extent, by means of a thin plate of steel with a toothed edge, is called sawing, and the instruments themselves are called saws, which are of several kinds, as the ripping saw, for dividing boards into separate pieces in a direction of the fibres; the hand saw, for crofs cutting and sawing thin pieces in a direction of the grain; the panel saw, either for crofs cutting or cutting very thin boards longitudinally; the tenon saw, with a thick iron back, for making an incision of any depth below the surface of the wood, and for cutting pieces entirely through, not exceeding the breadth of that part of the plate without the iron back; likewise a fish saw and a dovetail saw, used much in the same way as the tenon saw. From the thinness of the plates of these three last saws, it is necessary to stiffen them by a strong piece of metal called the back, which is grooved to receive the upper edge of the plate that is fixed to the back, and which is thereby secured and prevented from buckling. When it is required to divide boards into curved pieces, a very narrow saw without a back, called a compass saw, is used, and in cutting a very small hole a saw of a similar description, called a key-hole saw, is employed. All these saws have their plates longer and thinner, and their teeth finer, as they succeed each other in the order here mentioned, excepting the two last, which have thicker plates and coarser teeth than either the fish or dovetail saw. The external and internal angles of the teeth of all saws are generally formed at an angle of 60 degrees, and the front edge teeth slope backward in a small degree, but incline or recline from the straight line drawn from the interior angle perpendicular to the edge in the plane of the plate, as the saw may be employed in ripping or in crofs cutting, or cutting perpendicular to the fibres. The teeth of all saws, except turning and key-hole saws, are bent on contrary sides of the plate, each two teeth succeeding each other, being alike bent on the different sides of the plate; viz. the one as much to the one side as the other is to the other side, and consequently all the teeth on the same side alike bent throughout the length of the plate for the purpose of clearing the sides of the cut which it makes in the wood.

Of all cutting tools whatever, the saw is the most useful to the joiner, as the timber or wood which he employs can be divided into slips or bars of any size, with no more waste of fluff than a slice, the breadth of which is equal to the depth of the piece to be cut through, and the thickness equal to the distance of the teeth between their extreme points on the alternate sides of the saw measured on a line perpendicular to the said sides: whereas, without the use of the saw, cylindrical trees could only be reduced to the intended size by means of the axe; in the use of which there would not only be an immense consumption of fluff, but also much greater labour would be required to straighten it.

Joiners use a small axe, called a hatchet, for cutting off the superfluous wood from the edge of a piece of a board, when the waste is not of sufficient consequence to be sawn.

All the above are what are commonly denominated edge tools, but there are others required to regulate the forms. All angles whatever are formed by other reversed angles of the same number of degrees as an exterior angle by an interior one, and the contrary. The instrument for trying right angles is called a square, and those for trying oblique angles are called bevels. The two sides which form the edge of a square are always stationary, but those of bevels are generally moveable one leg upon the other round a joint.

In some cases, where a great number of pieces are required to be wrought to the same angle, a stationary bevel, called a joint hook, is used.

When it is required to reduce a piece of stuff to a parallel breadth, an instrument called a gage is used for the purpose. The gage consists generally of a square piece with a square mortise, through which a bar at right angles thereto is fitted and made to slide. The bar, which is called the stem, has a sharp point, cutter, or tooth at one extremity, projecting a little from the surface, so that when the side of the gage, next to the end which has the point, is applied upon the vertical surface of the wood, with the flat side of the stem which has the tooth upon the horizontal surface, and pushed and drawn alternately by the workman from and towards him, the cutter will make an incision from the surface into the wood, at a parallel distance from the upper edge of the vertical side on the right hand. This line, so drawn, will mark out with precision, and shew the superfluous stuff to be taken away.

When a mortise is required to be cut in a piece of wood, a gage with two teeth is used. The construction of this instrument is the same as the common gage; but in addition thereto, the stem has a longitudinal slider with a tooth projecting from the end of the slider, so that the two teeth may be brought nearer, or to any remote distance from each other, at pleasure; and also to any distance, from the face of the head or guide within the reach of the stem.

When wood has been planed, and required to be sawn across the fibres, and as it is necessary to be kept stationary while sawing, in order to prevent the sides or the edges from being bruised, joiners use a flat piece of wood with two projecting knobs on the opposite sides, one at each end, called a side hook. The vertical side of the interior angle of one of the knobs is placed close to the vertical side, and the under side upon the top of the bench; then the wood is pressed against the knob which projects from the upper surface while it is cutting with the saw; but the use of two side hooks is better, as they keep the piece of wood to be sawn more steady.

When it is required to cut a piece of wood to a mitre with one side; that is, to half a right angle, joiners use a trunk of wood with three sides, like a box without ends, or a top, the sides and bottom being parallel pieces, and the sides of equal heights; through each of the opposite sides is cut a kerf in a plane, perpendicular to the bottom, at oblique angles of 45 and 135 degrees, with the planes of the sides; and another kerf is made in the same manner, so as to have its plane at right angles to the former. The trunk thus constructed is called a mitre-box. When the wood is to be cut, the mitre-box is fixed steady against two side hooks, and the piece, which is always less than the interior breadth of the mitre-box, is laid within, and pressed against the farther interior angle of the mitre-box with the side downwards, to which the saw-kerf is intended to be perpendicular, and in this position it is to be cut. The two kerfs in the sides of the mitre-box are requisite, in order to form the acute angle on the right or left-hand side of the piece, as may be required.

When it is required to make a piece of wood straight in one direction, joiners use a slip of wood straightened on one edge, from which the slip of wood itself is called a straight edge. Its use is obvious; by its application it will be seen whether there is a coincidence between the straight edge and the surface.

When it is required to know whether the surface of a piece of wood is in the same plane, joiners use two slips of wood straightened each on one edge with the opposite edge

parallel, and both pieces of the same breadth between the parallel edges: each piece has therefore two straight edges. Suppose it were required to know whether a board is twisted or its surface in a plane, the workman lays one of the slips across the one end, and the other across the other end of the board, with one of the straight edges of each upon the surface; then he looks in the longitudinal direction of the board, over the upper edges of the two slips, until his eye and the two upper edges of the slips are in one plane; or otherwise, the intersection of the plane, passing through the eye and the upper edge of the nearest slip, intersect the upper edge of the farther slip. If it happen as in the former case, the ends of the wood under the slips are in the same plane; but should it happen as in the latter, they are not. In this last case the surface is said to wind; and when the surface is so reduced that every two lines are in one plane, it is said to be out of winding, which implies its being an entire plane: from the use of these slips they are denominated winding sticks.

Before we can proceed to the method of bringing a rough surface to a plane, it will first be necessary to shew how to make a straight edge or ruler.

Here the joiner must not lose sight of the definition of a straight line, *viz.* a straight line is that which will always coincide with another straight line, however applied together.

The operation of making the edge of a board straight is called by joiners shooting, and the edge so made is said to be shot.

Straight edges may be thus formed; plane the edges of two boards and apply them together, so that the superficies or faces of the boards be in the same plane, and if there be no cavity between the joint the edges will be straight; but if not, the faces must be applied to each other, the edges brought together, and planed and tried as before, until they are found to coincide.

Another mode is by having a plane surface given: plane the edges of a board as straight as the eye will admit of, and apply the face of it to that of the plane, and by the edge of the board draw a line, turn the board over with the other side upon the plane, and bring the planed edge to the line drawn before, and the extremities of the edges to their former places, and draw another line; then if all the parts of this line coincide with the former line, the edge is already straight; but if not, repeat the operation as often as may be found necessary.

Another mode is to plane the edge of a board as straight as the eye will admit of; then plane the edge of another board until it is made to coincide with the former; take a third board and plane the edge of this in like manner, by making it coincide with the edge of the first board; apply the edges of the two last boards together, then if they coincide the operation is at an end, but if not, repeat it as often as may be found necessary.

By any of the methods now shewn, the superficies of the boards, to be shot, are supposed to be parallel planes not very distant from each other; for if the faces be not parallel, or if the thickness be considerable, the operation will be the more liable to error.

To reduce the rough surface of a body to a plane.—This will not be very difficult, when it is known that a plane is that which will every where coincide with a straight line.

The most practical methods are the following: Let the workman provide two winding sticks, and apply them as before directed, making the ends out of winding if they are not found to be so; then if all the parts of the surface are straight on which the edges of the winding sticks were placed,

JOINERY.

placed, it is evident that the whole surface must be plane. If the surface is hollow between the said lines, one of the ends or both must be planed lower, until the surface acquires a small convexity in the length, and then, if straightened between the straight lines at the ends, it will be a perfect plane.

Another mode of forming a plane of the surface is of a quadrilateral form: apply a ruler along the diagonals, then if they are straight they are in a plane, but if they are both hollow, or both round, the surface to be reduced is either concave or convex, and must be straightened in these directions accordingly; and, lastly, if by trying across the diagonals with the straight edge it be found that the one be hollow and the other round, the surface of the board winds. In this case bring down the protuberant part of the convex diagonal, so as to be straight with the two extremities; then straighten the concave diagonal, by planing either of the two ends or both of them, according as the thickness of the board will require. Both diagonals being now straight, traverse the wood, that is, plane it across the fibres, until all the protuberant parts between the diagonals are removed; then the workman may proceed to smooth it by working it in the direction of the fibres.

To join any number of planks together, so as to form a board of a determinate breadth, the fibres of each running longitudinal to those of any other.—Shoot the two edges that are to be joined; turn the sides of the boards towards each other, so that the edges that are flat may be both uppermost; spread these edges over with strong glue of a proper consistence, made very hot; one of the boards being fixed, turn the other upon it, so that the two edges may coincide, and that the faces may be both in the same plane; rub the upper one to and fro in the direction of the fibres till the glue is almost out of the joint; let these dry for a few hours; then proceed to make another joint; continue to join as many boards or planks in the same manner, till the whole intended breadth be made out. If the boards or planks of which the board is to be composed are very long, the edges that are to be united would require to be warmed before a fire; and, for rubbing and keeping the joints fair to each other, three men would be found necessary, one at each extremity, and one at the middle. Boards, glued together with this kind of cement, will stand as long as the substance of the deals or planks composing them, if not exposed to rain or intense heat, provided that the wood has been well seasoned beforehand, and that the grain be free and straight, uninterrupted with few or no knots. When a board which is to be exposed to the weather is to be made of several boards or planks, the cement to be used for uniting them should not be of skin glue, but of white lead ground up with linseed-oil, so thin that the colour may be sensibly changed into a whitish cast: this kind of glue will require a much greater time to dry than skin glue. Boards to be exposed to the weather, when their thickness will admit, are frequently tongued together; that is, the edges of both boards are grooved to an equal distance from the faces, and to an equal depth; and a slip of wood is made to fit the cavity made in both: this slip should be made to fill the grooves, but ought not to be so tight as to prevent the joint from being rubbed with proper cement.

To glue any two boards together forming a given angle.—This may either be accomplished by shooting the edge of the one board to the whole of the given angle, and the face of the other straight; then, by applying these two surfaces together, and rubbing as before, they will form the angle required; or, if the two edges are flat to half the given angle, and the edges applied together and rubbed and

set as before, the faces of the boards will form the angle required. In both these methods, when only one side of the board is to be exposed to light, which is most commonly the case, pieces of wood called blocks are fitted to the angle, and the sides glued across the joint or legs of the angle, being previously planed for that purpose.

To form wooden architraves for apertures by gluing longitudinal pieces together.—Architraves may be formed out of the solid pieces; but as their formation in this way is attended with a waste of both stuff and time, the most eligible method is to glue the parts longitudinally together, as is best adapted to the nature of the mouldings. Architraves of the Grecian form, for doors and windows, generally consist of one or two faces in parallel planes, the one of which recedes only in a small degree from the other, while the outer edge is terminated with one or several mouldings which have a very prominent projection. In this case make a board of sufficient thickness, and in breadth equal to the breadth of the architrave; prepare a slip of wood of a sufficient thickness and breadth for the mouldings on the outer termination of the architrave; glue this slip upon the face close to the edge of the board, with the outer edge flush therewith. In the operation two men will be at least required to rub the slip to a joint with the board; and as it often happens that the side of the slip, which is to comply with the surface of the board, is considerably bent, the slip is nailed down to the board; but, previously, small square pieces of wood, called buttons, are bored with holes, one in each, and a nail is put through the hole to the head; then the slip is also bored with a brad-awl; and the nails, with the pieces thus described, are entered and driven home as far as the buttons will permit. The buttons may be about three quarters of an inch thick, and the other two dimensions each equal to, or something more than, the breadth of the slip. The slip is sometimes grooved; and the edge of the board is tongued, glued, and inserted in the groove, instead of the above method. Sometimes, also, the two faces are made of different boards tongued together at their joining; then the whole is afterwards stuck into mouldings.

To form the surface of a cylinder with wood, whose fibres are in planes perpendicular to the axis of the cylinder, such as may be used in circular dados, or the soffits of windows.

Method 1.—When the dimension of the cylindrical surface, parallel to the axis, is not broader than a plank or board: this may be done by bending and gluing several veneers together; and the first upon a mould or brackets, the edges of which are in the surface of the proposed cylinder parallel to its axis.

This may be accomplished by means of two sets of brackets fixed upon a board with hollow cylindrical space between them, of sufficient thickness for taking in the veneers, and double wedges for confining them. If this operation is carefully done, and the glue properly dried, the wedges may be slackened, and the cylindrical part so glued up will be found to stand very well; but it must be observed, that, as the wood has a natural tendency to unbend itself, the curve surface, upon which it is glued, should be somewhat quicker than that intended to be made.

Some workmen take another method by forming a hollow cradle, and bending the veneers into it, and confining their ends with wedges, which compress them together; and by a very small degree of rubbing, with a hammer made for this purpose, the glue will be forced out of the joint.

Another method is to form a cradle or templet to the intended surface, and lay a veneer upon it; then glue blocks

of

of wood upon the back of it, closely fitted to its surface, and the other joints to each other, the fibres of the blocks corresponding with those of the veneer.

A third method is to make a cradle and place the veneers upon it, confining one end of them [spread in the glue between the veneers with a brush, and fix a bridle across, confining the ends of this bridle either by nails or by screws; open the veneers again, and put in glue a second time between each two, and fix another bridle across them: proceed in this manner to the other extremity.

A fourth method is to run a number of equidistant grooves across the back of the board at right angles to its edges, leaving only a small thickness towards the face, let this be bent round a cradle or templet made on purpose; and let the grooves be filled with slips of wood, which, after the glue is quite dry, are to be planed down to the surface of the cylindrical board, which may be stiffened with canvas glued across the back.

Instead of using a grooving plane, workmen frequently make kerfs with the saw; but this is not so strong when finished, as it is very difficult to insert the slips, and very uncertain as to the depth of each of the kerfs, which will occasion a very unequal bending of the board, if not to a regular depth.

To bend a board, so as to form the frustum of a cone, or any segmental portion of the frustum of a cone, such as the shaft of the head of an aperture.—Find the form of the covering according to the geometrical principles of carpentry; cut out a board to this form, and run a number of equidistant grooves across it tending to the centre: this being fixed to a templet made to the surface of a cone, proceed and finish it in the same manner as in the last method shewn for a cylinder.

To bend boards so as to form a spheric surface.—Make a mould to the covering of a given portion of the sphere in plano, according to the geometrical principles of carpentry; complete the number of flaves by this mould; make a templet or mould to a great circle of the sphere; groove each of the flaves across at right angles to a line passing through the middle, and bend it round the templet; put slips in the grooves; lastly, shoot the edges of the flaves, so as to be in planes tending to the centre of the sphere: these flaves being glued together will form a spheric surface.

To glue up the shaft of a column.—Describe two circles of diameters, equal to those of the superior and inferior ends of the shaft.

Circumscribe these by polygons, consisting of the same number of regular sides as the column is to consist of flaves.

From the angles draw lines to the centre, which will give the bevels for working the edges of the flaves. In this process, after two pieces are glued together, and dried, proceed to glue a third piece in the same manner and so on to the last but one. The last, previous to being glued, the blocks should be fixed upon it, and then the whole may be closed in. N. B. The number of flaves should be eight or twelve, otherwise the joint will fall in the middle of the flaves, which should not be in the case. It is a very good method to diminish the flaves, previous to their being glued together, as otherwise the waste of stuff would be very great.

To glue up the base of a column in several horizontal courses, or rings, in order to be turned in a lathe.—Consider the number of horizontal or bevel joints, which are bent made at the internal angles of mouldings; prepare a board, so as to have a plain surface; let a circle be described on the plane of a

diameter, equal to the diameter of the greatest circle in the height of the course, and circumscribe an equilateral polygon about the circle, with as many sides as there are to be pieces in a course, and from the angles draw lines towards the centre: then any radial line, and one of the adjoining sides of the polygon, will form the angle by which the ends of every two pieces that are to form the course will meet, so as to make their planes coincide. The geometrical part being thus finished, prepare the pieces each in length equal to the side of the polygon, with an acute angle at each end from the outer side, equal to the aforesaid angle on the board, so that each piece will thus have a longer and a shorter side: apply the longer side of each piece to the polygon, the shorter side being next to the centre, so that one of the ends may coincide with a radial; then the other end will also coincide, and thus the whole will meet together, if the work be true. But as this is difficult, it is common to allow the pieces to be a small matter longer, in order to plane them, so as to make close work: for though the methods be true, the workman, though ever so careful, cannot work to geometrical exactness; even the thickness of shaving, or the smallest degree of twist in the board, will spoil the work. Suppose the course completely jointed, take the whole to pieces, and glue the surfaces which are to meet each other, and rub each two adjacent pieces to a joint, until the whole ring or course is firmly closed.

When the glue is dry, plane the upper side truly; take the radius of the greatest projecting member in the next course, and describe a circle upon the top of the course, on the same axis with the centre of the lower circle; and with the centre of this circle, in the plane of the top of the course, bisect any one of the arcs comprehended between two adjacent joints; and from the point of bisection, divide the circumference into as many equal parts as there are pieces in the under course, and draw radiating lines towards the centre: join every two nearest points in the circumference, and thus an inscribed polygon will be formed; draw lines to touch the circumference parallel to the sides of the inscribed polygon, and thus a polygon will be made to circumscribe the circle: produce the radiating lines, until they meet the angles of the circumscribing polygon; then the sides of the circumscribing polygon will be the situations of the bottom edge of the vertical outer sides of the second course, and the radiations the situations of the joints. Proceed, as in the first course, to adapt the pieces to their respective situations, making close work; glue each piece to its place on the lower course, and likewise the joints; and when the glue of this course is dry, its upper side may be planed true. Proceed with the uppermost course in the like manner, making the joints fall in the middle of the lengths of the pieces of the lower course; and when finished, the work may be sent to the turner.

To glue up the Ionic and Corinthian capitals for carving.—The abacus must be glued in parts, such that their joints may be in vertical planes. The leaves and caulicoles of the Corinthian capital may be first made of rectangular blocks, and fixed to the vans.

To make a cornice round a cylindrical body out of the least quantity of wood, when the body is greater than a half cylinder, and concave, and when the members will nearly touch a right line applied transversely.—Draw a section of the cylinder through its axis, and let the section of the cornice be represented upon the cylindrical section. Draw a transverse line touching the two extreme members of the cornice: parallel to this line draw another line within, at such a distance from the former as may be found necessary for thickness of stuff; produce this last line, until it meet the line representing the

axis of the cylinder. The junction will either be above or below, according as the cornice is applied to the convex or concave sides of the cylinder. This meeting is the centre of two concentric circles, whose radii are the distances between the nearest and farthest extremes of the section of the cornice. This is evidently an application of the method of finding the covering of a cone. When mouldings are got out in this manner, *viz.* by a piece which does not occupy the space, when set to the place represented by the height and breadth, they are said to be sprung.

When a cornice is to have much projection, the corona or middle part is got out of a solid piece, and the parts above and below, or one of them, as may be found necessary, only set to the spring, and supported by brackets.

To describe the various kinds of joinings in the practice of joinery.—*Fig. 1.* Plate XXII. is a section shewing the most simple method of joining boards, or any kind of framed work together at the angles; this kind of joining is much used in coarse work; it is called lap-joining.

Fig. 2. the method of joining troughs together.

Fig. 3. the method of joining dado together at an internal angle.

Fig. 4. the manner of fixing two pieces of framing together at the angle of their meeting with a returned bead, in order that the joint should be concealed. This is only used in common finishings; in good finishings a bead of $\frac{1}{2}$ of an inch broad is generally run close to the joint, and the angle is left entire.

Fig. 5. shews the common method of mitring. This form is always used in mouldings at an external angle, and sometimes also in internal angles; but for internal angles, scribing is to be preferred, when it can be applied, which may always be the case, when there are no quirked mouldings; that is, when mouldings are such that a perpendicular line to the plane of the wall may fall upon any part of them without going through the solid of the moulding.

Fig. 6. is another method of mitring. This may be used in all plane surfaces, at an external angle, but is not applicable to mouldings. This manner of mitring is much more preferable in point of strength to that of *fig. 5*, in cases where the two can be applied.

Dove-tailing is another mode of joining two plane surfaces together at an angle, by cutting pins of a prismatic form and trapezoidal section on the end of one piece, and notching the end of the other in the same manner, so that the exterior parts of the one is adapted to the indentations of the other, without leaving any cavity when the two sides are brought home to their places. This is the strongest method of joining plane boards; it should always be used in work which may be required to be moved from place to place. There are three sorts of dove-tailing. One kind, called common dove-tailing, shews the ends of the joints; another kind, called lap-dove-tailing, conceals the joints of the dove-tails, but shews a straight joint, not at the angle, but at a small distance parallel to it. The third sort is called mitre dove-tailing, which shews no joint but in the angle. This method is very neat, it is stronger than the straight joint shewn by the section *fig. 6*, and where both strength and beauty is required it must be preferred to any other. *Fig. 7.* *N*^o 1, is a section shewing the pins; *N* 2, the side of one of the pieces shewing the pins; *N* 3, shews the ends of the pins; *N* 4, the side of the other piece, shewing the indentations for receiving the pins.

Fig. 8. *N*^o 1, 2, 3, 4, and 5, different parts of mitre dove-tailing.

To join two pieces of wood together, the fibres of the one run-

ning transversely to the fibres of the other by mortise and tenon or dove-tailing.—One method is by cutting a mortise to a very small depth in the one piece, and a tenon of the same length in the other, and by bolting them together with one or two bolts; where the breadth of the piece having the tenon is considerable, the nuts are to be let in from that side of the tenoned piece which is not exposed to fight; the heads of the bolts upon the mortified piece may be sunk into the wood entirely below the surface, and the cavity may be filled up with a piece of the same kind of wood, neatly fitted in.

Definition.—1. A frame, in joinery, is the connection of several pieces of timber of an equal thickness, joined transversely to each other, made fast by means of mortises and tenons, leaving rectangular spaces between for other pieces of timber, called panels, each of which is inserted into each edge of the former by means of a groove.

2. Those parts of the frame which terminate the two vertical extremes are called flyles.

3. The horizontal parts, which are mortified into the flyles, are called rails.

4. If there be any intermediate pieces mortified into the rails, parallel to the flyles, such pieces are called muntins.

In framed-work, rails have several epithets, according to their situations; that bordering the framing at the lower extremity is called the bottom rail, that bordering the framing, at the other extremity, is called the top rail. The names of intermediate rails vary according to their number and situation. In doors, that in which the lock is inserted is called the middle, or lock rail; the intermediate rail next to the top rail, is called the fraeze rail.

Doors.—A door, in joinery, is a framed piece of timber-work, or boards nailed together, for the purpose of shutting up at pleasure any aperture in a wall or partition, in order to give or prevent passage from one apartment to another.

Plate XXIII. *fig. 1.* is a four equal-pannelled door: the form is only used in very common work, and is frequently without mouldings.

Fig. 2 is a nine-pannelled door, with square panels at the corners. This form is frequently used in street-doors, of which the back is often lined with boards, in the manner of *fig. 3*, flush with the flyles and top rail; the other rails and muntins must therefore be recessed upon one side to receive the boarding.

Fig. 4. is a six equal-pannelled pair of folding-doors, having two panels in the breadth.

Fig. 5. is a double margin, or a pair of folding-doors, with four panels in height, and two in breadth, having lying panels below the top-rail, and above the lock-rail.

Fig. 6. is a ten-pannelled pair of folding-doors, five in height, and two in breadth, having lying panels at the top, bottom, and in the middle, with long panels between them. Of this form is the ancient door of the Pantheon at Rome.

Fig. 7. a sash-door: this form, if not shut with another separate door, should have sliding-shutters, to cover the glass parts, fixed with bolts and nuts. For this purpose, it should at least be one inch and a quarter thicker than a pannelled door in the same place: this gives room for the outside of the shutter to be flush with the flyles of the door; but if otherwise, an ugly frame must be patched round the glazed parts, in order to contain the shutter.

Fig. 8. an ancient door, of which form are the windows and door of the temple of Vesta at Rome, and also those of the temple of Erechius at Athens.

Figs. 9 and 10. are doors of communication, or such as, when open, will not encumber the floor, as other kinds of recessed doors, by jetting into the room, but may either be concealed

concealed entirely within the partition, or folded close to it: they are used for the purpose of making a free communication between one room and another, at great meetings or balls, when any one of the rooms would be insufficient though large enough for common use.

Fig. 9. the elevation of a door to be folded close to the partition, by means of a hanging stile, or pilaster, on each side which is first hung to the jamb, then a folding door to each pilaster.

Fig. 10. is a door consisting of four parts: each middle part is hinged to each extreme part; each two parts, on each side, in time of company, may be removed entirely out of the way into hollows on each side of the partition, and guided by grooves at the top and bottom, and made to slide freely upon rollers.

Fig. 11. is a jib-door, that is, such a door as, when shut, may be as much concealed as possible from having the appearance of a door. Jib-doors are used, when only one aperture at the end of the side of a room is necessary; and when it is required to keep the symmetry of that side, without having the appearance of a door; the base, subsale, and paper are, therefore, continued over it as in the other parts of the room, the joint being only seen at the top, and upon the edge opposite the hinge.

JOINING of ISSUE. See ISSUE.

JOINT, the juncture, articulation, or assemblage, of two or more things. See ARTICULATION.

JOINT, in *Anatomy*, the connection of two or more bones to each other: these parts are generally so organized as to admit of motion, but in some instances this is not the case.

The joints or articulations are generally referred to three classes: the immovable, or *synarthrosis*; the half moveable, or *amphiarthrosis*; and the completely moveable, or *diorthrosis*.

The first of these includes the various kinds of suture; for the description of which, see CRANIUM.

The amphiarthrosis, or joint admitting of slight motion, is made up either of cartilaginous ligaments (*symphyse*), or of true cartilage (*synchondrosis*). The union of the bodies of the vertebrae to each other, and the articulations of the pelvis, are examples of the former; the connection of the first pair of ribs to the sternum, and of the different bones of the sternum to each other, exemplify the latter.

For the account of the third species, or moveable articulation, see DIARTHROSIS.

A general description of the composition of a joint will be found under the article EXTREMITIES, near the beginning; and in the same article the particular joints of the limbs are described. The account of the articulation of the lower jaw is given under DEGLUTITION; that of the connection of the head to the vertebral column under HEAD. The articulations of the vertebrae are considered in the article SPINE; those of the ribs, in RIBS; and of the pelvis, in PELVIS.

JOINTS, *Diseases of*. Under this head we intend to notice a few cases which belong to the department of *Surgery*, and are not elsewhere treated of in this publication.

Inflammation of Joints.—Idiopathic cases of this kind are not common. The complaint ordinarily originates in consequence of a contusion, sprain, wound, or other kind of injury done to the part affected. Phlegmonous inflammation, wheresoever situated, is uniformly attended with certain local symptoms, by which both its presence and degree may be ascertained. Pre-ternatural redness, increased heat, a throbbing pain, and a tense swelling, affecting the seat of its attack, are the common marks which denote its existence in all situations. When a joint is inflamed, the same local

phenomena are present, and the constitution is disturbed by the usual symptoms of inflammatory fever; but in these cases they are apt to be exceedingly severe. The inflammation attacks the capsular ligaments, and not remaining confined to any particular portion of them, it very quickly diffuses itself universally over their whole extent, as is commonly the case in all inflammations of smooth membranes. That there is this peculiarity in inflammation of membranes, is often strikingly proved in the instance of peritonitis, arising after the operation of lithotomy. Here, we know, that the inflammation commences in the bladder, is communicated to the portion of the peritoneum which covers the fundus and posterior surface of this viscus, and thence rapidly spreads over the whole extent of the abdomen.

The capsules of the joints are naturally endued with little sensibility; but, like the gums, and several other parts in a similar state, they become acutely painful when inflamed. The complaint is accompanied by an increased secretion of the synovia, which becomes of a more aqueous, and of a less albuminous quality than it is in a healthy state. Hence this fluid is not so well calculated for lubricating the articular surfaces and preventing the effects of friction, as it is in the natural condition of the joint. This circumstance may explain why a grating sensation is often perceived on moving the patella when the knee is inflamed.

The capsules of the joints may, as well as other membranes, be thickened by inflammation. At other times an exudation of coagulating lymph may take place upon their internal surfaces; and as, by a general law of the animal economy, the contiguous vessels are always prone to shoot into lymph thus effused upon an inflamed surface, the consequence frequently is, that organized substances, such as pieces of cartilage and bone, are produced in the interior of the joint. The inconveniences of these extraneous bodies, and the mode of relief, will be a subject which we shall presently have to consider.

When the inflammation is more vehement, suppuration may happen within the capsular ligament. Unfortunately, this is by no means an infrequent occurrence. At length the capsular ligament ulcerates, and purulent matter is effused beneath the integuments. The skin may next ulcerate, so that the abscess is discharged, and the case seems to be somewhat benefited. The openings through which such collections of matter are discharged, will be found, upon examination with a probe, to be the terminations of sinuses leading into the cavity of the joint.

A large joint seldom falls into a state of suppuration, in consequence of acute inflammation, without the constitution being at the same time so disturbed, that life itself is greatly endangered. In the most violent state of the inflammation, or that which is the immediate forerunner of suppuration, the pulse is exceedingly frequent; but not quite so full and strong as it would be if the part affected were of a structure better adapted to resist the ravages of disease. The patient's skin is dry and hot; he is restless and vigilant; and, in very bad cases, delirium and coma may ensue, and end fatally.

But the rapidity with which the common inflammatory fever assumes in such cases the hectic type is a circumstance which must not be passed over in silence. When an abscess has formed in a large joint, in consequence of a severe attack of common inflammation, the patient immediately begins to be affected with hectic symptoms, and the strong action attendant on the inflammatory fever suddenly ceases.

Local consequences, even worse than those above described, may follow inflammation of a joint. As the layer of the capsular ligament reflected over the cartilages of the articulation is often inflamed, the cartilages themselves are very liable

liable to have the inflammation communicated to them. Parts partaking of a cartilaginous fracture being very incapable of bearing the irritation of disease, are often absorbed, so that, in the instance before us, a portion, or the whole of the articular surface of the bones, may be left completely denuded of its natural covering. At length the heads of the bones entering into the formation of the affected joint inflame, and become carious.

Sometimes only such parts as are exterior to the capsular ligament of the joint are inflamed, and in this case the symptoms are never so severe, nor so obdurate, as when the complaint is more deeply situated. Even when suppuration takes place on the outside of the capsule, the case is not dangerous, provided the cavity of the joint be not involved in the inflammatory attacks. Every inflammation of a large joint may generally be considered as a case of considerable importance; yet certainly there are instances where the inflammation being mild in degree, and simple in its nature, the danger is not urgent. However, every surgeon ought to be well impressed with the fact, that though the inflammation be originally of a healthy sort, it is always very likely to be converted into one of a specific nature, whenever there is a tendency in the constitution to serofulous disease. A person, whose habit is serofulous, may sometimes continue, during life, exempt from any local diseases of this specific nature, provided he be fortunate enough to avoid all irritation of parts on which serofula is most particularly disposed to make its attack. Among such parts we must class the joints, especially the knee, hip, elbow, and ankle. Hence, when a joint is inflamed, how mild soever the affections may be, we ought never to forget, that when there is a tendency to serofula in the system, the original cause of simple inflammation is very apt to be the exciting cause of the white swelling, one of the most severe and intractable diseases which increase the catalogue of human miseries. Hence the prudence of adopting with exactness whatever method of treatment may be indicated. In the following observations, we shall suppose the case to be that of an inflamed knee. The means best calculated for the relief of an inflamed joint are, generally speaking, those which are called antiphlogistic. There are few cases in which general and topical bleeding is more necessary and useful. The violence of the inflammation, and the strength, age, and pulse of the patient, must determine with what freedom the lancet should be employed. Leeches, however, may always be applied, and their application be repeated several times with advantage. When the leeches have fallen off, the bleeding is to be promoted by fomenting the part. The surgeon should daily persist in this method, until the acute stage of the inflammation has entirely subsided. In conjunction with this treatment, he should take care to keep the joint continually surrounded with linen wet with the saturnine lotion. In no case of inflammation are the application of cold lotions, and the maintenance of a constant evaporation from the surface of the part affected, more strikingly advantageous.

Fomentations and emollient poultices, however, sometimes afford most ease to the patient, in which circumstance they ought to have the preference.

Together with the foregoing means, laxative and febrifuge medicines are to be exhibited, and in a case of severe pain and loss of sleep, opiates.

When the acute stage of the inflammation has abated, the plan of treatment may be a little altered. The grand object is now to remove the effects which have been left by the preceding affection. There are a thickened state of the capsular ligament, and parts surrounding the articulation; a stiffness of the joint, and pain when it is moved; a collection

of fluid in the capsule, &c. This state of the complaint, when neglected, and there is a tendency to serofula, may prove exceedingly obdurate, and even terminate in an irremediable specific distemper of the joint. When, therefore, the local redness, tension, and throbbing, and the symptoms of inflammatory fever subside, the activity of the practitioner ought not to be relaxed. The application of a blister to the joint will now be found particularly efficacious, and the discharge should be kept up for a few days with the favin cerate. Very large collections of fluid in the capsular ligament of the knee, great thickening about the joint, and other remaining effects of inflammation, may often, under such treatment, be quite got rid of in a week or ten days.

In other cases, in which the inflammation and its effects are slighter, lotions composed of spirit of wine, vinegar, and sal ammoniac, suffice for the removal of any chronic complaints which may continue after the acute inflammation is at an end.

When the inflammation of a large joint like the knee is induced by a wound, the stomach is often much affected, and the symptoms may be very violent and even fatal.

Of Preternatural Cartilaginous Substances in Joints.—The ancients have either neglected to notice this disease in their writings, or they have not been at all acquainted with it. Ambrose Paré is the first author who mentions it: he had made an incision, in order to discharge some fluid from the cavity of the knee-joint, when a hard, polished, white body, about as large as an almond, was discharged from the wound. (Livre 25. chap. 15.) Since the time of Paré, the complaint has been described by numerous surgical authors; but the most valuable information on the subject may be found in the works of Reimarus, Morgagni, Bromfield, Ford, Default, Home, Hey, and Abernethy.

The external part of the extraneous substances, to which allusion has been made, is in general of a cartilaginous consistence, while their central part is frequently ossificous. Their figure is subject to great variety; but they usually have one concave side, and another which is convex. They are, for the most part, formed in the knee, and have been supposed by Reimarus, and a few other writers, to be met with in no other articulation. Morgagni, however, has seen ossified bodies of this kind in the ankle-joint. Haller, also, discovered a great number of cartilaginous bodies in the articulation of the jaw, where the natural cartilages had been destroyed. Mr. Hey, of Leeds, mentions a case, in which there were two bodies of this description in the elbow-joint. The largest preternatural cartilage perhaps ever met with is mentioned by Mr. Home, as being nearly equal in size to the knee-pan itself, and situated in the knee-joint of a soldier, belonging to the 50th regiment. The greatest number ever known to be contained in one articulation is twenty-five. In most instances, we only find one.

These preternatural cartilaginous substances are either attached to some part of the inside of the joint, or they are quite unconnected, loose, and moveable. It is only when they become so situated, as to interpose themselves between two articular surfaces, which glide over each other in the motion of a limb, that much inconvenience commonly results from their presence. While they continue by the side of the patella they cause but little trouble; but when they slip under the ligament of that bone, or between the same bone and the condyles of the femur, or between the latter bone and the head of the tibia, then they impede progression, cause considerable pain, and often excite inflammation.

Much light was thrown upon the formation of loose cartilaginous tumours in the joint, by the penetrating genius of the

the late Mr. Hunter. It was his belief, that a coagulum of extravasated blood might, under certain circumstances, be converted into an organized vascular substance, by the vessels growing into it from the neighbouring living surface. No one doubts that the coagulating lymph has constantly a tendency to become vascular, when effused on the surface of an inflamed membrane. Now, if we take the trouble of perusing the cases which are related by different authors, we shall find, that the formation of loose cartilaginous substances in the joints, has generally been preceded by violence done to the part, and by symptoms of inflammation. Of this description are the examples published by Mr. Ford, M. Brochier in *Default's Journal*, Mr. Abernethy, and Mr. Hey. Latta mentions four instances which were preceded by rheumatism. In this state, we conceive that the capsular ligament, or its delicate layer, reflected over the articular cartilages, effuses coagulating lymph upon a part of its surface; that such lymph soon becomes vascular and organized; and that it gradually assumes a structure more or less like that of cartilage.

Loose preternatural cartilages are mostly attached to some part of the articular cavity, which does not suffer attrition when the joint is moved. Dr. Alexander Monro, in dissecting the knee of a malefactor, found in the joint an osseous tumour, which was connected by a ligamentous pedicle with the exterior edge of the cartilage covering the external cavity of the tibia. (*Edin. Essays*, vol. iv. p. 245.) Perfect quietude is essential to the growth of new vessels into coagulating lymph, and in the case just now quoted, if the exudation had taken place, where it would soon have been disturbed in the motion of the limb, its organization could scarcely have happened. Also, if such cartilaginous bodies were to be commonly formed on a part of the articular cavity, necessarily exposed to friction in walking, &c. then patients would experience pain from the first. But, as they do not feel inconvenience till the tumour has become very moveable by the gradual elongation, or sudden rupture of its pedicle, and only then when the tumour glides into a situation where it is pinched between the articular surfaces, we have a right to conclude, that most cartilaginous bodies of this kind grow originally in a situation, where they are not particularly exposed to disturbance in the motion of the joint. In most instances, the communication of vascularity must also happen, during the tenderness of the joint, at which period the patient naturally keeps his limb in a quiet state, in order to avoid pain. After all inflammation has subsided, the limb is again moved with freedom; the organized coagulum is gradually loosened by the motion, and at length it only remains connected with the joint to which it was originally attached, by means of a long slender pedicle, through which its nutrient vessels proceed. At last the pedicle breaks, and the cartilaginous substance is left quite loose, like an extraneous body, in the cavity of the joint.

The irritation of loose cartilages in the knee often occasions an increased quantity of fluid in the capsular ligament, but this is not invariably the case. When the irritation is such as to induce a degree of heat and tenderness in the joint, there is usually a preternatural quantity of the synovia secreted; when pain and inconvenience have not lately been felt, this fluid is generally not more abundant, than in the natural state of the joint.

With respect to the treatment of these cases, we are not acquainted with any certain means of freeing the patient from the inconveniences of the disease, if we except making an incision into the joint, for the purpose of extracting the cartilaginous substance. To this plan, the danger attendant on all wounds of so large an articulation as the knee is a very

serious objection. Hence, Middleton and Gooch tried another method, which was to conduct the extraneous body into a situation where it produced no pain, and to retain it in that position a long time, by means of bandages, under the idea, that the cartilaginous substance would adhere to the contiguous parts, and occasion no future trouble. These surgeons appear at least to have thus afforded temporary relief.

Mr. Hey, impressed with a just sense of the dangerous symptoms, which have occasionally resulted from the most simple wounds penetrating the knee-joint, tried the efficacy of a laced knee-cap, and the cases which he has adduced clearly demonstrate, that the benefit thus obtained is not transient, at least as long as the patient continues to wear the bandage. In one case, the method had been tried, for ten years, with all the success which the patient could desire.

All things considered, it is our decided opinion, that the effect of a knee-cap, or of a compress and roller, ought generally to be tried before having recourse to the knife, supposing the cartilaginous substance can be placed in a situation where it gives no pain, and admits of being compressed. But doubtless there are instances, in which it is the duty of the surgeon to operate. If a man be deprived of his livelihood by not being able to use his knee; if he cannot, or will not, take the trouble of wearing a bandage; if he be urgently desirous of running the risk of the operation, after circumstances have been impartially explained to him; if a bandage fail in affording sufficient relief; and lastly, if excessive pain, severe inflammation of the joint, and lameness, be frequently brought on by the disease; the employment of the knife seems justifiable and proper. It is very certain, that success has generally attended the operation; but small as the hazard may be of losing the limb, and even life, in the attempt to get rid of the complaint; yet, since the inconveniences of the disease are in most cases very bearable, and are also capable of palliation by means of a bandage, endangering the limb and life in any degree must appear to many persons contrary to the dictates of prudence.

We have no instance recorded, where there was a necessity for removing a cartilaginous tumour from any joint but the knee.

The disease being often attended with a degree of heat and tenderness about the joint, there can exist no doubt of the propriety of keeping the patient in bed a day or two before he submits to the operation, the danger of which is in a great measure proportioned to the subsequent inflammation. When the attempt to heal the wound by the first intention succeeds, much of the hazard is also paid. Therefore, the joint should be brought into as quiet a state as possible before the incision is practised, and besides a little confinement, the surgeon should direct leeches and cold saturnine lotions to be applied to the knee, and an opening draught or two to be taken.

As the loose piece of cartilage may, in general, be moved round the joint, the surgeon frequently has it in his power to choose the place where he will make the incision. Ford, Latta, and others have made the wound on the outside of the joint. *Default* used to bring the loose cartilage to the inner side of the articulation, against the attachment of the capsular ligament, and then make the cut in that situation. Mr. Abernethy has recommended bringing the extraneous substance to the outside of the internal condyle of the os femoris, and dividing the capsular ligament at that part. Mr. Russell advises us to push the moveable body upwards, on the inside of the thigh, in order that the incision may be as distant as possible from the moving surface of the joint, Mr. Hunter also preferred removing these loose bodies at the

upper part of the joint, because there the bag, which contains the synovia, has less of the nature of a capsular ligament.

But whatever place may be chosen for the incision, it is of great consequence that an assistant prevent the loose cartilage from slipping away, lest it should not easily be found again, and the purpose of the operation be frustrated. It is clear, that if the capsular ligament were wounded when an accident of this kind occurred, the patient would be exposed to all the danger of the operation, without any chance of being benefited by it.

All operators have followed the plan of drawing the integuments to one side before making the incision, so that as soon as the excision of the cartilage is accomplished, the wound in the capsular ligament may become immediately covered with skin. Thus the bad effects of the cavity of the joint being exposed, are materially prevented. The piece of cartilage, when brought into view, is to be directly extracted by means of a tenaculum.

The skin is then to be brought over the opening in the capsular ligament; the external wound is to be closed with sticking plaster; cold lotions are to be applied to the knee; and every antiphlogistic measure adopted, which may seem prudent and necessary.

Experience has further proved, that the patient is not completely out of danger as soon as the wound is united; and that he ought, for some time longer, to keep the limb at rest. See Bromfield's *Chirurgical Cases and Observations*, vol. i. p. 335, 336.

Of Hydrops Articulæ, or Dropsy of the Joints.—This disease consists of an accumulation of water in the capsular ligament of a joint, and is very analogous to the hydrocele, or collection of an aqueous fluid in the tunica vaginalis testis. Both these complaints, indeed, are alike, in not arising from a general dropsical affection of the constitution, the patient being frequently in other respects quite sound. There are, it is true, a few exceptions to the latter part of this observation. The knee is, of all joints, the most liable to the disease, perhaps on account of the largeness and looseness of its capsular ligament.

The precise causes of hydrops articuli are often beyond the reach of investigation. The disorder, however, is frequently preceded by severe rheumatic affections, fevers, and local violence. In most cases a fluctuation is very distinguishable, unless the joint be uncommonly distended. When the limb, also, is extended, so as to relax the extensor muscles of the leg, the knee-pan may be made to rise up, by pressing the tumour, and a fulness may then be discerned on each side of that bone. The complaint is in general unattended with serious pain, though some uneasiness, and a sense of stiffness are experienced.

In considering the treatment of this, as well as of most other diseases, it behoves us to pay especial attention to the causes where they are discoverable, the mere removal of them being often of itself capable of effecting a cure. Thus, when hydrops articuli occurs during the debility consequent to typhoid and other fevers, the complaint can hardly be expected to get well till the strength of the constitution is, in some degree restored. The connection between the local and constitutional disorder is well illustrated in a case which Mr. Russell has related, and in which every local remedy was tried without avail: the disease, which would not yield as long as the debility consequent to a typhus fever lasted, got well spontaneously immediately when the patient regained his strength. On Morbid Affections of the Knee, p. 102.

In ordinary examples hydrops articuli is quite a local disease, unconnected with any disorder of the constitution, and

may be dispersed by topical treatment. One of the most effectual means for this purpose, is the application of a blister, which should be kept open with the favin cerate. The operation of the blister may also be very materially promoted by the pressure of a bandage. In some instances, the action of the absorbents may be sufficiently excited by moderate exercise, and frictions with flannel impregnated with the steam of vinegar, or by electricity, and rubbing the joint with camphorated mercurial ointment. The patient should likewise be purged with calomel, or kali acetatum, unless any particular reasons forbid.

Surgical writers inform us of cases, which resist common treatment, are attended with immoderate distention, and even with such irritation upon a weak constitution, as seriously impairs the health. Here, the surgeon would be justified in making a small puncture into the joint, in order to discharge the fluid. Care should be taken to make the opening no larger than necessary, and to draw the integuments to one side, before introducing the lancet, or trocar, so that the wound in the capsular ligament, as soon as the operation is finished, may become covered with skin.

Excision of Diseased Joints.—In the year 1782, Mr. Park, a surgeon at Liverpool, made the proposal of totally extirpating many diseased joints, so as to do away the necessity of cutting off limbs, which might still be of more use to the patients than any artificial contrivance. It was his plan to effect an entire removal of the heads of such bones as composed the diseased articulation, and then to make the spongy extremities of the bones grow together, like the ends of a fracture.

After undertaking some experiments upon the dead subject, Mr. Park, in 1781, performed the operation of extirpating the diseased knee of a strong robust sailor, aged 33. The method pursued was much like that which had been previously tried upon the dead subject, and which was as follows: An incision began about two inches above the upper end of the patella, and extended about as far below its lower part. Another one was made across this at right angles, immediately over the patella, down to the bone, and nearly half round the limb, the leg being in an extended state. The lower angles, formed by these incisions, were raised, so as to lay bare the capsular ligament; the patella was then taken off; the upper angles were raised, so as fairly to denude the head of the femur, and to allow a small cutting to be passed across the posterior flat part of the bone, immediately above the condyles, care being taken to keep one of the flat sides of the point of the instrument quite close to the bone all the way. The cutting being withdrawn, an elastic spatula was introduced into its place, for the purpose of protecting the soft parts during the sawing of the thigh-bone. The head of the bone, thus separated, was carefully dissected out; the head of the tibia was then easily turned out and sawn off, and as much as possible of the capsular ligament dissected away. The quantity of bone removed in the operation was a very little more than two inches of the thigh-bone, and rather more than one inch of the tibia. The only large artery divided was one on the front of the knee, and it ceased to bleed before the operation was concluded; but the ends of the bones bled very freely. To keep the redundant integuments from falling inwards, and the edges of the wounds in tolerable contact, a few sutures were used. The dressings were light and superficial, and the limb was put in a tin case, which was long enough to receive the whole member, from the ankle to the trochanter major.

We learn from Mr. Park, that afterwards many troublesome circumstances occurred, arising chiefly from the difficulty,

culty of keeping the limb in a fixed position, the great depth of the wound, and the abscesses and sinuses which were formed in the part. The first symptoms, however, were not at all dangerous. But the patient was obliged to keep his bed nine or ten weeks, and it was many months before the cure was complete. The man afterwards went to sea, and so useful was his limb, that he was able to do his duty extremely well.

Mr. Park made another attempt to extirpate a diseased knee, but it was less favourable, as the patient lingered a few months after the operation, and died.

About the same time that Mr. Park made his proposal, a similar plan was suggested by P. F. Moreau, a French surgeon, and tried in several instances, upon the knee, elbow, &c. by himself and his son.

The excision of diseased joints seems, at present, to have no advocates among surgeons of judgment and experience. A full relation of all that is known on the subject has been lately published by Dr. Jeffrays, in a work entitled "Cases of the Excision of Carious Joints." In this book may be found a description of a very ingenious saw for facilitating the operation. The instrument is constructed with joints, like a watch chain, so as to allow itself to be drawn behind a bone with a crooked needle, and be calculated for cutting the bone from behind forwards, without injuring the soft parts. It was made by Mr. Richards, who was assisted by his nephew, the present Mr. Richards, of Brick Lane, London. In placing the saw under the bone, its cutting edge is to be turned away from the flesh. Handles are afterwards hooked on the instrument.

The reasons which keep the practice of cutting out diseased joints from being imitated, are, in our opinion, of the most invincible kind. We believe that it is only right to amputate a limb, on account of a diseased joint, when the patient's health is so reduced, that it cannot any longer bear the irritation of the local disease, and that as long as the strength holds out, the propriety of endeavouring to cure the disease, and preserve the limb, is dictated by every principle of good surgery, as well as humanity. If it be only in hopeless circumstances, and in a reduced state of the patient, that we are to turn our minds to the use of the knife, it seems improbable that a patient, after being greatly reduced by hectic symptoms, would in general recover from so bold and terrible an operation, as that of dissecting away the whole of the knee-joint. If some few should escape with life and limb preserved, would the bulk of persons treated in this manner have the same good fortune?

The extirpation of so large an articulation as the knee cannot be compared with the operation of amputation, in point of simplicity and safety. The chief objections are founded, however, not upon the pain, nor difficulty of the operation, but upon the great length of time which the healing of the wound requires, and which, in the first case recorded by Mr. Park, was no less than eight months. His second example, as we have already mentioned, ended fatally. Moreau's patient, though much debilitated, escaped the first dangers consequent to the operation; and "after three months confinement, the patient was in such a state, that Moreau expected he would be able to walk upon crutches in another month or six weeks!" In the mean time the young man died of a dysentery. Allowing the excision of the knee to be followed by all possible success, few men of judgment will also acknowledge, that the advantage of having a mutilated, shortened, stiff limb, instead of a wooden leg, is an adequate compensation for the more painful operation that has been endured, and the greater risk that has been run.

Many of the foregoing observations were originally published in a Treatise on the Diseases of the Joints by S. Cooper, 1807.

JOINTS, in *Mining*, are applied to the vertical fissures, or cutters, by which most of the strata are divided nearly vertically, into separate blocks and pieces. In the limestone quarries in Derbyshire, two very distinct kinds of joints are noticed in the rock, some that are peculiar to the particular beds of stone, (the fissures of W. Martin,) and rarely sink through more than two or three beds; and others, that break through all the beds of limestone, and form a perfectly straight wall often to the face of their quarries; these last seem perfectly allied to mineral veins, though often not more than the eighth, or a quarter of an inch wide, and have their sides fluted with fluor, or calcareous spar, or barytes, and are polished, or shew thicker sides in some instances, and often these joints contain small specks of lead ore; while it is very rare for the other, or partial joints, to contain spar or ore; these kinds of joints, when close filled with spar, so as to cement the parts of the rock firmly together again, seem to answer to the contemporaneous veins of Werner; and the spar-joints of other writers; Mr. William Martin calls them rifts, *Outlines*, p. 171. Quarrymen sometimes apply the term *joint* to the partings or thin way-boards which separate the different thin strata or beds of stone in a rock; but properly, these are called bed-joints, or strata-seams. The definition which M. Werner gives of strata, viz. "those parts of a rock which lie between parallel rents and fissures," (*Transl. of New Theory of Veins*, p. 2), is much too general, as it may include both the kinds of joints above-mentioned, and the impropriety also is striking, of applying the term *rent* to the bed-joints of a rock, or semi-strata of Martin; with such vague ideas as these, it is no wonder that many observers have mistaken the cutters or joints of thick strata, that happen to range parallel, for bed-joints or strata-seams, and described strata as vertical, which are in reality horizontal, or near it.

JOINTS, in *Architecture*, denote the separations between the stones; which are filled with mortar, plaster, or cement.

JOINT, in *Carpentry*, &c. is applied to several manners of assembling, or fitting, pieces of wood together. Thus we say, a dove-tail joint, &c. See JOINERY, MORTISE, DOVE-TAIL, &c.

JOINT, *Universal*, in *Mechanics*, an excellent invention of Dr. Hook, adapted to all kinds of motions and flexures; of which he has given a large account in his *Culterian Lectures*, printed in 1678. This seems to have given occasion to the gimboles used in suspending the sea-compass, the mechanism of which is the same with that of Defaguliers's rolling lamp.

JOINT, in *Ship Building*, a term signifying the juncture of the frame-timbers, which is represented by a line, whereby the shape of the vessel is determined at the stations of the frames, to which the moulds are made for forming the various timbers, and although the frame is composed of a double set of timbers, yet they are generally close enough that the mould, made at the joint or middle, gives the shape of the foreface of the one, and the aftside of the other.

JOINT *Actions*, in *Law*. In personal actions several wrongs may be joined in one writ; but actions found upon a tort, and on a contract, cannot be joined; for they require different pleas and different process.

JOINT-battery. See BATTERY.

JOINT-executors, in *Law*, are two or more persons appointed such by will; in which case they are accounted but as one single person, so that the actions done by one of them

are taken to be the acts of all, because they all represent the person of the testator; thus, where two joint-executors are possessed of a lease for years, in right of their testator, one of them may sell the term without the other's joining; and in like manner, where one joint-executor gives a release, the others are bound by it, each having an authority over the whole estate; but a joint-executor is not charged with the acts of his companion, any farther than he is actually possessed of the goods of the testator; however, if joint-executors enter into an agreement, that each shall intermeddle with particular parts of the testator's estate, in that case each becomes chargeable for the whole by agreement. It has been held, that two joint-executors cannot raise separate pleas, because their testator, if living, on an action brought against him, could have been allowed but one plea; and that, if all the executors are not named in any action brought by joint-executor, the action will abate. As to legacies, the receipt of one executor charges not the other. See EXECUTOR.

JOINT-LIVES, denote lives that continue during the same time, or that exist together. See *Levy-mortality*.

JOINT-PLACES. See *Assignment, joint-RULE*.

JOINT-TENANCY, in *Law*, see the next article.

JOINTENANTS, or **JOINT-TENANTS**, in *Law*, those who come to, and hold, lands and tenements by one title *pro indiviso*, or without partition.

These are distinguished from *seors*, or several-tenants, from *partners* and from *tenants in common*. Anciently they were called *participes*, and not *heredes*. See *SEVERALTY*.

An estate in joint-tenancy is where lands or tenements are granted to two or more persons to hold in fee-simple, fee-tail, for life, for years, or at will. This is sometimes called an estate in "jointure," which word, as well as the other, signifies a union or connection of interest. The "creation" of an estate of this kind depends upon the wording of the deed or devise by which the tenants claim title; for this estate can only arise by purchase or grant, that is, by the act of the parties, and never by the mere act of the law. Now, if an estate be given to a plurality of persons, without adding any restrictive, exclusive, or explanatory words, as if an estate be granted to A and B and their heirs, this makes them immediately joint-tenants in fee of the lands. For the law interprets the grant so as to make all parts of it take effect, which can only be done by creating an estate in them both. As, therefore, the grantor has thus united their names, the law gives them a thorough union in all other respects. The "properties" of a joint estate are derived from its unity; and this unity is fourfold; *viz.* the unity of interest, the unity of title, the unity of time, and the unity of possession; or in other words, joint-tenants have one and the same interest, accruing by one and the same conveyance, commencing at one and the same time, and held by one and the same undivided possession. With regard to unity of *interest*, it may be observed, that one joint-tenant cannot be entitled to one period of duration, or quantity of interest in lands, and the other to a different; one cannot be tenant for life, and the other for years; one cannot be tenant in fee, and the other in tail. (Co. Litt. 188.) But if land be limited to A and B for their lives, this makes them joint-tenants of the freehold; if to A and B and their heirs, it makes them joint-tenants of the inheritance. (Litt. § 277.) If land be granted to A and B for their lives, and to the heirs of A; here A and B are joint-tenants of the freehold during their respective lives, and A has the remainder of the fee in severalty; or, if land be given to A and B, and the heirs of the body of A; here both have a joint estate for life, and A hath a several

remainder in tail. (Litt. § 285.) Joint-tenants must also have an unity of *title*; their estate must be created by one and the same act, whether legal or illegal; as by one and the same grant, or by one and the same disseisin. (Litt. § 278.) Joint-tenancy cannot arise by descent or act of law; but merely by purchase, or acquisition by the act of the party; and, unless that act be one and the same, the two tenants would have different titles; and if they had different titles, one might prove good, and the other bad, which would absolutely destroy the jointure. There must also be an unity of *time*; their estates must be vested at one and the same period, as well as by one and the same title. As in case of a present estate made to A and B; or a remainder in fee to A and B after a particular estate; in either case A and B are joint-tenants of this present estate, or this vested remainder. But if, after a lease for life, the remainder be limited to the heirs of A and B; and during the continuance of the particular estate A dies, which vests the remainder of the one moiety in his heir; and then B dies, whereby the other moiety becomes vested in the heir of B; now A's heir and B's heir are not joint-tenants of this remainder, but tenants in common; for one moiety vested at one time, and the other moiety vested at another. (Co. Litt. 188.) Moreover, in joint-tenancy there must be an unity of *possession*. Joint-tenants are said to be seized "per my et per tout;" by the half or moiety, and by all; that is, they each of them have the entire possession, as well of every *part* as of the *wholes*. (Litt. § 288. 5 Rep. 10.) And therefore, if an estate in fee be given to a man and his wife, they are neither properly joint-tenants, nor tenants in common; for husband and wife being considered as one person in law, they cannot take the estate by *co-tenants*, but both are seized of the entirety, "per tout et non per my;" the consequence of which is, that neither the husband nor the wife can dispose of any part without the assent of the other, but the whole must remain to the survivor. (Litt. § 665. Co. Litt. 187. 2 Vern. 120. 2 Lev. 39.) From these principles we may deduce other incidents pertaining to the joint-tenant's estate. If two joint-tenants let a verbal lease of their land, reserving rent to be paid to one of them, it shall enure to both, in respect of the joint-reversion. (Co. Litt. 214.) If their lessee surrenders his lease to one of them, it shall also enure to both, because of the privity or relation of their estate. (Co. Litt. 192.) For the same reason, livery of seisin, made to one joint-tenant, shall enure to both of them. (Co. Litt. 40.) and the entry, or re-entry, of one joint-tenant, is as effectual in law as if it were the act of both. (Co. Litt. 319. 364.) In all actions, also, relating to their joint-estate, one joint-tenant cannot sue or be sued without joining the other. (Co. Litt. 195.) But if two or more joint-tenants be seized of an advowson, and they present different clerks, the bishop may refuse to admit either; because neither joint-tenant hath a several right of patronage, but each is seized of the whole; and if they do not both agree within six months, the right of presentation shall lapse. But the ordinary may, if he pleases, admit a clerk presented by either, that divine service may be regularly performed; and if the clerk of one joint-tenant be so admitted, this shall keep up the title in both of them. (Co. Litt. 185.) It is held also, that one joint-tenant cannot have an action against another for trespass, in respect of his land (3 Leon. 262.); for each has an equal right to enter on any part of it. But one joint-tenant is not capable by himself of doing any act which may tend to defeat or injure the estate of the other, as to let leases, or grant copy-holds (1 Leon. 234.); and if any waste be done, which tends to the destruction of the inheritance, one joint-tenant may have an action of waste

against the other, by construction of the statute Weitm. 2. c. 22. (2 Inst. 423.) So likewise, though at common law no action of account lay for one tenant against another, unless he had constituted him his bailiff or receiver (Co. Litt. 200.); yet now by the statute 4 Ann. c. 16. joint-tenants may have actions of account against each other, for receiving more than their due share of the profits of the tenements held in joint-tenancy. From the same principle also arises the remaining grand incident of joint estates; *viz.* the doctrine of *survivorship*; which see.

An estate in joint-tenancy may be severed and destroyed, by destroying any of its constituent unities. The first, indeed, cannot be effected by any subsequent transaction. But the joint-tenant's estate may be destroyed without any alienation, by merely disuniting their *possession*. Hence, if two joint-tenants agree to part their lands, and hold them in severalty, they are no longer joint-tenants, and the right of survivorship is by such separation destroyed. (Co. Litt. 188. 191.) By common law all the joint-tenants might agree to make partition of the lands; but one of them could not compel the other to do so (Litt. § 209.); but now by the statutes 31 Hen. VIII. c. 1. and 32 Hen. VIII. c. 32. joint-tenants, either of inheritance or other less estates, are compellable by writ of partition to divide their lands. Again, the jointure may be destroyed by destroying the unity of *title*. As if one joint-tenant alienes and conveys his estate to a third person, the joint-tenancy is severed, and turned into tenancy in common. (Litt. § 202.) But a devise of one's share by will is no severance of the jointure; for no testament takes effect till after the death of the testator, and by such death the right of the survivor, which accrued at the original creation of the estate, and has therefore a priority to the other, is already vested. (Litt. § 287.) It may be also destroyed by destroying the unity of *interest*. And therefore, if there be two joint-tenants for life, and the inheritance is purchased by or descends upon another, it is a severance of the jointure. (Cro. Eliz. 470.) In like manner, if a joint tenant in fee makes a lease for life of his share, this defeats the jointure, for it destroys the unity both of title and interest. (Litt. § 302, 303.) And whenever, or by whatever means the jointure ceases or is severed, the right of survivorship the same instant ceases with it. (Co. Litt. 108.) Yet, if one of these joint-tenants alienes his share, the two remaining tenants still hold their parts by joint-tenancy and survivorship (Litt. § 204.); and if one of three of these joint tenants releases his share to one of his companions, though the joint-tenancy is destroyed with regard to that part, yet the two remaining parts are still held in jointure (Litt. § 304.); for they still preserve their original constituent unities.

Things personal may belong to three owners, not only in severalty, but also in joint-tenancy, and in common as well as real estates. Thus if a house, or other personal chattel, be given to two or more absolutely, they are joint-tenants of it; and, unless the jointure be severed, the same doctrine of survivorship shall take place as in estates of lands and tenements. (Litt. § 282. 1 Vern. 482.) The entire cannot have a joint property with any person in one thing chattel, or such a one as is not capable of division or separation; but where the titles of a king and a subject concur, the king shall have the whole. Blackst. Com. b. ii.

JOINT-water, a term used by our farmers, for what the old writers in medicine have called *hydrarthros*; a running of a clear ichor from the joints, when they are either wounded or ulcerated; it is common in diseases of horses.

JOINTEE, in the *Manege*. See *HANDFUL*.

JOINFRESS, or *JOINTERESS*, she that hath an estate

settled upon her by her husband, to hold during her life, if she survives him.

JOINTURE, in *Law*, a covenant whereby the husband, or some friend in his behalf, makes over to his wife, on condition of marriage, certain lands and tenements for the term of her life, or otherwise, in lieu of dower.

Others define jointure a bargain and contract of livelihood, adjoined to the contract of marriage, being a competent portion of freehold lands or tenements, &c. for the wife, during her life at least, to take effect in profit or possession, after the death of her husband, if she herself is not the cause of the extinction or forfeiture of it.

And to make a perfect jointure within the statute of 27 Hen. VIII. c. 10. to bar dower, several things are to be observed. 1. It must be made to take effect for the life of the wife in possession or profit, presently after the decease of her husband. 2. It must be for the term of her own life, or a greater estate; but it may be limited to continue no longer than she remains a widow, &c. 3. It must be made for herself, and to none other in trust for her. 4. It is to be expressed to be in satisfaction of her whole dower, and not a part of it. 5. It may be made before or after marriage; if it be made before, the wife cannot waive it, and claim her dower at common law (4 Rep. 1, 2.); but if it be made after marriage, she has her election, after the husband's death, and may either accept it, or refuse it, and betake herself to her dower at common law; for she was not capable of consenting to it during coverture, unless the jointure be made by act of parliament. After the death of her husband, the wife may enter into her jointure, and is not driven to a real action, as she is to recover dower by the common law; and upon a lawful eviction of her jointure, she shall be endowed according to the rate of her husband's lands, whereof she was dowerable at common law.

A wife's jointure shall not be forfeited by the treason of the husband (Co. Litt. 37.); but feme-coverts, committing treason or felony, may forfeit their jointures, and being convicted of recusancy, they shall forfeit two parts in three of their jointures and dower, by 3 Jac. I. c. 4.

JOINVILLE, JOHN SIBERDE, in *Biography*, a French historian, born in the early part of the thirteenth century, made a considerable figure in the court of Lewis IX. This prince he followed in all his military expeditions, and assisted him also in the administration of justice. One of the duties which he had to perform, was to hear the pleas of applicants at the palace gate, and to report them to his majesty, and also to investigate the truth of the allegations. When Lewis took the cross, and made his expedition into Egypt in 1249, Joinville, imbued with the martial spirit and devotion of the age, attended him with a train of followers suited to his rank, and his narrative of this enterprize in his life of Lewis, is one of the most curious and valuable records of that age. The historian shared his sovereign's captivity, as well as the dangers which they all underwent from the common enemy. He returned in safety, and was so much impressed with the danger and impolicy of these expeditions, that he made no scruple of condemning those who advised Lewis to undertake his second crusade, and excused himself from accompanying the king, on the pretext of having been ruined by the first. Joinville's history was completed in the year 1309, when the author, according to Gibbon, must have been more than ninety years of age; it is a faithful detail of the facts which occurred under his own observation. "A monkish historian should have been content to applaud the most despicable part of his (the king's) character; but the noble and gallant Joinville, who shared the friendships and

and captivity of Lewis, has traced with the pencil of nature the free portrait of his virtues as well of his failings." The most valuable edition of this work is that of Du Cange in 1688; but the text of the Paris edition in 1761 is reckoned the most pure and authentic. It has been lately translated into the English, and published by Mr. Johnes of Hafod. Moreri, Gibbon.

JOINVILLE, in *Geography*, a town of France, in the department of the Upper Marne, and chief place of a canton, in the district of Wassy, situated on the Marne; 15 miles S.E. of St. Dizier. The place contains 3086, and the canton 476 inhabitants, on a territory of 145 kilometers, in 15 communes. N. lat. 48° 27'. E. long. 5° 13'.

JOIRE, *St.*, a town of France, in the department of Mont Blanc; 4 miles S.E. of Chambéry.—Also, a town in the same department; 15 miles S.E. of Geneva.

JOISTS, or **JOYSTERS**, in *Archit. cur.*, those pieces of timber framed into the girders and summers on which the boards of floors are laid.

Joists are from six to eight inches square, and ought seldom to be at a greater distance from each other than ten or twelve inches; nor ought they ever to bear at a greater length than ten feet: or to be less into the wall than eight inches. See *CHIMNEY*.

Sometimes the carpenters furr their joists, as they call it; that is, they lay two rows of joists, one over the other.

JOKALAY, in *Geography*, a town of Sweden, in the government of Abo; 22 miles N.W. of Abo.

JOKES. See *JESTING*.

JOKEI, in *Geography*, a town of Japan, in the island of Niphon; 50 miles N. of Meaco.

JOKIOS, a town of Sweden, in the province of Tavastland; 28 miles W.S.W. of Tavasthus.

JOKKAS, a town of Sweden, in the province of Tavastland; 17 miles N.E. of Tavasthus.

JOKKATO, a town of Africa, in the kingdom of Barra.

JOKO, a town of Africa, in Kaarta. N. lat. 14° 30'. W. long. 8°.

JOKOMI, a town of Japan, in the island of Niphon; 25 miles N. of Jedo.

JOLCOS, or, as Homer calls it, *Jascolis*, in *Ancient Geography*, a town of Thessaly, in Magnesia, at the lower extremity of the Pelagic gulf, seven stadia from Demetrias and the sea. It was anciently considerable, and had a famous port. Pliny says that Adrafte at this place invented the funeral games; and Strabo reckons it in the number of those towns which were destroyed in order to people the town of Demetrias. Jason, the son of Elon, was king of Jolcos, and from hence the Argonauts took their departure; and it is said that on their return they found the town in the possession of Pelias, brother of Jason, who had him put to death.

JOLIAN, in *Geography*, a town of Hindoostan, in Guzerat; 20 miles N. of Gogo.

JOLIBA, denoting, in the language of the Negroes, "great water," is a name which they give to the river Niger, called by the Moors "Nil il Abud," or the river of Sages. When Mr. Park, in his interesting Tour, first discovered this river, it appeared to him as broad as the Thames at Westminster, and flowing majestically, but slowly, from west to east, through the middle of a very extensive town, called Semo. This enterprising and ingenious traveller pursued the course of the Joliba from W. long 5° 30' to Silla, long. 1° 30', the utmost extent of his expedition. See *GUIX* and *NIGER*.

JOLIATHUS, in *Botany*, from *ios*, a violet, and *λθος*,

a stone, a cryptogamic plant, referred by Linnæus to the genus *Byssus*, by some others to that of *Lichen*. It is found in the form of broad crimson patches, when moist, smelling strongly of violets, or rather of Orris root, clothing the surface of stones in clear springs, as at Holywell in Flintshire, Tunbridge, and other places. Nothing is known concerning the fructification.

JOLLONE KEY, in *Geography*, a small island among the Bahamas. N. lat. 26° 12'. W. long. 77° 2'.

JOLO, or **SORE CARTA**, a town of Java, and capital of the kingdom of Socfoehocam.

JOLUCAR, a town of Spain, in the province of Granada; 7 miles N.E. of Motril.

JOLUT, an island near the west coast of East Greenland. N. lat. 60° 56'. W. long. 46° 50'.

JOLY, **CLAUDE**, in *Biography*, a French writer, was born at Paris in 1607. He was precursor of the cathedral of Paris, and died in that city in the year 1700. He was author of a book entitled "Maxims for the Education of a Prince," which was condemned by the judicature of Paris, and was burnt by the hands of the common hangman in 1665. He likewise wrote several other pieces, chiefly theological.

JOLY, **GUY**, a French writer of memoirs, was counsellor to the king, and syndic of the renters of the hotel de ville, in Paris. He was attached to the cardinal de Retz, whom he followed, for a considerable time, in all his various fortunes. After the return of that minister from Rome, Joly quitted him on account of want of mutual confidence. He drew up "Memoirs from 1648 to 1665," in two volumes 12mo. which are chiefly an abridged account of what the cardinal himself has recorded in his own memoirs: but they are written in a more exact style than those of the cardinal, and contain many additional curious facts. Joly was engaged to defend the rights of the queen, and drew up "Remarks on Two Treatises written by Peter Stockmans in opposition to her Claims on Brabant and the Low Countries." He was author of another work, entitled "Intrigues of Peace, or Negotiations at Court by the Friends of M. le Prince, after his retreat in Guienne." Moreri.

JOLY, in *Geography*, a port on the S. coast of Nova Scotia.

JOMELLI, **NICOLO**, in *Biography*, one of the most intelligent, learned, and affecting dramatic composers of modern times, was born at Avellino, a town about twenty-five miles from Naples, in which city he had his musical education under Leo and Durante. The first opera to which we find his name, is "Riccimero Rè de Goti," composed for the Argentina theatre at Rome, 1740: and between that period and 1758, he composed for that city fourteen operas, besides others for Venice and different Italian theatres.

From 1758 to about 1768, he resided in Germany, being engaged in the service of the duke of Wurtemberg, at Stuttgart, or rather at Ludwigsburg, his new capital, where Jomelli's works were performed. Here he produced a great number of operas and other compositions, by which he acquired great reputation, and totally changed the taste of vocal music in Germany. On his return to Italy, he left all these productions behind him, upon a supposition that he should again resume his station at Ludwigsburg, after visiting his native country. But as he never returned thither to claim these compositions, they fell into the hands of his patron, the duke of Wurtemberg, who preserved them as precious relics of this great master.

Proposals were published at Stuttgart, in 1783, and in Cramer's *Ægæ. det. Ægæ.* for September of the same year, for

for printing by subscription the entire dramatic works of Jomelli in score, which he composed during his residence at the court of the duke of Wurtemberg, consisting of fifteen serious operas, five pastoral dramas, and three burlettas; but whether this undertaking was ever accomplished, we have not been able to learn.

The serious operas which Jomelli composed for Stuttgart, are the following: "L'Olimpiade, La Clemenza di Tito, Nitteti, Pelope, Enea nel Lazio, Catone in Utica, Il Re Pastore, Alessandro nell' Indie, Ezio, Didone, Demofonte, Semiramide, Vologeto, Artaserse, and Fotonte." Pastoral dramas: "Imeneo in Atene, Il Pastore Illustre, and L'Isola Disabitata." Comic operas: "Il Matrimonio per Concorso, La Seliava Liberata, and Il Cacciatore Deluso."

Very few entire operas of Jomelli were ever performed in England: the first was "Attilio Regolo," in 1755, without any captivating singer. Serafini, first man, with little voice, though a good actor; and the Visconti, first woman, but now *passé*, were little able to render the music captivating, or even to do it justice. Yet an extraordinary circumstance happened during the whole run of this opera, which no other, perhaps, could ever boast. This drama was terminated by a piece of recitative without a subsequent air, in speaking which, Serafini was constantly encoored. A circumstance the more extraordinary, as the English in general, who are ignorant of the Italian language, hate recitative, and would never go a second time to an opera, if not attracted by the airs and fine singing.

In 1755, Jomelli's opera of "Andromaca" was performed in London; in which the first air, "Si soffre un cor trianno," has considerable merit; but the close of the allegro is now old fashioned. A great part of this opera was composed by Jomelli in his first manner; but originality and the hand of a master always appear. The air, "Eccoti il figlio," as sung and acted by Mingotti, was truly dramatic and affecting. The whole is very superior to almost all contemporary productions.

In 1759, a duet by Jomelli, in the pasticcio opera of "Vologeto," was extremely pleasing, and the first which we remarked on the present dramatic model, chiefly in dialogue, with only bursts of passion, in two parts. And Elisi, while he was in England, sung several grand airs by Jomelli, composed on purpose to display that singer's dexterity in hitting wide intervals.

In 1768, Guarducci, instead of an opera for his benefit, had the oratorio of "Betulia Liberata," written by Metastasio, and set by Jomelli, in which, among many admirable compositions, an air of supplication by the high priest, through which were heard the murmurs of the people in a distant chorus, crying for peace and bread in tones so subdued as scarcely to be heard, was justly admired for its fine and new effect.

After he quitted Germany, Jomelli composed a great number of operas expressly for the king of Portugal, who tried every expedient to tempt him to go to Lisbon; which honour, though he declined, on account of the delicate state of his wife's health, yet he annually furnished that prince with new productions, as well as with whatever he composed for other purposes.

He composed, after his return to Naples, three operas for that city: "Armida," in 1769; "Demofonte," 1770; "Ifigenia in Aulide," 1771. And in 1772, "Achille in Sciro," for Rome, which was his last.

Some of the music which he composed for the dances of his operas has been much celebrated, particularly his "Chaconne," which is well known in England, and has served as

a model for that species of dance throughout Europe, ever since it was composed.

The operas of Jomelli will be always valuable to professors and curious collectors, for the excellence of the composition; though it has been thought necessary, in compliance with the general rage for novelty, to lay them aside and to have the same dramas new set for the stage, in order to display the talents, or hide the defects, of new singers.

As Jomelli was a great harmonist, and naturally grave and majestic in his style, he seems to have manifested abilities in writing for the church, superior even to those for the stage.

Of the many oratorios he composed, we are only acquainted with three: "Iffacco Figura del Redentore;" "Betulia Liberata;" and "La Passione;" all written by Metastasio, and all admirably set. In the first accompanied recitative and air of "Iffacco," at the opening of the second part, beginning, "Chi per pietà mi dice, il mio figlio che fa?" in which are painted, with an uncommon degree of agitation and passion, the anxiety and terror of Sarah, during the absence of Abraham, whom the supposes is in the act of sacrificing her son Isaac, have been justly much admired.

We are in possession of a Te Deum and a Requiem of his composition, which manifest him to have been a great master of the church style; though he had acquired great fame as a dramatic composer before he began to exercise himself in this species of writing, concerning which he had never bestowed a thought since he left the music-school, or conservatorio, till about the year 1751, when it having been determined at Rome that the music for passion-week should be as excellent as possible, Durante, Jomelli, and Perez, were employed to set the lessons from the Lamentations of Jeremiah, for the three most solemn days of that holy time. Jomelli's composition was performed on Wednesday, Perez's on Thursdays, and Durante's on Good Friday. The first is entitled "Lettione Primo per li mercoledì finto, con Violini, Oboè, Viola, Flauti e Corni da Caccia." The second "Lettione Prima del Giovedì finto, a Soprano solo, con Violini, Viola, Oboè, e Corni da Caccia." And the third "Lettione Terza del Venerdì finto, a 4 Voci, con Violini, Viola, e Corni da Caccia." Having procured a score of these compositions at Rome, and lately examined them, we can venture to say that they all appear admirable; and as the composers were all men of great abilities, who exerted themselves on this honourable occasion, it is difficult to determine, in their several styles, which is the best. The productions of Jomelli and Perez are in an elevated, elegant, dignified, supplicating, and expressive oratorio style; and that of Durante more in the ancient style of church music: more learned in modulation, more abounding in figure, and more elaborate in the texture of the parts, as might be expected from his maturer age, and the solemnity of the day on which his music was to be performed.

But though Jomelli acquired considerable fame by this composition for the church, yet he was so far from being intoxicated by it, that in a visit to Padre Martini, at Bologna, soon after, he told this learned contrapuntist that he had a scholar to introduce to him. Padre Martini assured him, that he should be glad to instruct any one so well recommended. And a few days after, the good father asking who and where was the disciple he had talked of? Jomelli answered, Padre Martini; and pulling a *studio* of paper out of his pocket, on which he had been trying his

strength in modulation and fugue upon *canto fermo*, begged of him to examine and point out his errors.

From this period he produced many admirable compositions for the church, in which he united elegance with learning, and grace with bold design. Among other productions of this kind, the two following merit commemoration. An "Offertorio," or motet, for five voices without instruments, followed by an Alleluja of four parts in chorus; and a "Missa pro defunctis," or burial service, which he composed at Stuttgart for the obsequies of a lady of high rank and favour at the court of his patron, the duke of Wurtemberg. These compositions, which are learned without pedantry, and grave without dullness, will be lasting monuments of his abilities as a contrapuntist.

But the most elaborate of all his compositions, is the "Miserere," or fifty-first psalm, translated into Italian verse, by his friend Saverio Mattei, which he set for two voices, accompanied with instruments, in 1773, the year before his decease. In this production, which breathes a pious gravity, and compunction of heart suited to the contrite sentiments of the psalmist, there is a manifest struggle at extraneous modulation and new effects, perhaps too much at the expense of facility and grace. Though all the movements of this composition are slow, yet the execution is so difficult, both to the voices and instruments, that when it was performed in London at Marchetti's benefit, it was the opinion of the late Mr. Bach, that Jomelli had purposely written what he could not execute himself, in order to perplex the performers. This, however, must have been said in pleasantry, for Jomelli had no malevolence in his disposition; perhaps in striving at excellence with too great solicitude, he sometimes had recourse to art and study, instead of giving way to his own feelings. There are, however, admirable strokes of passion as well as science in the music that he has set to this psalm, which, though above the comprehension of common hearers, will afford great pleasure to those that are able to read the score, or to follow the performers through the labyrinths of art.

This admirable composer had, in general, such a facility in writing, that he seldom courted the Muse at an instrument; and so tenacious a memory, that Sacchini assured us he frequently composed an air on opening a book of lyric poetry, while, like a peripatetic, he has been walking about a room, which he remembered a year after, and then committed it to paper, as fast as he could write a letter.

As Raphael had three manners of painting, Jomelli had three styles of composition. Before he went to Germany, the easy and graceful flow of Vinci and Pergolesi pervaded all his productions; but when he was in the service of the duke of Wurtemberg, finding the Germans were fond of learning and complication, he changed his style in compliance with the taste and expectations of his audience; and on his return to Italy, he tried to thin and simplify his dramatic Muse, which, however, was still so much too operose for Italian ears, that in 1770, upon a Neapolitan being asked how he liked Jomelli's new opera of "Demofonte," he cried out with vehemence, *è scelerata, Signore!*

Climate seems to operate so much on music, however its influence may be disputed in manners and government, that what is admired in one country is detested in another. In cold climates labour is necessary to circulation; in hot, ease is the grand desideratum. This principle is carried to such excess in Italy, that whatever gives the hearer of music the least trouble to disentangle, is Gothic pedantic, and *scelerata*. As to difficulties of execution, in a single Paris, the composers and performers may spin their brains, and burst

their blood-vessels, and welcome, provided the texture of the parts is clear and simple.

The Gothic inventions, as they call them, of fugues, canons, and laboured counterpoint of the sixteenth century, they are willing to resign to the Flemings, who first brought them into Italy; but of which all the natives, except a few obdurate pedants, struggled to divest their music, particularly that for the stage, during the last two centuries.

It is the *exceps* only of learning and facility that is truly reprehensible by good taste and sound judgment; and *difficult* and *easy* are relative terms, which they only can define. To lovers of music who have heard much in various styles, little is new; as to others who have heard but little, all is new. The former want research and new effects, which, to the latter, old music can furnish. Palates accustomed to plain food find *ragôts* and *morceaux friands* too highly seasoned; while to those who have long been pampered with dainties, simplicity is insipid. How then is a composer or performer to please a mixed audience, but by avoiding too much complacency to the exclusive taste of either the learned, or the ignorant, the supercilious, or the simple?

The health of Jomelli began to decline in 1770, soon after we had seen him in perfect health at Naples. He was then corpulent, and reminded us of the figure of Handel. In 1771, he had a stroke of the palsy, which, however, did not impair his intellects, as he composed "Achille in Sciro" for the Roman theatre, and a cantata for the safe delivery of the queen of Naples, in 1772; and in 1773, his Italian "Miserere," the most elaborate and studied of all his works.

His learned friend, Signor Saverio Mattei, the translator of the psalms into Italian verse, from whose admirable version Jomelli had taken the "Miserere," or fifty-first psalm, drew up a very interesting account of the works and public funeral of the great musician, and printed it in his "Saggio di Poesia Latine et Italiane," published at Naples immediately after his decease.

The reverence and regard with which we have been long impressed for the works and character of this gifted man, have already rendered the article too long to admit of further extension, or we should have wished to insert Signor Mattei's whole account; but having given it elsewhere, we shall here only cite the introduction, which does equal honour to the author and his friend.

Naples, September, 1774. "Yesterday all the musicians of this city united in celebrating the funeral of the great Jomelli. The church was very finely ornamented; and a great number of wax tapers were placed about the pompous bier. Two orchestras of three rows each could scarcely contain the vocal and instrumental performers who assisted in executing the music that was expressly composed on the occasion by the worthy Sabitini, who beat the time himself, as *maestro di capella*. It was the celebrated Genaro Manna, composer of the archiepiscopal church, who first suggested this plan of a public funeral, in which all these musicians had an opportunity of manifesting their regard for Jomelli, and of furnishing an example to posterity of the gratitude due to great talents, which may likewise stimulate young artists to merit equal honours. At the desire of Signor Manna, not only every musician attended the funeral and performed gratis, but contributed likewise towards the expenses of this solemnity.

"Jomelli was my friend; he lived two years in my neighbourhood, and I had frequent opportunities of conversing with him, and of admiring his captivating manners, particularly his modesty in speaking of rival artists, whose compositions

positions he readily praised, though their authors were not equally candid in speaking of him.

"Jomelli had acquired considerable knowledge in other arts than music: his poetry was full of taste, and there is a fine ode of his writing, in the collection published at Rome, on the subject of the reconciliation between the pope and king of Portugal.

"He was ambitious of distinguishing himself from other composers in a way peculiar to himself. His invention was always fertile, his style lyrical and Pindaric; and just as Pindar darted from one subject to another, Jomelli changed his tones and themes in a way wholly new, and learnedly irregular."

This account is terminated with many excellent reflections on the style of Jomelli, and the casual and frivolous taste of the Neapolitans at the time of his death. All we shall add is, that the latter works of Jomelli will be ever regarded with reverence by real judges of composition, as there is no mixture of trivial or fantastical movements or passages in his truly classical, and often sublime works.

JON, in *Natural History*, the name of a gem described by Pliny, and said to be brought from the East Indies; he describes it as being of a purple or violet colour, but rarely very deep in the tinge. It seems to have been a species of amethyst.

Jon of Chios, in *Biography*, a tragic and lyric poet and philosopher, who first recited his poems in the 82d Olympiad, 452 years B. C., mentions in some verses quoted by Euclid, the ten-stringed lyre, *ἑξήχρονον*; a proof that the conjoint tetrachord was added to the scale in his time, which was about fifty years after Pythagoras is supposed to have constructed the octachord. Jon died, according to Fabricius, vol. i. p. 681. 419 B. C., and 78 years after Pythagoras. Besides tragedies and dithyrambs, Jon composed odes, means, hymns, and scolia, or convivial songs.

IONA, I, HII, or I-Colum-kil, in *Geography*, one of the western islands of Scotland, in the Atlantic ocean, is separated from the western point of Mull by a narrow channel, called the found of I. It measures about three miles in length, by three quarters of a mile in breadth. It is a place of much note in the early annals of the country, as the retreat of learning, during the age of barbarism and illiteracy which pervaded Europe after the overthrow of the Roman empire. Dr Johnson calls this place "the luminary of the Caledonian regions, whence savage clans and roving barbarians derived the benefits of knowledge, and the blessings of religion." The monkish writers called this island Iona, which signifies the island of waves; Bede calls it Hii; but the proper name is I, (founded like the English *ee*.) which in the Gaelic signifies island, this being called to by way of eminence. In more modern times, this insular district obtained the name of I-Colum-kil, that is, the island of Columb's-cell. The name Iona is now diffused, and the island is generally called I, except when the speaker would wish to mark it with peculiar emphasis, and then it is expressed I-Colum-kil. The Druids were undoubtedly in possession of this island prior to the introduction of Christianity; a green eminence, close to the found of I, is to this day called the Druid's burial place; and here are still extant the remains of a small Druidical temple, or circular row of upright stones, in a farm called Rossal, where, as the name imports, the courts of justice were held. The island seems to have been early the seat of a religious society of Christians, or order of monks, named Culdees, who settled here about the beginning of the sixth century. The foundation of a circular building or house, called the Culdees cell, still remains. The history of the Druids in this island is wholly

unknown; but that of the Culdees has been amply and learnedly narrated by Dr Jamieson, in a quarto volume, published in 1811. It was referred for Columba to raise the fame of the island to the great height it attained to in his own and after ages. This eminent man left his native country, Ireland, in the year 563, to preach the gospel to the Northern Picts; and having converted the Pictish monarch, obtained from him the grant of this sequestered isle, where he founded an abbey for canons regular. Having successfully presided here upwards of thirty years, he died June 9th, 597; leaving his abbey firmly settled, a people converted by his labours from Paganism to Christianity, and a name renowned for sanctity, piety, and "good works." The abbey acquired very extensive jurisdictions; held, for many ages, the chief sway among the Scottish and Pictish monasteries; and was liberally endowed by the piety and munificence of the kings and great men of Scotland. The Danes dislodged the monks in 807, and the abbey remained for several years depopulated; but on the retreat of the invaders, it received a new order of inhabitants, the Cluniacs, who continued to occupy it till the dissolution of monastic institutions, when the revenues were united to the see of Argyle; and, on the abolition of episcopacy, became the property of the duke of Argyle. The remains of the abbey, and its appendages, though much dilapidated, are, by the care and attention of the Argyle family, kept in better preservation than most ruins of the kind in Scotland. The late dukes built a wall round the whole abbey, to prevent further depredations; and prohibited their tenants from removing any fallen stones. Time has levelled some of the buildings with the ground; but the greater part is still standing. The cathedral, or St. Mary's church, is almost entire: it is built in the form of a cross, 115 feet in length, and 23 in width; the length of the transept 70 feet. In the church-yard is a cross of a single piece of red granite, 14 feet high, 22 broad, and 10 inches thick. St. Oran's chaire, said to be the first building begun by Columba, is still standing, but in a ruinous condition. The Virgin's chapel was entire till within a few years, when part of it fell. Most of the cloisters and the bishop's house are also standing. There is still remaining of the abbey, sufficient to give a tolerable idea of what it was. Of the nunnery, an establishment nearly coeval with the abbey, there are fewer remains; the church belonging to it is deprived of the roof. Here also stands what was called the parish church, yet entire, but verging to decay. Near the chapel of St. Oran is a large enclosure, called the "burying-place of Oran," in which are deposited the remains of forty-eight Scottish kings, four kings of Ireland, eight Norwegian monarchs, and one king of France, who were ambitious of reposing in this hallowed ground. In the same sanctuary, at a respectful distance, lie most of the lords of the isle.

The island of U is included in the united parishes of Kilfichen and Kilviceuen. It abounds with many valuable minerals. Here is but one small village, containing about 60 houses and 350 inhabitants. The parish minister of Kilviceuen visits this island every quarter of a year, which is the only opportunity of public worship and religious instruction which the people now enjoy. Strange reverie! that divine service should be performed but four times in the year, in a place where it was formerly celebrated as many times in a day. Snelcar's Statistical Account of Scotland, vol. xiv. Pennant's Tour in Scotland. Johnson's Journey to the Western Islands. Chalmers's Caledonia. Jamieson's Historical Account of the ancient Culdees, &c. 4to. 1811.

IONA, a town of Hindoostan, in the country of Delhi; 25 miles S. of Delhi.

JONÆ Pisces, the *Jonas-fish*, a name given by many authors to the common shark, the *canis carcharias* of authors.

It has this name from an opinion that it was the fish which swallowed up the prophet of that name. But there are many objections to such an opinion.

JONAH, or the *Prophecy of Jonah*, who was the son of Amittai, and a native of Gathhepher, a town belonging to the tribe of Zebulun, in Lower Galilee, a canonical book of the Old Testament, in which it is related, that Jonah was ordered to go and prophesy the destruction of the Ninevites; but that disobediently attempting a voyage another way, he was discovered by the rising of a sudden tempest, and cast into the sea, where he was swallowed up by a large fish. Having lodged three days and three nights in the belly of the fish, he was disgorged upon the shore: whereupon, being sensible of his pait danger, and surprizing deliverance, he betook himself to the journey and embassy to which he was appointed. Arriving at Nineveh, the metropolis of Assyria, he, according to his commission, boldly laid open to the inhabitants their sins and miscarriages, and proclaimed their sudden overthrow; upon which the whole city, by prayer and fasting, and a speedy repentance, happily averted the divine vengeance, and escaped the threatened ruin. Jonah, instead of admiring the divine clemency, was indignant under the apprehension that his veracity would be suspected, and that he would be deemed by the people to be a false prophet. Having retired from the city, he prepared for himself a booth, over which a plant sprang up miraculously in one night, which, by its spreading foliage, sheltered him from the burning heat of the sun. But the plant suddenly withering away, so that he was exposed to a suffocating wind and the sun's scorching beams, he again expressed his impatience, and his wish to die rather than to live in such circumstances of distress. At length, having been reprieved for his impatient, querulous temper, and the conduct of Providence in sparing the Ninevites having been justified to his full conviction, his complaints were silenced. Of his further history we have no authentic account. Jonah was the most ancient of all the prophets whose writings are preserved in the Scripture canon. Some have supposed that he prophesied in the latter end of Jehu's, or the beginning of Jehoahaz's reign, at which time the kingdom of Israel was brought very low by the oppressions of Hazael king of Syria. (2 Kings, xii. 22.) Others refer his predictions to the reign of Jeroboam II. king of Israel, or between the years 823 and 783 B.C. 2 Kings, xiv. 25. Newcome's Verion and Notes.

JONDAL, in *Geography*, a town of Norway, in the the diocese of Bergen; 30 miles E. of Bergen.

JONDISABUR, a town of Persia, in the province of Chufistan; 185 miles E.S.E. of Bagdad.

JONEIKISCHKEN, a town of Pruffian Lithuania; 36 miles W. of Tilit.

JONES, in *Biography*, a Welshman who was blind, and the best performer on the harp of his time. The old duchess of Marlborough would have retained him in her service, with a pension, as an inmate; but he could not endure confinement, and was engaged by Evans, the landlord of a well-acquainted home-brewed ale-house, at the Hercules' Pillars, opposite Clifford's Inn passage in Fleet-street, where he performed in a great room up stairs during the winter season. He played extempore voluntaries, the fugues in the sonatas and concertos of Corelli, and most of his solos, with many of Handel's opera songs, with uncommon neatness, which were thought great feats, at a time when scarcely any thing but Welsh tunes with variations was ever at-

tempted on that instrument in the hands of other harpers. He also played on the violin, and accurately imitated on that instrument, to the great delight of the home-brewed ale-drinkers, the fobs, sighs, and groans of a Quaker's fervor.

Evans dying, his widow took Cuper's Gardens in Surrey, opposite to Somerset-house; erected an orchestra there, which was reckoned the best for music in the kingdom; furnished it with an organ, which was played by little Harry Burgess, the harpichord-player at Drury-lane, with his usual unmeaning neatness; and established the Gardens as an evening place of entertainment for the summer season, like Vauxhall, with the addition of fire-works. But it was too much in the vicinity of Drury-lane and Covent-garden for order and decorum to be long preserved inviolate; so that after four or five summers, it was suppressed by the magistrates; and poor Jones, who had been admitted as a performer in the orchestra by mother Evans, (as she was usually called), losing both his salary and importance, died about the year 1748. He was buried in Lambeth church-yard, and his funeral procession, attended by a great number of musical people, was solemnized by the performance of a dead march by a voluntary band of innumerable instruments.

JONES, JOHN, late organist of St. Paul's, the Charter-house, and joint organist of the Temple with Stanley. The father of this musician, a worthy man of professional merit and good conduct, having lived many years at lady Vanbrugh's, Whitehall, as a domestic musician, prevailed on her ladyship to patronize his son; which she did so effectually, that though his abilities as a performer or composer were not above mediocrity, nor were his person or manners very captivating, yet, by the zeal and influence of his father's patroness, he obtained three places, which are regarded by musicians as the polls of honour in London, and more desirable, if the king's chapel be excepted, than any at which an organist can aspire.

JONES, JOHN, a physician of the 16th century, and author of several works, but of whose history little more is known than that he was born in Wales, or as of Welsh extraction; that he studied at both our universities, and took a medical degree at Cambridge; and that he became eminent in the practice of his profession at Bath, and in Nottinghamshire and Derbyshire. He mentions curing a person at Louth in 1562; and the date of his last publication is 1579. He wrote only in the English language, and left the following works: 1. "The Dial of Agues," Lond. 1556; 2. "The Benefit of the ancient Baths of Buckstone, which cureth most grievous Sickenesses," ibid. 1572. This work contains very little concerning either the nature or history of these baths; but chiefly general directions, compiled from ancient authors, relative to the diet and regimen proper to be used with a course of bathing; 3. "The Baths of Bath's ayde, wonderful and most excellent against very many Sickneses," ibid. 1572; 4. "A brief, excellent, and profitable Discourse of the natural Beginning of all growing and living Things, Heat, Generation, &c.," Lond. 1574; 5. "A Translation, from Latin into English, of Galen's four Books of Elements," ib. 1574. Dr. Aikin puts the following *quære*, after mentioning this work: "Is not this the same with the preceding piece?" 6. "The Art and Science of preserving Body and Soul in Health, Wisdom, and Catholic Religion," 1579, 4to. See Aikin, Biog. Mem. of Med.

Another physician, of the name of JOHN JONES, is mentioned by bibliographers, who was born at Landaff, and was admitted a member of the Royal College of Physicians, in

in London, near the end of the 17th century, and was author of the following publications: 1. "Novarum Dissertationum de morbis abstrusioribus Tractatus primus, de Febribus intermittentibus. In quo obiter de Febri continue natura explicatur," Lond. 1683; 2. "De morbis Hibernorum et de Dyfenteria Hibernica," ib. 1698; 3. "The Myfteries of Opium revealed," ib. 1701. Eloy. Diſt. Hiſt.

JONES, INIGO, an eminent architect, was born in London about the year 1572. He was probably intended for a mechanical employment, but his talent for the fine arts attracted the notice of ſome conſiderable perſons about the court, among whom were the earls of Arundel and Pembroke. To the latter of theſe noblemen he was indebted for that degree of patronage which enabled him to viſit Italy for the purpoſe of perfecting himſelf in landſcape-painting, to which his genius ſeemed firſt to point. He took up his reſidence chiefly at Venice, where it is ſaid the works of Palladio gave him a turn to the ſtudy of architecture, which branch of art he made his profeſſion. He was invited by Chriſtian IV. king of Denmark, to undertake the office of his firſt architect. Having been ſome years in the ſervice of that ſovereign, he accompanied him, in 1606, on a viſit to his brother-in-law, king James; and, expreſſing a deſire of remaining in his native country, he was appointed architect to the queen. He ſerved prince Henry in the ſame capacity, and obtained a grant, in reſervation, of the place of ſurveyor-general of the works. After the death of the prince, Mr. Jones viſited Italy again, and ſpent ſome years there in improving himſelf in his art. On his return he undertook the duties of the office of ſurveyor-general, and finding the Board of Works much in debt, he relinquished his own dues, and prevailed upon the other principal officers to do the ſame, till all arrears were cleared. In 1620 the king ſent him to inveſtigate the nature and purpoſe of that remarkable antiquity, Stonehenge; and he wrote a treatiſe to prove that it was the work of the Romans, but he made no converts to this opinion. He was now employed in building the banquetting-houſe at Whitehall, which remains a model of the pure and elegant taſte of the architect. He was likewiſe appointed a commiſſioner for repairing the cathedral of St. Paul's, which office, as well as his other poſts, was continued to him under the reign of Charles I. The repairs of St. Paul's did not commence till 1633; and he is accuſed of having committed, in that undertaking, ſome capital faults by mixing the Roman and Grecian ſtyle with the Gothic. He had much employment both from the court and nobility, and realized a handſome ſum, which was diminiſhed by his ſufferings during the troubles which ſucceeded. He was obnoxious as a favourite of his royal maſter, and as a Roman Catholic. He was firſt attacked in 1640, when he was called before the houſe of lords, on a complaint of the pariſhioners of St. Gregory's, for demolishing part of their church, in order to make room for his additions to St. Paul's. He was fined, in 1646, 545*l.* as a malignant. He was much afflicted by the king's death, and died, worn down by grief and miſfortune, in July 1651. He was the greateſt Engliſh architect previous to ſir Chriſtopher Wren. A collection of his deſigns was engraved and publiſhed by Mr. Kent, in two volumes folio, 1727. Others were publiſhed in 1743 and 1744. A copy of Palladio's architecture, with manuſcript notes by Mr. Jones, is in the library of Worceſter college, Oxford. Biog. Brit.

JONES, WILLIAM, father of ſir William, the ſubject of the next article, was born in the year 1680, in the iſland of Angleſey, North Wales. His parents were yeomen, or
VOL. XIX.

little farmers, in that iſland, and gave to their ſon the beſt education which their circumſtances would allow; but he owed his future fame and fortune to the diligent cultivation of the intellectual powers by which he was eminently diſtinguiſhed. Addicted from early life to the ſtudy of mathematics, he commenced his career of advancement in the humble office of a teacher of theſe ſciences on board a man of war. In this ſituation he attracted the notice, and obtained the friendſhip of lord Anſon. He appeared as an author in his 22d year; when his treatiſe on the art of navigation was much approved. We may judge of his predominant taſte for literature and ſcience by a trivial circumſtance which occurred at the capture of Vigo, in 1702. Having joined his comrades in pillaging the town, he ſelected a bookſeller's ſhop, in hope of obtaining ſome valuable plunder; but, diſappointed in his expectations, he took up a pair of ſciſſors, which was his only booty, and which he afterwards exhibited to his friends as a trophy of his military ſucceſs. On his return to England, he eſtabliſhed himſelf as a teacher of mathematics in London; and here, at the age of 26 years, he publiſhed his "Synopſis Palmariorum Matheſeos;" a work which has ever ſince been held in the higheſt eſtimation as a compendious but comprehensive ſummary of mathematical ſcience. Mr. Jones was no leſs eſteemed and reſpected on account of his private character and pleaſing manners, than for his natural talents and ſcientific attainments; ſo that he reckoned among his friends the moſt eminent perſons of the period in which he lived. Lord Hardwicke ſelected him as a companion on the circuit, when he was chief juſtice; and when he afterwards held the great ſeal, conferred upon him the office of ſecretary for the peace, as a teſtimony of his friendſhip and regard. He was alſo in habits of intimate acquaintance with lord Parker, preſident of the Royal Society, ſir Iſaac Newton, Halley, Mead, and Samuel Johnſon. So highly was his merit appreciated by ſir Iſaac Newton, that he prepared, with his permiſſion, and very much to his ſatisfaction, a very elegant edition of ſmall tracts in the higher mathematics. Upon the retirement of lord Maccleſfield to Sherborne caſtle, Mr. Jones reſided in his family, and inſtructed his lordſhip in the ſciences. While he occupied this ſituation he had the miſfortune, by the failure of a banker, to loſe the greateſt part of that property which he had accumulated by the moſt laudable induſtry and economy; but the loſs was in a great meaſure repaired to him by the kind attention of his lordſhip, who procured for him a ſecure place of conſiderable emolument. He was afterwards offered, by the ſame nobleman, a more lucrative ſituation; which, however, he declined, that he might be more at leiſure to devote himſelf to his favourite ſcientific purſuits. In this retreat he formed an acquaintance with Miſs Mary Nix, the daughter of a cabinet-maker, who had become eminent in his profeſſion, and whoſe talents and manners had recommended him to an intimacy with lord Maccleſfield. This acquaintance terminated in marriage; and the connection proved a ſource of perſonal ſatisfaction to Mr. Jones himſelf, and of permanent honour to his name and family. By this lady Mr. Jones had three children; two ſons and a daughter. One ſon died in infancy; the other will be the ſubject of the next article; and the daughter, who was married to Mr. Rainſford, an opulent merchant retired from buſineſs, perished miſerably, in the year 1802, in conſequence of her clothes accidentally taking fire. The death of Mr. Jones was occaſioned by a polypus in the heart, which, notwithstanding the medical attention and aſſiſtance of Dr. Mead, proved incurable. Of the ſingular ſelf-poſſeſſion and promptitude of Mrs. Jones, the following anecdote is related. A friend,
3 A who

who knew her husband's dangerous situation, addressed him with a letter of condolence, recommending acquiescence and resignation from a due consideration of the brevity of life. Mrs. Jones, perceiving its purport, and probably dreading its effects on the spirits of her husband, when she was desired by him to read it, composed, at the moment another letter to clearly and to rapidly, that he had no suspicion of the direction; and this she executed in a style of cheerful and entertaining, that, instead of being depressed, he was greatly exhilarated by it. His disorder lengthened out to his death, which happened soon after the incident we have related, in July 1749. The property of which he had possessed was moderate; but his reputation was universally acknowledged. After his death, the widow was favoured with many offers of service by those who respected her deceased husband; and she was under peculiar obligations to Mr. Baker, author of a treatise on the microscope, &c. for assistance in arranging the collection of shells, fossils, and other curiosities left by Mr. Jones, and disposing of them to the great advantage. His library was bequeathed to Lord Macclesfield. It has been said by the compilers of the Biographical Dictionary, that Mr. Jones had completed a very important mathematical work, and had actually sent the first sheet to the press, but that the progress of his disorder obliged him to discontinue the impression. It is now her faith that the MS. fairly transcribed, was circulated a few days before he died, to the care of Lord Macclesfield, who promised to publish it for the honour of the author, and the benefit of his family. If this account be true, and a work, which was to have been entitled, "The Introduction to the Mathematics," had been actually prepared, the MS. might have been lost, as it could not be found among his books and papers of Lord Macclesfield, who survived his friend many years. Among the memoranda of Sir William Jones, there is no document that serves to confirm or disprove this account. The mathematical works of Mr. Jones, that have been published, are much admired for neatness, brevity, and accuracy; and they afford ample evidence, testified also by his correspondence with Mr. Cotes of Cambridge, that he was a very eminent mathematician. We have already mentioned his "New Compendium of the whole Art of Navigation," 8vo. 1702; and his "Synopsis Palmarum Mathematicarum; or, a new Introduction to the Mathematics, containing the Principles of Arithmetic and Geometry, demonstrated in a short and easy Method," 8vo. 1706. In the Philosophical Transactions, we have several papers on logarithms, on the properties of conic sections, on the disposition of equations for exhibiting the relations of geometrical lines, &c. communicated to the Royal Society, of which he was a member. He was also the editor of some mathematical works of Sir Isaac Newton, under the title of "Analysis per quantum series, fluxus, ac differentias; cum enumeratione linearum tertio ordinis." Memoirs of the Life, Writings, and Correspondence of Sir William Jones, by Lord Teignmouth.

Jones, by Mr. Jones, the loss of the subject of the present article, was attended, by the material side, from some of the most prominent families of North Wales; but his merit being known to the great amount of such was represented and the information of those of letters, mathematics, and astronomy, which raised him to a rank of distinction, and has been attended by the course of a century, and more than a century, and has been the subject of Lord Teignmouth, in an ample and excellent "Memoirs of the Life, Writings, and Correspondence of Sir William Jones." In addition to these, a separate account from well known, we find he was able to give an account of this dis-

tinguished person, which, however imperfect it may be, and however inadequate to our sentiments of personal respect, and feelings of lively gratitude, cannot fail of being interesting to our readers; nor will they need any apology if we exceed our usual limits on this occasion.

Sir William Jones was born in London on the eve of the festival of St. Michael, in the year 1746; but having lost his father when he was three years old, the care of his education devolved upon his mother, who appears to have been eminently qualified to direct and superintend it, more particularly in his infant years. Her character has been delineated by her husband in the following terms: "She was virtuous without bluntness, generous without extravagance, frugal but not niggard, cheerful but not giddy, close but not fallen, ingenious but not conceited, of spirit but not passionate, of her company cautious, in her friendship truly, to her parents dutiful, and to her husband ever faithful, loving and obedient." Mrs. Jones took great pains, by the study of algebra, trigonometry, and navigation, to qualify herself for being the preceptors of her father's son; and to these sciences, rather remote from a lady's province, she paid particular attention, because he was destined to a maritime profession. Her solicitude for the improvement of her own son induced her to decline accepting the kind invitation of the countess of Macclesfield to remain at Sherborne castle, after her husband's death; and her discriminating judgment led her, in her plan for his instruction, to reject the severity of discipline, and to conduct his mind insensibly to knowledge and exertion, by exciting his curiosity and directing it to useful objects. In consequence of her attention, he was, in his fourth year, able to read distinctly and rapidly any English book; and with a view to the cultivation of his memory, she caused him to learn and repeat some of the most popular speeches in Shakspeare, and the best of Gay's fables. His propensity to reading was equally manifested in his fifth year; and in his sixth he was initiated by the assistance of a friend in the rudiments of the Latin grammar. At Michaelmas 1753, in the close of his seventh year, he was placed at Harrow school, of which Dr. Thackeray was the head master. During the two first years of his residence in this seminary, he was distinguished more by diligence than by superiority of talents; but his faculties gained strength by exercise, and the prospect of the eminence to which he afterwards attained gradually brightened. His mother, who anxiously watched over his progress, improved the opportunities which his vacations, and the absence of 12 months from school, in consequence of the fracture of his thigh-bone, afforded, of increasing his acquaintance with his native tongue, and with English authors, and of teaching him also the rudiments of drawing, in which he herself excelled. During this interval, the progress of his classical studies was interrupted. However, on his return to school, he was placed in the class to which he would have attained, if no interruption had occurred. This error of judgment, on the part of his master, though it subjected him to corporal punishment and degradation for non-performance of exercises which should not have been required, and though it produced in his mind an invincible abhorrence of his master's conduct, served to rouse his emulation, and to call forth the exertion of his native powers; so that in a little while he was advanced to the head of his class, and might, if he had been disposed, have retorted on his class-fellow, those former reproaches of his indolence or dilations. In his 12th year, he was removed to the upper school. At this time a circumstance occurred, which afforded signal evidence of the strength and tenaciousness of his memory. His school-fellow proposed

to amuse themselves with the representation of a play; and at his recommendation the *Tempest* was selected; but not being able to procure a copy, he furnished them with it from his memory; and in the exhibition he performed the part of Prospero. As he advanced in the school, his diligence increased; and he commenced the study of the Greek language. At this time he translated into English verse several of the epistles of Ovid, and all the pastoral of Virgil; and he composed a dramatic piece on the story of Melagor, which he denominated a tragedy, and which, during the vacation, was acted by some of his most distinguished school-fellows; the part of the hero being performed by himself. His acquaintance with profody was very diffused; so that he was able to scan the trochaic and iambic verses of Terence, before his companions suspected that they were any thing but mere profod. At school he wrote the exercises of many boys in the two superior classes, and those in his own class were happy to become his pupils. During the holidays he learned the rudiments of French and arithmetic; and in this early age he was highly gratified by being honoured with an admission to the Society of learned and ingenious men at the house of Mr. Baker and his friend Mr. Pond. At the request of his mother he read the "*Spéctacle de la Nature*;" but derived greater amusement, as he acknowledged, from the Arabian tales, and from Shakspeare, whose poems and plays he repeatedly perused with increased delight. At Harrow he invented a political play, in which Dr. Bennet, bishop of Cloyne, and the celebrated Dr. Parr, were his principal associates. "They divided the fields in the neighbourhood of Harrow, according to a map of Greece, into states and kingdoms; each fixed upon one as his dominion, and assumed an ancient name. Some of their school-fellows consented to be styled barbarians, who were to invade their territories and attack their hill-towns, which were denominated fortresses. The chiefs vigorously defended their respective domains against the incursions of the enemy; and in these imitative wars the young statesmen held councils, made vehement harangues, and composed memorials, all doubtless very boyish, but calculated to fill their minds with ideas of legislation and civil government. In these unusual amusements Jones was ever the leader." In his 15th year Dr. Thackeray was succeeded by Dr. Sumner, who soon discovered the talents and acquisitions of his pupil; and who afforded him every advantage in the prosecution of his studies which he had it in his power to grant him. Indeed this excellent instructor of youth, with an excusable partiality and an amiable modesty, was heard to declare, "that Jones knew more Greek than himself, and was a greater proficient in the idiom of that language." During the two years which he spent with Dr. Sumner, he employed his time in reading and imitating the best ancient authors of Greece and Rome; and, devoting the night as well as the day to study, he acquired the knowledge of the Arabic characters, and a sufficient acquaintance with the Hebrew language to enable him to read some of the Psalms in the original. His reputation was at this early period of his life so extensive, "that he was often flattered by the inquiries of strangers, under the title of great scholar. Some of his juvenile compositions, both in profod and vers, may be found in the fragment of a work which he began at school, and entitled "*Limn*," in imitation of Cicero, and may be found in the complete edition of his works. His incessant application occasioned a weakness in his sight, which rendered it necessary for Dr. Sumner to interdict it during the last months of his residence at Harrow. The intervals of interrupted study, which he reluctantly allowed himself, were employed in learning chiefs, by practising

the games of Philidor. As he was intended for the profession of the law, for which, however, he does not seem to have had any great predilection, some of his friends recommended his being placed, at the age of 16, in the office of a special pleader; others, however, wished him to be removed from Harrow to one of the universities. The choice of an university was for some time the subject of deliberation; but at length Oxford was preferred in consequence of the recommendation of Dr. Glaff, and the inclination of his mother, who was desirous to relate with him at the university. In the summer of 1764 he was not indeed admitted into University college; and in the following term, after having passed a few months at Harrow, in order to finish a course of lessons in which he was much interested, he fixed himself at Oxford. Upon his first settlement in the university he was rather disappointed and displeas'd with the plan of education. "I had of great principles on the subjects of metaphysics, history, and practical morals, he complained that he was required to attend dull comments on Aristotle's ethics, and logic couled in such barbarous Latin, that he profess'd to know as little of it as he then knew of Arabic." The only topic then in fashion was that of the faculty; and in a memorandum written by himself, which," says his biographer, lord Prigmouth, "as my authority for these remarks, I find an anecdote related of one of the fellows, who was reading Locke with his own pupils, that he carefully pass'd over every passage in which that great metaphysician discusses the old system." After a residence of a few months at the university, on the 31st of October, 1764, Mr. Jones was unanimously elected one of the four fellows on the foundation of sir Simon Bennet, for which assistance he was grateful; more especially as the prospect of a fellowship was remote. Added to oriental literature for several years, he now indulg'd his inclination by the study of Arabic under the example and encouragement of a fellow student, and with the assistance of a native of Aleppo. His situation at the university became gradually more pleasant to him than it was at first; for his college tutors, perceiving that his whole time was devoted to improvement, dispensed with his attendance on their lectures, and even allowed him to pursue his studies in a manner agreeable to his taste and inclination. To the perusal of the principal Greek poets and historians, and of the entire works of Plato and Lucan, he added the study of the Arabic and also of the modern Persian languages. During his vacations, which he spent in London, he attended the schools of Angelo, in order to acquire the elegant accomplishments of riding and fencing; and at home he directed his attention to the modern languages; reading the best authors in Italian, Spanish, and Portuguese. The prospect of a fellowship, which he was anxious of obtaining, partly for relieving his mother from the burden of his education, and partly for securing some kind of independence, however inconsiderable to himself, was still at a distance; and he had almost despair'd of obtaining it. Having been recommended to the family of earl Spencer by Dr. Stopley, to whom he was not perfectly known, but who was not unacquainted with his compositions at Harrow, an offer was made to him by Mr. Arden, related by marriage, to his friend Sumner, of being private tutor to lord Althorpe, now earl Spencer. The proposal was cheerfully accepted, and upon an interview with his pupil, then seven years of age, he was so pleas'd, that he determin'd to give up all thoughts of a profession, and to devote himself to the faithful discharge of the duties of education now devolved upon him. In the summer of 1765, he wholly left the university, and entered on his new office. At Wimbledon,

where he resided till the approach of winter, he found leisure to compose many of his English poems, and to read the greatest part of the Old Testament in Hebrew, particularly the book of Job, and the Prophets, which he studied with great attention. In the following summer a fellowship became vacant, and he was elected to it Aug. 7, 1766. At this time he was offered by the duke of Grafton, then at the head of the treasury, the place of interpreter for Eastern languages, which he politely declined, apprehending that it would be inconsistent with his other engagements and pursuits. In the course of this summer he formed an acquaintance with a young lady, Anna Maria, the eldest daughter of Dr. Shipley, then dean of Winchester, who was visiting at Wimbledon, to which he owed the happiness of his future life. But such were his views of an honourable independence, and his resolution never to owe his fortune to a wife, or her kindred, that, notwithstanding the impressions made upon his heart by the person and conversation of this lady, he could not then admit any idea of a matrimonial connection. In the following winter he attended the two schools of Angelo, and by a secret arrangement with Gallini, acquired the accomplishment of dancing. Having occasion to accompany Lord Spencer's family to Spa in the summer of 1767, he improved himself, during the short period of three weeks' residence in this place, in the art of dancing, by the lessons of Janouf of Aix-la-Chapelle, and acquired a very considerable knowledge of the German language. In the year 1768 application was made to Mr. Jones by the secretary of state, on behalf of the king of Denmark, then in England, requesting him to give a literal translation of the life of Nadir Shah in the French language. Having for some time declined the proposal, he at length accepted it; and the translation was published, after some delay, in the year 1770. To the history of Nadir Shah, he added a treatise on Oriental Poetry, which treatise, executed by a young man in his 23d year, has been justly considered as an extraordinary performance; "instructive and elegant, interesting from its novelty, entertaining from its subject and variety, and exhibiting the combined powers of taste and erudition." Being at Tunbridge in 1768, he then began to learn music, and afterwards received lessons from Evans on the Welsh harp. We may here mention his attendance on a course of anatomical lectures by the celebrated Hunter, and his study of the mathematics, which he so well understood, as to be able to read and understand Newton's Principia.

In the beginning of this year he had commenced an acquaintance with Reviczki, afterwards the imperial minister at Warsaw, and ambassador at the court of England, with the title of count. This accomplished nobleman being captivated by the charms of oriental literature, cultivated an intimacy with Mr. Jones, which was continued by a correspondence, that was carried on for many years. Many of the letters that passed between them on their favourite subject are published in the life by Lord Teignmouth. In the summer of 1769, Mr. Jones attended his pupil at Harrow; and it was with peculiar satisfaction that he renewed that intercourse with Dr. Smuer, which had been for some time interrupted, though not altogether discontinued. Here he translated a Persian grammar, which three years before he had composed for a school-fellow, who was destined for India; he also began a dictionary of the Persian language.

Of the religious principles of Mr. Jones some account may be reasonably expected. While he was at Harrow, in his 24th year, we have reason to believe that his faith in Christianity was not unblended with doubts. Indeed no particular attention seems to have been paid to this part of his education; a circumstance which, we confess, appears to us

surprising, and for which we are unable to account. His mind, however, was so upright and so well disposed, that he expressed his doubts, not in the too fashionable mode of conceited cavilling, but with a sincere desire of obtaining a solution of them. Finding himself disappointed, he determined to examine the subject for himself, and to peruse the whole scripture in the original, that he might be enabled to form a correct judgment of the connection between the two parts, and of their evidence both internal and external. The result was a firm belief in the authenticity and inspiration of the sacred writings. About this time he drew up a series of propositions, which have been found in his own hand-writing in a Hebrew copy of the book of Hosea, and which contain the sketch of a demonstration of the divine authority of the Christian religion. To these propositions, transcribed by his biographer, the following note is subjoined: "what must be the importance of a book," of which it may be truly said, "if this book be not true, the religion which we profess is false?"

Towards the end of the year 1766, Mr. Jones accompanied Lord Spencer's family to the continent. Soon after his return he adopted the resolution of altering his plan of life. The course which he was pursuing, however agreeable it was rendered to him by the family with which he was connected, did not exactly correspond to that idea and spirit of independence which marked his character. "He united the laudable desire of acquiring public distinction and of making his fortune by his own efforts; above all, he was animated with the noble ambition of being useful to his country;" accordingly he determined to devote himself to the study and practice of the law; and with this view he was admitted into the Temple on the 19th of September 1770. His attachment to Oriental literature and to general science, however, continued unabated, notwithstanding the time and attention which he devoted to his new profession. In 1772 he published a small volume of poems, consisting chiefly of translations from the Asiatic languages, with two profuse dissertations annexed: and though he does not appear to have communicated any paper for the Philosophical Transactions, he was, on the 30th of April 1772, elected a fellow of the Royal Society. On occasion of taking his Master's degree in the university in 1773, he composed an oration, intending to have spoken it in the theatre. The speech was published 10 years after, and the topics that characterize it are, "an ardent love of liberty, an enthusiastic veneration for the university, a warm and discriminate eulogium on learned men, who devoted their talents and labours to the cause of religion, science, and freedom." In the commencement of 1774, he published his commentaries on Asiatic poetry, a work begun in 1766, and finished in 1769, when he was in his 23d year, which "was received with admiration and applause by the oriental scholars of Europe in general, as well as by the learned of his own country." To these commentaries is annexed an elegant address to the Muse, in which Mr. Jones declares his purpose of renouncing polite literature, and devoting himself altogether to the study of the law. In January 1774 he was called to the bar; and for some years he seems to have inflexibly adhered to the above-mentioned resolutions. For some time he declined practice, and sedulously applied himself to his legal studies. In 1775, for the first time, he attended the spring circuit and sessions at Oxford; perhaps more as a spectator than an actor; and in the following year he was regular in his attendance at Westminster-hall. In 1778 he published a translation of the speeches of Hæmus, in causes concerning the law of succession to property at Athens, with a prefatory discourse, notes critical and historical, and a commentary. The year

1784 forms an interesting era in the memoirs of Mr. Jones. His professional practice had increased, and afforded a prospect of farther enlargement with augmented profit; but as his views were particularly directed to the vacant seat on the bench of Fort William in Bengal, and as lord North had encouraged his expectation of occupying it, he was less anxious about the augmentation of business in his legal profession. In this state of suspense, the political events of the times engaged his attention. To the American war, in its commencement and further progress, he was decidedly adverse. At this time the reflections which he indulged dictated a very animated and classical ode to Liberty, which he composed in Latin, and published under the title of "Julii Melegoni ad Libertatem," the assumed name being formed by a transposition of the letters of Gulielmus Jonesius. This ode strongly displays his genius, erudition, feelings, and political principles. The vacancy of a seat in parliament for the university of Oxford being likely to occur, Mr. Jones was encouraged by his friends to offer himself as a candidate; but though he was ambitious of this honour, the disappointment gave him no great concern. Although this contested election occupied a considerable portion of his thoughts and time, he found leisure to publish a small pamphlet, entitled "An Inquiry into the legal Mode of suppressing Riots, with a constitutional Plan of future Defence." In a speech, eminently characteristic of his principles and feelings, which he intended to have delivered at a meeting of the freeholders of Middlesex, assembled Sept. 9th of this year, for nominating two representatives in the new parliament, he reprobated the American war and the conduct of the late parliament in supporting it: he expressed his sentiments without reserve on the African slave trade, and avowed the conduct which he would have pursued, if he had been placed in the house of commons. In the course of this year, the death of his mother, to whom he was attached by every possible tie of nature, affection, and gratitude, involved him in the deepest affliction. In this and the following year he was diligently employed in his professional studies and practice, whilst literature and politics also engaged a degree of his attention; but the principal object of his ambition and hopes was the vacant seat on the bench in India. Whatever was connected with this object interested his thoughts; and hence he was led to undertake the translation of an Arabian poem on the Mohammedan law of succession to the property of intestates. In the year 1782 the public attention was much occupied with attempts to procure, by constitutional means, a reformation of parliament. This was a business congenial to Mr. Jones's sentiments and feelings; and he concurred in the public efforts for this purpose, both by speaking and writing. About this time he published his "Essay on the Law of Bailments;" and in the same year, 1782, he became a member of the Society for Constitutional Information. In his letter of acknowledgment for being elected into this society, he professes his attachment to the excellent constitution of his country; and then adds, "on the people depend the welfare, the security, and the permanence of every legal government; in the people must reside all substantial power; and to the people must all those, in whose ability and knowledge we sometimes wisely, often imprudently, confide, be always accountable for the due exercise of that power with which they are for a time entrusted." Whilst he was at Paris, in the year 1782, he wrote a little "jeu d'esprit," as he calls it; and of which he says, in a letter to lord Althorp, "it was printed here by a society, who, if they will steer clear of party, will do more good to Britain, than all the philosophers and antiquaries of Somerset house. But to speak the truth, I greatly doubt, whether they, or any other man in this country, can do it

substantial good. The nation, as Demosthenes says, will be fed like a consumptive patient, with chicken broth and panada, which will neither suffer him to expire, nor keep him wholly alive." This "jeu d'esprit" was a "Dialogue of Government." After a bill of indictment had been found against the dean of St. Asaph, for the publication of the edition, which was printed in Wales, sir William Jones sent a letter to lord Kenyon, then chief-justice of Chester, in which he avowed himself to be the author of the dialogue, and maintained that every position in it was strictly conformable to the laws and constitution of England. In the beginning of 1783, Mr. Jones published his translation of the seven Arabian poems, which he had finished in 1781. The most interesting period of Mr. Jones's life was now approaching; for in March 1783, by the active friendship of lord Ashburton, and under the administration of lord Shelburne, he was appointed a judge of the supreme court of judicature at Fort William in Bengal, on which occasion he received the honour of knighthood; and in the April following, he married Anna Maria Shipley, the eldest daughter of the bishop of St. Asaph, a lady to whom he had been long attached, who deserved his most affectionate esteem, who contributed in a very high degree to his domestic happiness, and who lamented his death with a most pungent and permanent grief. To the publications of sir William Jones, which we have already noticed, we shall here add an abridged history of the life of Nadir Shah, in English, and a history of the Persian language, intended to be prefixed to the first edition of his Persian grammar.

Sir William Jones embarked for India in the Crocodile frigate, and in April 1783 left his native country. He was now in his 37th year, with his faculties in full vigour, in possession of the appointment to which his views had been long directed, indulging the expectation of acquiring an ample independence, and having no reason to apprehend that the climate of India would be hostile to his constitution. He could not be sorry to abandon the political discussions, that divided his friends and alienated them from one another; and which must have produced mutual rancours and reserve between him and those to whom he was in other respects attached; and which served to agitate the whole country. He had with him a companion and friend, from whose society he could not but derive the greatest satisfaction and comfort, which kindred minds and united hearts are capable of receiving and communicating. In such society, and with ample resources in his own mind, a kind of temporary banishment from his country would be tolerable, the long voyage would not be tedious and uninteresting, and a settlement for important and beneficial purposes in a foreign land would be regarded without anxiety and aversion. In September 1783 he landed safely at Calcutta, and was received with cordial congratulations by those who were chiefly interested in his arrival. In the following December he entered upon his judicial functions, and at the opening of the sessions, delivered to the grand jury his first charge, which was concise, elegant, appropriate, and conciliatory. Scientific objects, during the intervals of professional duties, engaged his attention; and in order to combine the efforts of many in useful pursuits, he devised the institution of a society in Calcutta, similar in its plan and objects to those that have been established in the principal cities of Europe. See SOCIETY.

In the year succeeding that of his arrival, sir William Jones was attacked with a disorder which exhausted his strength, and threatened his valuable life. As soon, however, as he was able to undertake it, he projected a journey to Benares,

principally with a view of opening sources of useful information. He proceeded by way of Moorshedabad, Jmpeore, Bhagilpoor, and Patna, to Benares. In the course of this journey his disorder once and again returned upon him, and seemed to excite in his mind an apprehension of its fatal termination. That this was the case we learn from a prayer which he composed on this occasion, and which is as follows :

“ O thou bellower of all good ! if it please thee to continue my easy talks in this line, grant me strength to perform them as a faithful servant ; but if thy wisdom hath willed to end them by this thy visitation, admit me, not weighing my unworthiness, but through thy mercy declared in Christ, into thy heavenly mansions, that I may continually advance in happiness, by advancing in true knowledge and awful love of thee, thy will be done !”

After a short residence at Benares, he returned by the Ganges to Bhagilpoor ; and in his journey from hence to Calcutta, he visited Gour, once the residence of the forefathers of Bengal. In a letter written to a friend after his return, he says, “ As we approached Calcutta we perceived the difference of climate, and thought of Bhagilpoor with pleasure and regret.” “ I am just returned,” says he, in another letter, “ as it were from the brink of another world, having been absent near seven months ; and reduced to a skeleton by fevers of every denomination, with an obdurate bilious flux at their heels. My health is tolerably restored by a long ramble through South Bahar, and the district of Benares.” During this tour he wrote two tracts ; one a little tale in verse, under the title of “ The Enchanted Maid,” or “ Hindu Wife ;” and the other, “ A Treatise on the Gods of Greece, Italy, and India,” afterwards presented to the Society, and published in the Asiatic Researches. The design of this work is to evince a resemblance, too strong to have been accidental, between the popular worship of the old Greeks and Italians, and that of the Hindus, and between their strange religion and that of Egypt, China, Persia, Phrygia, Pizenicia, and Syria, and even remoter nations. This resemblance, if it were established, would authorize, as Sir William Jones conceives, an inference of a general union and affinity between the most distinguished inhabitants of the primitive world, at the time when they deviated, as they did too early deviate, from the rational adoration of the only true God. Sir William Jones, with his restored health, renewed his functions in the supreme court of judicature, and renewed the meetings of the society, interrupted by his absence. The society of Sir William Jones was so much valued and sought for, and he was subject to so many intrusions, that, for the sake of enjoying the benefit of air and exercise, and of pursuing his literary pursuits without interruption, he made choice of a residence at Cishnagar, where the soil is sandy, and the air pure. To the Asiatic Miscellany, a periodical work undertaken at Calcutta in 1785, but afterwards discontinued with the Asiatic society, Sir W. Jones contributed occasional compositions. Sir William, having been proposed making an excursion to Chatigan, the eastern part of the British dominions in Bengal, executed his design after the recess of the court in the beginning of 1786, and repaired thither by sea. During his short residence at Chatigan, he found leisure, amidst other occupations, to peruse the heroic poem of Firdusi, the Homer of Persia, supposed to contain 60,000 couplets. But the work to which his principal attention and labour were directed, was a translation of the Hindu and Mohammedan laws. Accordingly, in one of his letters, he says, “ Sanscrit and Arabic will enable me to do this country more essentially service, than the introduction of arts, (even if I should be able to introduce them,) by procuring an accurate digest of Hindu and Mo-

hammedan laws, which the natives hold sacred, and by which both justice and policy require that they should be governed.” Accordingly, he addressed a letter to the governor-general, Lord Cornwallis, on this subject. The marquis Cornwallis considered the accomplishment of the proposed plan, as calculated to reflect the highest honour on his administration. With this sanction Sir W. Jones set on foot the execution of the work ; and having carefully selected, from the most learned Hindu and Mohammedan, a sufficient number of persons fully qualified for the task of compilation, he traced the plan of the digest, provided its arrangement, and pointed out the MSS. from which it was to be formed. Although it is much to be regretted that Sir W. Jones did not live to translate the digest of Hindu law, to the compilation of which he had devoted so much attention and labour ; yet it is satisfactory to know, that his benevolent intentions have not been disappointed, and that Mr. H. T. Colbrooke, in the civil service of the East India company at Bengal, from motives of public spirit, and a laudable hope of distinction, has completed a translation of it with an ability which does him the highest credit. Sir W. Jones suggested an improvement in the police at Calcutta, so as to render it more efficient, and more conformable to the British constitution. His suggestions were adopted in an application to parliament, and confirmed by its sanction. The application of Sir W. was incessant ; and after what he calls his “ seasoning,” the state of his health allowed his devoting seven hours a day for four or five months in the year to professional engagements, and unremitting attention, during the vacations, to a complete knowledge of India, which was to be obtained only in the country itself, where it was his intention not to prolong his stay beyond the last year of the eighteenth century. Among other literary occupations which engaged his attention, he undertook the charge of editing the elegant poem of Hateti, on the unfortunate loves of Laili and Majnun, an Arabian youth and princess. He published the book at his own expence, and appropriated the profits of the sale to the relief of insolvent debtors in the gaol at Calcutta. The business that was devolved upon him as president of the society at Calcutta, and in consequence of preparing the various excellent papers which he contributed to it, will be more particularly noticed in our account of that society. In the year 1789, Sir William presented to the public a translation of an ancient Indian drama, entitled “ Sacontala,” or the “ Fatal Ring,” exhibiting a very pleasing and authentic picture of old Hindu manners, and one of the greatest curiosities that the literature of Asia had yet brought to light. Calidas, the author of it, called by Sir W. the Shakespeare of India, lived in the first century B. C., and wrote several other dramas and poetical pieces. The principal sources of amusement of which Sir W. availed himself, was the conversation of the Pundits, with whom he talked freely, in the language of the gods (Sanskrit), and botany, in which latter study, if it may be so called, he was much assisted by Eby Jones. Their evenings were generally passed together, and devoted to the perusal of the best modern authors in the different languages of Europe. We find, however, from a serial of his letters, that he felt great anxiety concerning the debilitated state of her health, and that, painful as must be their mutual separation, he had offered her promise to take her passage for Europe in January 1793. Such was her affectionate attachment to her husband, that she remained in India in opposition to the advice of her physicians, though she could entertain no reasonable expectation of recovering her health in the climate of that country. It was finally settled, however, that she should return to England ; and it was his determination to follow

follow her in the ensuing season, hoping at that period to have discharged his engagements with the government of India, and intending to pursue his researches through Persia or China by a circuitous route, to his native country. Lady Jones embarked in December 1793. Soon after her departure, viz. in the beginning of 1794, sir William Jones published a translation of the Ordinances of Menu, comprising the Indian system of duties, religious and civil. In this work he had been long engaged from motives similar to those which had induced him to undertake the compilation of the digest; viz. to aid the benevolent intentions of the legislature of Great Britain, in securing to the natives of India the administration of justice, to a certain extent, by their own laws.

To those who entertain a just sense of the importance of the principles and the utility of the duties of religion, the following prayer, composed by sir W. Jones on the first day of the year 1782, about fifteen months before his embarkation for the India, and more than twelve years before his death, will not be unacceptable:—“Eternal and incomprehensible *Mind*, who, by thy boundless *power*, before time began, created innumerable *worlds*, for thy *glory*, and inimitable orders of *beings* for their *happiness*, for which thy infinite *wisdom* prompted thee to devise, and thy infinite *wisdom* enabled thee to know! We, thy *creatures*, vanish into nothing before thy supreme *majesty*; we hourly feel our *weakness*; we daily bewail our *vices*; we continually acknowledge *your guilt*; thou only we *adore* with *triple veneration*; thou we thank with the most fervent *zeal*; thou we *praise* with *admiration* and rapture; to thy *power* we humbly submit; of thy *goodness* we devoutly implore protection; on thy *grace* we firmly and cheerfully rely. We do but open our *eyes*, and instantly we perceive thy divine existence; we do but exert our *reason*, and in a moment we discover thy divine *attributes*; but our eyes could not behold thy *splendour*, nor could our *minds* comprehend thy divine *essence*; we *feel* thee *only* through thy stupendous and all-perfect *works*; we *know* thee *only* by that ray of sacred light which it has pleased thee to reveal. Nevertheless, if creatures too *ignorant* to *adore*, and too *depraved* to *pursue*, the means of their own happiness, may, without presumption, express their wants to their *CREATOR*, let us humbly supplicate thee to remove from us that *evil*, which thou hast permitted for a *time* to exist, that the *ultimate good* of all may be complete, and to secure us from that *vice*, which thou sufferest to spread snares around us, that the triumph of virtue may be more conspicuous. Irradiate our minds with all *useful truths*; instill into our hearts a spirit of *general benevolence*; give *understanding* to the foolish; *meekness* to the proud; *temperance* to the dissolute; *fortitude* to the feeble-hearted; *hope* to the desponding; *faith* to the unbelieving; *diligence* to the listless; *patience* to those who are in *pain*; and *any celestial aid* to those who are in *danger*; comfort the *afflicted*; remove the *distressed*; supply the *hungry* with satiate food; and the *thirsty* with a plentiful stream. Impute not our *doubts* to indifference, nor our *slowness* of belief to hardness of heart; but be indulgent to our *imperfect nature*, and supply our *imperfections* by thy *beneficent favour*. “SARVE SAT, we anxiously pray, suffer not *oppression* to prevail over *innocence*, nor the *might* of the *warrior* over the *weakness* of the *just*! Whenever we shall be true in our resentment from the vanities of the world, if we pray we *forfeits* *grace*; if *presumptuous*, *perdition*; if *unable* to see, grant them, all-powerful *God*, grant them; and, as with our *living* voices, and with our *dead* lips, we will express our submission to thy *decrees*, adore thy *providence*, and bless thy *dispensations*; so in all future *states*, to which we reverently hope thy *goodness* will raise us, grant

that we may continue *praising, admiring, venerating, worshipping* thee more and more, through *worlds* without number, and *ages* without end!” This prayer is undoubtedly the effusion of a truly pious mind, impressed with just sentiments of the Deity and of human nature; and though it does not express any explicit faith in the doctrines of Christianity, these sentiments are such as reason and experience suggest, and such as revelation expressly teaches us. It should also be recollected, that long before this prayer was written, sir W. Jones had demonstrated, as we have already observed, to his own satisfaction, that Jesus was the Messiah predicted by the prophets. We have also further evidence, which no incredulity can contest, of his firm belief in the divine authority of the scriptures and divine mission of Jesus Christ. Of the sacred writings, he says, in a passage transcribed from his own MS. in his bible: “I have carefully and regularly perused these holy scriptures; and am of opinion, that the volume, independently of its divine origin, contains more sublimity, purer morality, more important history, and fewer brains of eloquence, than can be collected from all other books, in whatever language they may have been written.” It would indeed be strange to cite passages from his writings, which demonstrate his firmness in the subject of a revelation, and at the same time to pretend to doubt to impress his own belief on others. In this connection we cannot forbear transcribing a passage from the Minutes of the Librarian, which do honour to his judgment and his labors.

“In matters of eternal concern,” says lord Teignmouth, “the authority of the highpriesthood is to be respected to be admitted, as a ground of belief; but it may, with the strictest propriety, be opposed to that of men of inferior learning and penetration; and, whilst the gods derive satisfaction from the perusal of sentiments, according with their own, those who doubt or disbelieve, should be induced to weigh, with candour and impartiality, arguments which have produced conviction in the minds of the best, the wisest, and the most learned of mankind.”

After the departure of lady Jones, “whose facility had sweetened the toil of application, and cheered his hours of relaxation,” sir William mixed more in promiscuous society; “but his affections were transported with her to his native country,” and, without doubt, led him to anticipate, with an anxiety bleed-d with delight, the period which he had fixed in his own mind for leaving India, and renewing his intercourse with her, and with other friends. But Providence had otherwise determined. On the evening of the 26th of April, or nearly about that date, in 1793, he prolonged his walk to a late hour; in consequence of which he complained of aguish symptoms; but feeling no alarm he repeatedly repeated an old adage; “An aguish is the spring is medicine for a king.” But his complaint, of which he had no apprehension, was that which is common in Bengal, viz. an inflammation in the liver. The medicines prescribed by the physician who attended him, and who had discovered the nature of his disorder, were administered without effect. The progress of the disease was unceasingly rapid, and terminated fatally, on the 27th of April 1794. His last words, preserved by the surgeon of the hospital, “I have been bed in a pain of inflammation, and the only symptoms of resolution has been a small degree of motion in the bowels, which are now almost ceased, and he expired without a groan or groan. His sudden departure, from the completion of his finances and the state of his attitude, could not have been foreseen; and his words must have derived confirmation from that country where he had been in the habit of looking it, and where, alas, in our last moments, it can never be recalled.”

found." On the following day the funeral ceremony was performed, "with the honours due to his public itation; and the numerous attendance of the most respectable British inhabitants of Calcutta evinced their sorrow for his loss, and their respect for his memory."

The following epitaph, evidently intended for himself, was written by sir William Jones, not long before his demise. It displays some striking features of his character, resignation to the will of his Creator, love and good-will to mankind; but it is modestly silent upon his intellectual attainments.

Here was deposited
the mortal part of a man,
who feared God, but not Death;
and maintained independence,
but fought not riches;
who thought
none below him, but the base and unjust,
none above him, but the wife and virtuous;
who loved
his parents, kindred, friends, and country,
with an ardour
which was the chief source of
all his pleasures and all his pains;
and who, having devoted
his life to their service,
and to
the improvement of his mind,
resigned it calmly,
giving glory to his Creator,
wishing peace on earth,
and with
good will to all creatures,
on the [Twenty-seventh] day of [April]
in the year of our blessed Redeemer
One thousand seven hundred [and ninety-four.]

By a unanimous vote of the Court of Directors of the East India Company, it was resolved, that a monument to his memory should be ordered, for the purpose of being erected in St. Paul's cathedral, with a suitable inscription; and that a statue of sir William Jones should be prepared at the expence of the company, and sent to Bengal, with directions for its being placed in a proper situation there. A society of gentlemen in Bengal, who had received their education at Oxford, subscribed a sum to be given, as a prize, for the best dissertation on his character and merits, by any of the students of that university; and the premium was adjudged to Mr. Henry Philpotts, A. M. Fellow of Magdalen college. Lady Jones testified her affection for sir William, and her desire to perpetuate his fame, by an elegant monument erected, at her expence, in the anti-chamber of University college, Oxford, and by the publication of his works in an elegant edition of six 4to. volumes; thus strictly conforming to his opinion, that "the best monument that can be erected to a man of literary talents, is a good edition of his works."

"In the short space of 47 years," says his biographer, "by the exertion of rare intellectual talents, he acquired a knowledge of arts, sciences, and languages, which has seldom been equalled, and scarcely, if ever, surpassed." Without considering him as a competitor in Grecian literature with a Porson or a Parr, he deserves to be ranked high among classical scholars; and "as a philologist, he could boast an universality in which he had no rival. His skill in the idioms of India, Persia, and Arabia, has perhaps never been equalled by any European; and his compositions on

oriental subjects display a taste, which we seldom find in the writings of those who had preceded him in these tracts of literature. The language of Constantinople was also familiar to him; and of the Chinese characters and tongue, he had learned enough to enable him to translate an ode of Confucius. In the modern dialects of Europe, French, Italian, Spanish, Portuguese, and German, he was thoroughly conversant, and had perused the most admired writers in those languages." The following transcript of a paper written by himself, will inform us, how far his knowledge of languages extended;

LANGUAGES:

Eight languages studied critically;
English, Latin, French, Italian,
Greek, Arabic, Persian, Sanscrit.

Eight studied less perfectly, but all intelligible with a dictionary;

Spanish, Portuguese, German, Runick,
Hebrew, Bengali, Hindi, Turkish.

Twelve studied less perfectly, but all attainable;

Tibetan, Pali, Phalavi, Deri,
Ruffian, Syriac, Ethiopic, Coptic,
Welsh, Swedish, Dutch, Chinese.

Twenty-eight languages.

In another memorandum, he mentions having read a grammar of the Russian and Welsh. The knowledge of languages, however, was, in sir W. Jones's estimation, inferior and subordinate to other objects. They were, in his possession, the keys of universal literature and science, and served, according to the use which he made of them, to unlock storehouses of ancient and modern treasures, for the amusement, instruction, and general benefit of mankind. The eleven discourses which he addressed to the Asiatic society, and to which we shall have occasion to refer under future articles, are specimens of the uses to which he applied them.

"A mere catalogue of the writings of sir William Jones," says his biographer, "would shew the extent and variety of his erudition; a perusal of them will prove, that it was no less deep than miscellaneous. Whatever topic he discusses, his ideas flow with ease and perspicuity, his style is always clear and polished; animated and forcible, when his subject requires it. His philological, botanical, philosophical, and chronological disquisitions, his historical researches, and even his Persian grammar, whilst they fix the curiosity and attention of the reader, by the novelty, depth, or importance of the knowledge displayed in them, always delight by elegance of diction. His compositions are never dry, tedious, nor disgusting; and literature and science come from his hands, adorned with all their grace and beauty. No writer, perhaps, ever displayed so much learning, with so little affectation of it." With regard to his law publications, it is said, that his "Essay on Bailments" was sanctioned by the approbation of lord Mansfield; and all his writings in this department shew, that he had thoroughly studied the principles of law as a science. As to his opinion of the British constitution, it appears from repeated declarations that occur in his letters, and particularly in his 10th discourse, delivered to the Asiatic society in 1793, that he considered it as the noblest and most perfect that ever was formed. With regard to his political principles, he was an enlightened and decided friend to civil and religious liberty. Like many others of the same principles, he entertained a favourable opinion of the French revolution at its commencement,

ment, and wished success to the exertions of that nation for the establishment of a free constitution; but subsequent events must have given him new views, not so much of the principles on which the revolution was founded, as of the measures which have been adopted by some of its zealous partizans. To liberty, indeed, his attachment was enthusiastic, and he never speaks of tyranny or oppression, but in the language of detestation. He dreaded, and wished to restrain every encroachment on liberty; and though he never enlisted under the banners of any party, he always concurred in judgment and exertion with those who wished to render pure and permanent the constitution of his country. With this view he was a zealous advocate for a reformation in the representation of the country, as the only means of restoring the balance of the constitution, and in one of his letters to lord Althorp, he expressly declares, that "on the popular part of every government depend its real force, the obligation of its laws, its welfare, its security, its permanence." The last political publication of sir W. Jones is prior to the year 1783.

As a judge in India, his conduct was strictly conformable to the professions which he made in his first charge to the grand jury at Calcutta. "On the bench he was laborious, patient, and discriminating; his charges to the grand jury, which do not exceed six, exhibit a veneration for the laws of his country; a just and spirited encomium on the trial by jury, as the greatest and most invaluable right derived from them to the subject; a detestation of crimes, combined with mercy to the offender; occasional elucidations of the law; and the strongest feelings of humanity and benevolence. His knowledge of the Sanscrit and Arabic eminently qualified him for the administration of justice in the supreme court, by enabling him to detect misrepresentations of the Hindu or Mohammedan laws, and to correct impositions in the form of administering oaths to the followers of Brahma and Mohammed. The inflexible integrity with which he discharged the solemn duty of this station will long be remembered in Calcutta, both by Europeans and natives.

Having through life directed his attention to various branches of literature and science, in all which he had made considerable proficiency, his last and favourite pursuit was the study of botany; and this constituted the principal amusement of his leisure hours.

It might naturally be inquired by what arts or method he was enabled to attain that extraordinary degree of knowledge for which he was distinguished. His faculties were naturally vigorous and strengthened by exercise; his memory, as we have before observed, was, from early life, singularly retentive; his emulation was ardent and unbounded; and his perseverance invincible. In India his studies began with the dawn; and, with the intermission of professional duties, were continued throughout the day. Another circumstance, which has been exemplified in some other instances that might be mentioned, and which gave him peculiar advantage in the exercise of his talents, was "the regular allotment of his time to particular occupations, and a scrupulous adherence to the distribution which he had fixed;" so that "all his studies were pursued without interruption or confusion." With sir W. Jones it was a favourite opinion, "that all men are born with an equal capacity for improvement." Accordingly sir I. Newton modestly declared, "that if he had done the world any service, it was due to nothing but industry and patient thought." Sir W. Jones having maintained the above-mentioned opinion in conversation with a friend, Thomas Law, esq. received the following unpremeditated reply:

"Sir William, you attempt, in vain,
By depth of reason to maintain,
That all men's talents are the same,
And they, not nature, are to blame.
Whatever you say, whatever you write,
Proves your opponents in the right.
Lest genius should be ill-descri'd
I term it *your superior mind*,
Hence to your friends 'tis plainly shewn,
You're ignorant of your self alone."

Sir William Jones's Answer.

"Ah! but too well, dear friend, I know
My fancy weak, my reason slow,
My memory by art improv'd,
My mind by baseless trifles mov'd.
Give me (thus high my pride I raise)
The ploughman's or the gardener's praise.
With patient and unceasing toil,
To meliorate a stubborn soil,
And say, (no higher need I ask,
With zeal hast thou perform'd thy task,
Praise, of which virtuous minds may boast,
They best confer, who merit most."

Besides the finished productions of sir William Jones's skill and labour, he had contemplated many more than he had executed: and for this reason, as well as many others, we cannot forbear regretting his premature death.

It is needless to add any thing in commendation of his private and social virtues. The independence of his integrity, his probity and humanity, and also his universal philanthropy and benevolence, are acknowledged by all who knew him. The compiler of this article joins with many others in a grateful and respectful remembrance of his disposition to perform acts of kindness; and he has reasons, peculiar to himself, for regretting his premature death. In every domestic relation, as a son, a brother, and a husband, he was attentive to every dictate of love, and to every obligation of duty. In his intercourse with the Indian natives, he was condescending and conciliatory; liberally rewarding those who assisted him, and treating his dependents as friends. His biographer records the following anecdote of a circumstance that occurred after his demise: "The Pundits who were in the habit of attending him, when I saw them at a public *durbar*, a few days after that melancholy event, could neither restrain their tears for his loss, nor find terms to express their admiration at the wonderful progress which he had made, in the sciences which they professed." Upon the whole, we may join with Dr. Parr, who knew his talents and character, in applying to sir William Jones his own words: "It is happy for us that this man was born."

Having attained, by the assiduous exertion of his abilities, and in a course of useful service to his country and mankind, a high degree of reputation; and by economy that did not encroach upon his beneficence, a liberal competence, he was prepared, one would have thought, at the age of 47 years, to enjoy dignity with independence. His plans, and the objects of his pursuit, in the prospect of future life, were various and extensive; and he would naturally indulge many pleasing ideas in the view of returning, at a fixed period, to his native country, and to beloved friends, who would anxiously wish for his arrival. Few persons seemed to be more capable of improving and enjoying prolonged life than sir William Jones; and few persons seemed to be better prepared for a more exalted state of progressive improvement,

and of permanent felicity, than that to which the most distinguished and prosperous can attain within the regions of mortality.

We shall close this article with observing that lady Jones, since the demise of sir William, has presented to the Royal Society a collection of MSS. Sanferit and Arabic, which he reckoned inestimable, and also another large collection of Eastern MSS; of which a catalogue, compiled by Mr. Wilkins, is inserted in the 13th volume of sir William Jones's Works, 8vo. ed.

JONES, SIR THOMAS, lord chief justice of the Common Pleas in the reigns of Charles II. and James II., is celebrated for his reply to the latter, who consulted him on his dissolving power, and said he could soon have twelve judges of his opinion: sir Thomas answered, "Twelve judges you may possibly find, sir, but not twelve lawyers." He was author of Reports. Granger.

JONES, JEREMIAH, a learned English non-conformist divine in the eighteenth century, is supposed to have been born about the year 1693. It is not known where he received his grammar learning, but he was, at an early age, distinguished for his proficiency in useful knowledge. He pursued his academical studies under the tuition of his uncle, the Rev. Samuel Jones of Tewksbury, in Gloucestershire, from whose seminary many pupils were sent into the world, who became distinguished for their literature or rank in life. Among these were Butler, afterwards bishop of Durham; Secker, afterwards archbishop of Canterbury; and Samuel Chandler, minister of the Old Jewry meeting-house. When Mr. Jones had finished his course of academical learning, he settled with a congregation of Protestant Dissenters at Avening, in Gloucestershire. He obtained a high character for sound and very extensive learning; and he was popular as a preacher. Though a hard student and a profound scholar his manners were not severe or forbidding: he would even relax from his studies and join a party in his neighbourhood in the exercise of bowls. He died in 1724, when he was only in his thirty-first year. During his life he published "A Vindication of the former Part of St. Matthew's Gospel, &c." But his most valuable and important work, which he had prepared for the press before his death, but which was not published till the year 1726, was his "New and full Method of settling the Canonical Authority of the New Testament." The works of Mr. Jones remain as monuments of his learning, ingenuity, and indefatigable industry, and would have done credit to the assiduity and ability of a literary man of sixty. They were become exceedingly scarce, and bore a very high price, when, about ten years since, the conductors of the Clarendon press republished them. "Mr. Jones," observes Dr. Maltby, "has brought together, with uncommon diligence and judgment, the external evidence for the authenticity of the canonical books; and he has, with equal ability and fairness, stated his reasons for deciding against the apocryphal." Had his life been spared, Mr. Jones would have drawn up another and distinct volume on the apocryphal fathers. Monthly Magazine.

JONES, WILLIAM, a worthy clergyman of the church of England, was born at Lowick, in Northamptonshire, in the year 1726. He laid a good foundation of grammar learning in the country, and when he was of a proper age he was admitted a scholar at the Charter-House in London, where he made a rapid progress in the Latin and Greek languages, and at the same time shewed a turn for philosophical pursuits. When he was about eighteen years of age, he was entered of University college, Ox-

ford, and in this seminary he pursued the usual course of studies with unremitting diligence. Here he adopted the Hutchinsonian opinions in theology and natural philosophy. Mr. Jones was admitted to the degree of B. A. in the year 1749, and was, in the same year, admitted to deacon's orders. In 1751, he was ordained priest, and in 1753, he published his "Full Answer to Bishop Clayton's Essay on Spirit," in which he endeavoured to support the cause of orthodoxy by an appeal to the religion and learning of heathen antiquity. His next work was entitled the "Catholic Doctrine of the Trinity," which was favourably received by the orthodox party. He now engaged in a course of experiments with the view of elucidating and establishing his favourite theory. In this he was liberally supported by friends who subscribed among themselves very large sums to enable him to purchase such an apparatus as he stood in need of. The result of his labours was "An Essay on the first Principles of Natural Philosophy," published in 1762. In the year 1764, he was presented by archbishop Secker with the vicarage of Betheriden, in Kent. Here, to increase his income, he undertook the tuition of a few pupils, an office for which he was admirably qualified. In 1765, the archbishop presented him to the rectory of Pluckley, where he continued his plan of education, and at the same time discharged the pastoral duties with exemplary zeal and diligence. In the year 1769, he published "A Letter to a Young Gentleman at Oxford, intended for Holy Orders, containing some reasonable Cautions against Errors in Doctrine." From this time, to the year 1781, he published several other pieces, chiefly theological, and in the latter year he gave the world his "Physiological Disquisitions, or Discourses concerning the Natural Philosophy of the Elements." This work contains much instructive, and much fanciful matter, ingeniously applied in an attempt to investigate the causes of things, and to construct a theory of nature on the principles of the author's favourite system. His next publication was theological; it consisted of lectures on the figurative language of the Holy Scriptures, and the interpretation of it from the Scripture itself. This was published in 1788, and, in 1790, he gave the public two volumes of sermons on moral and religious subjects, which include discourses on natural history, delivered at an annual lecture at Shore-ditch church, of which the preacher is appointed by the Royal Society. In the year 1792 he employed his pen in the service of politics, and printed a two-penny pamphlet, entitled "A Letter from Thomas Bull to his Brother John, which was most indutiously circulated throughout the kingdom by the friends of administration. Mr. Jones attempted to form a society "for the reformation of principles," but it did not succeed: he was the founder of the periodical publication entitled the "British Critic," and he edited a collection of tracts in two volumes, which had been originally published by Mr. Law, Mr. Norris, Dr. Horne, and others. This work was entitled "The Scholar armed against the Errors of the Time, or a Collection of Tracts on the Principles and Evidences of Christianity, the Constitution of the Church, and Authority of civil Government." In 1795 he published "Memoirs of the Life, Studies, and Writings of the Right Reverend George Horne, D.D. late lord bishop of Norwich," to the second edition of which he prefixed a concise exposition of Mr. Hutchinson's leading theological and philosophical opinions. His last publication was "A Discourse on the Use and Intention of some remarkable Passages of Scripture, &c." Shortly after this, he suffered most severely from a paralytic seizure, which at length, in February

1800, put an end to his life in the seventy-fourth year of his age. Mr. Jones's learning was very respectable, his attachment to truth was zealous and ardent, and his moral conduct highly exemplary. He delighted in doing good, and was a vigilant and affectionate pastor. He was, in addition to his other learning, a proficient in music, and composed ten church-pieces for the organ, and four anthems, which have been much admired. His works have been published in 12 vols. 8vo. See Gentleman's Magazine for 1800.

JONES, PAUL, a naval adventurer, was a native of Selkirk, in Scotland, but settling in America, he obtained, in 1775, the command of a ship under commodore Hopkins, and distinguished himself in several engagements, on which account he received a captain's commission. He then sailed to France, and being well acquainted with the coast of Ireland, and the northern part of England, he conceived the design of effecting a descent. He accordingly landed at Whitehaven, and did considerable mischief there. He afterwards sailed for Scotland, where he landed on the estate of the earl of Selkirk, and plundered his lordship's house of all the plate: he next took the Drake sloop of war, with which he went to Breit. After this he sailed round Ireland to the North sea, with three ships, viz. the Richard, Pallas, and Vengeance. Having committed great mischief on that coast, he fell in with the Baltic fleet, convoyed by the Serapis frigate, and another armed vessel, both of which he captured off Flamborough-head. For these services the king of France conferred on him the order of merit, and gave him a gold-hilted sword. We hear no more of his exploits after the conclusion of the American war. He died at Paris in 1792. Monthly Mag.

JONES, in *Geography*, a county of North Carolina, in Newbern district, bounded N. by Craven, and well watered by the river Trent and its tributary streams. It contains 424 free inhabitants, and 1899 slaves. Its chief town is Trenton.

JONES, *St.*, a town of America, in Kent county, Delaware, containing 1586 inhabitants.

JONES'S *Creek*, a river of Pennsylvania, which runs into the Delaware. N. lat. 40° 58'. W. long. 75° 15'.

JONES'S *Island*, an island in Hudson's bay. N. lat. 61° 52'. W. long. 63°.

JONES'S *Keys*, a small island in the Spanish Main, near the Mosquito shore, surrounded with rocks. N. lat. 15° 35'. W. long. 82° 27'.

JONES'S *Town*, in Pennsylvania. See WILLIAMSBURG.

JONESBOROUGH, a post-town of America, and chief town of Washington district, in Tennessee, and also the seat of the district and county courts, 26 miles from Greenville and 40 from Abingdon, in Virginia.—Also, the chief and post-town of Camden county, Edenton district, North Carolina; containing a court-house and a few dwelling houses.

JONESIA, in *Botany*, is a genus dedicated by Dr. Roxburgh to the memory of the celebrated Sir William Jones, who, amongst the varied and unrivalled accomplishments he attained in almost every department of science, was by no means unskilled in botanical researches. Roxb. Afiat. Researches, v. 4. 355. Willd. Sp. Pl. v. 2. 287. (Asjogam; Hort. Malabar. v. 5. 117. t. 59.) Clafs and order, *Hep-tandria Monogynia*. Nat. Ord. ?

Eff. Ch. Calyx of two leaves. Corolla funnel-shaped, with a clofed, fleshy tube; limb four-lobed. Nectary a little ring bearing the stamens, inserted into the throat of the tube of the corolla. Germen pedicelled. Pod-shaped like a cymitar, turgid, containing from four to eight seeds.

1. *J. pinnata*. Willd. (J. Afoca; Roxb. Afiat. Researches, v. 4. 355.) A native of the East Indies.—This

tree rises to the height of about 15 feet. Root whitish, covered with a blackish bark, in dorous, finally fixed in the ground and spreading by means of numerous fibres. Leaves alternate, unequally pinnate, confisting of from four to six pair of oblong-lanceolate, smooth, shining, strong leaflets. Flowers making a dense cyme, odorous, of a fine yellow colour. Stamens long and slender, of a beautiful shining red, with dark purple tops. Style greenish-white, with a round tip.

We have seen a beautiful specimen of this plant which is gathered and preserved by lord Valentia in his Travels through India; and this authorizes us to say that the *Asjogam* of the *Hortus Malabaricus* is a most correct delineation of our *Jonesia*. It is found in gardens about Calcutta, where it grows to be a very handsome tree. The plants and seeds were originally brought from the interior of the country, where it is indigenous.

JONGLEURS, musicians, players on instruments, in the infancy of French poetry, who attached themselves to the troubadours or provincial poets.

The history of the French theatre informs us that a kind of merry-andrews were thus called that accompanied the troubadours, who began to flourish about the beginning of the eleventh century. The term jongleur seems to be a corruption of the Latin word *joculator*, in French *joueur*, and in English player on an instrument. Mention is made of the jongleurs from the time of the emperor Henry II, who died in 1056. As they played upon different instruments, they associated with the troubadours and singers, to execute the works of the first, and thus, in their company they gained admission into the palaces of kings and princes, and drew from them magnificent presents. Some time after the death of Joan I. queen of Naples and Sicily, and counts of Provence, which happened 1382, all those of the profession of troubadours and jongleurs, separated into two different classes of actors. Some, under the ancient name of *troubadours*, joined singing to instruments, or the recitation of voices; others simply took the name of players, or *joculators*, as they were named in their certificates.

About the year 1330, the minstrels of Paris, including the jongleurs, formed themselves into a company, and obtained a charter. The police frequently repressed their licentiousness, and regulated their conduct: Philip Augustus banished them the first year of his reign; but they were recalled by his successors, and united under the general name of *menftroules*, minstrelsy; having a chief appointed over them, who was called *king of the minstrels*. Lewis IX. exempted them from a tariff or toll at the entrance into Paris, on condition that they would sing a song and make their monkies dance to the tollman, perhaps to prove their title to such indulgence; and hence arose the well-known proverb: *Payer en gambades et en monnoie de fange*.

The associated minstrels inhabited a particular street, to which they gave the name, which it still retains, of *St. Julien des Menftriers*. It was here that the public was provided with musicians for weddings and parties of pleasure; but as a greater number of them usually attended on such occasions than were ordered, and all expected to be paid the same price, William de Germont, provost of Paris, in 1331 prohibited the jongleurs and jongleresses from going to those who required their performance in greater numbers than had been stipulated, upon a severe penalty. In 1395 their libertinism and immoralities again incurred the censure of Government, by which it was strictly enjoined that they should henceforth, neither in public nor private, speak, act, or sing any thing that was indecorous or unfit for modest eyes and ears, upon

pain of two months imprisonment, and living on bread and water.

Though the word *minstrel*, in English, is confined to strolling musicians, players on instruments; yet the term *jongleur*, in old French, included buffoons, fortune-tellers, flight of hand, tumblers, &c. besides *violans*, or performers on the violle or viol; *juglers*, or flute players; *musars*, or players on other instruments; *comiques*, or comedians.

All these, at last, assumed the name of *jongleurs*, as the most ancient, and the women who followed this profession were designated *jongleureselles*. They settled at Paris in one particular street, which thence was called "la rue des jongleurs," and which is still called the street of "St. Julien des Menestriers." In that street people used to apply for performers on festivals, and for parties of pleasure.

By an ordonnance of William of Clermont, provost of Paris, 14th Sept. 1393, the jongleurs were forbidden to utter, represent, or sing in public places, or elsewhere, any thing that would occasion scandal, on pain of fine and two months imprisonment. Since that time we hear no more of them, except their dancing and performing tricks with swords and other weapons. These were called *batalores*, in Fr. *buteurs*, merry-andrews; and, at length, tumblers and rope-dancers. See *MINSTREL*.

IONIA, in *Ancient Geography*, so called from the Ionians, who inhabited this part of Asia Minor, was bounded on the N. by *Æolia*; on the W. by the *Ægean* and *Icarian* seas; on the S. by *Caria*; and on the E. by *Lydia* and part of *Caria*. It lies between the 37th and 40th degrees of north latitude, but its extent in longitude, which has not been accurately determined, was inconsiderable. The most remarkable cities of Ionia were Phocæa, Smyrna, Clazomenæ, Erythræ, Teos, Lebadaus, Colophon, Ephesus, Priene, and Miletus. The islands of Chios and Samos were likewise inhabited by the Ionians, and belonged to their confederacy. See the next article.

IONIANS, constitute a class of people among those who were the most celebrated of the Greeks. They derived their origin from the Hellenes, who were so called from Helen, the son of Deucalion, and who formed a small tribe in Thessaly; and from Dorus, *Æolus*, and Ion, his more remote descendants, the Hellenes were discriminated by the names of Dorians, *Æolians*, and Ionians. The name of the latter was gradually lost in the more illustrious appellation of Athenians, settled in the less barren parts of Attica. (See **ATTICA** and **ATHENS**.) When the Hæradidæ took possession of the Peloponnesus, 80 years after the taking of Troy, B.C. 1104, a signal revolution took place in several states of Greece; and those tribes, which occupied the islands and coasts of Asia Minor, were either expelled by their conquerors, or migrated to seek new settlements. The *Æolians* were the first of these emigrants, they crossed the Hellespont 88 years after the taking of Troy, B.C. 1096, and established themselves in the country, afterwards called *Æolis* or *Æolia*. According to Blair's tables their migration took place before the return of the Hæradidæ, in the year B.C. 1124. (See **ÆOLIS**.) Upon the death of Codrus, B.C. 1070, the monarchical form of government was abolished in Athens, and succeeded by the administration of Archons. Dissatisfied probably with this change, Neleus and Androclus, younger sons of Codrus, determined to leave their country. Accordingly being joined by many refugees, and Athenian citizens, who complained that Attica was too narrow and barren for maintaining the increasing number of its inhabitants, sailed to Asia Minor, and, expelling the ancient inhabitants, seized the central and most beautiful portion of the Asiatic coast.

Their colonies were gradually diffused from the banks of the Hermus to the promontory of Posideion. They afterwards took possession of Chios and Samos; and all these countries were united by the common name of Ionia, to denote that the Ionians composed the most numerous division of the colony. The Ionic migration is fixed in Blair's tables at the year B.C. 1044, 60 years after the return of the Hæradidæ; but others refer it to the year B.C. 1055. The last tribe which emigrated was that of the Dorians, who, in the year B.C. 944, sailed to the islands of Rhodes and Crete, already peopled by Doric tribes; while others transported themselves to the peninsula of Caria, which, in honour of their mother country, received the name of Doris. (See **DORIS**.) In consequence of this establishment, which was formed 240 years after the Trojan war, the western coast of Asia Minor was planted by the *Æolians* in the north, the Ionians in the middle, and the Dorians in the south. The Ionians, in particular, settled in a country of great extent and fertility, enjoying the most delicious climate, and peculiarly adapted to a commercial intercourse with the most improved nations of antiquity. Thus favoured, they silently flourished in peace and prosperity, till their growing numbers and wealth excited the avarice or jealousy of the powers of Asia. They were successively conquered by the Lydians and Persians, but never thoroughly subdued. "Having imbibed," says Dr. Gillies (Hist. of Anc. Greece, vol. 1. chap. 3.) "the principles of European liberty, they spurned the yoke of Asiatic bondage. In their glorious struggles to reassume the character of freemen, they solicited and obtained the assistance of their Athenian ancestors, and occasioned that memorable rivalry between the Greeks and Persians, which having lasted two centuries, ended in the destruction of the Persian empire. In this illustrious contest, the first successes of the Greeks against enemies far more powerful, and incomparably more numerous than themselves, inspired them with an enthusiasm of valour. Their exploits merited not only praise but wonder; and seemed fit subjects for that historical romance, which, in the progress of literature, naturally succeeds to epic poetry." In process of time the Ionians, possessing the delightful country above-mentioned, together with the mouths of great rivers, having before them convenient and capacious harbours, and behind, the wealthy and populous nations of Asia, whose commerce they enjoyed and engrossed, attained such early and rapid proficiency in the arts of navigation and traffic, as raised the cities of Miletus, Colophon, and Phocæa, to an extraordinary pitch of opulence and grandeur. Their population increasing with their prosperity, they diffused new colonies every where around them. Having obtained footing in Egypt, in the eighth century before Christ, they acquired, and thenceforth preserved, the exclusive commerce of that ancient and powerful kingdom. Their territories, though in their greatest breadth compressed between the sea and the dominions of Lydia to the extent of scarcely forty miles, became not only flourishing in peace, but formidable in war. With the utmost industry and perseverance they improved and ennobled the useful or elegant arts, which they found already practised among the Phrygians and Lydians. They incorporated the music of those nations with their own. Their poetry far excelled whatever Pagan antiquity could boast most precious. They rivalled the skill of their neighbours in moulding clay and casting brass. They appear to have been the first people who made statues of marble. The Doric and Ionic orders of architecture perpetuate, in their names, the honour of their inventors. Painting was first reduced to rule, and practised with success among the Greeks; and we may be assured, that, during

the seventh century before Christ, the Ionians surpassed all their neighbours, and even the Phœnicians, in the arts of design, since the magnificent presents which the far-famed oracle of Delphi received from the ostentation or piety of the Lydian kings, were chiefly the productions of Ionian artists. In the following century Ionia gave birth to philosophy; and both science and taste were diffused from that country over Greece, Italy, and Sicily. (Gillies, ubi supra.) The Ionians, however, soon degenerated from the valour of their ancestors, and became a superstitious, effeminate, and voluptuous people, inasmuch that, in the time of Herodotus, they were looked upon as quite unfit for any military service. They and the Greek colonies settled in Asia, enjoyed their liberties, and lived, according to their own laws, from the time of their migration in the reign of Cræsus, king of Lydia, to whose superior power they were forced to submit, after having baffled all the attempts of his predecessors. Before Cyrus invaded Lower Asia, he earnestly intreated the Ionians (B. C. 547) to share the glory of his arms; but having lived at ease under the mild government of Cræsus, they preferred their allegiance to him before the friendship of another unknown master. Accordingly they opposed him when he first invaded Lydia, and rejected the advantageous proposals of that prince; but after the defeat of Cræsus they sent ambassadors to the conqueror, offering submission upon the terms which had been formerly granted them by Cræsus. Cyrus having heard them with attention, answered them by the following apologue: "A piper seeing numerous shoals of fishes in the sea, and imagining he might entice them ashore by his music, began to play; but finding his hopes disappointed, he threw a net into the water, and drew a great number to the land. When he saw the fish leaping on the ground, since you would not dance, said he, to my pipe before, it is unnecessary for you now to dance, since I have ceased to play." They now perceived that if they would escape the rigour of servitude, they must owe their safety to the strenuous exertions of a brave defence, not to the clemency of Cyrus. The Lacedæmonians, to whom they applied, interposed in their behalf, and remonstrated with Cyrus against his design of subduing the Asiatic Greeks; but without effect. The Ionians had previously formed a powerful confederacy with the other states. Cyrus, having ordered Cræsus into captivity, was eager to return towards the East to complete his conquests in Upper Asia; and he committed the reduction of all the countries of Lower Asia to the skill of his lieutenant, Harpagus (B. C. 539.) This general, in a few months, completely executed his commission, and made himself master of all the countries in Lower Asia, possessed by either Greeks or Barbarians. In the reign of Darius Hytaspes, they made an attempt to recover their ancient liberty, and maintained a war against the whole power of the Persian monarchy for six years; but they were constrained to submit, and punished with great severity for their presumption in endeavouring to regain their rights. The Ionians assisted Xerxes in his expedition against Athens with 300 ships; but they were persuaded by Themistocles to abandon the Persians, and their flight contributed not a little to the famous victory gained by the Athenians at Salamis. A similar expedient was recurring to at Mycale, so that few Persians escaped slaughter. The Lacedæmonians were so pleased with their behaviour on this occasion, that they proposed to transplant them out of Asia into Greece; but they declined accepting the proposal. On the conclusion of the peace between the Greeks and Persians, which happened in the reign of Artaxerxes, one of the articles

sworn to by both parties was, that all the Greek states of Asia should be made free, and allowed to live according to their own laws. The Ionians, thus delivered from the Persian yoke, formed an alliance with the Athenians; but were treated by them rather like subjects than allies. Their fortune was various; at one time subject to the Persians, and at another time revolting from them, till they were at length delivered by Alexander, who restored all the Greeks in Asia to the enjoyment of their ancient rights and privileges. After the death of Alexander, they fell under the power of the kings of Syria, till the Romans obliged Antiochus III. surnamed the Great, to grant the same liberty to the Greek colonies in Asia, which they had procured for the Greek states in Europe. On this occasion, most of the free cities entered into an alliance with Rome, and enjoyed that kind of liberty which the Romans used to grant; till they were again brought under subjection by the famous Mithridates, king of Pontus, whom they joined against the Romans. By his order they massacred, without distinction, all the Romans and Italians whom trade, or the salubrity of the climate, had drawn into Asia. Nor would they suffer even their famous temple of Diana to be an asylum to those who fled to it for refuge. Upon Sylla's arrival in Asia they abandoned Mithridates, and declared for the Romans. Sylla, having routed all the armies of Mithridates, and reduced all the Lesser Asia, revenged on the Asiatics the death of so many thousand Romans, whom they had inhumanly murdered in compliance with the savage orders of Mithridates, by depriving them of their liberty, and laying such heavy taxes and fines on their cities, as reduced them to beggary. The city of Ephesus was treated with the greatest severity; Sylla having suffered his soldiers to live there at discretion, and obliged the inhabitants to pay every officer 50 drachmas, and every soldier 16 denarii a-day. The whole sum which the revolted cities of Asia paid Sylla, amounted to 20,000 talents, that is, three millions eight hundred and seventy-five thousand pounds sterling; for the rating of which they were forced to sell not only their moveables, but even a great part of their lands. This was a most fatal blow to Asia; nor did the inhabitants ever after recover their ancient splendour, notwithstanding the favour shewn them by many of the emperors, under whose protection they enjoyed some shew of liberty. Gillies's Hist. of Greece. Anc. Un. Hist. vol. vi.

IONIC ORDER, an order of *Architecture*, which owes its invention to the people of Ionia, and was first employed in the temple of Diana, at Ephesus. This order is an improvement upon the Doric; the column is more slender and graceful, and, according to Vitruvius, is intended to describe the delicate proportions of the female figure, as the Doric indicates the stronger characteristics of the male. This idea, he says, is preserved throughout its decorations: the capital having two spirals, peculiar to this order, on either side, in imitation of ringlets of hair projecting from the head; the cymatium indicates the locks hanging over the forehead; while the mouldings of the base represent the turn and shape of the shoes worn by women in the age when the order was invented. Its general appearance is simple, though graceful and majestic; and as forming a medium between the masculine Doric and the virginal slenderiness of the Corinthian; it has been, in figurative language, compared to a sedate matron in decent, rather than in rich attire.

This order may be used in all places consecrated to peace and tranquillity; accordingly we meet with it in churches, colleges, and libraries; and the ancients used it in temples dedicated

IONIC ORDER.

dedicated to Diana, Juno, Apollo, Fortune, Concord, &c. It may also be employed in palaces, halls of justice, and private houses.

In erecting the temple at Ephesus, the bold characteristics of the original but were omitted; and instead of the triglyphs and mutules of the Doric order, the more delicate dentils of the Ionic were substituted. The omission of these large members obviates the difficulty experienced in the execution of the Doric in confined situations, particularly in internal angles.

The Ionic base, according to Vitruvius, consists of a torus and two scotias, with astragals between them. In the Athenian Ionics, the base consists of two tori, with a scotia or trochilus between them, and two fillets, each separating the scotia from the torus above and below. The fillet above the torus generally projects as far as the extremity of the upper torus, and the lower fillet beyond it. The scotia is very flat, and its section forms an elliptic curve, joining the fillet on each side. The tori and scotia are nearly of equal heights. In the Ionic temple on the Illyfus, a bead and fillet are employed above the upper torus, joining the fillet to the scape of the column. In this temple, and in that of Erechtheus, the upper torus is fluted, except the lower part, where it joins the upper surface of the fillet, which is preferred entire. The bases of the antæ of the latter temple are also recessed. In the temple of Minerva Polias, the upper scotia is enriched with a guilloche, and the bases of the antæ are striated, the flutes being separated from each other by two small cylindrical mouldings of a quadrantal section, which join each other at their convexities. This is the true Attic base, it was invented by the Athenians, and is the most favourite base both with the ancients and moderns, being lighter in its upper part than the Ionic, more pleasing in its contour, and elegant in its general appearance. The Romans did not confine the use of this base to their Ionics, but very frequently adopted it in the Corinthian and Composite orders. They, however, differed very much from the Greeks in the proportions they assigned to it; for they always make the upper torus of a less height than the lower one, have both tori plain, and give the scotia a much greater convexity. The bases of the Ionic and Corinthian orders on the Coliseum, the Ionic on the theatre of Marcellus, and the temple of Fortuna Virilis at Rome, have nearly the same proportions with those described by Vitruvius. In the temples of Minerva Polias, at Priene, and of Apollo Didymæus, near Miletus, the Ionic bases consist of a large torus, three pairs of astragals, separated by two scotias inverted towards each other; the upper pair of astragals lying below the torus. In the former temple the torus is elliptical, and separated from the shaft by the intervention of an astragal. The under part of this torus is also fluted, and there is a flute cut in the upper part near the bead. In the latter temple, the upper torus is plain, of a semi-circular section, with a narrow fillet between each bead of every pair. The base of the Asiatic Ionics differ very little from that of Vitruvius, except that they have the scotia inverted towards each other, which gives a greater variety in the profile than when both stand in the true position. The Ionians also sometimes used the Attic base, as may be seen in the temple of Bacchus, at Teos.

The Ionic shaft is sometimes plain, but more frequently fluted into 24 flutes, with an equal number of fillets.

The volute is a distinguishing feature in this order, and is variously executed. In all the Athenian Ionics, and in the temple of Minerva Polias, at Priene, the lower edge of the canal between the volutes is formed into a graceful curve,

bending downwards, and coiling round the spirals which form the volutes. The volutes of the capitals of the temples of Minerva Polias, and of Erechtheus at Athens, exceeded every other remain of antiquity for singularity and beauty: each volute has a double channel, formed by two distinct spiral borders, which leave between them a deep recess or groove, diminishing gradually in its breadth till it is entirely lost on the side of the eye. In the former temple, the shaft is terminated with a single fillet below the lower edges of the volutes; and in the latter, with a fillet and astragal. In both, the Colorino is decorated with wood-bines, formed alike in the alternate courses, but differing in the adjoining ones. The upper annular moulding of the column is of a semi-circular section, embellished with a guilloche. In the temple of Bacchus, at Teos, the great theatre at Laodicea, and in all the Roman Ionics, the connecting channel of the volutes has no border on the lower edge, but is terminated with a horizontal line, which falls a tangent to the beginning of the second revolution of each volute. When columns are given to the flanks as well as the front of a building, the angular volute of the outside column is double, and made to face both the contiguous sides of the building; examples of which are to be met with in the temples of Fortuna Virilis at Rome, of Minerva Polias at Priene, of Bacchus at Teos, and of Erechtheus, and the temple on the Illyfus, at Athens. Sometimes the capitals of all the columns are made to face the four sides of the abacus alike, as in the temple of Concord at Rome, from which example the Scammozian capital, as it is called, was first imitated by Michael Angelo, as may be seen in the Conservatorium, embellished by him with this capital during the pontificate of Paul III. before Scammozzi was known as an architect.

Both Grecian and Roman Ionic capitals have the echinus, astragal, and fillet. The echinus is uniformly cut into eggs, surrounded with borders, and tongues between every two borders. The astragal consists of a row of beads, two large and two small alternately. In all the Roman buildings, except the Coliseum, these mouldings are cut alike, differing only in the taste of the foliage.

In the temple of the Illyfus, the architrave consists of one broad fascia, crowned with a cymatium. The parts of the cornice visible in front are the corona, with its cymatium and sima. The cymatium of the frieze is wrought under the cornice, and consists of a sima reverse, and bead below it. The height of the architrave is about two-fifths of the entablature; and by dividing the upper three-fifths into five other parts, the plain part of the frieze will be found to occupy three, and the cornice two parts. The architraves of the temples of Erechtheus and Minerva Polias at Athens, consist of three fasciæ and cymatium; the cymatium of the frieze being mostly wrought under the corona. Divide the height of the entablature, from the bottom of the lower fascia to the top of the cymatium of the corona, into 10 parts, and the architrave, with the part of the frieze that is seen, will be found to occupy 16, viz. eight for the architrave, and as many for the frieze; the other three parts will comprise the corona, including the larimer and cymatium.

In general, the height of the entablature may be two diameters; but in buildings requiring grandeur as well as elegance, it should not be less than a fourth.

The Asiatic Ionic differs materially from the European or Attic. In the former, most of the remains are without the friezes, so that the height of the entablatures cannot be precisely determined, notwithstanding that the architraves and cornices have been accurately measured. In the great theatre

theatre at Laodicea, however, this order has a puledated frieze, whose height is rather less than a fifth of that of the whole entablature. In the temples of Bacchus at Teos, and of Minerva Polias at Priene, the architraves are divided into three fasciæ below the cymatium. In all the Asiatic specimens, the crowning moulding is a *firma recta*, less in projection than in height; the dentils are constantly used, and their height is about a mean proportion between that of the *firma recta* and that of the larimer; it being always greater than the height of the larimer, and less than that of the *firma recta*. The cymatium of the denticulated band being wrought almost entirely out of the soffit of the corona, receded upwards, its elevation is almost concealed from the eye of the beholder. The height of the cornice, from the top of the *firma*, to the lower edge of the dentils, is about equal to that of the architrave. The altitude of the frieze, exclusive of its cymatium, or upper mouldings, may be taken at about a fourth of the whole entablature. To give it a greater proportion, would make the entablature too high for the columns.

In the Ionic examples of Greece, there is a constant ratio between the upper part of the cornice, from the lower edge of the corona upwards, and the height of the entablature, which is nearly as two to nine. This is a very distinct division, occasioned by the great recess of the mouldings under the corona; for which reason the cornice is not reckoned too cumbrous, though the whole denticulated band and cymatium of the frieze be introduced below it; and this seems to be the characteristic difference between the European and Asiatic Ionics. This order, as found in Ionia, is complete; while the specimens of Attica want the dentil band, though in other respects they are very beautiful. But the most exquisite remains we have of this order, are to be found in the temple of Minerva Polias at Priene, which, for beauty of proportion and elegance of decoration, exceeds every other specimen.

Plate XXVIII. exhibits a representation with the proportions of this magnificent example, the proportions being marked upon the outline.

Plate I. exhibits in *figs. 1, 2, 4, 5*, different bases applicable to the Ionic orders, *fig. 1*, from the temple of Jupiter Olympus; *fig. 2*, from that of Minerva Polias, at Athens; *fig. 4*, an Ionic base according to Vignola; *fig. 5*, elevation of the capital of the temple of Minerva Polias, at Athens. This is perhaps the most elegant specimen that is to be found of the Ionic capital.

IONIC Architrave, base, capital, cornice, entablature, frieze, pedestal. See the substantives.

IONIC Dialect, in Grammar, a manner of speaking peculiar to the people of Ionia.

At first, it was the same with the ancient Attic; but passing into Asia, it did not arrive at that delicacy and perfection to which the Athenians attained; instead of that it rather degenerated in Asia Minor; being corrupted by the admission of foreign idioms.

In this dialect it was that Herodotus, Hippocrates, and Galen wrote. See DIALLECT.

IONIC Sect was the first of the ancient sects of philosophers, and was called the Ionic school.

The founder of this sect was Thales, (see his article,) who, being a native of Miletus, in Ionia, occasioned his followers to assume the appellation of Ionic.

It was the distinguishing tenet of this sect, that water was the principle of all natural things.

This is what Pindar alludes to in the beginning of his First Olympic Ode.

But Thales could not mean to assert, that water is the

efficient cause of the formation of bodies; but merely, that this is the element from which they are produced. It is not improbable, that by "water," he meant to express the same idea, which the Cosmogonists expressed by the word chaos, the notion annexed to which was that of a turbid and muddy mass, from which all things were produced. (See CHAOS.) It has been much debated, whether Thales, besides the passive principle in nature, which he called water, admitted an intelligent, efficient cause. Those who have maintained the affirmative lay great stress upon sundry aphorisms concerning God, which are ascribed by the ancients to this philosopher, particularly the following; that God is the most ancient being, who has neither beginning nor end; that all things are full of God; and that the world is the beautiful work of God. They also allege the testimony of Cicero, who says, (*De Nat. Deor. l. i. c. 10.*) that Thales taught, that water is the first principle of all things, and that God is that mind which formed all things out of water. Those who are of the contrary opinion, urge that the ancients, and even Cicero himself, though not very consistently, ascribe to Anaxagoras the honour of having first represented God as the intelligent cause of the universe, and they add that the evidence in favour of Thales rests only upon traditional testimony, which may be opposed by other authorities. (*Elem. Alex. Strom. l. ii. p. 364. Aug de Ca. Dei. l. viii. c. 2. Euseb. Prep. Evang. l. i. c. 7.*) The truth may probably be this; that Thales, though he did not expressly maintain an independent mind as the efficient cause of nature, admitted the ancient doctrine concerning God, as the animating principle or soul of the world. Concerning the material world, Thales taught, that night existed before day, which doctrine he probably borrowed from the Grecian theologians, which placed Night, or Chaos, among the first divinities. He held that stars are fiery bodies; that the moon is an opaque body illuminated by the sun, and that the earth is a spherical body, placed in the middle of the universe. In mathematics, Thales is said to have invented several fundamental propositions, which were afterwards incorporated into the elements of Euclid; particularly the following theorems, *viz.* that a circle is bisected by its diameter; that the angles at the base of an isosceles triangle are equal; that the vertical angles of two intersecting lines are equal; that, if two angles and one side of one triangle be equal to two angles and one side of another triangle, the remaining angles and sides are respectively equal; and that the angle in a semicircle is a right angle. Of his knowledge of the principles of mensuration, and consequently of the doctrine of proportion, his instructions to the Egyptian priests for finding the height of their pyramids, are a sufficient proof. His method was this; at the termination of the shadow he erected a staff perpendicular to the surface of the earth; and thus obtained two right-angled triangles, which enabled him to infer the ratio of the height of the pyramid to the length of its shadow, from the ratio of the height of the staff to the length of its shadow. (*Laert. l. i. § 24, 25. 27. Proclus in Euclid. l. i. Plin. Hist. Nat. l. xxxviii. c. 17.*) Astronomy, as well as mathematics, seems to have received considerable improvement from Thales. He was able to predict an eclipse, though probably with no great degree of accuracy as to the time; for Herodotus, who relates this fact (*l. i.*), only says, that he foretold the year in which it would happen. He taught the Greeks the division of the heavens into five zones, and the solstitial and equinoctial points, and approached so near to the knowledge of the true length of the solar revolution, that he corrected their calendar, and made their year to contain 365 days. The seeds of natural science, which had been sown

by Thales, the father of the Grecian philosophy, were successfully cherished in their growth by Anaximander. He was followed in the Ionic school by Anaximenes, Anaxagoras, Diogenes Apollonietes, and Archelaus of Miletus, who may be considered as the last preceptor in the original Ionic school. See the several biographical articles. Socrates is commonly reckoned to have been the disciple of Archelaus. He was himself the founder of a school; for an account of which see SOCRATES and SOCRATIC school. The inferior sects in the Ionic succession were the *Cyrenaic*, the *Megaric*, and the *Ellic* or *Eretriac*. Those of higher celebrity were the *Academic* and the *Cynic*, from which latter arose the *Peripatetic* and the *Stoic*, which was the last branch of the Ionic school. See each of these articles.

The Ionic philosophy, notwithstanding the celebrity of its first professors, soon failed in the Grecian schools, and never afterwards recovered its ancient reputation and authority. This was owing to the suspicion of impiety under which it lay in Athens, to the early growth of new branches from the Socratic stock, and to the rise and spread of the Eleistic and Epicurean philosophy. In later times, the universal prevalence of the Platonic and Aristotelian systems precluded every idea of reviving the physiognomy of the Ionic school, till, in the 17th century, an attempt was made for this purpose by Berigard, but in a manner so circumspect and covert, that this philosopher was commonly ranked among the followers of Aristotle, and even supposed to be deeply tainted with the impiety of his system. Claud Berigard was born at Molena in Spain in the year 1592, and studied first at Aix, then at Paris, and afterwards at Pisa, where, by the favour of the duke of Tuscany, he was appointed professor of mathematics and botany. His fame, which spread through Italy, induced the republic of Venice, in the year 1640, to appoint him, with a liberal stipend, professor of philosophy in Padua. Here he remained till his death in 1668. In the year 1632, he published, under a fictitious name, a work entitled "Dubitaciones in Dialogos Galilaei de Terrae Immobilitate;" but his principal work is his "Circuli Pisani," in which he relates the disputation which were held at Pisa, on the physical writings of Aristotle, and gives his own sentiments upon them. Berigard, having perceived the folly of that implicit obedience which had been long paid to the authority of the flagyrite, became a determined opponent of his philosophy, not openly, which would have been hazardous, but in the indirect and concealed method of dialogue. Adopting the Ionic system, he framed a disputation between the Aristotelians and Ionics, in which he made Aristotle refute the reasoning of Charielus, and support the doctrine of the Ionic school, by an appeal to experience, as well as by many ingenious arguments. However he saw, and confessed, that both the Peripatetic and Ionic systems were materially defective, and in many particulars erroneous; and therefore much inclined to philosophical scepticism. Nevertheless he endeavoured to prove, that the followers of Thales approached nearer to truth than those of Aristotle, the dangerous tendency of whose tenets, in several particulars, he clearly exposed. Among the doctrines of the flagyrite, those which he chiefly reprobated were the following, *viz.* that the world is eternal; that the residence of the first mover is confined to the outer sphere of the universe; that neither the world, nor any being, can properly be said to have been created; and that there is one soul common to the whole human species. In opposition to these opinions, which Berigard rejected as capital errors, from which many others must arise, he maintained the Ionic doctrine of the eternity of the primary particles of matter; of a forming

and presiding mind, by whose agency these particles were collected into distinct bodies; and of the combination and dispersion of these as constituting the formation and dissolution of all things. In short, Berigard seems to have prepared the way for the revival of the Atomic system of Epicurus, which was, soon after this time, restored and defended by Gassendi, Brucker's Hist. of Philos. by Enfield, Bayle.

IONIC Transmigration was heretofore a celebrated epocha, which took its rise from the retreat of the Athenian colonies; who, upon the death of Codrus, put themselves under the command of his son Neleus, and established the twelve cities of Ionia in Asia.

Those colonies, according to Eratosthenes, were established fifty years after the return of the Heraclidae; and, according to Marsham, seventy-seven years after the taking of Troy. See IONIA.

IONIC, or IONIAN *Mod*, in the *Ancient Greek Music*. The Ionian mode, reckoning from the grave to the acute, was the second of the five middle modes in the Grecian system. This mode was also called *Jastian*, and Euclid still terms it the *grave Phrygian mode*. See MODE.

IONIS, in *Surgery*, a carbuncle of a violet colour.

JONKAKONDA, in *Geography*, a town of Africa, in the kingdom of Yani, on the N. side of the Gambia. N. lat. 13° 37'. W. long. 13° 50'.

JONKIOPING, a town of Sweden, in the province of Smaland, beautifully situated between two small lakes, at the southern extremity of the Wetter lake; it is the capital of the province, and the seat of the parliament or superior court of justice for the kingdom of Gotland. The town is two miles in circumference, and contains 3000 inhabitants; the houses are mostly of wood, covered with turf. This town contains two faubourgs, three churches, an arsenal, and a manufacture of arms; 156 miles S.W. of Stockholm. N. lat. 57° 45'. E. long. 13° 59'.

JONKS, or JOXQUEUS, in *Ship Building*, vessels very common in the East Indies, about the bignets of our fly-boats, but differing in form of building, according to the various methods of the nations in those parts. See JUNK.

JONOOL, in *Geography*, a town on the N.W. coast of the island of Timor. S. lat. b. 59'. E. long. 125 13'.

JONQUETIA, in *Botany*, was so called after Denis Jonquet, who, in the year 1663, published the *Hortus Regius Parisiensis*, in folio. This catalogue contains about 4000 plants, of which indeed the greater part are only varieties; but amongst them are many Canadian and Alpine plants.—Schreb. 308. Willd. Sp. Pl. v. 2. 750. Mart. Mill. Diét. v. 2. (Tapiroia; Aubl. Guian. v. 1. 470.—Tapiroia, Juss. 372.) Class and order, *Decandria Pentagynia*. Nat. Ord. *Trochintaceae*, Juss.

GEN. CH. Cal. Perianth of five, roundish, deciduous leaves. Cor. Petals five, roundish, concave, spreading, longer than the calyx. Stam. Filaments ten, shorter than the corolla, affixed to a gland; anthers roundish. Pist. Germen five-sided, surrounded by a glandule; styles none; stigmas five. Peric. Capsule somewhat globular, roundish, five-fruited, of one cell and five valves. Seeds five, ovate, unilobed, each affixed to the valves.

EFF. CH. Calyx of five leaves. Petals five. Capsule five-globular, of one cell, five valves, and five arillated seeds.

1. *J. paniculata*. Willd. (J. guianensis; Mart.—Tapiroia guianensis; Aubl. Guian. t. 188.)—A native of woods in Guiana, where it flowers in November, and brings forth fruit in April. It is there called Tapiroia.—This tree rises to the height of fifty feet, has a smooth russet bark, and a white uncompact wood. Leaves alternate, unequally pinnate; consisting of four or five pairs of smooth, thin,

ectire,

entire, oval, pointed leaflets. *Flowers* small, numerous, white, axillary, and terminating in large, wide, scattered panicles.

JONQUIL. See **NARCISSUS.**

JONSAC, in *Geography*, a town of France, and principal place of a district, in the department of the Lower Charente; nine miles S.E. of Pois. The place contains 2,500, and the canton 11,941 inhabitants, on a territory of 18½ kilometres, in 20 communes.

JONSBURG, a town of Sweden, in East Gothland, near the coast of the Baltic; 22 miles E. of Nördkiöping.

JONSON, or **JOHNSON, BENJAMIN,** in *Biography*, an English poet, was born, in 1573, at Westminster, about a month after his father's death. He was educated at Westminster school under the learned Camden, and had made great progress in his studies, when his mother, who had married a bricklayer for a second husband, took him from school to work under his father-in-law. From this employment he escaped, enlisted for a common soldier, and served in the army, contending with the Spaniards in the Netherlands. On his return from a service in which he had gained much reputation, he entered himself at St. John's college, Cambridge; but the state of his finances obliged him soon to quit this residence. He next attempted the profession of an actor on the stage, but his talents were but ill adapted to this business; and from the life of an actor he undertook the more arduous task of dramatic writing. He was patronized by the immortal Shakspeare. The first piece which Jonson printed was "Every Man in his Humour," acted in 1598; his success in this effort led him to furnish a play yearly, till his time was occupied by the composition of the masques, &c. with which the accession of king James was celebrated. In 1609, he produced his "Epicene, or Silent Woman," which is accounted the most perfect of his comedies; and in the following year "The Alchemist" was performed with great applause. So industrious had his life been, that in 1616 he published a folio volume of his works, and in the same year he received a grant from the king of the salary of poet-laureat for life; the office being at that time occupied by another, but to the duties of which Jonson succeeded in 1616. He continued to write for the court and stage, but, in 1629, one of his comedies was hindered off the stage. From this time he fell into necessitous circumstances, owing as well to the negligence of his disposition, as to his fondness for convivial society. It has been asserted, that king Charles I. hearing of his distress, sent him ten pounds, a present very unsuitable to the means of a great monarch, and which the poet received with an ill grace; the fact has, however, been doubted, because in Jonson's works it to be found an epigram, "To King Charles for an hundred pounds he sent me in my sickness, 1629." From this period the powers of his mind and body seemed to droop together, and his later productions are but mendicant poems addressed to different patrons. He died in 1637, at the age of sixty-three. He was interred in Westminster Abbey, and the inscription "O rare Ben Jonson" was placed over his grave. This short sentence shews in what estimation his talents had been held. He had indeed been regarded as at the head of English poetry, and was addressed by the wits with the reverential title of "Father Ben." The bust that now marks his place in Westminster Abbey, was put up by the second earl of Oxford. The fame of Jonson is principally founded upon his comedies, which were for a long time reckoned the most perfect in the English language; but they have gradually disappeared from the stage. It is now generally admitted that his excellence was comprised within

narrow limits, and chiefly consisted in the preservation of the unities and the skillful management of the plot, but he was defective in almost every thing which makes comedy pleasant. "As a general poet, Jonson is for the most part harsh, frigid, and tedious, perpetually in pursuit of some uncommon thought, which he wants taste and genius to render striking and agreeable." *Biog. Brit.*

JONTHLASPI, in *Botany*. See **CALYPTOLA.**

JONTHOS, *Scorpius*, in *Medicine*, signifies small inflamed tumours, or pimples, which occur in the face. It was translated *scarus* by the Latins, which term they also applied to the *acne* of the Greeks. The *intubi*, or *cori*, according to Sauvages, "are those small, red, hard, and oblong tumours, which scarcely ever suppurate, do not itch, are not painful, and only appear in the face." He considers them as of the same nature with the *Gutta rosea*.

JOOD-BOODANG, in *Geography*, a town on the W. coast of the island of Celebes. S. lat. 1° 39'. E. long. 119° 21'.

JOODPOUR, a circar of Hindoostan, being one of the three great principalities into which Rajpootana is divided. It was also named Marwar. In Achar's division of the empire, these principalities were classed as belonging to the foubah of Agimere, which is sometimes called Marwar. This principality lies to the N.W., bordering angularly on the other two, *viz.* Oudipour and Jyenagur. The revenues are stated to have been, in 1759, 40 lacks of rupees. This, as well as Oudipour, is very mountainous, with a sandy soil in the valleys. (See **RAJPOOTANA**).—Also, a town in the above circar, in the country of Agimere; 8½ miles W.S.W. of Agimere. N. lat. 26° 7'. E. long. 73° 48'.

JOOGDANPOUR, a town of Bengal; 16 miles N.W. of Kishenagur.

JOOGDYA, a town of Bengal; 70 miles S. E. of Dacca.

JOOKY, a town of Bengal; 14 miles N.E. of Bogli-pour.

JOOSTLAND, ST., a small island of Holland, separated from the island of Walcheren, by a narrow channel, and containing one village.

JOOTSISIMA, or **JAOTSISIMA,** two small islands of Japan, near the N. coast of Niphon. N. lat. 37° 56'. E. long. 137° 50'.

JOPPEAN, among the ancients, an exclamation used on account of a victory, or some prosperous event. Hoffman thinks that *Io Pœan* is a contraction of the Hebrew *Jaa*, from *Jehovah*, and *7125*, *r. spiritus*; and was the same with *Jehovah Pœebis*, *i. e.* *Domini spiritus in-nos*. Something like this exclamation still remains among the Syrians, a people of the West Indies, who, on any joyful occasion, frequently cry out *To Pœo*.

JOPPA, in *Ancient Geography*, a town of Phœnicia, situated at the southern extremity of the plain of Saron, on a high hill, which commanded a full prospect of the sea on one side, and of a fertile country on the other. It had the town of Jamnia on the S.; Cafarea Palestina on the N.; and Rama, or Ramula, on the E.; and it is often mentioned both in the Old and New Testament. The Greeks and Phœnicians ascribe to it a very high antiquity; and it is certain that it existed 500 years before the Christian era, since Joshua marks the limits of the tribe of Dan in the vicinity of Joplo, the Phœnician name of this town. Joppa, which had a good port, and the only one that the Jews had on the Mediterranean, belonged successively to the Chaldeans, Persians, the Lagides of Egypt, and the Seleucide of Syria; and it was under the dominion of these last 163 years B. C. The inhabitants of this place provoked the

indignation of Judas Macchiabæus, by a violation of their treaties, and by precipitating 200 Jews into the sea, which induced him to fall upon them by surprize in the night and to burn all their vessels. Joppa underwent various revolutions until the arrival of Pompey in Syria, about 64 years before our era. This general restricted Judea within its ancient bounds, and obliged Hyrcanus to evacuate the towns of Phœnicia; but Augustus gave this town to Herod. In consequence of the revolt of the Jews, Gallus Cæsius, governor of Syria, took it and set it on fire, A.D. 65. The Jews made several efforts to re-establish it; but Vespasian, in the year 67, dispatched a body of troops from Cæsarea, who took it without difficulty. The Jews betook themselves for refuge to the sea; but being beset by a violent tempest, more than 4000 of them perished. The Romans again destroyed it. (Josephus de Bell. Jud.) The town was so entirely ruined during the holy war, that it had scarcely any buildings left standing but the old castle, situated on an eminence above it, and another near the seaside. The town was afterwards rebuilt towards the sea with good stone-houses; and is now called *Jossa*, or *Yafa*, which see.

JOPPA, in *Geography*, a small town of America, in Harford county, Maryland; 20 miles E. by N. of Baltimore.

JORBORG, a town of Samogitia, on the Niemen; 20 miles S. of Roshene.

JORDAENS, JACON, in *Biography*, a painter of history and portraits, possessed of very superior abilities in his art, was born at Antwerp in 1594. He first studied with Adan Van Oort, whose daughter he married at an early period of his life; but it was to Rubens he stood indebted for the principal part of his knowledge; though it is dubious whether he ever was admitted into the school of that master. Certain it is, however, that he more forcibly carried into effect his principles than any of his disciples, except Vaedye.

It is said by Sandrart, that Rubens was jealous of him, and if to great a man were capable of that mean passion, certainly the talents of Jordaens might well excite it. He painted with almost incredible force and brilliancy. Neither Rubens nor Tintoretto, in that respect, excel him; his compositions are full of bustle, and designed with great truth, even grandeur of form. His defect (and it must be allowed that it is a great one, in an art whose principal end is to adorn, to improve, to please mankind) is grossness of subject and of form; not indecent, but vulgar, low common life.

His power to give rotundity and relief to his figures, is amazing; and his execution is of the most masterly kind.

The French have possessed themselves of many of his principal works; two are particularly noticeable in the gallery of the Louvre, the Flemish celebration of Twelfth night. known by the appellation of "Le Roi boit," and Christ driving the money-changers from the temple.

He was remarkable for the rapidity of his execution, and appears to have studied his figures and effects by candle light, or in bright sun-shine. Having obtained great renown and success, he died in 1678.

JORDAN, in *Ancient Geography*, the chief river of Palestine, which had its source in the lake of Phiala, about 10 miles N. of that of Samachon; which origin of the river was ascertained by Philip the tetrarch, who made the experiment of throwing some straw or chaff into the lake, which came out at the Panion, or Panceas, where the river emerges out of the earth, after having run about 120 furlongs under ground. This lake Phiala, a name commonly given to all other reservoirs of that kind, is situated in a most

delightful country, so well adapted for commerce, that marts and fairs are held in the adjacent places through the summer by the neighbouring inhabitants. The etymology of the name has been variously assigned. Jordan, in Hebrew *Jard-n*, is derived from *jerad*, *descendit*, or *jorden*, *defensus*, from its rapid descent through that country. This origin is more probable than several others which have been given by different writers. Some say that it is formed of the oriental *Jor*, a stream, and *Dan*, a town, near which it had its source. Hardouin says that this name signifies the "river of delight," or the "delightful river." Others say, that *dan* or *dun* signifies depth, whence it was named the "deep river," to distinguish it from others in Palestine, all which were comparatively brooks or rivulets. The Arabs call it Arden or Harden, or Ordonnon; the Persians, Aerdon; and the Nubian geographer Edrisi gives it the name of Zaechar, which, in Arabic, signifies swelling or overflowing. Jordan is so considerable, in comparison with others, that it is sometimes styled, by way of emphasis, "the river." The course of the Jordan is mostly southward, bending a few degrees towards the west. After a run of about ten or twelve miles, it passes quite through the Samachonite lake, whence, after a course of about eighteen or twenty miles more, exclusive of its windings, it enters into the sea of Tiberias on the N. side, and comes out again on the S. side, at a small distance from a city of that name. Thence it proceeds still south-westward through a plain and desert of about 60 miles, and falls into the Asphaltite lake. Its course is very rapid, though its bed is deep. Pococke compares its breadth to that of the Thames at Windsor. Shaw gives it only 30 yards, whilst he states its depth, even at its brink, to be three yards. Its banks are occasionally beautiful, and in some places covered with high and thick reeds, cane, and trees, such as willows and tamarisks, which afford a convenient lodging for lions and other wild beasts. This river, it is said, constantly overflowed its banks about the time of the early harvest, or soon after Easter; and in this respect differed from other rivers, which commonly swell most during the winter. This inundation has been ascribed to its subterraneous communication with the Nile. But it is more probably owing to the melting of the snows about that time, and the early rain which falls in great abundance. Modern travellers inform us, that it is no longer subject to these overflows; because, as they conceive, it has, by the rapidity of its current, worn its channel deeper than formerly, or, perhaps, diverted some of its waters another way. Its water is commonly very turbid, occasioned by its rapidity; but it is said to be very wholesome and incorruptible: and superstition has even invellid it with the property of washing away the sins of mankind. Dr. Pococke, who mentions this circumstance, adds, that not only men, but women, are ambitious of deriving benefit from these salutiferous waters, by bathing and swimming in it, even at the hazard of their lives. The Latin priests erect altars along its banks, where they say mass to the devout pilgrims. We shall only add, that the plain on both sides of this river, from the sea of Tiberias to the Asphaltite or Dead sea, is very dry, sultry, and insalubrious during the heat of summer, and every where barren, except in that part which lies near the river, and is watered by it. *Anc. Un. Hist. vol. ii.*

JORDEN, EDWARD, M. D. in *Biography*, was born in the year 1569, at High Halden, in Kent, and probably educated at Hart-hall, Oxford. After completing his studies in his own country, he travelled abroad, visiting several foreign universities, and taking his degree of doctor in that of Padua. On his return, he practised for a time in London,

where he became a member of the College of Physicians, and was in great reputation for learning and abilities. He gave an instance of his good sense in detecting the imposture of one Ann Gunter, who was affected with strange and singular symptoms, which were imputed to witchcraft. Dr. Jordan removed, after some time, from London to Bath, where he spent all the latter part of his life, universally respected as well in his private character as in his medical capacity. The studious and sedentary life which he led, aggravating the disorders to which he was constitutionally subject, the gout and stone, he died in his sixty-third year, on January 27th, 1632. He was author of two publications: "A brief Discourse of a Disease called the Suffocation of the Mother, &c." Lond. 1603; and 2. "A Discourse of Natural Baths and Mineral Waters;" Lond. 1631, 4to. This soon went through a second edition, and was afterwards reprinted in 1659, in 8vo, by Dr. Guidott, and again in 1673. It is a work of considerable learning and ingenuity, written in a clear style and judicious method. Aikin's *Biog. Mem.* of Med.

JORE, in *Geography*, the highest mountain in the Cherokee country, through which the Tennesse river forces its waters.

JORGA, a town of Asiatic Georgia, in the province of Kaketi; 85 miles S.E. of Tefisi.

JORGE GREGO, a small island near the coast of Brazil.

JORGE, *St.*, a town of Brazil, in the government of St. Salvador, and chief place of the captaincy of Illicos, situated on land projecting into the Atlantic. S. lat. 13 45'. W. long 22 45'.—Also, a town of New Mexico, on the Bravo; 20 miles E. of Sumas.

JORGE de Olancha, *St.*, a town of Mexico, in the province of Honduras; 100 miles E. of Valladolid. N. lat. 14° 35'. W. long. 86 36'.

JORGEN, a town of Norway, in the diocese of Bergen; 33 miles S.W. of Roskilde.

JONGEN, *St.*, a town of the duchy of Stiria; 14 miles S.E. of Gratz.—Also, a town of Austria; 12 miles S.E. of Ips.—Also, a town of the duchy of Bremen; 5 miles N.N.E. of Bremen.

JORGENAW, a town of Prussia, in the circle of Nantagen; 22 miles S.S.E. of Konigsberg.

JORGENBURG, a town of Austria; 14 miles S.S.W. of Steyr.

JORONTAL, a town of Prussia, in the province of Oberland; 6 miles S.W. of Leibnitz.

JORONTAL, a town of Bohemia, in the circle of Leitmeritz; 6 miles N.E. of Kunitz.

JORJAN, or CORCAN, a town of Persia, and capital of a district, to which it gives name, in the western part of Chorasan, bordering on the Caspian sea, situated on the Abiscoun. It was anciently the capital of Hyrcania, and named Syringes; 300 miles N. of Ispahan. N. lat. 36° 54'. E. long 54 54'.

JORKO V, a town of Bohemia, in the circle of Saatz; 13 miles N. of Saatz. N. lat. 50° 28'. E. long. 13 26'.

JOROPOUR, a town of Bengal; 38 miles N.N.E. of Calcutta.

JORQUERA, a town of Spain, in New Castile, on the Xucar; 38 miles S.S.E. of Alarcón.

JORRACH, a town of Arabia, in the province of Hiedfjas; 188 miles S.S.E. of Mecca.

JORSA, one of the smaller western islands of Scotland, between Scarba and Kerrera.

JORFIN, JOHN, in *Biography*, born in London in 1698, was son of Renatus Jortin, a native of Bretagne, in France, who came over as a refugee on the repeal of the Edict of Nantes,

and who was appointed one of the gentlemen of the privy-chamber to king William III. in 1701. He was afterwards secretary to admiral Russel, earl of Orford, and fir Cloudesley Shovel, and perished with the latter when his ship struck on the rocks of Scilly. This was in October 1707, when his son John, only nine years of age, was sent to the Charter-house as a day-scholar, where he laid the foundation of an exact and elegant classical taste. In 1715 he was admitted pensioner of Jesus college, Cambridge, and so distinguished himself by his talents and application, that, while he was under-graduate, he was engaged, by the recommendation of Dr. Thirlby, to translate some of Eusebii's notes on Homer for Mr. Pope. He performed the work to the satisfaction of the poet, who, however, did not think it worth while to make any personal enquiry after a young student at college. "I was," says Mr. Jortin, "in some hopes, in those days (for I was young), that Mr. Pope would make enquiry about his coadjutor, and take some civil notice of him. But he did not, and I had no notion of obtruding myself upon him—I never saw his face." Mr. Jortin was admitted to the degree of bachelor of arts in January 1718-19, and was elected fellow of Jesus college in October, 1721, and in the following year he took his degree of M. A. In this latter year he was appointed one of the moderators at the disputations, and appeared likewise as a writer, by the publication of his "Lusus Poetici," a collection of Latin poems, which have been ranked among the most elegant and truly classical compositions of the kind produced by a modern scholar. They have been frequently reprinted, and retain their original reputation. He was admitted to priory's orders in 1724, and in 1727 was presented by his college to the vicarage of Swaveley, near Cambridge. In 1730-1, he resigned his vicarage, and settled in London, where he served a chapel belonging to St. Giles in the Fields, in New-street, Bloomsbury, about sixteen years. His first publication, after his arrival in the metropolis, consisted of four sermons on the truth of Christianity, which have since been incorporated in some of his subsequent publications. In the years 1731 and 1732, Mr. Jortin, in conjunction with bishop Pearle, Dr. Taylor, Mr. Upton, Dr. Thirlby, and others, published, in a series of twenty-four six-penny numbers, "Miscellaneous Observations upon Authors, ancient and modern," which were highly applauded by the learned of his own country, and which were translated into the Latin language at Amsterdam. He next published "Remarks on Spenser's Poems," to which were subjoined "Remarks on Milton;" he published likewise "Remarks on Seneca." In 1747 he was appointed by his friend Dr. Pearle, then rector of St. Martin in the Fields, to be afternoon preacher at a chapel in Oxendon-street. In 1749, Mr. Jortin, at the recommendation of archbishop Herring and bishop Sherlock, was appointed preacher of Boyle's lecture. The substance of the discourses which he delivered on this occasion, was afterwards inserted in his "Remarks upon Ecclesiastical History." Of this work, the first volume was published in 1751, and the second and third in the years 1752 and 1754, the other volumes were given to the world after the author's death. In 1751, he had been presented by archbishop Herring with the rectory of St. Dunstan in the East; and in the year 1755 he was presented by the same prelate with a Lambeth degree of D. D. The principal work of Dr. Jortin was his "Life of Erasmus," of which the first part was published in 1758, in one volume 4to; the second volume, printed in 1760, consisted only of observations on the writings of Erasmus. The groundwork of this piece of biography, is one drawn up by the celebrated Le Clerc, and published in his "Bibliothèque

.Choife." "The life of Erasmus," says Dr. Knox, "abound with matter interesting to the scholar; but the style and method are such as will not please every reader. There is a carelessness in it, and a want of dignity and delicacy." Nevertheless it extended the reputation of Dr. Jortin beyond the limits of his native country, and established his literary character in the remotest universities of Europe. The declining years of Dr. Jortin were cheered by some substantial proofs of the esteem which he had inspired for his character and abilities. In 1762, he was collated by bishop Osbaldilton to a prebend in the cathedral of St. Paul's, and in the same year he was presented by the same friend to the valuable vicarage of Kennington. The bishop, as another proof of his determined patronage of our author, appointed him archdeacon of London, in April 1764, and it is believed he offered him the rectory of St. James, Westminster, upon the death of Dr. Samuel Nicol's, in November 1765, but he chose to continue at Kennington, that being a situation better adapted to his advanced age. Dr. Jortin died on the 5th of Sept. 1770, in the 72d year of his age. The tranquil composure of his last moments was expressed in the words he spoke to his nurse, who urged him to take more nourishment: "No," said he, "I have had enough of every thing." He left a widow and two children. The private character of Dr. Jortin was truly estimable: he had a spirit which raised him above every thing mean and illiberal, and would not permit him to stoop for preferment. His manners were simple, and in some respects rustic: he had true urbanity in his temper, and benevolence in his heart. As a public defender of religion, he is classed by bishop Watson among those great and eminent names who have honourably and successfully laboured to establish the truth and illustrate the doctrines of Christianity. Dr. Knox, speaking of his "Discourses on the Christian Religion," which was one of the first fruits of his theological pursuits, says they abound with sound sense and solid argument, which entitled their author to a rank very near the celebrated Grotius. He farther adds, "as a poet, a philosopher, and a man, he served the cause of religion, learning, and morality." Besides the works already noticed, Dr. Jortin was author of an "Essay on Musical Expression;" of "Six Dissertations on different Subjects;" and after his death his "Sermons and Charges," in seven volumes, were given to the world. His works were published a few years since in an uniform manner, and may be had with or without the life of Erasmus. Of these works a full account will be found in the "Memoirs of the Life and Writings of Dr. Jortin," by the Rev. Dr. John Diney, who has also given the character of the author as drawn by the energetic pen of Dr. Parr. "Jortin," says he, "whether I look back to his verse, to his prose, to his critical, or to his theological works, there are few authors to whom I am so much indebted for rational entertainment, or for solid instruction. Learned he was, without pedantry. He was ingenious without the affectation of singularity. He was a lover of truth, without hovering over the gloomy abyss of scepticism, and a friend to free inquiry, without raving into the dreary and pathless wilds of latitudinarianism. He had a heart which never disgraced the powers of his understanding. With a lively imagination, an elegant taste, and a judgment most masculine, and most correct, he united the artless and amiable negligence of a school-boy. Wit without ill nature, and sense without effort, he could at will feather upon every subject, and in every book the writer presents with a near and distinct view of the real man."

JORVIS, in *Geography*, a town of Sweden, in the government of Kuopio; 43 miles S. of Kuopio.

IOS, in *Ancient Geography*, one of the Cyclades islands, E.N.E. of the island Sicinos, N.N.W. of Thera, and S.S.W. of Naxos. This island derived its name from a colony of Ionians, who were its first inhabitants. It is famous only for being the place of Homer's death and burial. It is said that the town of Arges was accustomed to send every five years a deputation to this island, commissioned to offer libations in its name on the tomb of the poet, which was an object of public veneration.

JOSEPH, in *Scripture Biography*, a Hebrew patriarch, who sustained a rank and character that entitle him to particular notice. He was the son of Jacob by his wife Rachel, and born about the year 1745 B.C. As he was the favourite of his father, on account of his personal and mental endowments, he became the object of the jealousy and hatred of his brethren; and they fold him to some Ishmaelites who were travelling to Egypt (B.C. 1728), feigning a tale that he had been devoured by wild beasts. When the Ishmaelites arrived in Egypt, they fold Joseph to Potiphar, an officer of the royal household. In this situation Joseph conducted himself with such prudence, industry, and fidelity, that his master committed all his affairs to his management. After ten years service Potiphar's wife assailed him with a temptation, which every principle of gratitude and honour, as well as of religion, induced him to resist; but the consequence of his integrity was her repentment, and a resolution, as far as she could prevail, to effect his ruin. Accordingly she formed an artful story, intimating that Joseph had made an attempt upon her virtue; and she contrived to impose upon her husband Potiphar, and to procure Joseph's commitment to prison. The patriarch's conduct, during his imprisonment, engaged confidence, and he was entrusted with the care of his fellow-prisoners. Among these were two persons of some distinction, who had belonged to Pharaoh's household. Both of them had dreams in the same night, which they communicated to Joseph, and which he undertook to interpret. One of them was to be restored to his office, and the other was to be hanged; and the events corresponded to his predictions. Upon the future advancement of one of these persons, who was the chief butler, the other

other being the chief baker, he was altogether unmindful of Joseph, and made no effort, notwithstanding his application to him, to procure for him his liberty. In process of time Pharaoh had two dreams, by which his mind was much impressed, and which none of the wise men who belonged to his court were able to interpret. The chief butler was thus reminded of Joseph, and acknowledging to the king his ingratitude for neglecting him, related the circumstances pertaining to himself and the chief baker. Upon this information, Pharaoh ordered Joseph to be brought to him. The king imparted to him his dreams; and Joseph, modestly disclaiming all pretensions to superior wisdom, and relying on that divine suggestion with which he had been favoured, interpreted them to his satisfaction. (B.C. 1715.) These dreams and their interpretation it is unnecessary for us minutely to recite. It is sufficient to observe, that the king was then favoured of seven years of fertility and abundance, which were to be succeeded by the same period of sterility and famine; and he found it necessary to make previous provision accordingly. With this view Joseph, who was near thirty years of age, was appointed general superintendent of the affairs of the kingdom, and invested with authority next to that of Pharaoh himself, who also gave him in marriage the daughter of Potipherah, priest of On. The course of events was precisely such as Joseph had pre-figured by his interpretation of Pharaoh's dreams; so that granaries were established under his direction in the cities of Egypt, and corn collected in great quantities, and laid up in store, during the years of plenty, for the supply, not only of Egypt, but of neighbouring countries in the succeeding years of scarcity. The years of famine began B.C. 1708. In this period of general distress Jacob sent ten of his sons, from Canaan to Egypt, in order to purchase corn. As this business was wholly committed to the management of Joseph, they were referred to him. Joseph instantly recognized their persons, though he was unknown to them; but in order the more effectually to prevent their discovery of him, and, probably, to excite in their minds a due sense of their past crime, he questioned them in an angry tone, and by an interpreter, concerning their country; and being informed that they had come from the land of Canaan, charged them with being spies, which charge they obviated by giving a true account of their father and family. A younger brother, they said, was left at home with his father, and another was now no more. Joseph still persisted in the charge, and required their verifying the account which they had given of themselves, by dispatching one of their number to fetch their younger brother, while the rest remained in custody. However, he afterwards relented, and proposed that one of them should remain till the arrival of the younger brother, and that all the rest should go home with corn for their families. During their detention they accused one another for the cruelty of their conduct towards Joseph, who, still feigning himself a stranger to their language, heard their mutual reproaches with an emotion which he could not suppress, and which, therefore, required his withdrawing from them. At length he gave them leave to depart, informing them, that if their account of themselves was true, they would be permitted to traffic in the land. Simeon, who is supposed to have been the principal aggressor in the treatment of Joseph, was kept in custody; and the others were dismissed. Before their departure orders had been given that when the sacks were filled with corn, each man's money should be returned in his sack's mouth. This circumstance, when it was discovered in their journey homewards, very much alarmed them; and they concluded

that this was done in order to furnish a pretence for enslaving them when they next visited Egypt. Jacob heard their adventures with surprise and concern; more especially when he found that Simeon was left behind in custody, and that they were pledged to take Benjamin with them before they could obtain his release. At length, as the scarcity increased, and their supply was nearly exhausted, Jacob, with great reluctance, consented to go with Benjamin; and having ordered them to propose presents for the ruler of Egypt, and to carry with them twice as much money as before, he committed them to the blessing of heaven, and dismissed them. Upon their arrival in Egypt, they hastened to present themselves for Joseph; and were kindly received and liberally entertained at a public dinner which he had provided for them. Some circumstances occurred on this occasion which might have brought their brother to their recollection; but they again departed with their sacks and money as before, and to Benjamin's sack was the silver cup out of which Joseph had drunk. Upon their return towards Canaan they were followed by an officer, who charged them with ingratitude for the hospitality with which they had been treated, and with the theft of his lord's silver cup. All of them protested their innocence; but upon searching the sacks, the cup was found to their great surprise and concern in that of Benjamin. They were therefore taken back to Joseph, who insisted upon detaining Benjamin as a slave, until they might be allowed to return home in peace. Recalling the reluctances with which his father had parted with his son Benjamin, and that they were suitors for his return, they urged various pleas for his being allowed to accompany them. Judah was the advocate for his brother's liberty; and he offered himself as a substitute if he were permitted to return. Joseph was at length overcome; disguise became intolerably irksome to him; and he could no longer refrain from discovering himself to his brethren. (B.C. 1705.) This part of the sacred history is wrought up with incomparable beauty and pathos, and must suffer by any attempt to abridge it, or to relate it in different language. The discovery being made, they were all received, and particularly Benjamin, his brother by the same mother, with expressions of the tenderest and most affectionate regard; nor did Joseph, the viceregent of Egypt, for such was the high rank he occupied, lose any time in acquainting Pharaoh with the arrival of his brethren, and with the circumstances of his father and his family. The king immediately gave orders for their being sent for to Egypt, and for setting them in the richest part of the country. Goshen was the district which Joseph allotted to them; and there they were supplied with ample means of subsistence, whilst the inhabitants of other parts of Egypt were suffering great distress on account of the famine, which still continued. The long duration of this calamity drained the people of all their money, and constrained them at length to part with their cattle, their houses, their land, and even their personal freedom for support. (B.C. 1705.) Thus the whole kingdom of Egypt, the lands of the priests excepted, became the demesne of the crown; and all the people were reduced to the servile condition of bondsmen to the crown. Moreover, the old owners were separated from one another, and dispersed through different parts of the kingdom, that they might thus forget their interest in the lands which they had sold, and be precluded from forming combinations for regaining them. In this instance, Joseph's zeal for Pharaoh's interest caused him to overlook the habits which found policy and justice prescribed; and contributed to establish a despotism, which eventually proved very oppressive to the dependants of Joseph, and the rest of the

Israelites. In the last year of the famine, Joseph informed the Egyptians that they might expect a crop during the following year; and that he would enable them to renew their attention to agriculture, by distributing among them fresh lands, cattle, and corn: but he stipulated this condition with them, that from henceforward the fifth part of all the products of their lands should be reserved for the king, and that the residue should be their own. From this time, (B.C. 1702), as the people consented to this regulation, it became a law, that remained in force for several centuries, that the fifth part of the produce of the whole kingdom of Egypt, the lands of the priests excepted, should belong to the crown. After the death of Jacob, and the return of his brethren to Egypt from Canaan, whether they had attended the remains of their father (see JACOB), they were apprehensive that Joseph might retaliate the injuries which they had done him; and therefore they informed him, by a messenger, that it was their father's dying request that he would forgive them, and continue to afford them his protection. Joseph immediately took an opportunity of removing their suspicion and anxiety, by repeated assurances of his unabated affection and zealous concern for their welfare. Having survived his father about 60 years, he informed his brethren (B.C. 1635), that God, according to his promise, would bring their posterity from Egypt to the land of Canaan; and he therefore made them pledge themselves on oath, to bury him with his ancestors. Joseph, having occupied under six sovereigns the office of viceroy of Egypt, during 80 years, retained it till his death, which happened when he had attained the age of 110 years, in the year 1635 B.C. When the Israelites took their departure from Egypt, they observed his injunction concerning the removal of his body; and as we read in Josh. xxiv. 32. it was buried at Shechem, in the field which Jacob bought of Hamor. From Jerome we learn, that the Israelites erected a noble monument to his memory, which was to be seen in his time. We shall not enlarge this article by an account of the tales of the Talmudists and of the Koran (chap. xii.), but refer the reader to D'Herbelot's *Bibl. Orient. art. Joseph*, for specimens of these legendary tales. Gen. xxx.—I. Anc. Un. Hist. vol. iii.

JOSEPH I., in *Biography*, emperor of Germany, son of the emperor Leopold, was born in 1678. He was declared hereditary king of Hungary, and crowned in 1687. In 1690 he was elected king of the Romans, and ascended the imperial throne on the death of his father, in 1705. He pursued the system of the late emperor, and maintained the alliance against France, with England, Holland, and Savoy, in support of the claim of the archduke Charles to the crown of Spain; in which war the allies were successful. Joseph was of a haughty and arbitrary disposition, employed violent measures against all the opposers of his authority, and supported with a high hand all the claims of his house. In 1706 he put the electors of Bavaria and Cologne to the ban of the empire, for taking part with France; and having deprived those princes of a great part of their estates, he bestowed the same on his own relations and favorites. He quarrelled with the pope, whom he afterwards obliged to recognize his brother the archduke Charles as king of Spain. He made himself master of Italy, and levied contributions on Mantua, Parma, Modena, Lucca, Genoa, and other places. His armies defeated the revolted Hungarians; but in the midst of his successes, he was carried off by the small-pox, in April 1711, at the age of thirty-three, owing, it was believed, to the unskilfulness of his physicians. His character has been variously represented. He was impatient of opposition, active, and enterprising; and fre-

quently pursued from motives of resentment what he had first undertaken from policy. In his imperial capacity, he governed with more despotism than any of his predecessors; and the house of Bavaria was a monument of the inflexibility of his temper. *Univer. Hist.*

JOSEPH II., emperor of Germany, son of Francis of Lorraine and the empress-queen Maria Theresia, was born at Vienna, in March 1741. Great care was taken of his education; and at the age of nineteen, he was married to Isabella, the infanta of Parma. He had, at an early period, displayed a desire of distinguishing himself, and military glory was his first passion. He was crowned king of the Romans in 1764; and having lost his first wife, to whom he was tenderly attached, he married, in 1765, the sister of the elector of Bavaria. In this same year, on the death of his father Francis I., he succeeded to the imperial crown without opposition. He now displayed great talents and activity, by new-modelling the armies, and reforming all the departments of government. He travelled through his dominions, and visited Prussia, Italy, France, and Russia; and on his return, among many other wise and excellent regulations which he adopted, he set apart one day in every week for receiving petitions and complaints from all his subjects, without any distinction of birth or fortune; and the officers of his court were expressly forbidden to repulse any, even the meanest object, who came to implore his protection. "It behoves me," said the emperor, "to do justice; and it is my invariable intention to render it to all the world, without respect of persons." In the year 1771, Germany suffered the horrors of a famine, which was more or less felt in all the countries of Europe. But in several parts of Germany, the scarcity was so great, that vast numbers of people actually perished for the want of the commonest necessaries of life. During these calamities, the emperor joined the monarchs of Prussia and Russia in the dismemberment of Poland. The first treaty for this iniquitous business was signed in 1772, and which finally terminated in the total extinction of that unhappy kingdom. In 1780, by the death of the empress-queen, Joseph succeeded to the crown of Hungary and Bohemia; and in the following year, he issued a decree in favour of the liberty of the press, which was followed by others equally liberal, particularly one in favour of a more liberal toleration. The suppression of the inquisition at Milan may be attributed to the prevalence of a similar spirit in the imperial councils. He extended the privileges of subjects to the Jews; and he shewed his attention to economy, by certain regulations relative to pensions, and by retrenching many which had been granted by the benevolent facility of his mother. He promulgated a decree in favour of the liberty of the press; and by one of the articles, he allowed a free circulation to literary reviews, and other periodical publications: he even permitted that all strictures upon the throne itself might be published with full security, provided they did not descend to the character of libels or pasquinades. "If," said he, "they be founded in justice, we shall profit by them; if not, we shall disregard them." In a journey to the Netherlands, the emperor gained the love of the people by his courtesy and generosity. He carried into effect a project for re-suming that line of fortresses which was called the Dutch barrier, and was garrisoned by their forces. There were all dismantled, and the materials sold. On this visit he declared Ostend a free port, and ordered several improvements to be made in the harbour at his own expence. The emperor afterwards demanded of the Dutch the free navigation of the Scheldt; but in this he was unsuccessful. On his return to Vienna, he abolished the system of vassalage; and

and took the most decisive steps in ecclesiastical reform, and the reduction of the power of the church. Numerous suppressions of religious houses took place throughout all his dominions; and in an imperial rescript, all subordination whatever, in secular affairs, to the holy see was formally disclaimed. Such proceedings awakened the most lively alarms in the papal court; and on this occasion, pope Pius VI. made a journey to Vienna; but notwithstanding the very flattering attentions which he received on his arrival, he found it impossible to procure an intermission of those reforms, which were now extended to the secular clergy and hierarchy, as well as to the religious orders or regulars; and only obtained a respite for some threatened religious foundations. In 1786 the emperor followed his attack on the papal authority, by calling an assembly of the ecclesiastical princes at Ratibon, in which it was resolved to withdraw from the jurisdiction of the pope. In 1788 a declaration of war was published against the Turks, and in the same year the emperor in person reduced Schabat; but this was followed by the defeat of prince Lichtenstein, who fell in the action. Soon after a bloody battle was fought between the Imperialists and the Turks, on the heights of Rohadin, in which neither party could claim the victory. The emperor now prepared to attempt the reduction of Belgrade; but notwithstanding the great preparations made on this occasion, his plans were defeated, and he had the mortification to witness the rapid destruction of his troops by a dreadful mortality. Putrid fever and dysenteries of the most malignant kind spread their influence through the imperial armies; discontent and complaint became universal; and in a short time, one of the finest armies in the world was reduced, in a single campaign, to less than half the number of its original combatants; the remainder being lost by mortality, desertion, and the sword, or rendered incapable of present service by disease. In the mean time, Joseph was labouring under the rapid decline of health, but still continued to employ himself indefatigably in public affairs. These, however, were moily of a kind to aggravate, by vexation and anxiety, his bodily disorder. The Low Countries were again in a flame, and the most violent measures were taken to reduce the people to submission. Military execution took place in several cities, and a general gloom, bordering on despair, overspread the provinces. At length an open insurrection broke out, conducted with so much prudence and valour, that the imperial troops were repeatedly defeated: several important cities were taken possession of by the insurgents; and the states of Flanders, on November 2^d, 1789, seized the government of the province, openly declaring that the emperor had forfeited all title to sovereignty. By the end of the year, Brussels had expelled its garrison; and a treaty of confederation was formed between all the Belgic provinces as independent states. Joseph, almost on his death-bed, was farther mortified by a remonstrance from the Hungarian nobility, demanding the restoration of their ancient rights and privileges. Willing to die in peace, he consented to all their requisitions, but insisted upon retaining three articles, which were highly creditable to his heart, *viz.* a general toleration, provision for the parochial clergy out of the revenues of some suppressed monasteries, and certain concessions in favour of the liberty of the peasants. He died with great composure, on the 20th of February 1790. Leaving no issue, he was succeeded by his brother Leopold. Joseph had many private virtues, as well as many of the qualities of a great and good sovereign. He was patient of fatigue, and possessed of an ardent mind. He applied himself with unremitting diligence to the suppression of intolerance and superstition, and the promotion of industry,

throughout his dominions. He has been accused of encroaching on the liberties of his Flemish subjects; and it will be readily conceded that he was not perfect; but his faults almost vanish among the truly glorious actions which contributed to the aggrandizement of his own name, and the permanent felicity of his people. Univer. Hist.

JOSEPH, king of Portugal, of the family of Braganza, was born in the year 1714, and succeeded his father in 1750. He was much beloved by his people, a circumstance that enabled him to effect several important regulations, in which his good sense and moderation were eminently conspicuous. Sensible of the danger of sudden changes, he advanced his designs by almost imperceptible steps, so as to prevent all just grounds of alarm and complaint. He subjected the powers of the infamous Inquisition to some restriction, by directing that none of its sentences should be carried into execution till reviewed and approved by the privy council. He carried into effect a treaty concluded between Spain and Portugal just before his father's death, which was considered as inimical to his country, on the principle "that all engagements among sovereigns should be held sacred and inviolable." This reign was marked, in 1755, with the terrible disaster of an earthquake, which destroyed a great part of the capital. A conspiracy in 1758, headed by the duke of Aveiro, and favoured by the Jesuits who had been banished from court, brought his life into great danger. The principal conspirators were seized and executed, and the whole order of Jesuits was banished the kingdom. Joseph had afterwards a dispute with the court of Rome, and a war with Spain; in the latter, Portugal was assisted by the English, whose battalions, under general Burgoyne, checked the career of the invaders, and obliged them, before the end of the campaign, to retreat within their own limits. After the peace of 1763, little of importance occurred in the affairs of Portugal. The king's councils, in the latter years of his reign, were entirely governed by the marquis de Pombal, a man of enlarged views, but of a haughty and violent disposition. A dispute with Spain, about the limits of the two nations on the borders of Rio de la Plata in South America, occasioned hostile preparations on both sides, but little was effected by either. Joseph died February 1777, and was succeeded by his daughter, Maria Frances Isabella, who is still queen, though in a deranged state of mind, and an exile in South America. See PORTUGAL.

JOSEPH of Exeter, or JOSEPHUS ISCANUS, is mentioned as a remarkable example of purity of literary taste and elegance of style, in an age generally reputed barbarous. He was a native of Devonshire, and flourished in the close of the twelfth, and the commencement of the thirteenth centuries. He was an ecclesiastic, and patronized by Baldwin, archbishop of Canterbury. According to the learned Camden, he accompanied Richard I. of England into the Holy Land. He was author of two epic poems in Latin heroic, The first, in six books, is on the Trojan war; the other is entitled "Antiocheis," the war of Antioch, or the Crusade; of this last only a fragment remains, in which the heroes of Britain are celebrated. The style of Joseph is not only, for the most part, pure, but rich and ornamented, and his versification approaches the best models of antiquity. His diction is compounded chiefly of Ovid, Statius, and Claudian, the favourite poet of the age. "Italy," says Mr. Warton, in his History of English Poetry, "had at that time produced no poet comparable to him." He was author of love verses, epigrams, and miscellaneous poems.

JOSEPH, *St.*, in Geography, a small island in the Indian Sea. S. lat. 5 45'. E. long. 54 10'. Also, a town of Africa, in the country of Gelan, on the Senegal; 120 miles E.S.E.

JOSEPH de Oraniz, St., a town on the W. coast of the island of Trinidad. N. lat. 10 25'. W. long. 60 55'.

JOSEPH de Precheur, St., a town of the island of Martinico.

JOSEPHINIA, in *Botany*, so named by Ventenat, in honour of his munificent patroness Josephine, the now divorced empress of Buonaparte, whose claim to such commemoration we have already admitted; see *HUMEA*. Ventenat. Malmais. 67. Brown. Prodr. Nov. Holl. v. 1. 519. Class and order, *Dioscorea Angiosperma*. Nat. Ord. *Liliadae*, Linn. *Bignonia*, Juss. *Pedalaria*, Brown.

Gen. Ch. Cal Perianth inferior, in five deep, nearly equal, acute segments. Cor. of one petal, ringent; tube not much longer than the calyx; throat dilated, bell-shaped; limb five-lobed, spreading, two-lipped, the upper lip in two equal rounded segments, lower in three, of which the middle one is largest. Stam. Filaments four, awl-shaped, shorter than the corolla, two of them shorter than the rest, with the rudiment of a fifth; anthers heart-shaped, of two cells. *Pyl.* Germen superior, pyramidal, rugose; style cylindrical, about equal to the stigma; stigma in four equal, oblong, acute segments. *Pist.* N. ovary, mucicated, of from four to eight cells. Seeds solitary, erect, oblong.

Ess. Ch. Calyx in five deep segments. Corolla ringent; throat bell-shaped; limb five-lobed, the middle segment of the lower lip longish. Stigma four-lobed. Nut of several cells, mucicated. Seeds solitary, erect.

1. *J. Imperialis*. Vent. Malmais. t. 67.—Germen of about four cells. Leaves imbricate; elliptical, acute, downy beneath like the stem. Segment of the calyx equal. *Specimen*.—Gathered by the French voyagers on the west side of New Holland, who brought the seeds to the garden of La Haye, where they grew well. The plant is biennial, flowering in the middle of summer, decumbent, of an elegant or rural aspect, with large, toothed, dull-green leaves. *Flowers* axillary, solitary, about an inch long, white, variegated and spotted with dull purple.

2. *J. prostrata*. Brown. Prodr. v. 1. 520.—Germen of eight cells. Leaves imbricate, pointed, slightly downy beneath. *Specimen*.—Upper segment of the calyx half the length of the rest. Lower segment of the corolla more than twice as long as the others. *Specimen*.—Gathered by Mr. Brown on the west part of New Holland.

JOSEPHSTHAL, in *Geography*, a town of Bohemia, & metropolis of Boleslaw; 12 miles N.N.E. of Turnau.

JOSEPHUS; FLAVIUS, in *Biography*, an eminent Jewish historian, was born in the year 37, when Caligula was emperor. His father was Mattathias, descended from the ancient high-priests of the Jews: by his mother he was of the royal lineage of the Asmonæans, who, for a considerable time, had the supreme government of the Jewish nation. He was educated together with his brother Matthias, and made such proficiency in knowledge, that when he was but fourteen years of age, the high-priests, and some of the principal people of the city, came frequently to consult him about the right interpretation of things in the law. In his sixteenth year he retired into the wilderness, where he lived in great abstemiousness, and habits of self-denial during the space of three years. He studied the principles of the leading sects, and embraced, as the rule of his life and conduct, those of the Pharisees, and being now nineteen years of age, he began to act in public. At the age of twenty-six he went to Rome, where, by means of a itage-player of his own nation, he obtained an introduction to Poppæa, the emperor Nero's wife, by whose interest he procured the release of some priels, whom Felix had sent prisoners from Jerusalem. Returning home, he was appointed by the revolted Jews governor of the two Gallicies, in which capacity, as a general, he bravely defended Jotapata against Vespasian, but which was taken after a siege of forty-seven days. When the city was in the hands of the conqueror, he gave orders to search for Josephus, who had escaped the general massacre, by concealing himself in a cavern cut in a rock. In this gloomy recess he met with forty men of eminence who had concealed themselves, and had with them provisions sufficient for their support several days. Upon being discovered, he proposed to the forty men who had taken refuge there with him, that they should all surrender, and upon their determination rather to perish by mutual wounds, he persuaded them to cast lots successively, who should kill the next man, and by an extraordinary circumstance he and one other were left the survivors of the rest. This single companion was easily prevailed upon to join him in accepting the proffered mercy of the Romans. On being taken before Vespasian, he boldly predicted that within a short time the empire would fall to the share of that general, by which prediction, which was afterwards fulfilled, he secured a favourable reception from him; though he was retained as a prisoner on account of the use which Vespasian intended to make of him in the farther prosecution of the war against the Jews. It should seem that Josephus flattered himself with the notion that he was inspired with a knowledge of future events. "It is likely" says the judicious and learned Lardner, "that he often thought of Joseph in Egypt, and of Daniel in Babylon, and was in hopes of making a like figure at the court of Rome. But I suppose it may be no disparagement to Josephus to say, that he was not equal to them in wisdom, or in virtue and integrity." As soon as Vespasian was seated on the imperial throne, Josephus was set at liberty, and was taken by Titus with him when he marched to lay siege to Jerusalem. Here he saw the ruin of his country, of which he afterwards became the historian. He was sent into the city with offers of peace upon condition of the submission of his countrymen. They despised his offers, and rejected his counsels with scorn. The Jews now considered him as a deserter and traitor to their cause, and it is a fact that they never manifested any great respect for his writings. During the progress of the siege he did not cease exhorting them to avoid their inevitable fate by a timely surrender, and once, approaching too near the walls, he received a wound which laid him senseless on the ground. At the capture of the city, Josephus obtained the libera-

tion of Matthias and several friends without ransom; he had permission also to have what he pleased out of the ruins; but he contented himself with a copy of the sacred writings. The emperor heaped upon him his favours, and as a mark of his gratitude, he assumed their family surname of Flavius. He employed his leisure in drawing up those works which have immortalized his name. There are, 1. "The History of the Jewish war, and the taking of Jerusalem," in seven books. It was written in the language of his own country, and he afterwards published it in Greek for the benefit of other nations. He professes to have written with great fidelity, and appeals, for the truth of his history, to living witnesses. He presented the work to Vespasian and Titus, of whom the latter ordered it to be published, and signed it with his own hand to shew that it was authentic. 2. "The Jewish Antiquities" in twenty-four books, or the history of the Jews from the creation to the 12th year of Nero, in which the war began. To this is subjoined his life, written by himself, and dedicated to Epaphroditus, of whom we know nothing but from Josephus himself, who describes him as a lover of all kinds of learning, but as principally delighted with the knowledge of history, and this on account of his having been himself concerned in great affairs, and many turns of fortune, and having shewn a wonderful vigour of an excellent nature, and an immovable virtuous resolution in them all. 3. He wrote also "Two books against Apion of Alexandria," which is a vindication of the Jewish people against the calumnies of that Egyptian author. "A Discourse on the Martyrdom of the Maccabees" is sometimes ascribed to him, but its genuineness is disputed. and Mr. Whiston who translated the other works would not give this a place in his volumes. The works of Josephus, though slighted by the Jews, are held in high estimation by Christians; his style is pure, agreeable, and sometimes eloquent; he has been called the Greek Livy; and, like that Roman writer, he is fond of displaying the powers of his own imagination by long speeches. The history of the Jewish war, of which he was a spectator, is a most interesting narrative. The best editions of the works of Josephus, are those of Hudson in two vols. folio. Oxford, 1726, and of Havercamp, in two vols. Amsterdam 1726. There have been a multitude of English translations; to that of Whiston we have already referred. Univ. Hist. Lardner, vols. i and vii. edit. 1788. And Josephus's own Life.

JOSHUA, a canonical book of the Old Testament containing a history of the wars and transactions of the person whose name it bears, who succeeded Moses in the government of the Israelites, in the year 1451 B.C. at the age of 90 years, and was their conductor to the land of Canaan. He was the son of Nun, of the tribe of Ephraim, and born in the land of Gushen, in the year 1536 B.C. At the period of the Exodus (which see), Joshua was distinguished by his talents and virtues, so that he was taken into the confidence of Moses, and selected to command the Israelites, when they were attacked by the Amalekites, in their march from Mount Horeb to mount Sinai. He was likewise honoured with the privilege of accompanying Moses to mount Sinai, and of remaining with him forty days, when he received directions for the future government of the Israelites, and the laws written on the first tables of stone. He also accompanied Caleb, and other ten persons who were deputed to examine the land of Canaan, previous to the invasion of it by the Israelites. When Moses was apprized of his approaching dissolution, he confirmed Joshua as his successor in the most public and solemn manner. Although he was advanced in years when he conducted the Israelites to Canaan, he performed this arduous undertaking with singular prudence and

valour. When they were passing the river of Jordan, in this extraordinary manner which is recorded in their history, he directed two monuments to be erected as a memorial of their miraculous passage, one on the spot where the ark had stood in the bed of the river, and the other on the shore; and from the banks of Jordan he proceeded towards the plains of Jericho, and pitched his tent for the first time in Canaan, the land of which he was taking possession at Gilgal. For the conflicts and successes that attended his future progress, we refer to his history. Having surveyed and divided the lands among the several tribes (B.C. 1455), he governed Israel in peace; and when he became sensible that the termination of his life could be at no great distance, he summoned all the tribes of Israel to Shechem, and recited the extraordinary operations of the providence of God in their favour, and having awakened in their minds a becoming sense of gratitude, enforced upon them the wisdom and duty of persevering obedience to his laws, and exhorted them to renew the covenants by which they had already engaged to worship and serve him. This transaction was then solemnly registered, and a monument for perpetuating it was erected near a great oak which was in Shechem. Soon after this event, viz. in the year B.C. 1426, Joshua, having exhibited ample evidence of the propriety of his name, which denoted "Saviour," died in his retirement at Timnath-hera, at the age of 110 years. The book of Joshua, supposed to have been written by himself, and to have received some additions from Samuel and Ezra, (see BIBLE and CANON,) may be divided into three parts; the first of which is a history of the conquest of the land of Canaan; the second, which begins at the twelfth chapter, is a description of that country, and the division of it among the tribes; and the third, comprised in the two last chapters, contains the renewal of the covenant he caused the Israelites to make, and the death of their victorious leader and governor. The whole comprehends a term of seventeen, or, according to others, of twenty-seven years.

JOSIAH, king of Judah, deserves particular mention on account of his wisdom and piety, and some memorable events that occurred in the course of his reign. He succeeded to the throne, upon the assassination of his father Amen, at the age of eight years, in the year B.C. 640, and at a period when idolatry and wickedness, encouraged by his father's profligate example, very generally prevailed. Josiah, who manifested the influence of pious and virtuous principles at a very early age, began in his sixteenth year to project the reformation of the kingdom, and to adopt means for restoring the worship of the true God. At the age of twenty years he vigorously pursued the execution of the plans which he had meditated. He began with abolishing idolatry, first at Jerusalem, and then through different parts of the kingdom; destroying the altars which had been erected, and the idols which had been the objects of veneration and worship. He then proceeded, in his twenty-sixth year, to a complete restoration of the worship of God, and the regular service of the temple. Whilst he was prosecuting this pious work, and repairing the temple which had been long neglected, and which had sunk into a state of dilapidation, the book of the law, which had been concealed in the temple, was happily discovered. This was probably a copy of the Pentateuch, which had been lodged there for security by some pious man in the reign of Ahab or Manasseh. Josiah, desirous of availing from himself and the kingdom threatened judgments, determined to adhere to the directions of the law, in the business of reformation which he had undertaken, and to observe the festivals enjoined by Moses, which had been shamefully neglected. With this view he assembled all the elders of the people in the temple at Jerusalem, and

having ascended the throne, read the book of the Mosaic law, and then entered into a solemn covenant to observe the statutes and ordinances which it enjoined. To this covenant the whole assembly testified their consent. The ark was re-located to its proper place; the temple was purified; idolatrous utensils were removed; and those appropriate to the worship of God substituted in their room. After these preparations, the passover was observed with singular zeal and magnificence. This took place in the eighteenth year of Josiah's reign. But in pursuing his laudable plans of reformation, he was resisted by the inveterate habits of the Israelites, so that his zealous and persevering efforts were ineffectual. Their degeneracy was so invincible, that the Almighty sovereign was provoked to inflict upon them those calamities which were denounced by the prophet Zephaniah. In the thirty-second year of Josiah's reign, Pharaoh Necho, king of Egypt, advanced with his army against Carchemish, a city situated on the river Euphrates; and he was opposed by the king of Judah; so that a bloody battle ensued at Megiddo, in which Josiah received a mortal wound, which terminated in his death, after he had been conveyed to Jerusalem, in the thirty-ninth year of his reign, B.C. 609. His death was greatly lamented by all his subjects; and an elegy was written on the occasion by the prophet Jeremiah, which is not now extant. 2 Kings, xxii. xxiii. 2 Chron. xxxiv. xxxv.

JOSIDA, in *Geography*, a town of Japan, in the island of Nippon; 16 miles E. of Seoda.

JOSLOWITZ, a town of Moravia, in the circle of Znavin; 8 miles S.E. of Znaym.

JOSNIOW, a town of Poland, in Podolia; 48 miles N.W. of Kaminiac.

JOSQUIN DES PREZ, or, as he is called in Latin, *Josquinus*, or *Jodocus Pratenfis*, and in Italian *Giofquino del Prato*, in *Biography*, a Netherlander, the disciple of Okenheim, and maestro di cappella to Louis XII. king of France, was the greatest musician of his time; and, in many particulars, of any time, since the invention of counterpoint.

His compositions for the church, though long laid aside, and become obsolete by the gradual changes in notation, continue still to merit the attention of the curious. Indeed the laws and difficulties of canon, fugue, augmentation, diminution, reversion, and almost every other species of learned contrivance allowable in ecclesiastical compositions for voices, were never so well observed, or happily vanquished, as by Josquin; who may justly be called the father of modern harmony, and the inventor of almost every ingenious construction of its constituent parts, near a hundred years before the time of Palestrina, Orlando di Lasso, Tallis, or Bird, the great musical luminaries of the sixteenth century, whose names and works are still held in the highest reverence, by all true judges and lovers of what appears to us the true and genuine style of choral compositions.

This ingenious, learned, and voluminous composer, is enumerated, by Lewis Guicciardini, among Flemish musicians. However, the constant addition of Pratenfis, or Del Prato, to his name, seems rather to make him a native of Prato, in Tuscany; and the frequent mention that is made of him by Italian writers, implies at least, if he was not a native of Italy, that he had lived there, and that his works were very familiar to them; for not only by the name of Josquino, Judoco del Prato, is he often mentioned by Franchinus, and all the musical writers of Italy in the next age, as a most excellent composer, but by miscellaneous writers, who only speak of music incidentally. As a proof of this, we need give no better authority than the following passage in Caltigione's admirable "Cortegiano."

"This author, speaking of the operations of prejudice in favour of great names, tells us of the eagerness and delight with which a polite company of his acquaintance had read a copy of verses, supposing them to have been written by San-nazaro, who afterwards, when it was certain that they were not of his composition, thought them execrable. "So likewise," says one of the interlocutors, "a motet sung before the dukes of Urbino was unnoticed, till it was known to be the production of Josquin."

Franchinus, enumerating the great musicians of his time, specifies Tinctor, Gulielmus, Guarnierus, Jusquin de Pret, Gaspar, Agricola, Loyset, Obrecht, Brumel, Isaac, and calls them *most distinguished composers*.

The same author, in another work, lets us know that he had been personally acquainted with Josquin: for, speaking of some inaccuracies in the sequialterate proportion, he says: "Di questi inconvenienti ne advertite gia molti anni passati Jusquin Despriet et Gaspar dignissimi Compositori." This was printed in 1508, so that "many years ago," must throw these composers far back into the fifteenth century; and, he adds, "though they acquiesced in my opinions, yet, having been corrupted by long habit, they were unable to adopt them."

Zarlino, who likewise speaks of him among the *pratici periti*, gives another instance of predilection in favour of Josquin at Rome, "which," says he, "was at the expense of my friend, the admirable Adrian Willaert, who has often himself confirmed the fact." The motet "verbum bonum et suave," for six voices, having been long performed in the pontifical chapel at Rome, on the festival of our Lady, as the production of Josquin, was thought to be one of the finest compositions of the time; but Willaert, having quitted Flanders, in order to visit Rome, in the time of Leo X. and finding that this motet was sung as the composition of Josquin, whose name was affixed to it in the chapel books, ventured to declare it to be his own work, and not that of the famous Josquin: but so great was the ignorance, envy, and prejudice of the singers, that, after this declaration, the motet was never again performed in the pontifical chapel.

Adami, in his historical list of the singers in the pope's chapel, mentions Josquin next to Guido, as one of the great cultivators and supporters of church music; he calls him "Uomo insignie per l'inventione," and says that he was a singer in the pontifical chapel during the time of Sixtus IV.

After quitting Italy, he was appointed maestro di cappella to Lewis XII. of France, who reigned from 1498 to 1515, and it is hardly probable that such an honour should have been conferred upon him till he had arrived at great eminence in his profession; he must either have acquired the public favour by his works or performance, before he could be noticed by a sovereign; indeed the impediments to his approximation must have been reciprocal, and it has been well observed, that it is as difficult for a prince to get at a man of merit, as it is for a man of merit to approach a prince.

It is related, that when Josquin was first admitted into the service of Lewis, he had been promised a *benefice* by his majesty; but this prince, contrary to his usual custom, for he was in general both just and liberal, forgot the promise he had made to his maestro di cappella; when Josquin, after suffering great inconvenience from the shortness of his majesty's memory, ventured, by a singular expedient, to remind him publicly of his promise, without giving offence; for being commanded to compose a motet for the chapel royal, he chose part of the 119th Psalm: "Memor ero verbi tui servo tuo;" "Oh think of thy servant, as concerning thy word;" which he set in so supplicating and exquisite a manner, that it was universally admired, particularly by the

king, who was not only charmed with the music, but felt the force of the words so effectually, that he soon after granted his petition, by conferring on him the promised preferment: for which act of justice and munificence, Josquin, with equal felicity, composed, as a hymn of gratitude, another part of the same Psalm: "Bonitatem fecisti cum servo tuo, Domine," "Oh Lord, thou hast dealt graciously with thy servant."

Josquin seems to have been possessed of a certain vein of wit and humour, as well as musical genius; of which Glareanus has given his readers several instances, besides those just related. In consequence of the long procrastination of the performance of Lewis XIIth's promise relative to the benefice, Josquin applied to a nobleman, in high favour at court, to use his interest with this prince in his behalf, who, encouraging his hopes with protestations of zeal for his service, constantly ended with saying, "I shall take care of this business, let me alone"—*Laissez faire moi (laissez moi faire)*, when, at length, Josquin, tired of this vain and fruitless assurance, turned it into solfima, and composed an entire mass on these syllables of the hexachords *La sol fa re mi*; which mass is among the productions of our author in the British Museum, and is an admirable composition.

The following circumstance, which likewise happened during Josquin's residence at the court of France, has been recorded both by Glareanus and Merfennus. These writers inform us, that Lewis, though music afforded him great pleasure, had so weak and inflexible a voice, that he never was able to sing a tune, and that he desired his maestro di cappella to compose a piece of music in which it was possible for him to bear a part. However the musician accepted the challenge, and composed a canon for two voices, to which he added two other parts, one of which had nothing more to do than to sustain a single sound, and the other only the key note, and its fifth, to be sung alternately. Josquin gave his majesty the choice of these two parts, and beginning with the long note, after some time, his royal scholar was enabled to continue it, as a drone to the canon, in despite of nature, which had never intended him for a singer.

Rabelais, in his prologue to the third book of Pantagruel, places Josquin des Prez at the head of all the fifty-nine *Joyeux Musiciens* whom he had formerly heard. Josquin, among musicians, was the giant of his time, and seems to have arrived at universal monarchy and dominion over the affections and passions of the musical part of mankind. Indeed his compositions seem to have been as well known and as much practised throughout Europe, at the beginning of the 16th century; as Handel's were in England sixty years ago.

In the music book of prince Henry, afterwards Henry VIII., which is preserved in the Pepys's collection, at Cambridge, there are several of his compositions, and we are told that Anne of Boleyn, during her residence in France, had collected and learned a great number of them. In a very beautiful MS. in the British Museum, consisting of French songs of the 15th century, in three and four parts, there are likewise many of Josquin's compositions. But the most capital collection of his works, and of contemporary contrapuntists which we believe is now subsisting, is in the British Museum, consisting of the first and third set of the masses of Josquin, composed for the pope's chapel, during the pontificate of Sixtus IV., who reigned from 1471 to 1484; with masses by Pierre de la Rue, Aut. Fevin, John Moreton, &c.

All these were printed by Ottavio Petruccio da Fossombrone, under a patent from Leo X. signed by cardinal Bembo, his secretary. These masses were the first musical productions that issued from the press after the invention of

printing. And these very curious compositions must have been studied, and frequently rehearsed, before their performance; for though no rapidity of execution is required, yet, as there are no bars, and the value of the notes is frequently changed by position, as well as by the modal signs, upon very short notice, this, joined to the difficult solution of the canons, must have made it impossible for them to have been sung at sight, even by those who were accustomed to the notation.

Specimens of these compositions in score may be seen in Burney's History of Music, vol. II., and whoever examines them will find that no notes have had admission by chance, or for the sake of *remplissage*, but that, like the prints of Hogarth, every thing not only contributes to the principal design and harmony of the whole, but has a specific character of its own.

But Josquin's masses, though more frequently cited and celebrated by musical writers than those of any other author, and indeed than any of his other works, seem inferior to his motets in every respect; for these are not only composed on subjects of his own invention, or in fragments of the most beautiful and solemn chants of the church, but in a style more clear and pleasing.

In the third and fourth collection of motets published at the beginning of the sixteenth century, under the title of "Mottetti della Corona," there are many by Josquin, which are truly admirable, particularly a *miserere* for five voices, which, as it consists of three movements, is too long to be inserted in a work of this kind, but appears to us a model of choral composition, without instruments; as the subjects of fuge and imitation are simple, and free from secular levity; the style is grave and reverential; the harmony pure; the imitations are ingenious, and all constructed upon a fragment of canto fermo, to which the second tenor is wholly confined: repeating it, in the first part, a note lower every time, beginning at the fifth of the key, and descending to its octave; in the second part, ascending in the same manner; in the third part, beginning at the fifth, and descending to the key note.

This species of laboured composition has been frequently censured, and stigmatized by the name of pedantry, and Gothic barbarism, which, perhaps, it would now deserve, out of the church; but in the time of Josquin, when there was little melody, and no grace in the arrangement, or measure of single notes; the science of harmony, or ingenuity of contrivance in the combination of simultaneous sounds, or music in parts, as it was the chief employment of the student, and ambition of the composer, for the merit of both, and the degree of regard bestowed upon them by posterity, should be proportioned to their success, in what was their chief object, and not in what had no existence at the time in which these musicians lived.

With respect to some of Josquin's contrivances, such as augmentations, diminutions, and inversions of the melody, expressed by the barbarous Latin verb *canerizare*, from the retrograde motion of the *crab*, they were certainly pursued to an excess; but to subdue difficulties has ever been esteemed a merit of a certain kind, in all the arts, and treated with respect by artists. Michael Angelo, in delineating the difficult attitudes into which he chose to throw many figures in his works, and which other artists had not courage, or perhaps abilities to attempt, procured himself a great name among the judges of correct drawing, and bold design, though a great part of the spectator's pleasure in viewing them must arise from reflecting on the difficulty of the undertaking. There are different roads to the temple of Fame in every art; and that which was followed by Josquin, and his

emulators, was too full of thorns, brambles, and impediments, to be purified by men of common genius and abilities. Painting and sculpture, which are to delight and deceive the eye, do not, any more than music, confine their powers to the mere endeavour at pleasing the sense of which they are the object; and there are pictures, statues, and musical compositions, which afford very little pleasure but what is intellectual, and arising from reflection on the learning, correctness, and great labour which the artist must have bestowed on them.

Canons of difficult solution were, to musicians, a species of problem, and served more to exercise the mind than please the sense; and though a peculiar genius, or penetration, is requisite for the quick discovery of riddles and riddles, yet, still more cunning is necessary to their production; and, however contemptuously these harmonical contrivances may be treated by the lazy lovers of more airy and simple compositions, the study of them is still of such use to musical students, in their private exercises, that a profound and good contrapuntist has, perhaps, never yet been made by other means. Those who despise this seeming Gothic pedantry too much, resemble such half-bred scholars, as have expected to arrive at a consummate knowledge of the Roman classics, without submitting to the drudgery of grammar and syntax. Indeed a great composer has, perhaps, never existed since the invention of counterpoint, who, at his moments of leisure, has not attempted to manifest superior learning and skill in the production of canons, and other difficult arrangements and combinations of sound; and who, if he succeeded, was not vain of his abilities. Before the cultivation of dramatic music, as canon and fugue were universally studied and revered, they were brought to such a degree of perfection, as is wonderful; and though good taste has long banished them from the theatre, yet the church and chamber still, occasionally, retain them, with great propriety: in the church they preclude levity, and in the chamber exercise ingenuity.

As Euclid ranks first among ancient geometriicians, so Josquin, for the number, difficulty, and excellence of his musical canons, seems entitled to the first place among the old composers, who have been most assiduous and successful in the cultivation of this difficult species of musical calculation.

But though the style of Josquin, even in his secular compositions, is grave, and chiefly in fugue, imitation, and other contrivances, with little air or melody; yet this defect is amply supplied to contrapuntists, and lovers of choral music, by purity of harmony and ingenuity of design. Indeed, we have never seen, among all his productions that we have scored, a single movement which is not stamped with some mark of the great master. And though fugue and canon were so universally cultivated in his time, when there were many men of abilities in this elaborate and complicated kind of writing; there is such a manifest superiority in his powers, such a simple majesty in his ideas, and such dignity of design, as wholly justify the homage which he received.

It will, perhaps, be thought that too much notice has been taken of this old composer and his works; but as he is one of the great heroes of the art, and the type of all musical excellence at the time in which he flourished, the less need be said of his contemporaries, who, in general, were but his imitators.

Josquin, according to Walther (*Musicalisches Lexicon*), was buried in the church of St. Gudule, at Brussels, where his figure and epitaph are still to be seen. His death must have happened early in the 16th century.

JOSS, or JOOSTE, in *Mythology*, an idol worshipped by the Chinese at some of their grand festivals, which they observe by way of intercession for the sick at Batavia and elsewhere. To this idol they offer costly presents; and they also make a large vessel of paper and combustible materials, adorning it with flags, and then setting it on fire till it is consumed. The name Joolje, given to this idol by the Dutch, which the English seamen call Joss, is a Dutch nick-name for the devil, and was probably given to this idol by the Dutch, when they first saw it, either from its appearance, or from the principle that all idolatry is demonolatry.

JOSELIN, in *Geography*, a town of France, in the department of Morbihan, and chief place of a canton, in the district of Ploermel; 19 miles N.N.E. of Vannes. The place contains 2678, and the canton 14,157 inhabitants, on a territory of 215 kilometres, in 10 communes. N. lat. 47 57'. W. long. 2° 28'.

JOSSLIOKA, a town of Poland, in the palatinate of Sandomirz; 76 miles S.S.W. of Sandomirz.

JOSVO, a town of Hungary; 16 miles W. of Caschau.

JOTAKO, a small island in the Mediterranean; 2 miles E. of Teaki.

JOTAN, a town of Asiatic Turkey, on the W. coast of Natolia, near cape Arbre; 10 miles N. of Milets.

JOTAPATA, in *Ancient Geography*, a town of Phœnicia, situated in the vicinity of Ptolemais. It was defended by Josephus the historian, but at last taken by Vespasian, in the reign of Nero, A.D. 67. Its defence lasted for seven weeks, and 40,000 Jews were killed. Joseph. de Bel. Jud.

JOUAN de L'ISLE, *St.*, in *Geography*, a town of France, in the department of the North Coasts, and chief place of a canton, in the district of Dinan; 24 miles S. of St. Malo. The place contains 683, and the canton 8543 inhabitants, on a territory of 150 kilometres, in 8 communes. N. lat. 48° 12'. W. long. 2° 29'.

JOUBERT, LAURENT, in *Biography*, a learned physician, and royal professor at Montpellier, was born at Valence, in the province of Dauphiné, in France, on the 16th of December 1729, of a good family. After he had finished his school education, he went to Montpellier, where he was matriculated in the faculty of medicine on the 1st of March 1750, and took his degree of bachelor the following year. He afterwards studied at Padua, where he attended the lectures of the celebrated Fallopius, and at some other places; but returning to Montpellier, he finished his exercises, and received the degree of doctor in the year 1758. The manner in which he had performed his acts procured for him so much of the confidence and esteem of Honoré Castellan, that this professor, being summoned to court in the following year, to hold the office of first physician of Catharine de Medicis, queen of Henry II. he nominated Joubert to give the lectures in the schools during his absence; and his nomination met with the sanction of the faculty. Joubert shewed himself worthy of the honourable appointment, and acquitted himself in so distinguished a manner, that on the death of professor Rondelet in 1566, he was immediately named his successor in the chair. He was likewise the second successor of Rondelet in the dignity of chancellor, having followed Saporta in 1574. He was called to Paris by Henry III. in 1579, who entertained hopes that Joubert would be able to cure the baronnets of Louisa de Lorraine, his queen. But his attempts proved unsuccessful; and he returned to Montpellier with the title of physician in ordinary to the king, and continued to practise his profession there to the end of his life, which

happened

happened on the 21st of October 1583, when he was on the road from Thouloufe.

This physician was the author of several works, and wrote with much correctness and even elegance. A collection of those, which were written in the Latin language, has been frequently reprinted under the title of "Opera Latinorum Tomus primus et secundus." The first edition is that of Lyons, in 1582, folio; the subsequent ones appeared at Frankfurt, in 1599, 1645, and 1668, also in folio. The following have been published separately: "Paradoxa Medica, seu de Febribus," Lyons, 8vo. 1566; "De Pelle, Quartana, et Paralyfi," *ibid.* 1567, 8vo. The treatise on the plague was also published in French, in 1581; "De affectibus pilorum et cutis, præsertim capitis, et de Cephalalgia. De affectibus internis partium Thoracis," Geneva, 1572. Lugd. 1577, 1578; "Traité du Ris, son essence, ses causes et effets," Paris, 1574, 1579, 8vo.; "Medicine Practicæ Libri tres," Lugd. 1577, 12mo.; "Pharmacopœia a Johanne Paulo, sangmeistero, edita," *ibid.* 1579, 8vo.; "Traité des arcubufades," *ibid.* 1581. This, however, is the third edition; the work was several times printed, and contains very correct opinions and precepts respecting the nature of gun-shot wounds; "Guidonia de Cauliaco Chirurgia Magna," *ibid.* 1585, with notes by the editor. The same work was translated into French, by Isaac Joubert, his son, and went through nine or ten editions; "Traité des Eaux," Paris, 1603, 12mo. But of all the works of Laurent Joubert, that in which he ventured to raise his voice against popular medical errors, was the most distinguished; "Erreurs populaires touchant la Médecine," Bourdeaux, 1579. This work made so great an impression upon the public mind, that it was printed ten successive times in the course of six months. Eloy, Dict. Hist. de la Med.

JOUER *des INSTRUMENS*, *Fr.* to play upon musical instruments. The French say *jouer du violon, de la basse, du hautbois, de la flûte; toucher le clavecin, et les orgues; sonner la trompette; donner du cor; pincer la guitare.* They play on the violin, the violoncello, the hautbois, and the flute; but they touch the harpsichord and the organ; *font* the trumpet and French horn; and *pinch* the guitar.

JOUGH-HOLES, in *Mining*, is the name, in some parts of Derbyshire, for leucular cavities, principally in the vertical joints or in the veins, which are lined with crystals. These are called tick-holes, druses, lochs, nests, &c. in other situations. The manner in which these curious holes were formed and left is endeavoured to be explained in Mr. Farey's Report on Derbyshire, vol. i. p. 247.

JOVIALE ARCANUM. See ARCANUM.

JOVIALE Bezoardicum. See BEZOARDICUM.

JOVIAN, in *Geography*, a Roman emperor, born about the year 331, was a native of Singidunum, in Pannonia, and son of count Varronian, who had a high reputation in the state, and who was enjoying, in honourable retirement, the fruit of his long services. The son had been brought up to arms, and had obtained so much reputation as a commander, that although an avowed Christian, the emperor Julian would not suffer him to resign, upon offering to do so rather than quit his religion. On the death of Julian, in his expedition against the Persian empire, June 363, Jovian, who was but the first of domestics, was nominated to the purple. At first a few voices only saluted him with the names of Emperor and Augustus. The tumultuary acclamation was instantly repeated by the guards who surrounded the tent, and passed, in a few minutes, to the extremity of the line. No prince was ever raised to the throne under more critical circumstances. The Roman army, distressed and dissipated, was retreating from the enemy's country

towards its own frontiers, pursued and continually harassed by a much superior force. He made a disadvantageous peace with Persia, shut up the heathen temples, recalled the banished clergy, and from henceforth it was determined that Christianity should enjoy an uninterrupted triumph over heathenism. On arriving at Antioch he displayed his attachment to the orthodox doctrine, by restoring the churches to all the adherents of the council of Nice. At the same time, in order to quiet the minds of his subjects of the old religion, he issued a decree of toleration, permitting the exercise of the ceremonies of the pagan worship. He left Antioch in the winter-season, and proceeded to Constantinople. He caused some ornaments to be added to the tomb of Julian, at Tarsus, as he passed. At Ancrea he assumed the title and ensigns of the consuls, and conferred the same on his infant son. Dadaftana, an obscure town, at about an equal distance from Ancrea and Nice, was marked for the fatal term of his journey and his life. After indulging in a plentiful, perhaps an intemperate supper, he retired to rest, and in the next morning he was found dead in his bed. The body of the deceased emperor was sent to Constantinople to be interred with his predecessors. His sudden death was imputed either to the effects of an overloaded stomach, or to the gas arising from burning charcoal, which had been placed in his chamber to dry the walls. This event happened in the eighth month of his reign, and in the thirty-third year of his age. Gibbon, Univ. Hist.

JOVIUS, PAUL, an eminent historian, was born at Como, in Lombardy, in 1453. Having received a good education, he went to Rome, where he wrote a work, entitled: "De Piscibus Romanis." He had a pension from Francis I. king of France; and Clement VII. gave him the bishopric of Nocera, an office to which he did no credit, on account of his debauched manner of living. He died at Florence in 1452. His principal work is a history of his own time, which was published at Strasburgh in 1556. He also wrote the lives of illustrious men. He had a brother who wrote a history of Switzerland. Moreri.

JOULOPPED, in *Heraldry*, a term applied to the gills of a cock, when borne of a different tincture from his head.

JOULTS, in *Mining*, is applied, in Derbyshire, to pieces of spar and lead-ore intermixed, from the size of walnuts to that of the fist. Sometimes these are called knockings, or hannaway. See Farey's Derbyshire Report, vol. i. p. 369.

JOUNPORA, in *Geography*, a town of Hindoostan, in Bahar; 25 miles S.W. of Patna.

JOURA, a barren island in the Grecian Archipelago, about 10 miles in circuit; 12 miles S.W. of Andros. N. lat. 37° 37'. E. long. 24° 46'.

JOURKOUPE, a town of Asiatic Turkey, in Carmania; 50 miles E.N.E. of Akserai.

JOURNAL, a day-book, register, or account of what passes daily. See DAIRY.

JOURNAL, in *Merchants' Accounts*, is a book into which every particular article is posted out of the wattle book, and made debtor. This is to be very clearly worded, and fairly engrossed. See BOOK-KEEPING.

JOURNAL, in *Sea Affairs*, is a register kept by the pilot and others, wherein notice is taken of every thing that happens to the ship, from day to day, and from hour to hour; with regard to the winds, the tides, the raker, soundings, &c. in order to enable him to adjust the reckoning, and determine the place where the ship is.

JOURNAL.

In all sea-journals, the day, or what is called the twenty-four hours, begins at noon, and is counted thence twenty-four hours to the next noon; the first twelve hours, from noon to midnight, are marked with P. M. signifying after mid-day; and the second twelve hours from midnight to noon are marked with A. M. signifying after midnight; so that the ship account is twelve hours earlier than the shore account of time. There are various ways of keeping journals, according to the different notions of mariners concerning the articles that are to be entered. Some writers

direct the keeping such a kind of journal as is only an abstract of each day's transactions, specifying the weather, what ships or lands were seen, accidents on board, the latitude, longitude, meridional distance, course, and run. These particulars are to be drawn from the ship's log-book, or from that kept by the person himself. Other authors recommend the keeping only of one account, including the log-book, and all the work of each day, with the deductions drawn from it. The form of the latter kind of journal, with an example of the work of a single day, is as follows:

Abstract of a JOURNAL from England towards Madeira.

JOURNAL is now become a common name for newspapers, which detail the daily transactions of Europe.

JOURNAL is also used for the title of several books which come out at fixed times; and give abstracts, accounts, &c. of the new books that are published, and the new improvements daily made in arts and sciences.

The first journal of this kind was, the "Journal des Sçavans," printed at Paris: the design was set on foot for the ease of such as are too busy, or too lazy, to read the entire book themselves. It seems an excellent way of satisfying a man's curiosity, and becoming learned upon easy terms; and so useful has it been found, that it has been executed in most other countries, though under a great variety of titles.

Of this kind are the "Acta Eruditorum of Leipzig;" the "Nouvelles de la Republique des Lettres" of M. Bayle, &c.; the "Bibliothèque Universelle, Choiseif, et Ancien et Moderne," of M. le Clerc; the "Memoires de Trevoux, &c." In 1692, Juncker printed in Latin, an "Historical Treatise of the Journals of the Learned," published in the several parts of Europe; and Wolfius, Struvius, Morhof, Fabricius, &c. have done something of the same kind. The "Philosophical Transactions of London;" the "Memoirs of the Royal Academy of Sciences;" those of the "Academy des Belles Lettres;" the "Miscellanea Naturæ Curiosiorum;" the "Experiments of the Academy del Cimento;" the "Acta Philo-exoticorum Naturæ et Artis," which appeared from March 1686, to April 1687, and which are a history of the Academy of Bressle; the "Miscellanea Berolinensia," or Memoirs of the Academy of Berlin; the "Commentaries of the Academy of Peterburg;" the "Memoirs of the Institute at Bologna;" the "Acta Literaria Suecicæ;" the "Memoirs of the Royal Academy at Stockholm," begun in 1740, the "Commentarii Societatis Regiæ Göttingensis," begun in 1750, &c. are not so properly journals, though they are frequently ranked in the number. Juncker and Wolfius give the honour of the first invention of journals to Photius. His "Bibliotheca," however, is not altogether of the same nature with the modern journals; nor was his design the same. It consists of abridgments, and extracts of books which he had read during his embassy in Persia. M. Salo first began the "Journal des Sçavans," at Paris, in 1665, under the name of the Sieur de Hedouville; but his death soon after interrupted the work. The abbé Galois then took it up, and he, in the year 1674, gave way to the abbé de la Roque, who continued it nine years, and was succeeded by M. Coufin, who carried it on till the year 1702, when the abbé Bignon instituted a new society, and committed the care of continuing the Journal to them, who improved and published it under a new form. The other French journals are the "Memoirs and Conferences of Arts and Sciences, by M. Dennis, during the years 1672, 1673, and 1674;" the "New Discoveries in all the Parts of Physic," by M. de Blegny; the "Journal of Physic," begun in 1684, and some others, discontinued almost as soon as begun. "Rozier's Journal de Physique," begun in July, 1771; "Annales Chimiques," &c. &c. The "Nouvelles de la Republique des Lettres," News from the Republic of Letters, were begun by M. Bayle in 1684, and carried on by him till the year 1687, when M. Bayle being disabled by sickness, his friends, M. Bernard and M. de la Roque, took them up, and continued them till 1699. After an interruption of nine years, M. Bernard resumed the work, and continued it till the year 1710. The "History of the Works of the Learned," by M. Bafnage, was begun in the year 1686, and ended in 1710. The "Universal His-

torical Library," by M. Le Clerc, was continued to the year 1693, and contained twenty-five volumes. The "Bibliothèque Choiseif," of the same author, began in 1703. The "Mercury of France" is one of the most ancient journals of that country, and was continued by different hands; the "Memoirs of a History of Sciences and Arts," usually called *Memoires des Trevoux*, from the place where they are printed, began in 1701. The "Essays of Literature" reached but to a twelfth volume in 1702, 1703, and 1704; these only take notice of ancient authors. The "Journal Litteraire," by father Hugo, began and ended in 1705. At Hamburg, they have made two attempts for a French journal, but the design failed: an "Ephemerides Sçavantes" has also been undertaken, but that soon disappeared. A "Journal des Sçavans," by M. Dartis, appeared in 1694, and was dropped the year following. That of M. Chauvin, begun at Berlin in 1666, held out three years, and an essay of the same kind was made at Geneva. To these may be added, the "Journal Litteraire," begun at the Hague in 1715, and that of Verdun, and the "Memoires Litteraires de la Grande Bretagne," by M. de la Roche; and the "Bibliothèque Angloise," and "Journal Britannique," which were confined to English books alone. The Italian journals are, that of abbot Nazari, which lasted from 1668 to 1681, and was printed at Rome. That of Venice began in 1671, and ended at the same time with the other: the authors were Peter Moretti, and Francis Miletti. The "Journal of Parma," by Roberti and father Bacchini, was dropped in 1690, and resumed again in 1692. The "Journal of Ferrara," by the abbé de la Torre, began and ended in 1691. "La Galeria di Minerva," begun in 1696, was the work of a society of men of letters. Seigneur Apostolo Zeno, secretary to that society, began another journal in 1710, under the protection of the grand duke: it was printed at Venice, and several persons of distinction had a hand in it. The "Fatti Eruditi della Bibliotheca Volante," were published at Parma. There has appeared since, in Italy, the "Giornale del Letterati."

The principal among the Latin journals is that of Leipzig, kept under the title of "Acta Eruditorum," begun in 1682: P. P. Manzani began another at Parma. The "Nova Litteraria Maris Balthici," lasted from 1698 to 1708. The "Nova Litteraria Germanica," collected at Hamburg, began in 1703. The "Acta Literaria ex Manuscriptis," and the "Bibliotheca Curiosa," began in 1705, and ended in 1707, are the work of Struvius. Messrs. Kuitler and Sike, in 1697, began a "Bibliotheca Novorum Librorum," and continued it for two years. Since that time there have been many Latin journals; such, besides others, is the "Commentarii de Rebus in Scientia Naturali et Medicini gestis," by M. Ludwig. The Swiss journal, called "Nova Litteraria Helvetica," was begun in 1702, by M. Scheuchzer; and the "Acta Medica Hafnensia," published by T. Bartholin, make five volumes, from the year 1671 to 1679.

There are two Low Dutch journals; the one under the title of "Boeckzal van Europe;" it was begun at Rotterdam, in 1692, by Peter Rabbus; and continued, from 1702 to 1708, by Sewel and Gavern: the other was done by a physician, called Ruitler, who began in 1710. The German journals of best note are, the "Monatlichen Unterredungen," which held from 1689 to 1698. The "Bibliotheca Curiosa," begun in 1704, and ended in 1707, both by M. Tenzel. The "Magazin d'Hambourg," begun in 1748, is the "Physikalische Belustigungen," or Philosophical Amusements, begun at Berlin in 1751. The "Journal of Hanover," begun in 1700, and continued for two years by M. Eccard, under the direction of M. Leibnitz, and
afterwards

afterwards carried on by others. The *Theological Journal*, published by M. Loetner, under the title of "Altes & Neues," that is, Old and New. A third at Leipzig and Frankfurt, the authors Messrs. Walterek, Kraufe, and Grochanius, and a fourth at Hall, by M. Turk.

The English journals are, the "History of the Works of the Learned," begun at London, 1699; "Censura Temporum," in 1708. About the same time there appeared two new ones, the one under the title of "Memoirs of Literature," containing little more than an English translation of some articles in the foreign journals, by M. de la Roche; the other a collection of loose tracts, entitled "Bibliotheca Curiosa," or a Miscellany. These, however, with some others, are now no more; but are succeeded by the "Monthly Review," which began in the year 1749, and gives a character of all English literary publications, with the most considerable of the foreign ones; the "Critical Review," which began in 1756, nearly on the same plan; the "Anti-jacobin Review," begun in 1793; the "American Review," in 1811; the "British Critic," in 1798; the "British Review," in 1811; the "Eclectic Review," in 1805; the "Edinburgh Review," in 1803; the "London Medical Review," in 1808; the "Quarterly Review," in 1809. Besides these we have several monthly pamphlets, called Magazines, which, together with a chronological series of occurrences, contain letters from correspondents, communicating extraordinary discoveries in nature and art, with controversial pieces on all subjects. Of these are the following: viz. the "Agricultural," begun in 1709; the "Baptist," in 1809; the "Botanical," in 1786; the "British Farmer's," in 1811; the "European," in 1782; the "Evangelical," in 1703; the "Farmer's," in 1800; the "Flower's Political," in 1807; "Freethinking," in 1811; "Gentleman's," in 1731; "Golf's," in 1806; "Lady's," in 1771; "Methodist," in 1777; the "Monthly," in 1709; "Musical," in 1809; "Military," in 1811; "Philosophical," in 1768; "Sporting," in 1792; "Universal," in 1747. To these may be added several other periodical publications under different titles, such as "Ackerman's Repository," begun in 1810; "Antiquarian Cabinet," in 1809; "Aræna," in 1810; "Army List," in 1809; "Christian Observer," in 1802; "Christian Guardian," in 1809; "Dramatic Censor," in 1811; "Edinburgh Medical Journal," in 1805; "General Chronicle," in 1811; "La Belle Assemblée," in 1802; "Lady's Museum," in 1798; "Literary Panorama," in 1809; "Medical Observer," "Medical Compendium," in 1809; "Medical Bureau," in 1790; "Monthly Repository," in 1806; "Military Chronicle," in 1810; "Naturalist's Miscellany," in 1780; "Naval Chronicle," in 1799; "Nicholson's Journal," in 1802; "Philanthropic," in 1810; "Repository of Arts," in 1703; "Retrospect," in 1806; "Reflector," in 1810; "Satirist," in 1807; "Scourge," in 1811; &c. &c.

JOURNCHOPPERS, in our *Old Writers*, regrotors of *journal*; which formerly, perhaps, was called *journal*. They are mentioned in the Rat. S Hen. VI. c. 5.

JOURNET, FURSTENBERG, in *Biography*, one of the great actresses that has appeared on the stage of the French revolutions. She was at first admired for the excellence of her voice, her noble figure, and the elegance of her action. She had an air and carriage for striking, and something of interesting and touching in her countenance, that she drew tears from those who only looked at her in the part of Iphigenia. She had eyes and arms which guided to the heart all the expression of what she had to paint.

She quitted the stage in 1720, after fifteen years applause and admiration, and died in 1722. Effais for la Musique.

JOURNEY, in *Dictionary*, signifies as much ground as can be ploughed over in a day, though it is not applied in the same way in all districts, or has the same signification, as in some it is used to express a much less proportion of labour. It often signifies the length of time the team is engaged in labour, either in ploughing or any other sort of work. With all horses under team labour, great attention should be paid by the person who has the care of them, in feeding and dressing them. See *TEAM*.

JOURNEY, Sabbath-day. See *SABBATH*.

JOURNEY-MAN, formed from the French *journalier*, *a day's work*; anciently signified a person who wrought with another by the day, though now, by the statute, it extends to those likewise who covenant to work with another in their occupation or trade by the year.

JOUTRA, in *Geography*, a town of Sweden, in Tavastland; 65 miles N.E. of Tavallus.

JOUVENCY, JOSEPH, in *Biography*, a learned Jesuit, was born at Paris in 1643. He entered the society of Jesus in 1659, and was chosen professor of rhetoric in its seminaries, first at Caen, then at La Fleche, and finally at Paris, where he taught with great reputation for nearly twenty years. He was invited to Rome in 1699, to assist in writing the continuation of the history of the society, and died in that city in 1719. His part of the history of the Jesuits comprises the period from 1591 to 1616, and was printed in folio in the year 1710. As a philologist he is known by his "Latin Harangues delivered on different occasions," in two volumes, 12mo.: "Appendix de Diis et Heroibus Poeticis," which is a compendium of the heathen mythology; "Notes on Terence, Ovid, Horace, Persius, Juvenal, Martial, and some of the works of Cicero." He gave also a Latin version of the first Philippic of Demosthenes. He is said to have displayed, in his several works, great purity, elegance, and facility of style, for which he is more distinguished than for novelty or depth of thought. Moren.

JOUVENET, JOHN, an historical painter, born at Rouen, in Normandy, in 1644. He received his first instructions from his father; but his principal teacher was Poussin, and his most useful studies the works of that master.

He had a ready invention, and was therefore employed to adorn the apartments of Versailles and the Trianon. In the Hospital of the Invalids at Paris, he painted the twelve apostles; each figure 14 feet high. It must be acknowledged, however, that he failed in true taste. His style partakes too much of French Bignancy; the substitution of something striking for what is solid and good; and his colouring is heavy. It is said, that, being deprived of the use of his right hand by paralysis, he painted ever after with his left. He died in 1717.

JOUVENU, in *Geography*, a town of France, in the department of the Saone and Loire, and chief place of a canton, in the district of Macon. The place contains 1469, and the canton 10,491 inhabitants, on a territory of 165 kilom. tres, in 23 communes.

JOUX LA VILLE, a town of France, in the department of the Yonne; 9 miles N. of Avallon.

JOUX, *Mont*, a part of mount Jura, near the source of the river Doubs, on the borders of Switzerland, and that part of the canton of Berne which borders on France.

JOUX, a lake of Switzerland, in the canton of Berne, situated on a part of mount Jura; 4 miles W. of Romandinot.

JOWA TOWNS, *Lower*, a town of North America, on the

E. side of the river Mississippi; which, between twenty and thirty years ago, could furnish 300 warriors. N. lat. 40° 30'. W. long. 91° 15'.—The *Upper Iowa town* is about 15 miles below the mouth of the river Iowa, on the E. side of the Mississippi, and could formerly furnish 400 warriors.

JOHAN d' MUGRAH, a town of Algiers; 30 miles S.W. of Geseh.

JOHGONG, a town of Bengal; 18 miles S.E. of Burdwan.

JOHRASSER, a town of Hindoostan, in Oude; 16 miles S.E. of Lucknow.

JOYRIES, a cluster of small islands in the Mediterranean, near the E. coast of Tunis, opposite to Lempta, anciently called Tarichis, and thought by Caesar to be of so much importance, that he appointed several stationary vessels to secure them. N. lat. 35° 38'. E. long. 10° 46'.

JOY, in *Ethics*, is that passion which is produced by love, regarding its object as present, either immediately or in prospect; in reality or imagination. This passion has been found to increase the perspiration and urine of human bodies. See PLEASURE and PAIN.

JOYEUSE, in *Geography*, a town of France, in the department of the Ardèche, and chief place of a canton, in the district of L'Argentiere, 21 miles S.S.W. of Privas. The place contains 1074, and the canton 12,616 inhabitants, on a territory of 212½ kilometers, in 18 communes. N. lat. 44° 29'. E. long. 4° 19'.

JOYNAGUR, a town of Meckley; 8 miles N.W. of Munyaur.

JOYNARANSHAUT, a town of Bengal; 18 miles E.N.E. of Ilamabad.

JOYNER'S PRESS. See PRESS.

JOYNERY, the art of working in wood, and of fitting or joining various parts or members of it together.

The French call it *menuiserie*, from *minutaria*, small work; by which it is distinguished from *carpenterie*, which is conversant in the larger and less curious work. See JOINERY.

JOYNEY, *Column of*. See COLUMN.

JOYPOUR, in *Geography*, a town of Bengal; 18 miles E.N.E. of Ilamabad.—Also, a town of Affan; 16 miles S.S.E. of Gentia.

JOZE, Sr., a town of Brazil, on the Tapajos; 45 miles S. of Pauxis.—Also, a town of Brazil, in the government of Minas Geraes; 80 miles S.W. of Villarica.—Also, a town of Brazil, in the government of Goyas; 75 miles E.N.E. of Villa Boa.

JOZE, Sr., *de Dera*, a town of Brazil, on the Rio Negro; 205 miles from Fort Rio Negro.

Jozi *Azu*, a town of Brazil, in the government of Para; on the river Tocantin; 70 miles S.W. of Para.

JOZO, in *Iethyology*, the name of a small sea-fish, of the sea-gudgeon, or rock-fish kind, common in the Mediterranean, and called *gobius albus* by some authors. It is brought to market at Rome and Venice. See GOBIUS.

JOZZI, GIUSEPPE, in *Biography*, an Italian opera singer of the second class, with a soprano voice, came into England with Monticelli, at the beginning of lord Middlesex's regency in 1742. He was a much better performer on the harpichord than a singer. He gained great reputation here by his very accurate, brilliant, and expressive manner of executing Alberti's lessons, and a considerable sum of money by printing and selling them as his own compositions.

JPAM, in *Geography*, a town of Africa, on the Gold coast; 30 miles S.W. of Aera.

IPANEMA, a town of Brazil; 160 miles S.W. of Pernambuco.

IPECACUANHA, or IPECACUANHA, in *Pharmacy*, a

little wrinkled root about the thickness of a moderate quill, brought hither from several parts of the West Indies; much used as an emetic, and against diarrhoeas and dysenteries.

The first European who brought this root into use was an apothecary of Brazil, whose name was Michael Tritaon. The book which the author published on this subject falling into the hands of the English, is translated into our language, and stands, among a number of like accounts, among Purchas's Pilgrims.

He says it is an excellent remedy against dysenteries and fluxes of all kinds. He says also, in its description, that the stalks are a quarter of a yard long, and the roots nearly as much; and that the leaves grow only four or five upon a plant.

This agrees very well with all that we have since discovered of this plant: and the method of using it at that time, we find, was not as a vomit; but they bruised the fresh root, and steeped it about twelve hours in water, at the end of which time the patient drank the water early in the morning; it operated by stool; but after its operation, the natural purging and voiding of blood ceased. This seems the original account we have of this drug. De Laet, from this, compiled his account, which is almost a literal translation of this into Latin: from his hint Piso and Marggrave enquired after it more carefully upon the spot, and from them came the first accurate accounts we had of it; so that all seems, *ab origine*, deduced from Michael Tritaon's account of it. Miller apprehends that the plant which furnishes the true ipecacuanha belongs to the genus of *Triofum*, or *fesse ipecacuanha*. It is, as some have thought, the *Psychotria emetica* of Linnæus the younger. But the authority on which Mutis received the information is not to be implicitly followed.

Piso divides this root into two sorts, the white and the brown; or, according to Geoffroy, the Peruvian and Brazilian ipecacuanha: but three sorts, says Dr Woodville, are distinguishable in our shops; *viz.* ash-coloured or grey, brown, and white. The *ash-coloured* is brought from Peru, and is a small wrinkled root, bent and contorted into a great variety of figures, brought over in short pieces full of wrinkles and deep circular fissures, down to a small white woody fibre that runs in the middle of each piece; the cortical part is compact, brittle, and appears smooth and refinous upon breaking; it has very little smell, the taste is bitterish and sub-acrid, covering the tongue, as it were, with a kind of mucilage. The *brown* is small, somewhat more wrinkled than the foregoing; of a brown or blackish colour without, and white within; this is brought from Brazil. The *white* sort is woody, has no wrinkles, and no perceptible bitterness in taste. The first, that is, the ash-coloured or grey ipecacuanha, is that usually preferred for medicinal use. The brown has sometimes observed, even in a small dose, to produce violent effects. The white, though taken in a large one, has scarcely any effect at all.

There are divers false species of ipecacuanha, or root, which, on account of their external appearance, bear the denomination of ipecacuanha, and are sometimes sold for it. Dr. Douglas mentions two: the one white, resembling the true white, only larger in size, straighter, and softer to the touch; the other brown, of a deeper colour than the true brown, and sometimes mixed with red, whence it has also been called red ipecacuanha. These are both produced in Maryland and Virginia, where they are used as vomitives by the lower sort. Sir Hans Sloane has discovered that the latter is no other than the root of a poisonous apocynum, described by him in his Natural History of Jamaica. See Plul. Transf. N. 410.

The genuine ipecacuanha has scarcely any smell, and is

IPECACUANHA.

during its pulverization, or infusion in Equors, when it emits a faint nauseous one. Geoffroy observes, that in pulverizing considerable quantities, the finer powder that flies off is apt to affect the operator with difficulty of breathing, a fiting of blood, a bleeding at the nose, or a swelling and inflammation of the eyes and face, and sometimes of the throat; which symptoms go off in a few days, spontaneously, or by the aid of coagulation.

Dr Irving ascertained by experiments, that this root contains a gummy and resinous matter, and that the gum is in much greater proportion, and is more powerfully emetic, than the resin: that the cortical part is more active than the ligneous; and that the whole root manifests an antiseptic and astringent power. He also found its emetic quality to be most entirely converted by means of the acetic acid, from which ten grains of the powder, taken in two ounces of wine, produced only five loose stools.

The bark of *ipecacuanha* is said to be preferable to its root, as an emetic; acting equally well, and with equal safety, in all its different states, either in powder, or infusion. Six grains of the bark, infused for a night in an ounce and a half of old Rhine, proves a good emetic. See Phil. Trans. N. 476. Sect. 10.

The brown *ipecacuanha* yields, by distillation, a smaller quantity of oil than the grey; and the left portion of the spirit which comes over with the oil, on urging the fire to the greatest violence, though it be considerably acid to the taste, yet does not seem to contain less, but rather more volatile particles than the spirit drawn in the same manner from the grey. On mixing the spirits of both kinds also with salt of tartar, the volatile parts of that from the brown escape with more rapidity than those from the spirit of the grey, and affect the nose more sensibly.

It is rational to conclude from hence, that if the brown *ipecacuanha* contains less oil than the grey, it also contains less resin; and that as this last portion of spirit contained more volatile parts, it must naturally be expected that it should prove more violent in its operation than the grey. This observation also, which is countenanced by fact, may in some degree favour the opinion of those who affirm, that the purgative virtues of medicines are excited by a volatile salt, and that they are more or less violent, as they contain more or less of this salt.

The brown *ipecacuanha*, as well as the grey, will afford two sorts of extracts, a resinous and a saline one; but both these are yielded in a smaller quantity from the brown than from the grey, and consequently the residuum is always greater from the brown. Eight ounces of the grey *ipecacuanha* yield, with spirit of wine, ten drams of the resinous extract; the same quantity of the brown, treated in the same manner, yields only six drams. From the residuum of this quantity of the grey kind, thus distilled only of its resin, by the spirit, there may be prepared, by a watery solvent, two ounces of a saline extract; but the residue of this same quantity of the brown will yield only five or six drams of the extract by the same treatment. The residue of the grey, thus distilled of its resinous and saline parts, will weigh for ounces; and the residue of the brown, after the same treatment, will weigh for ounces. Hence it is very evident, that the active principles are much more abundant in the grey than in the brown kind of this useful root.

Newman says that sixteen ounces of good *ipecacuanha* will yield three ounces of a resinous matter, in which its virtue consists, by means of spirit of wine; and from the same quantity, by means of water, five ounces of gummy matter were extracted.

If the process of this analysis be varied, and the watery

menstruum used first, the proportion of the saline extract will be greatly increased by it, and that of the resinous greatly diminished; eight ounces of the grey *ipecacuanha*, thus treated, yielding three ounces and a half of saline extract, and only thirty-six grains of the resinous one afterwards by spirit of wine; and the same quantity of the brown yielding one ounce and three drams of the saline extract, and only twenty-four grains of the resinous one, by means of spirit of wine afterwards used. From all this it is easy to perceive, that the brown *ipecacuanha* contains much less of the active parts, and much more of the terrestrial, than the grey; and yet it is equally certain from trial, that the brown is much more violent in its operation than the grey.

This seems a perplexing sort of paradox; but to explain it we must remember, that the virtues of medicines are not to be measured by their bulk nor their weight, the most powerful of all acting in the smallest quantities. It has been observed, that the last portion of spirit drawn from the brown is more pungent and strong than that from the grey; and probably this part of the root has as much power to irritate the internal parts of the intestines as the resinous parts.

The best menstruum for extracting the active virtue of the root, appears to be a mixture of one part of pure spirit, with two or three parts of water. In the shops, wine is employed: an ounce of the root is macerated or digested in a pint of Champaign, or fifteen ounces of mountain, to which some add a quarter of an ounce of dried orange-peel. These tinctures, in doses of from half an ounce, or less, to an ounce and upwards, prove mildly emetic. Lewis Mat. Med.

It has been found by experience, that this is the mildest and safest emetic with which we are acquainted; having this peculiar advantage, that if it does not operate by vomit, it readily passes off by the other excretories. It was first introduced to us with the character of an almost infallible remedy in dysentery and other inveterate fluxes, as diarrhoea, menorrhagia, and leucorrhoea, and also in disorders proceeding from obstructions of long standing; nor has it lost much of its reputation by time. The use of *ipecacuanha* in these fluxes is thought to depend upon its restoring perspiration; for in these cases, especially in dysentery and diarrhoea, the skin is dry and tense; and while the common diaphoretics usually pass off by stool, small doses of this root have been administered with the best effects, proving both laxative and diaphoretic. Dr. Caslen attributes its good effects entirely to its purgative quality. In common cases of dysentery, it is said soon to perform a cure, by bringing on a rice diaphoresis, or plentiful sweat, after the patient has taken a purge or two, and is covered up warm in bed. In putrid or malignant dysenteries, it requires to be continued for several days, and repeated as an evacuant, with the assistance of rhubarb, cordial antiseptics, and mild opiates, or other agents. In cases requiring plentiful evacuation, or when the offending matter is lodged deep, Sir John Pringle recommends it to be given in small doses, and repeated at proper intervals, till vomiting and purging come on.

In the spasmodic asthma, Dr. Akenfield remarks, that when nothing contraindicates repeated vomiting, he knows no medicine so effectual as *ipecacuanha*. In violent paroxysms, a scruple procures immediate relief. When the complaint is habitual, from three to five grains every morning, or from five to ten every other morning, may be given for a month or six weeks. This medicine has been also successfully used in hæmorrhages. Several cases of menorrhagia are mentioned by Dahlberg, in which one-third or

half of a grain was given every four hours, till it effected a cure. These small doses are likewise found of great use in catarrhal and even constitutive cases, as well as in various kind of fever. Dr. Cullen (Mat. Med. vol. ii.) informs us, that he knew a practitioner who cured intermittents by giving five grains of ipecacuanha, or enough to excite nausea, an hour before the accession of the fit was expected; and that Dr. Theophrastus, formerly of Montreux, proposed to cure agues by the employment of emetics given at the time of accession, or at the end of the cold stage; and this practice has also been successful, and may indeed be extended by farther emetics; but by trying such practices, the ipecacuanha was found more manageable than the other, and generally more easy to the patient. Woody. Med. Bot.

IPERACUANHA, *Boissard*, in *Bacon*, is a species of *Achillea*, or wall-wort.

IPERACUANHA, *Falck*, or Dr. Tinker's weed, from his having been one of the first professors who brought the root into use. See *THORNTREE*.

IPICACUANHA, in *Ornithology*, the name of a Brazilian species of duck. It is of a middle size between the duck and goose, and is kept tame there for breeding and eating. It will swim as well on dry land as when it has the use of water, and lays a vast number of eggs.

IPECATI-APOA, the name of a Brazilian species of duck called *Asi*, by the Portuguese; the word in that language expressing goose. It is nearly of the size of the goose, but is exactly of the shape and figure of the common duck. It is very common in the Brazilian rivers, and is fleshy and well tasted.

IPECU, the name of a Brazilian bird of the wood-pecker kind, called by Mr. Ray, *picus varius Brasilensis*. It is of the size of a common pigeon. Its beak is straight, and very hard and sharp, and it pierces the bark and wood of trees with it, in the same manner as the European kinds. See *PICUS lineatus*.

IPEK, in *Geography*, a river of Servia, which rises in mount Hæmus, and runs into the Danube, near Galombatz.

IPERSHEIM, a town of Germany, in the county of Schwarzburg; 13 miles S.W. of Schainfeld.

IPERUQUIBA, in *Ichthyology*, a name by which some have called the *remora*, or sucking-fish; called also by the Portuguese, *peixe pegador*, and *peixe piolho*. See *ECHINETS*.

IPHICRATES, in *Biography*, a celebrated Athenian general, was born in a humble rank of life; but by improving the situation in which he was thrown, he, at an early age, raised himself to a high military command. As he advanced in the army, he shewed himself a strict disciplinarian, and attentive to every circumstance of military improvement. He made war against the Thracians, obtained some victories over the Spartans, and assisted the Persian king against Egypt. He changed the dress and arms of his soldiers, and rendered them more alert and expeditious in using their weapons. In the fiscal war, a fleet was fitted out by the Athenians for the recovery of Byzantium, under the joint commands of Iphicrates, Timotheus, and Chares. The two former differed from the latter on his proposal to attack the enemy's fleet during a violent storm, and were in consequence charged by him with treasonable intentions. They were recalled by the people of Athens, and publicly prosecuted. Timotheus was condemned, and went into exile; Iphicrates defended himself with great spirit, and was acquitted. He was indebted for this not only to his eloquence, but to the menaces of the people, who threatened the tribunal,

of several military partizans. When reproached for allowing and encouraging to violent a proceeding, he replied, "I have long borne arms for the safety of my country, and should be a great fool not to employ them to save myself." From this time, however, he ceased to serve in the army. He lived to a great age, and saw his countrymen fully reconciled to him. He left one son, named Menætheus, by the slaughter of the king of Thrace. Univer. Hist. Græc. Nepos.

IPIOFEN, in *Geography*, a town of Germany, in the duchy of Würzburg; 15 miles E.S.E. of Würzburg.

IPIALES, a town of South America, in the province of Popayan; 36 miles S. of Pató.

IPONCEA, in *Botany*, so called by Linnæus, from *id*, which he accountably mistakes for the *Convolvulus* plant, whereas it means a creeping sort of worm that infests and corrodes vines; and *ponce*, *like*. By this appellation he evidently intended to express the close resemblance of *Iponcea* to the genus *Convolvulus*, with which it agrees in habit altogether. Linn. Gen. 87. Schreb. 116. Willd. Sp. Pl. v. 1. 879. Mart. Mill. Dict. v. 2. Art. Hort. Kew. ed. 2. v. 1. 338. Brown Prodr. Nov. Holl. v. 1. 484. Juss. 134. Lamark Illustr. t. 104. (Quamoclit; Tourt. t. 39.) Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. *Convolvulidæ*, Juss.

Gen. Ch. Cal. Perianth inferior, oblong, small, in five deep segments, without any appendages, permanent. Cor. of one petal, funnel-shaped, or bell-shaped; tube somewhat cylindrical, very long; limb five-cleft, spreading, with five plaits. Stam. Filaments five, awl-shaped, nearly the length of the corolla; anthers roundish. Pistil Germen superior, roundish; style three-d-shaped, the length of the corolla; stigma capitate, nearly globose, in two or three lobes. Peric. Capsule roundish, of two or three cells. Seeds few, large, roundish, sometimes hairy.

Ess. Ch. Calyx deeply five-cleft, naked. Corolla with five plaits, somewhat funnel-shaped. Stigma capitate and globose, lobed. Capsule of two or three cells. Seeds two in each cell.

A large genus, more correctly distinguished from *Convolvulus* by the globose form of its stigma, than by the more narrow or tubular shape of the corolla. For want of attending to this, Linnæus and others have misplaced several species. Jacquin in his *Coltæana*, v. 3. 303, has called the attention of botanists to this subject, and Mr. R. Brown in his *Prodrum* has recently thrown further light upon it, indicating, moreover, the want of bractæ or appendages to the calyx in *Iponcea*, which are found in *Convolvulus*.

Examples of *Iponcea*, eminent for their beauty, are: 1. *Quamoclit*, Linn. Sp. Pl. 227. Curt. Mag. t. 244; a native of the East Indies, remarkable for its finely pinnate leaves, and rich crimson blossoms.—1. *coccinea*, Linn. Sp. Pl. 228. Curt. Mag. t. 221, found in the West Indies, and easily cultivated, as an annual, in our gardens.—1. *Brasiliensis*, Linn. Sp. Pl. 228. Curt. Mag. t. 752, found also in the West Indies, and rarely seen with us. The flowers of the last are large and white; we should from their size, as well as their appearance, guess them to be fringed in the evening.

IPOMŒA, in *Gardening*, comprehends plants of the herbaceous flowery kinds; of which the species chiefly cultivated are the winged-leaved ipomœa (1. *quadrata*), and the scarlet-flowered ipomœa (1. *coccinea*).

Of the second species there is a variety with orange coloured flowers.

Method of Culture.—These plants are increased by sowing the well-ripened seeds in small pots, plunging them in sand

hot-bed, or in the earth of the bed, in the early spring months, proper air and water being given. When the plants have attained some growth, and in the first root begin to climb, they should be removed, with balls of earth about their roots, into the places where they are to grow; or, which is better for the first kind, into separate large pots, replanting them in the bark hot-bed. They should have proper sticks set for them to twine about; some pots of the first kind being placed in the stove, as being more tender in their nature.

The first sort affords variety in the stove, and among other tender potted plants in the summer; and the latter, in the fronts of warm borders, as well as among the less tender potted flowering plants.

I POMOPSIS, in Botany, so called, by Michaux, from *ipso*, to strike forcibly, and *opsis*, the sight, in allusion, as it should seem, to the dazzling brilliancy of the flowers of the original species. Michaux Amer. v. 1. 141. Sm. Exot. Bot. v. 1. 23. Ait. Hort. Kew ed. 2. v. 1. 342. Class and order, *Pentandria Monogynia*. Nat. Ord. *Campanaceae*, Linn. *Polonia*, Juff.

Gen. Ch. Cal. Perianth inferior, bell-shaped, membranous at the base; its limb in five, long, equal, linear, erect segments. Cor. funnel-shaped; tube cylindrical; limb in five, deep, ovate, nearly equal segments. Stam. Filaments five, inserted into the upper part of the tube, awl-shaped, shorter than the limb; anthers roundish, two-lobed. Pist. Germen superior, ovate; style thread-shaped, about as long as the tube; stigma in three, deep, oblong, downy, spreading segments. Peric. Capsule rather shorter than the calyx, ovate, obtuse, of three cells, and three valves. Seeds several in each cell, in two rows, acutely angular.

Eff. Ch. Calyx in five segments, membranous at the base. Corolla funnel-shaped. Stamens springing from the tube. Stigma three-cleft. Capsule superior, of three cells and three valves. Seeds several, angular.

1. *I. elegans*. Scarlet Ipomopsis. Michaux Amer. v. 1. 142. Sm. Exot. Bot. t. 13. (*Ipomoea rubra*; Linn. Syst. Veg. ed. 14. 204. *Polemonium rubrum*; Linn. Sp. Pl. 2: 13. *Ca. tua coronopifolia*; Willd. Sp. Pl. v. 1. 879. *Quamoclit pennatum erectum*, floribus in thyrsum digellis; Dill. Elth. 321. t. 241.) "Stem erect, straight. Corolla thrice as long as the calyx."—A native of South Carolina, whence it was originally brought to Sherard's garden at Eltham. It has occasionally been imported since from the same country, and was lately raised in great perfection at Messrs Lee and Kennedy's, where the excellent figure in exotic botany was drawn. It flowers in September or October, and consequently ripens seed with difficulty. According to all appearance this beautiful plant is a biennial. Root fibrous. Stem solitary, erect, becoming panicled at the height of four or five feet, round, leafy, and clothed, like the whole herbage, with short, glandular, white hairs. Leaves pinnatifid; segments long and narrow, those of the radical leaves shorter and broader; floral leaves simple. Flowers on short stalks, drooping. Corolla equally five-cleft, of a brilliant scarlet, elegantly dotted on the inside. Stamens slender, red; anthers yellow. Germen smooth, pale green. Capsule almost membranous, the partitions from the centre of the valves. Seeds in two rows, small, not winged.

2. *I. inconspicua*. Little Blue Ipomopsis. Sm. Exot. Bot. t. 14. Ait. Hort. Kew ed. 2. v. 1. 342.—"Stem much branched and spreading. Corolla scarcely longer than the calyx. Segments of all the leaves linear."—Native of North America, and first raised, in 1793, at Sion House, by Mr. Thomas Hoy, F.L.S. It flowered in November. Root annual. Stems numerous, about a foot high, leafy,

round, pubescent as in the last species. Leaves alternate, pinnatifid; segments long and narrow, generally simple. Flower-stalks various in length, simple, solitary or in pairs, erect. Calyx with rather broader teeth than the foregoing. Corolla blue, with a white tube, by no means striking or beautiful. Stigma purplish. Capsule ovate, thin, whitish.

Dr. Smith has observed, that this species serves to confirm the *Ipomopsis* of Michaux, with which it agrees so completely in every botanical character, that we find it not very early to establish even a specific difference on sound principles; while, on the other hand, it shews how different this natural genus is from *Cantua*, and all others to which it has been referred. The same author mentions a third species, *I. albidula*, gathered by Donkey, at Lima, much like this, but upright; its leaves doubly pinnatifid, with somewhat elliptical lobes, and its flowers whitish.

I P P O, in Natural History. See *MACASSAR Poison*.
IPS, in Geography, a town of Austria, situated near the conflux of the Ips and Danube, on the site of the ancient Pons Iis, on Ilipontium; 48 miles W. of Vienna. N. lat. 48 13'. E. long. 15 5'.

IPSALA, or **SKIPSALAR**, a town of European Turkey, in Romania; 53 miles S.W. of Adrianople.

IPSARA, called by the ancients *Plyrea* or *Plyryia*, an island in the Grecian Archipelago, about six miles long and three wide; the soil is in general stony, and affords no great resources to agriculture and commerce. It, however, produces figs, grapes, a small quantity of cotton, and some corn, and red wine is an article of commerce. The inhabitants are chiefly Greeks, about 1000 in number, who pay a tribute of about 1000 crowns, and are subject to the cadi of Scio; six miles N.W. of Scio. N. lat. 38 43'. E. long. 25 55'. About a league from Ipsara lies a smaller and desert island, called "Anti-ipsara, scarcely two leagues in circumference. Between these two islands ships find a very good anchorage.

IPSEHEIM, a town of Germany, in the principality of Culmbach; 17 miles N.N.W. of Anspach.

IPSILI, a small island in the gulf of Engia.

IPSUS, in Ancient Geography, a town and river of Asia, in Phrygia, S.E. of Synnada; famous for a battle fought here in the year 300 B.C. between Antigonus and Demetrius, having an army of 70,000 foot, 10,000 horse, and 75 elephants, and the kings of Seleucus, Lyfimachus and Cassandra, who had 74,000 infantry and 10,500 cavalry, 400 elephants, and 20 chariots of war. Antigonus was defeated and killed. Demetrius fled into Greece. The conquerors divided their lands between them.

IPSWICH, formerly called *Gippeswich*, *Gippeswid*, *Gyp-p-wic*, &c. in Geography, a borough and the county town of Suffolk, England, is seated on the northern bank of the river Orwell, at the distance of 18 miles N.E. from Colchester, 54 S.W. of Yarmouth, 12 N.W. of Harwich, and 69 N.E. of London. In the year 1800, it contained 2221 houses, and 74,262 inhabitants. Near this place the river Gippen, or Gipping, unites its waters with the Orwell, which is navigable for 12 miles to the sea at Harwich, where is a commodious haven, or harbour. Ipswich appears to have been a town of some consequence during the Anglo-Saxon dynasty; for it was fortified with a vallum and foss when the Danes made their depredatory incursions into this part of the island. Within the space of ten years they pillaged this town twice: first in, or near the year 691, and again in 1000. In the fifth year of king John's reign, the fortifications were repaired and materially strengthened. The walls were provided with, at least, four fortified gates; which were respectively called, from their relative

relative situations, East-Gate, West-Gate, North-Gate, and South-Gate; and the town was also divided into four leets or wards. Some fragments and parts of the old walls are still remaining. Of the castle, no vestige is left, either to prove its site, or define its character. The liberties of the borough, however, extend beyond the walls, and comprehend the four hamlets of Stoke-Hall, Wickes-Uford, Brooks-Hall, and Wickes-Bishop. The extent of these liberties comprises an area, measuring about four miles from east to west, and nearly five miles in a transverse direction. The corporation has also jurisdiction and advantageous privileges by water, on the Orwell to the sea-port of Harwich. In the time of king Edward the Confessor, his queen held two parts of the borough, and her brother, earl Guert, a third part. When the Domesday book was made, Roger Bigot, earl of Norwich, possessed the half hundred of Gippeswid. At the former period, there were 538 burgesses residing here, who paid custom to the king, but at the conquest there were only 110 burgesses, and in the Norman record it is stated, that "328 houses are now empty." The first charter granted to the borough is dated 25th of May 1109, 11th of king John; this grants to the burgesses, 1. That the borough with all its appurtenances, liberties, &c. to be holden of the king and his heirs by the payment of the right and usual annual farm, and 100 shillings more at the exchequer." This sum is supposed to have amounted to sixty marks, or 42*l.*: 2. The burgesses were also exempted from the payment of all taxes under the names of tholl, leffage, stidage, passage, pondage, and all other customs by land, and at sea-ports: 3. To have a merchant's gild, and hanse of their own: 4. No person to be quartered on them without consent, or any thing taken from them by force: 5. That they might hold their lands and recover their just dues from whomsoever they be owing:" which implies that the inhabitants were then constituted lawful subjects: 6. That they should hold their lands and tenures within the borough, according to the custom of the borough of Ipswich: 7. That none of them shall be fined or amerced, but according to the laws of the free-boroughs: 8. And that they might choose two bailives and four coroners out of the more lawful men of the said town." Suffolk Traveller.

After this charter was ratified and obtained, the burgesses assembled in the church-yard of St. Mary at Tower, and there held their first great court; appointed officers, &c. Here they continued to transact their public business till the 13th year of Edward I.'s reign, when that monarch seized the borough, and held it in subordination for six years. He then renewed and confirmed the charter, by public act, dated at Berwick, A. D. 1291. For this liberty the burgesses were required to pay an annual rent of 60*l.* to the king. Another charter was granted by king Henry VI.; but the most material act of this kind was procured in the 17th year of king Charles II. Among the privileges conferred on the burgesses by these charters, is that of sending two members to parliament, who are elected by the votes of about 700 burgesses. The officers of these, and who are entrusted with the civil government of the place, are two bailiffs, a recorder, 10 portmen, and 24 common-councilmen. The borough is said to have returned members *ab origine*. Like the generality of parliamentary boroughs, this has been the cause of much bribery, corruption, and litigation. A memorable instance of the latter occurred before a committee of the house of commons in 1780, when Mr. Caor, who had obtained a majority of votes by bribery, &c. was declared disqualified to take a seat in the house, and a new writ was issued to elect another person. The particulars of

this case are fully narrated in Oldfield's "History of Boroughs," vol. ii.

In addition to the privileges already noticed, the corporate officers of Ipswich are authorized to pass fines and recoveries, try civil and criminal causes, and hold pleas of the crown. They also hold assizes of wine, bread, beer, &c. and have an admiralty jurisdiction, whereby they are entitl'd to all waifs, strays, and goods cast on shore. No freeman can be compelled to serve on juries out of the town; and every burges's is entitl'd to several advantageous privileges on sailing to different ports.

Ipswich at present contains twelve parish churches. In the Domesday book nine are specified: and in the year 1287 it is related in Stowe's Annals that some churches in this town, at Yarmouth, at Dunwich, &c. were destroyed by a violent storm, and by the waves of the agitated sea. The names of the present parishes, are, 1. St. Clement's, which is consolidated with St. Helen's, and has no church: 2. St. Helen's, or Hellen's, is a rectory: 3. St. Lawrence's church is said to have been begun by John Bottold, who died A. D. 1431. The chancel was erected by John Balwyn, who died in 1449; and a chantry was founded here, in 1514, by Edmund Dauntry, a postman of this town, who also caused the market cross to be built: 4. St. Margaret's was appropriated to the priory of the Holy Trinity, the church of which was formerly standing near St. Margaret's church-yard: 5. St. Mary's, at Elms: 6. St. Mary's, at Kay: 7. St. Mary's, at Stoke: 8. St. Mary's, at Tower: 9. St. Matthew: 10. St. Nicholas: 11. St. Peter's: 12. St. Stephen's. Besides these, the three following churches are in the vicinity of the town: 1. Thurlston: 2. Whitton: and 3. Wellerfield. The monastic establishments within the town were formerly very numerous, and several houses, parts of buildings, and places, still retain the names of the respective societies. These were, 1. The Holy Trinity, or Christ Church, a priory of Black canons: 2. St. Peter and St. Paul, a priory of Black canons: 3. St. Mary Magdalen, and St. James, a hospital for leprous persons: 4. Dandy's Alms-houses: 5. A house of Austin friars: 6, 7, and 8. Black friars, Gray friars, and White friars. For accounts of these establishments, see Tanner's Notitia Monastica.

Ipswich formerly contained several large houses belonging to wealthy merchants and eminent persons. Of these a few remain in reduced and dilapidated conditions. Among these are walls and a brick gateway to a building called Wolley-college, which was appropriated and enlarged by Cardinal Wolley for a dean, 12 secular canons, 8 clerks, and 8 choiristers. To this college was annexed a grammar school: but before the founder's design was carried into effect he was arrested by king Henry VIII. and is supposed to have taken poison to escape an ignominious trial and execution. The site of the college comprised about six acres of land. The bishop of Norwich had a palace called Curson's-house, in Silent-street. Sir Andrew Windfor, afterwards lord Windfor, had a house in the parish of St. Mary, at Stoke. The archdeacon of Suffolk possessed a house, called Place or Palace, in Upper Brook-street. Part of the outer wall and gates lately remained. In the parish of St. Stephen were formerly two houses, or mansions of considerable note: one of which belonged to, and was inhabited by Charles Brandon, duke of Suffolk; and the other to sir Anthony Wingfield, knight of the Garter, vice-chamberlain and privy-councillor to king Henry VIII. Some apartments of the latter still remain, and are curious examples of the style in which such mansions were ornamented. Several little houses in this town are embellish'd, both exter-

ternally and internally, with carved and stuccoed devices; but these are chiefly of the age of James I. and Charles I.

The commerce and trade of Ipswich, though not upon a large scale, furnish employment to many of the poorer inhabitants, and fortunes to those who possess property to speculate with. Several vessels belong to this town, and many have been built here. Four building yards are attached to the port. The chief trade of the place is malting. Ipswich is supplied with five fairs annually, and five days out of the seven are appropriated for markets. For the accommodation of persons frequenting these, a large, commodious market-place has been erected from designs by Mr. Brown, an architect of this town. A series of buildings, on pillars, is disposed round two quadrangular courts, in which persons who frequent the market may be provided with shelter and accommodation for a small annual, or weekly rent. The plan is judicious, and admirably adapted to its purpose. In this town are five charity-schools for the education and clothing of poor children.

On the quay is a custom-house: it was determined in the reign of Edward III. that the bailiff and burgessees of Ipswich had the sole right to take custom-house duties for goods landed at the port of Harwich: whence it is inferred that the latter was a subordinate, and dependant port to the former. The tide commonly rises from 10 to 12 feet; but at low water the river is shallow and narrow. At Ipswich are the following public buildings: a town-hall, council-chamber, and shire-hall; a workhouse, or hospital, and some almshouses.

Adjoining the town is a feat and park called Christchurch, occupying the site and lands of an ancient priory; and to the south of Ipswich are the following feats: Tattington-hall, Wolverton-hall &c.—to the west are Chauntry, Sproughton, Burial, and Bramford, Hintlesham-hall, Stoke-hall, and Hill-house. Among the eminent natives of this town, the name of Thomas Wolsey is particularly distinguished. He is said to have been the son of a butcher, but this is doubted by the editor of the second edition of "The Suffolk Traveller." It is evident, however, that he rapidly advanced from a low rank in society, to be even the master of his tyrannical and selfish monarch; but at length he fell a sacrifice to his own ambition and to the caprice of his king. He was born here March 1471, and died at Leicester Nov. 29, 1530. Several memoirs and accounts of him have been published, but a "important life" of him "is still a desideratum in English biography." Chalmers, in his interesting "History of the Colleges and Halls, &c. of Oxford," has given a short and discriminating memoir of him, with references to, and observations on the cardinal's different biographers. The following names occur as "worthies" of Ipswich: Ralph Browning, D.D. and bishop of Exeter; William Butler, physician, who, according to Fuller, "is a worthie of England" (vol. ii. p. 340.) was the "Euclypius of the age." Mr. Raw, a respectable bookseller of Ipswich, is printing a history of this town. Suffolk Traveller, 2d edit. 8vo. 1764.

Ipswich, the *Agave* of the Indians, a post-town and port of entry in America, pleasantly situated on both sides of Ipswich river, in Essex county, Massachusetts, 30 miles N.E. by N. of Bolton, and about a mile from the sea. The township of Ipswich is divided into four parishes, and contains 601 houses, and 13305 inhabitants; who are chiefly farmers; a few vessels are employed in the fishery, and some in trade to the West Indies: fish, tallow, and lace, or white light tallow, are manufactured here in large quantities, by women and children, and sold for use and exportation in Bolton and other mercantile towns. Ipswich township was incorporated in 1734. It was formerly a place of considerable

importance; but its decline is attributed to a barred harbour, and shoals in the river. N. lat. 42° 43'. W. long. 70° 50'.

IPSWICH, *New*, a township in Hillsborough county, Hampshire, containing 1266 inhabitants; situated on the W. side of Souhegan river, and separated from Whatstock mountain by the N. line of Massachusetts; 56 miles N.W. of Bolton. It was incorporated in 1762, and has a flourishing academy.

IQUEIQUY, or IQUIQUE, an island in the Pacific ocean, near the coast of Peru, about a mile in circumference, situated in a small gulf, which affords shelter for vessels, but no fresh water. It is inhabited by Indians and slaves belonging to the Spaniards, who are employed in collecting a yellow earth, formed by the dung of birds, as manure for vines, and with which eight or ten ships have been loaded annually for a century. S. lat. 20° 0'.

IQUISENOU, one of the islands of Japan, situated near the S.E. coast of the island of Ximo. This island is very small. N. lat. 32°. E. long. 132° 45'.

IRABAD. See HIRABAD.

IRABATY, a name given to the river Ava, in some part of its course.

IRAC, ARABIAN, a country of Arabia Deserta, situated to the south of the Tigris and Euphrates; the ancient Babylonia or Chaldea. This country, towards the N.E., is watered by branches of the Euphrates, and is fertile, containing a number of cities and towns; towards the S.W. it is a dreary wilderness. One of the principal places in it is Bassora.

IRAC, or *Irac Ajemi*, a province of Persia, chiefly corresponding with the ancient Ecbatana; is bounded on the N. by Ghilan and Mazanderan, on the E. and N.E. by Chorasan, on the S. by Farfahan, and on the W. by Khusfahan or Chusfahan, and the Arabian Irac. This province contains a part of ancient Media and Parthia: it is about 150 leagues in length, and 120 in breadth; and part of it consists of barren mountains, or sandy plains, which are altogether unproductive, but near the rivers there are extensive and fertile plains. The air is healthy, but very dry; the climate is hot; and it hardly ever rains in the summer for six months together. Mount Taurus, which traverses the province, furnishes the animal that yields musk: manna, of an exquisite whiteness, is found in several places; galbanum is collected in the mountains near Ispahan; and in several places they cultivate grapes, some of which are dried, and others afford white wine. In this province are reckoned about 40 towns or cities. Ispahan, the capital of Persia, is the chief.

IRACOUBO, a river of Guiana, which runs into the Atlantic. N. lat. 5° 35'. W. long. 54° 27'.

IRACUNDUS MUSCULUS, in *Anatomy*, a name given by some authors to one of the muscles of the eye, called also the rectus exterior and abducens. It is one of the quatuor recti oculi of Albinus, and is called by him and Douglas, as well as many others, the abductor.

IRAMALLY, in *Geography*, a town of Hindoostan, in the circar of Dindigul; 30 miles W.N.W. of Dindigul.

IRAPILLY, a town of Hindoostan, in the Myfore country; 12 miles S.E. of Sankeridurgum.

IRASBURG, a township of America, in Orleans county, Vermont, situated on Black river; 12 miles S. of the Canada line; containing 15 inhabitants.

IRASCIBLE, in the *Metaphysics*, a term applied to an appetite, or a part of the soul, where anger and the other passions, which animate us against things difficult, or odious, were supposed to reside.

Of the eleven kinds of passions attributed to the soul, philosophers ascribe five to the irascible appetite; *viz.* wrath, hatred, fear, hope, and despair; the other six are charged on the concupiscible appetite; *viz.* pleasure, pain, desire, aversion, love, and hatred.

Plato divided the soul into three parts; the reasonable, irascible, and concupiscible parts. The two last, according to that philosopher, are the corporeal and mortal parts of the soul, which give rise to our passions.

Plato fixes the seat of the irascible appetite in the heart; and of the concupiscible in the liver; as the two sources of blood and spirits, which alone affect the mind.

IRAVATI, or IRAVATI, in *Hindu Mythology*, the name of an elephant on which Indra, the regent of the firmament, and prince of the benevolent genii rides. (See *INDRA*.) It is generally painted with three trunks, or proboscides, and is driven by Indra's charioteer named Mitra. The Hindustani vehicles, which they call vahan, to their different deities, male and female. Thus, the vahan of Indra is Iravat (see *VAHAN*); but not, it would appear, exclusively, for Major Moore, in the *Hindu Pantheon*, p. 261, says, that he has pictures in which other deities, Rama and Krishna in particular, are mounted on this favoured animal. Indra being a personification of the visible heavens, his attributes and decorations partake of immaterial allusions. In his wars he employs many elephants, who are in fact clouds; and their names translated mean *thunder, bearer, black, white, rumbler, growler*, &c. The chief of all these is Iravat, which means *waters*, the aqueous property of clouds being that most apparent; and we may, in this appropriate nomenclature, fancy that we discern some appearance of connection in the mythological machinery of the Hindus, generally at the first view so apparently anomalous and extravagant.

IRBEN, in *Geography*, a town of the duchy of Cornwall, on the coast of the Baltic; 18 miles E.N.E. of Windau.

IRBITSKAIA, a town of Russia, in the government of Perm, on the Irbis; 100 miles N.E. of Ekaterinburg.

IRCUNDA, a town of Hindoostan, in the circar of Ciscaia; 20 miles S.W. of Ciscaie.

IRE HOLMES, two islands among the Orkneys, a little to the W. of the island of Sanda.

IREBY, *HIGH*, or *MAR-IREBY*, a parish and market-town in the dean's ward, in the county of Cumberland, England, situated near the source of the river Ellen, 303 miles E. from London, and contained, according to the population returns of the year 1829, 73 houses, and 358 inhabitants. Here are two annual fairs, and a weekly market on Thursday. The town, though now inconsiderable, is of great antiquity, and was, in the opinion of Camden, the "Ardea of the Romans, where the Barcarii Tigrienses were stationed;" but Horley disputes this evidence, and asserts, that no Roman antiquities were ever found here; and that the affinity of names has less force in this instance, as there is another Ireby in Lancashire, on the borders of Westmoreland and Yorkshire. The gentleman, with Mr. Ward, places the Arbia at Morby, where remains have been dug up, and the site of a station is evident. Beauties of England and Wales, vol. iii.

IREDELL, a county of America, in Salisbury district, North Carolina, surrounded by Surry, Rowan, and Burke. The climate is salubrious, the lands beautifully variegated with hills, and the soil rich. It contains 8761 inhabitants, of whom 1481 are slaves. Iredell court-house has a post-office; 25 miles from Salisbury.

IREGA, a town of Hindoostan, in the circar of Adoni; 50 miles W.N.W. of Adoni.

IREJA, a town of Hindoostan, in the circar of Gohud; 70 miles E. of Narwa. N. lat. 25 37'. E. long. 79 40'.

IRELABOO, a town on the N. coast of the island of Sumatra. N. lat. 5 6'. E. long. 96 15'.

IRELAND, a large and fertile island in the Atlantic ocean, lying on the west of Great Britain, from which it is separated by the Irish sea, or St. George's Channel. It contains the most western land in Europe, if we except Iceland, and it has no country between it and the coast of Labrador in North America. The sea which separates it from Great Britain, varies in breadth from 14 to 49 leagues; but is contracted between Scotland and the county of Down to a channel only six leagues wide, and farther north to a still narrower strait of 14 is than four, between the N.E. point of the coast of Antrim and the Mull of Cantyre.

The general figure of Ireland somewhat resembles a parallelogram, the greatest length of which can be measured along a meridian, is from Bally Farland Point, in the county of Down, to the Stags of Cork Harbour; this does not exceed 185 Irish, or 235 English miles. It is much indented on the east by the Irish sea, and on the west by the Atlantic ocean, so that its breadth is very unequal. Between Emlagh Rath, in May, and the mouth of Strangford lough, which is the greatest, there are 143 Irish (182 English) miles, whilst between the bays of Dublin and Galway there are but 80 Irish miles, and between Donegal and Ballyshannon no more than 67. It will not, therefore, appear surprising, that there is not a spot in Ireland which is fifty miles distant from the sea. If a diagonal line be drawn from Fairhead, the north-eastern point, to Mrenhead, the south-western point, it will measure 241 Irish, or 305 English miles, which is the greatest distance between any two points of the island. The number of Irish plantation acres is above 12 millions, which is nearly equal to 20 millions of English acres.

The situation of Ireland is peculiarly favourable for receiving and bestowing the reciprocal benefits of external commerce. Its communication is open and direct with England, France, Spain, Portugal, the coast of Africa, the East Indies, South America, the West Indies, the United States of America, Newfoundland, Hudson's Bay, Greenland, &c., with by far the greatest part of the richest, the most fertile, the most commercial, and the most mutually dependent countries in the world; with countries abounding in an endless variety of commodities, furnishing every material on which the varied industry of man can be employed, and presenting the usual advantages to the enterprising trader. It seems destined by nature, says Mr. Newnam, to be the great emporium of the commodities of Europe and America; and, indeed, of those of almost every maritime country upon the surface of the globe.

The face of the country affords a pleasing variety. In some parts there are rich and fertile plains, watered by large and beautiful rivers; in others frequent hills produce that interesting succession of objects with which a flat country can never abound. In two or three counties, there are most romantic and picturesque scenes, whilst in others, extensive plain have been converted into mossy morasses. A sufficient quantity of wood, however, is wanting in most parts to render the views as interesting as the general character of the country would lead us to expect. That this was not the case in former times, is evident from various accounts. Giraldus Cambrensis, quoted by Camden, Stauhurst, and other old writers, speak of it as covered with woods, which are also often referred to in acts of parliament, and other public documents.

ements. These were partly cut down to deprive the natives of their fallowes, and partly for the purpose of extending agriculture. In the reigns of James I. and Charles I., during the continuance of peace, a very extensive exportation took place, chiefly of pipe staves and other small timber; and besides what was consumed in domestic fuel, immense quantities were charred for the iron works which were carried on in different parts of the island. As no attention was paid to renewing them, the forests were speedily reduced. Yet Boate, whose work was published about the middle of the seventeenth century, informs us that there were still sundry great woods remaining in all the provinces, some of them many miles long and broad. All these have since been demolished, and there does not exist in Ireland any tract deserving the name of a forest: but the whole country is cleared for the purposes of agriculture, and retains none of the vast woods to be found in the savage state, yet Ireland is not destitute of woods that are both useful and ornamental. A spirit of planting has been prevalent for some years past, which has been powerfully encouraged by the premiums of the Dublin Society, as well as by several acts of parliament for the protection of timber, so that the country begins to assume a less naked appearance, and will, perhaps, become once more entitled to its old name of the Woody island.

Ireland has been ever celebrated for the fertility of its soil. The richest land is that which lies near the principal rivers, but there is not much which can be called bad; and the proportion of that which is waste was not thought by Mr. Arthur Young, so long ago as the year 1778, to be as great as in England. The most uncultivated tracts are the mountainous districts in all the western counties, which seem placed as barriers against the fury of the vast Atlantic. In every part of Ireland there is stone either near the surface or at no great depth, which Mr. Young considered as the greatest singularity of Ireland. "May we not recognize in this," he continues, "the hand of bounteous Providence, which has given, perhaps, the most stony soil in Europe to the moistest climate in it? If as much rain fell upon the clays of England, (a soil very rarely met with in Ireland, and never without much stone,) as falls upon the rocks of her sister island, those lands could not be cultivated. But the rocks here are clothed with verdure; those of limestone, in particular, with only a thin covering of mould, have the softest and most beautiful turf imaginable." Light sandy soil is seldom met with, and chalk has not been found in any part of the island, though there is a white limestone somewhat resembling it.

The mountainous chains in Ireland are neither numerous nor important; but an upland ridge divides the country from the N.E. to the S.W., giving birth to several of the rivers. The Irish hills generally form short lines or detached groups, which are so dispersed through the country, that there is scarcely any part in which the prospect is not terminated by this species of majestic scenery. There are none, however, equal in height to several in Great Britain, the highest probably falling short of 3000 feet; yet there are a few, such as Mangerton and McGillicuddy's Reeks, near the lake of Killarney, and Brandon, near Dingle, in Kerry; Croagh Patrick and Nephin in Mayo; and Sliebh-Donard, one of the Mourne mountains, in the county of Down, which deserve the attention of the naturalist, as they have been found to produce many of those plants peculiar to Alpine regions.

As the whole of the country is found to have stone near the surface, it was natural to expect that it contained valuable minerals; and we accordingly find that such an expectation was early formed, though, hitherto, much pains do not

seem to have been taken to discover them, and render them useful. A plan was indeed recommended by Mr. Kirwan, which, if it had been adopted, would have established a complete mineralogical school in Ireland, and would thus have not only led to the discovery of the minerals, but have also instructed in the mode of procuring them with most advantage. As, latterly, attention has been excited to the subject, much progress may be shortly expected. The limestone quarries, which abound almost every where, are now generally worked, and afford a most valuable manure. A great variety of marbles is found, some of which are uncommonly beautiful, and capable of a very high polish, so as to leave little cause to regret the difficulty of procuring Italian marbles. Gypsum, so valuable a material in the hands of the ornamental artist, is found in great abundance near Belfast, and fuller's-earth has been found in several counties. The mountains of granite in Wicklow and Carlow supply the capital with this useful stone for building; and flats of excellent quality are found in many parts of the island. The beds of coal, to be seen in various regions of Ireland, have not yet been properly explored. That of Kilkenny, found at Castlecoomer, is deservedly celebrated among mineralogists as the purest coal of the kind to which it belongs, which is the *stone* or *unflammable* coal. This is the kind generally found in the southern parts of Ireland; but in the counties of Tyrone and Antrim some mines of slate-coal have been worked. Iron ore is very abundant; and before the forests were consumed, there was a great number of iron works in various parts. Boate divides the iron mines of Ireland into three descriptions: 1. What he styles the bog-mine, or, what is now termed lowland ore, found in moors and bogs; the ore resembling yellow clay, but mouldering into a blackish sand. 2. The rock mine; a bad sort; the ore intimately combined with stone. 3. That found in various mountains; the ore spheric and of a whitish grey colour; balls of the best ore contained kernels full of small holes, whence the name honey-comb ore. Boate praises this iron as frequently rivaling that of Spain; and Mr. Kirwan affirmed, before the house of commons, that the Arigna iron was better than any iron made from any single species of ore in England. A defective supply of coal renders, however, the abundance of this ore of no avail. There are also valuable mines of lead, copper, and cobalt, some of which have been wrought to advantage; and gold has been found in the county of Wicklow, though not of such consequence as to promise much national advantage.

The bogs of Ireland form a very remarkable feature of the country. These are of different kinds, and in some places are very extensive. As trees, and even utensils of different kinds have been found in these bogs, they are supposed not to be of very great antiquity; and the most probable account seems to be, that when forests had been cut down, the trees were suffered to lie on the spot, and the cultivation of the ground neglected. These trees intercepted and confined streams of water with the various rubbish they brought with them; and became gradually covered with a vegetation of moss, sedge grass, rushes, and various aquatic plants. Notwithstanding attention was directed to the recovery of these extensive wastes more than a century ago, very little has yet been effected, which is rather to be attributed to want of proper exertion, than to such recovery being impracticable. In the year 1809, however, on the recommendation of the Right Hon. John Foster, at that time chancellor of the exchequer, who will be long remembered as a zealous promoter of the interests of Ireland, when party animosity will be forgotten, com-

missioners were appointed "to enquire into the nature and extent of the bogs of Ireland; and the practicability of draining and cultivating them." As the vast extent of these bogs has not enabled the commissioners to complete the task committed to them, it can only be observed, that the first of a number of districts contains 36,430 English acres of bog, and that the expense of the operations which a very able engineer deemed necessary for completely draining it, was 70,014*l.* 7*s.* 3*d.* The bogs in the King's county alone, exceeding 500 acres each, contain at least 124,000 acres. The drainage of these bogs is, therefore, a matter of vast importance, not only to Ireland, but to the empire at large, as these lands, now of little or no value, would, when drained and properly cultivated, yield a vast supply of food, for which England has had to pay large sums in gold to her most bitter enemy. It has also been made evident, that this drainage would increase the quantity of turf fuel, so as to render it both more easily procurable and cheaper. At present only the final bogs, which it is not intended to drain, and the edges of the large ones, are accessible to the turf-digger, but the drainage would enable an approach to the interior parts of them; and such is the quantity, that after every exertion to reclaim, there will remain more for turf than an increased consumption can possibly exhaust in the course of ages. This is an observation of much importance, because the want of this excellent fuel would be very severely felt in a country where few coal mines are worked, and where the supply of coal is consequently uncertain and expensive. The instructions of the commissioners do not authorise them to examine the numerous boggy tracts on the sides of mountains, which not being in general deep, afford at times good pasturage. The best mode of reclaiming these would be to introduce the culture of Fiorin, as recommended by the Rev. Dr. Richardson, and thus render them good meadows.

Perhaps no country of the same extent is more bountifully watered by fine rivers and lakes, or more indented by noble harbours, than Ireland is, so as to possess, in an eminent degree, those great requisites for agriculture, manufactures, and the most extensive commerce. The rivers, besides abounding with an infinite variety of fish, communicate uncommon fertility to the lands which they beautify, and afford a multitude of the best situations for the machinery of manufactures, so that wind-mills are very rarely met with in this country. But though many of these rivers are very considerable in point of size, and run a pretty long course, and some of them are capable of bearing large boats many miles above their fall into the sea; yet there are none which can be called navigable in the same sense as the Thames or the Severn. This is partly occasioned by rocks running across their beds, and thus forming cataracts; partly by the practice of breaking down the banks to make fords for the convenience of travellers, when bridges were less frequent than they are at present; and partly by weirs made either to serve mills, or for the sake of catching salmon. Much, however, may be done by labour, attention, and expense, to remove these impediments, and extend internal navigation; and so sensible was the Irish legislature of this, that a sum of money has been appropriated, under the direction of commissioners, for this purpose. The Shannon is the principal river of Ireland, which, rising in the northern part of Connaught, almost inflates that province and the county of Clare, and after a course of 150 miles, in which it expands into six different lakes, it flows into the Atlantic ocean, between the counties of Clare and Kerry, being navigable for large vessels as far as Limerick. The Suir, the

Barrow, and the Nore, which ~~Spenser~~ has described as three brothers, proceeding in different directions from Scabloom, a ridge of mountains between the King's and Queen's counties, and in the north of Tipperary, pour their united streams into the bay of Waterford.

The number of lakes or loughs in Ireland is very great, and some of them are large, and even magnificent. Many of those sheets of water, however, which are called by this name, are in reality arms of the sea, as Lough Swilly, Lough Foyle, and others. Of those which are, strictly speaking, lakes, Lough Neagh, Lough Erne, and Lough Corrib, are the most considerable in point of extent; and Lough Lane, or the Lake of Killarney, is the most distinguished for its beauties. There are also many mineral springs in different parts, the most remarkable of which will be noticed under their respective counties.

The harbours of Ireland are very numerous. These have been divided into the principal havens, and the lesser or barred havens; but the distinction seems of little use, as they will deserve notice, rather on account of their being frequented, than on account of natural advantages. Those indeed which are most capacious, on the S. and S.W. have hitherto been little frequented, except by the smuggler, or by vessels unable to reach their destined port. Waterford and Cork harbours on the S.; Bantry and Dingle bays on the S.W.; the estuary of the Shannon, and the vast bay of Galway on the W.; that great opening on the N.W. of which the bay of Sligo is a part; Lough Swilly and Lough Foyle on the N., are the most considerable. On the eastern side, there are none possessed of great natural advantages, yet from the greater improvement of the adjoining country and the vicinity of England, there are many which are much frequented, especially the harbours of Belfast and Newry, and the barred havens of Dublin, Drogheda, and Wexford. The principal commercial towns are Dublin, Cork, Belfast, Limerick, and Waterford.

With respect to the climate of Ireland, strangers soon perceive that it is in general less hot in summer, and less cold in winter than in England, and other countries in the same latitude; and that very hot or very cold weather, when it does take place, continues for a much shorter time. If, however, the climate be more temperate, it is also much damper, both on account of a greater fall of rain, and of a moisture in the atmosphere when there is no rain, which produces a very striking effect on the walls of houses, on furniture, and various other articles. This prevalence of moisture seems to be occasioned by the winds blowing from the vast Atlantic ocean, and is more perceivable in the western and southern parts. Though the frequent showers answer very well for pasturage, and clothe the limestone rocks with verdure, yet they often interfere with the gathering in of the harvest, and render expedition on the part of the farmer, in using fine weather whilst in his power, more necessary. This short continuance of heat is not sufficient to ripen peaches, grapes, and other fruits, without great care and attention; but the broad-leaved myrtle (*Myrtus communis*) grows luxuriantly, with very little care, in the southern counties, being seldom injured by the cold of winter; and the arbutus (*Arbutus unedo*) is not found as a native in any other country so far distant from the equator. Perrous advanced in life complain of an unfavourable change in the climate, saying that it is much severer and more uncertain than it used to be; and an ingenious writer, Dr. W. Hamilton, (in the 6th vol. of *Transactions of the Royal Irish Academy*), has stated some facts which appear to add credibility to such complaints. The pine-tree, especially that species called the Scotch fir, formerly grew on many

IRELAND.

of the mountains of this island, and in parts of the northern and western coasts exceedingly bare and open to storms. Vast roots and noble trunks of this species of pine have been seen, and examined with attention, in situations where human industry cannot now rear a twig of the hardiest tree. The devastation occasioned by sands in some parts of the northern coast, and even in the south, and the greater influxes of the tide, seem to prove the more frequent recurrence and greater violence of the Atlantic storms. The destruction of the forests may perhaps account satisfactorily for some of these facts, whilst others may have been occasioned by circumstances not yet sufficiently attended to. Dr. Paterson, in his "Observations on the Climate of Ireland," has adduced many facts to controvert the opinion of a change; and the observations made a century and a half ago, are so applicable to the country at present, that it may be inferred the present seasons do not materially differ from former ones, and that the influence of the Atlantic has always been much the same. The winds most prevalent in Ireland are the west and south-west, which, contrary to the poetical description of zephyrs, are frequently attended with rain and storms. Easterly winds are less common, and are generally dry and keen; these are found prejudicial to health, and invalids avoid being exposed to them. On the whole, if the climate of Ireland be not the most agreeable, it is found very wholesome; instances of longevity are frequent, and if peculiar circumstances occasion much sickness in many of the large towns, the peasantry are very healthy, and, in consequence of it, robust and hardy. The bogs, which some have supposed to be unwholesome, are of a very different nature from the morasses in other countries, which appears both from the timber preserved in them, and from the effect produced on the skins of animals unfortunately lost in them.

The productions of Ireland, and the animals found in it, do not differ much from those in England. The most valuable ones in both seem to have been imported from other countries, and the variety of these must be greater in England, on account of its superior cultivation. The domestic animals are the same, and from the care taken of late years to improve the breeds, it may be expected that our sheep and oxen will not be surpassed. Bede, who has commemorated the praise of Ireland for abundance of honey and milk, also mentions numerous herds of deer, which animal the progress of cultivation has now rendered rare. In various parts of Ireland are dug up enormous horns of deer, which some writers have imagined to be of the species called moose deer in America; but Mr. Pennant has demonstrated that the animal must have almost doubled in size the American moose, which is sometimes found seventeen hands in height. The Irish horns have been found of the extent of fourteen feet from tip to tip, furnished with brow antlers, and weighing 300 pounds; the whole skeleton is frequently found with them. It is supposed that the animal must have been about twelve feet high. Wolves infested the country formerly, but are said to have been extirpated by Oliver Cromwell. It has been asserted that no poisonous animal will live in Ireland, and even that no spiders will haunt Irish timber, which, as is said, was the cause why it was often employed in magnificent ceilings in the middle ages. "Whether it be owing to the soil or the climate," says Dr. Beaufort, "certain it is that in Ireland there are neither moles nor toads, nor any kind of serpents; and it is not a hundred years since frogs, of which there are now abundance, were first imported from England. But though the fane experiment has been made with snakes and vipers, it has happily been unsuccessful." The rivers, lakes, and seas

are stocked with a great variety of fish, which yield a plentiful article of food to all ranks of people. The fisheries on the coast give employment to great numbers, and have become, in some instances, an object of national attention and legislative encouragement, though they have never yet been carried on as extensively as they might be, or there could have been no occasion for an importation of fish from foreign countries. Jephson Oddy, esq. in his prospectus of a western fishery company, mentions that the Nymph bank, and others near the coast of Ireland, abound with the finest cod, ling, hake, turbot, pollock, &c., and that the adjoining seas are frequented at different periods by mackerel and herrings in great quantities; and he forcibly urges that if this fishery was carried on with spirit, it would supply both England and Ireland with abundance of fish, so as to render importation unnecessary, whilst it would at the same time give employment to numbers, and prove a valuable nursery for seamen.

The native grasses are those esteemed most valuable by the farmer, so that Ireland has ever been celebrated for the excellence of its pastures; the number of cultivated vegetables is daily increasing; and in consequence of the attention lately paid to botanical knowledge, it appears that native plants have not been bestowed with a sparing hand. The introduction of the potatoe, the value of which is universally acknowledged, and which forms the principal part of the food of the Irish peasantry, has been commonly attributed to Sir Walter Raleigh.

To this general and brief account of the natural state of Ireland, it may be proper to subjoin a list of the counties into which Ireland is divided. The population of each, as stated by Dr. Beaufort, is added; at the same time it must be observed, that this most probably falls far short of the real population, as in so many years as have elapsed since its publication, there must have been a considerable increase. It may serve, however, to give some idea of the comparative population of different counties, until more satisfactory documents than at present exist enable us to give a more correct statement. The number of counties is 32, which are contained in four provinces. A particular account of each will be found under their respective names.

Mr. Pinkerton is of opinion that Ireland was early discovered by the Phœnicians. "On the first dawn of history," says he, "and when the north-west of Europe was as obscure to the Greeks, as the islands on the north-east of Siberia were recently to us, it would seem that Ireland constituted one of the Cassiterides. The poems ascribed to Orpheus deserve no credit, but it appears that the island was known to the Greeks by the name of *Juveona*, about two centuries before the birth of Christ. When Cæsar made his expedition into Britain, he describes *Hibernia* as being about half the size of the island which he had explored; and while the Romans maintained their conquests in the latter region, Ireland continued, of course, to be well known to them, and Ptolemy has given a map of the island, which is superior, in accuracy, to that which represents Scotland. Towards the decline of the western empire, as the country had become more and more known, and had been peopled with various tribes, the Romans discovered that the ruling people in Ireland were the *Scoti*; and thenceforth the country began to be called *Scotia*, an appellation retained by the monastic writers till the seventh century, when the name *Scotia* having passed to modern Scotland, the ancient name of *Hibernia* began to re-assume its honours. It is supposed that this name, and the Gothic denomination *Ireland*, are mere modifications of the native term *Erin*, implying the country of the well."

"It is probable," says the same writer, whose attention to the subject of antiquities gives great weight to his opinion, "that the original population of Ireland passed from Gaul, and was afterwards increased by their brethren the *Guydl* from England. About the time that the Belgæ seized on the south of England, it appears that kindred Gothic tribes passed to the south of Ireland. These are the *Firbolg* of the Irish tradition; and appear to have been the same people whom the Romans denominated *Scoti*, after they had emerged to their notice, not only extending their conquests to the north and east of Ireland, but had begun to make maritime excursions against the Roman province in Britain. But Ireland had been formerly crowded with Celtic tribes, expelled from the continent of Britain by the progress of the German Goths, that the Belgæ almost lost their native speech and distinct character; and from intermarriage, &c. became little distinguishable from the original population, except by superior ferocity, for which the *Scoti*, or those who affected a descent from the Gothic colonies, were remarkable; while the original Gael seem to have been an innocuous people." Such is Mr. Pinkerton's account of the early state of Ireland, but as very different ones have been given respecting this, and as it still continues to be a subject of controversy, it will be proper to give a brief abstract of the principal opinions, and the authority on which

they rest. The celebrated Edmund Spenser, in his "View of the State of Ireland," supposes it to have been first peopled by the *Seythians*, from whom the name *Scotia* was derived. These settled in Ulster, and a colony from them went to Scotland. Another nation came out of Spain to the west part of Ireland, and finding it waste, or weakly inhabited, possessed it. These he supposed to have been Gauls, who had learned letters in Spain, where they were introduced by the Phœnicians, and brought them to Ireland, where it is certain they were known at a very early period. From the *Seythians*, Spenser supposes the Irish to have derived, 1st, the custom of keeping their cattle, and living themselves, for the most part of the year, in *hollies* or herds, pasturing upon the mountains and waste wild places; and removing still to fresh land, as they had depastured the former. This custom, which seems to have continued to Spenser's time, was very injurious. The hollies were receptacles for outlaws and loose people, who there evaded justice; and those who lived in them grew more barbarous, and lived more licentiously than they could in towns, using what manners they liked, and practising what mischief and villanies they would either against the government, or private individuals. Another *Seythian* custom was the wearing of mantles, and long glibbes, which is a thick curled bush of hair, hanging down over their eyes, and monstrously disguising them. These mantles Spenser describes as convenient for outlaws, rebels, and thieves. As the passage is curious, and the work less known than it ought to be, the insertion of it may afford some entertainment to the reader. "First the outlaw being for his many crimes and villanies banished from the townes and houses of honest men, and wandering in waste places, far from danger of law, maketh his mantle his house, and under it covereth himselfe from the wrath of heaven, from the offence of the earth, and from the sight of men. When it raineth, it is his pent-house; when it bloweth, it is his tent; when it freezeth, it is his tabernacle. In sommer he can wear it loose; in winter he can wrap it close; at all times he can use it; never heavy, never cumbersome. Likewise for a rebell it is as serviceable. For in his warre that he maketh (if at least it deserve the name of warre) when he hath fled from his foe, and lurketh in the thick woods, and thicke passages, waiting for advantage, it is his bed, yet not his bed; and his headfold full. For the wood is his house; and all weather, and his mantle is his couch to sleep in. Then in his wrappeth himselfe round, and coucheth himselfe snugly against the goat, which in that country doth more annoy the naked rebell, which they keepe the woods, and doe more sharply wound them than all their common swords, or spears, which can scarce come nigh them; yea, and at such times the rebell serveth them, when they are thus driven, being wrapped about their left arme, instead of a target, for it is hard to cut thorough with a sword, besides it is light to beare, light to throw away, and being as they cannot see nor feel, it is to them all in all. Lastly, for a thief it is to lay downe, as it may seeme it was first invented for him; for under it he may easily convey any of his pilage that cometh handfull in his way; and when he goeth abroad in the night in freebooting, it is his bed, and sure friend; for being as they often doe, two or three nights together abroad to watch for their booty, with that they can prettily shroud their selves under a bush, or a bank side, till they may conveniently doe their errand; and when all is over, he can, in his mantle, passe through any town or company, being close hooded over his head, as he useth, from knowledge of any to whom he is endangered. Besides this, he, or any man else that is disposed to mischief or villany, may under his mantle goe privily armed without

suspicion of any, carry his head-piece, his spear or pistol if he please, to be always in readiness." In like manner he considers the long hair or glibbe as serving the purpose of concealment. The Irish cry, or *hubub* as he calls it, which the kerne or soldiery use at their first encounter, he also considers of Scythian origin; and also the calling upon the name of some chieftain, as *Ferragb* for instance, which he supposes to be the name of a chief under whom they fought successfully against the Africans. To this he adds their lamentations at their burials, "with dismal out-cries and immoderate wailings," which favour greatly of the Scythian barbarism. Our ingenious author next proceeds to shew that the Irish arms and weapons are Scythian, and the same also as those used by the old Scots, who were of the same stock; that the Irish resembled the Scythians in their confused kind of march without order or array; and also in certain religious ceremonies. From all these circumstances he infers that the Irish are anciently derived from the Scythians. He afterwards adduces customs derived from the Spaniards and Gauls in proof of colonies of them having been established in Ireland, but they are fewer in number and less remarkable. The use of saffron shirts, the giving the charge of all household affairs at home and abroad to their women, the manner in which these sat on horse-back, with a few others, are slated as of Spanish origin; whilst the use of long darts and wicker shields is mentioned as derived from the Gauls. Such is Spenser's opinion respecting the origin of the Irish, founded, as may be seen, on conjectures, for the inferences drawn from customs can scarcely deserve any other name. The colony from Spain, which he admits, though he speaks doubtfully of the origin of the people, and gives no particulars, is laid great stress on by the advocates for the ancient glory of Ireland. "Not to speak of the original settlement by Partholan," says Dr. Leland, "it is maintained that about 500 years before the Christian era, a colony of Scythians, immediately from Spain, settled in Ireland, and introduced the Phœnician language and letters into this country; and that however it might have been peopled still earlier, yet Huber, Heremon, and Ith, the sons of Milesius, gave a race of kings to the Irish, distinguished from their days by the names of Gadelians and Scots or Scots. Hence their writers trace a gradual refinement of their country from a state of barbarous feuds, factions, and competitions; until the monarch, celebrated in their annals by the name of O'lam-Fodla, established a regular form of government, erected a grand seminary of learning, and instituted the *Fes*, or triennial convention of provincial kings, priests, and poets, at Teamor or Tarch, in Meath, for the establishment of laws and regulation of government. Keating, the Irish historian, who transcribed his accounts from poetical records, mentions little more of this boasted assembly, than that its great object was to introduce civility, and to guard against those crimes which predominate in days of rudeness and violence. The magnificent detail of its grandeur and solemnity, the scrupulous attention paid by its members to the national history, laws, and genealogies, are nothing more (as I am assured) than the interpolations of an ignorant and presumptuous translator. But whatever were the institutions of this monarch, it is acknowledged that they soon proved too weak for the wildness and disorder of the time. To Kimbath, one of his successors, the annals give the honour of reviving them; besides that of regulating Ullar, his family province, and adorning it by the stately palace of Eamania, erected near Armagh." One of his successors, to secure his power, divided the island into twenty-five dynasties, instead of six; but the pentarchal government was restored about a century

before the Christian era. Anarchy, sedition, and murder continued prevalent, notwithstanding the wife laws occasionally enacted; and an Irish chieftain is said to have addressed himself to Agricola, and to have encouraged him to make a descent on Ireland. Those, however, who warmly contend for the honour of Ireland, say that such a descent would not have been effectual; and record with triumph that the Irish monarch of this time, instead of dreading an invasion of the Romans, failed to the assistance of the Picts, led an irruption into the Roman province, and returned in triumph laden with foreign spoils. After this, the old Firbois or Belgic inhabitants grew so powerful and turbulent as to establish a monarch of their own race, and to harass the country by what was called the Attacotic war. Tuathal, a Milesian prince, restored the power of his family; and in the time of his grandson, in the third century, Finn, the son of Conhal, better known by the name of Fingal, is said to have lived, and to have been general of his troops. The succession of kings of the Milesian family, to the year 1198, is said to have been 171.

General Vallancey, who has paid very great attention to the antiquities of Ireland, and whose great learning and personal respectability, as well as his exertions for the good of society, should secure him from petulant and wanton abuse, has, in his "Vindication of the ancient History of Ireland," maintained the truth of the leading facts mentioned by Keating and others. The Scythians, by whom the country was peopled, were, according to him, not the Northerners, but Southern Scythians, the same people as the Phœnicians, who are to be distinguished from the Canaanites, and were the navigators of the latter, acknowledged as subjects, but never admitted to a share in the government, or to the rank of noblesse. They had the use of letters, a knowledge of astronomy, of marine astronomy in particular, and of navigation; but had no knowledge of the fine arts, their religion forbidding it. These Phœnicians are supposed to have been originally Persians or Indians, proceeding from that eastern district, the supposed source of all civilization; and the late writers on Indian antiquities produce many circumstances tending to establish a knowledge of Ireland in that oriental people, and an intercourse with it at a very early period. It would occupy more room than the nature of a Cyclopaedia would allow, to enter upon the arguments adduced by the learned general in support of his opinions. Suffice it to say, that they chiefly rest on the etymology of names, on a resemblance in certain words, and on a resemblance also in certain religious ceremonies and old customs, which are thought to have originated in fire-worship, which is supposed to have been once prevalent throughout Ireland. The Rev. Dr. Ledwich, author of an elaborate work on the "Antiquities of Ireland," endeavours, with all the eagerness of a partizan, to expose and ridicule all pretensions to early civilization. He contends that Ireland was first peopled from Great Britain by the Celts, who were wandering savages, of whom little is recorded, and that little proclaims their ignorance and barbarism. The Belgæ and other northern tribes afterwards settled in it; and it had at no time arrived to a greater degree of improvement than when visited by the English under Henry II. To be qualified to form an opinion on the preceding subject would require a long course of study, the acquisition of languages, a little more except to the antiquary, and the perusal of many volumes in the highest degree dry and uninteresting; and, after all, such is the want of written documents of an early date, that the most we could arrive at would be probable conjecture. At the same time, it does not appear improbable, much less absurd to suppose, that the Phœni-

tians might have civilized Ireland at an early period, and introduced their laws, customs, and knowledge; and that a comparatively high state of civilization; and that these might have been gradually lost amidst the disturbances of the country, and at last completely destroyed by the irruptions of the Oilmén, so as to have reduced Ireland to a barbarous state, previous to the English invasion.

The conversion of Ireland to Christianity is generally attributed to Patrick, who has been called the "tutelary saint of Ireland." He is said to have landed in Ireland A.D. 430. The people were, however, prepared for his preaching by the labours of some former missionaries. Notwithstanding the introduction of Christianity, the petty princes and people retained their ferocity of manners; and the avails abound in horrid instances of revenge, and hideous effects of avarice and ambition. "Yet Christianity, as then taught," says Dr. Leland, "although it could not eradicate, at least restrained the national vices. A numerous body of ecclesiastics, secular and regular, quickly swarmed over the whole country; frequently became umpires between contending chieftains; and when they could not confine them within the bounds of reason and religion, at least terrified them by denouncing vengeance against their excesses. An ignorant people listened to their tales of pretended miracles with a religious horror. In the midst of every provincial contest, and every domestic strife, they were sacred and inviolate. They soon learned to derive their own splendour from the public veneration. The infant church was every where amply endowed, and the prayers of holy men repaid by large donations. Some of the oldest remains of Irish literature, as they have been explained to me, inform us, that the people were taught to dedicate the first-born of all cattle to the church, as a matter of indispensable obligation. But if the clergy thus acquired riches, they applied them to the noblest purposes. The monks, says Mr. O'Connor, fixed their habitations in deserts, which they cultivated with their own hands, and rendered the most delightful spots in the kingdom. These deserts became cities; and it is remarkable enough, that to the monks we owe so useful an institution in Ireland, as bringing great numbers together into one civil community. In these cities the monks set up schools, in which they educated the youth, not only of the island, but of the neighbouring nations. The testimony of Bede is unquestionable, that about the middle of the seventh century, in the days of the venerable prelates Finian and Colman, many nobles and other orders of the Anglo-Saxons retired from their own country into Ireland, either for instruction, or for an opportunity of living in monasteries of stricter discipline; and that the Scots (as he styles the Irish) maintained them, taught them, and furnished them with books, without fee or reward—a most honourable testimony, says the elegant Lord Lyttelton, not only to the learning, but likewise to the hospitality and bounty of that nation! A conflux of foreigners to a retired island, at a time when Europe was in ignorance and confusion, gave peculiar lustre to this seat of learning: nor is it improbable or surprising that seven thousand students studied at Armagh, agreeably to the accounts of Irish writers; though the seminary of Armagh was but one of those numerous colleges erected in Ireland. But the labours of the Irish clergy were not confined to their own country. Their missionaries were sent to the continent. They converted heathens; they confirmed believers; they erected convents; they established schools of learning; they taught the use of letters to the Saxons and Normans; they converted the Picts, by the preaching of Columba-kil, one of their renowned ecclesiastics. Burgundy, Germany, and other countries received

their instructions: and Europe with gratitude confessed the superior knowledge, the piety, the zeal, the purity of the "Island of Saints." Such are the events on which Irish writers dwell with an enthusiastic delight. The first Christian missionaries seem to have industriously avoided all unnecessary violence to the ancient manners of the Irish. Their poets they favoured and protected; the remains of the Druidical order were not persecuted; and although divine vengeance was thundered against the worshippers of the sun, stars, and winds, it is evident that some Pagan superstitions were overlooked with too great indulgence, for they subsist at this day in Ireland: fires are lighted up at particular times, and the more ignorant Irish still drive their cattle through those fires, as an effectual means of preserving them from future accidents." Such is the abstract given by Leland, in his preliminary discourse of the introduction and establishment of Christianity. Dr. Ledwich, however, not only gives a different account of these, but even calls in question the existence of St. Patrick, regarding him as an ideal personage. He supposes, and with great appearance of reason, that Christianity, which had been brought to Gaul by Pothinus and Irenæus, disciples of Polycarp, who had been himself instructed by John the Evangelist, from Gaul reached Britain, and from Britain was carried to Ireland, in the third or fourth century, as early as the supposed time of St. Patrick, or even earlier. It seems a strong circumstance in favour of this opinion, that the Irish Christians, or the Saxons converted by them, did not acknowledge the Roman pontiff till long after the rest of the Christian world; which would not have been the case, had their instruction proceeded from one sent immediately from Rome to convert them, as Patrick is said to have been. If such a person as Patrick really preached Christianity in Ireland, it seems at least to be certain that not only the miracles assigned to him are monkish inventions, but that his episcopal dignity, and many other circumstances recorded, are without foundation. Columba appears to have been the founder of the Irish monasteries; and, like the Scotch, the Culdee sect was prevalent amongst them, and was not completely overthrown until pope Adrian, in the plenitude of his presumption, bestowed Ireland on Henry II. in 1155. See CULDEES.

Ireland was divided into five separate kingdoms, and in each of these were powerful and factious dynasties. All indeed acknowledged one monarch, but his power was remarkably weakened; and if the people were not wretched, it was because the evils of their political constitution were in some measure corrected by the reverence paid to religion and learning. As the armies collected by such governments are temporary, they are ill calculated for resisting a foreign invasion; and such was found to be the case in Ireland. Bede mentions, that, in 684, the general of Egfrid, king of Northumberland, made a descent on Ireland. But instead of mentioning any gallant resistance made by the natives, he informs that they trusted more to prayers than arms; and in the plaintive style of compassion laments the miserable havoc of a people, inoffensive, and ever most friendly to the English. But Ireland experienced a still more formidable invasion, when the Danes, Norwegians, and other Scandinavian adventurers began to rove in search of new settlements. These were called Normans, Euterlings, or Oilmén, and also Galls or foreigners. Their piratical expeditions commenced about the end of the eighth century, and whilst they infested England and France, Ireland did not escape. Their first invasions were made in small parties for the sake of plunder, and were frequently repulsed. By degrees the invaders, either by force or treaty,

obtained some small settlements; and at length Turgefinus, a warlike Norwegian, in 815, lauded with a powerful armament, and committed every kind of outrage. Having reduced the inhabitants to slavery, after a residence of 30 years, he was proclaimed monarch of the kingdom; but at length Melachlin, prince of Meath, contrived to seize upon the tyrant in a time of apparent peace, and the Danes, surprised by a sudden insurrection, were massacred or dispersed. A new colony, however, arrived, and were allowed to settle in some maritime towns. These gradually strengthened themselves, and maintained their independence, though frequently engaged in wars with the Irish princes, and repeatedly overcome in battle. The most celebrated of these engagements was at Clontarf, near Dublin, in 1012, when the Irish were successful, but lost their monarch, Brian Boiromhe, at the age of 88, and his son Moreland. After this event Ireland continued to be distracted by civil wars, and the situation of the people was as wretched as can almost be conceived; so that the island was rendered an easy prey to any daring invader.

It has been already noticed that the clergy of Ireland were of the Culdee sect, by which the Roman pontiff was not acknowledged. This is indeed matter of controversy; but it seems indubitable that they were very irregular, and that it was an object with the pope to bring them to obedience. The pontificate, however, by the interested zeal of its numerous and active emissaries, at length contrived to extend its influence even to this remote island, alarmed the Irish clergy with fears of the irregularity of their ecclesiastical constitution, and persuaded them to submit to a reform, modelled and dictated by Rome. Cardinal Papire, or Papefon, came to Ireland as legate in 1148; and in 1151, or 1152, summoned a council, which was attended by about 3000 ecclesiastics, and four bulls were solemnly received from the pope by the prelates of Armagh, Dublin, Cashel, and Tuam. At the same time, it is said that the celebration of Easter was adjusted according to the Roman decisions, the liberty of the clergy was enforced, and the pre-eminence of Rome generally acknowledged. Whether Adrian, at that time pope, did not think this submission of the Irish clergy sufficiently established, or, as an Englishman, was willing to gratify the English monarch, though at the expense of his newly acquired dependant, he issued a bull in 1155 conformable to the wishes and purposes of Henry, who, at the very commencement of his reign, meditated the subjugation of Ireland, and sent his chaplain to solicit the pope's assistance. For such an invasion so just pretence could be offered. Ireland was entirely independent; and, though almost none had been afforded in a former reign to the sons of David, yet there had been for many years nothing which could be regarded as hostile. It was asserted, indeed, that a few men had been sold as slaves in Ireland; but this was a crime in which both nations were equally involved, and which, therefore, could not be urged to justify such an attempt. The depavity and barbarism of the Irish were, however, still more; the honour of God was to be promoted by their subjugation; and the pope was to receive the tribute of St. Peter's penes as the reward of his compliance. A bull was accordingly issued, which, as Leland observes, afforded a striking instance of the profligacy and impiety of papal authority. Much has been said of the depraved state of the Irish at this period; but the accounts proceed from a very suspicious source, those whose object it was to defend the proceedings of the English monarch; and it may be questioned whether they were really worse than their neighbours, or to bad as those who have thus dignified them. But whatever their moral defects might be, their

political ones were very great; they were truly a divided people. A monarch, little more than titular, depending on his own abilities and vigour for power and influence, was harassed by faction, and opposed by powerful rivals; whilst a number of provincial chieftains, who assumed the title and the rights of royalty, paid a precarious tribute to their superior, and united, if they were disposed to unite with him, as allies rather than subjects. Thus was in a great degree the state of France and some other countries; but in Ireland the monarchical dignity was not hereditary; and was the subject of frequent dispute. Favourable as such a state was to the wishes of Henry, yet it was long before he could avail himself of the bull he had received. In France and England he found full employment for many years; and scarcely had he secured his dominions before he was involved in that contest with Becket, which kept him in a continual state of agitation. The circumstance which led to the accomplishment of his design, was the expulsion of Dermot, king of Leinster, from his dominions, and that prince's taking refuge in England. Dermot, a man of a turbulent and oppressive spirit, had, by his conduct, provoked the vengeance of Roderic O'Connor, the monarch of Ireland, whilst his own immediate dependants deserted him in the hour of his distress. He applied to Henry for assistance to recover his dominions; but, whether from the perplexity of his own affairs, or, as Sir John Davies supposes, a wish to avoid the expense, this monarch did not undertake the cause, but gave licence, by his letters patent, that such of his subjects might pass over into Ireland as would at their own charge become adventurers in that enterprise. Notwithstanding this permission, he did not for some months succeed in obtaining succour; but at length he prevailed on Richard, earl of Pembroke, generally called Strongbow, to espouse his cause, promising him his daughter Eva in marriage, and with her the inheritance of his kingdom. And on his return to Ireland, to prepare for Strongbow's arrival, he engaged two Welsh leaders, Fitzlilphen and Fitzgerald, with their followers, on the condition of ceding to them the town of Wexford, with a large adjoining territory, as soon, as by their assistance, he could be re-instated in his rights. The invasion of Ireland was therefore the act of private adventurers. Fitzlilphen and Fitzgerald first broke the ice with a party of 350 men in 1170. The earl Strongbow followed them with 1200 men; and their good success on the sea coasts of Leinster and Munster drew over the king in person, who landed at Waterford in 1172, with 500 knights and about 4000 soldiers. Strongbow immediately surrendered to him the city of Waterford, and did homage to him for the principality of Leinster, which he claimed in right of his wife, the daughter of Dermot, whose death had taken place in the preceding year. The neighbouring Irish princes in like manner submitted, and acknowledged his authority; and even Roderic, after some delay, thought it more prudent to follow their example. Henry assumed the title of lord of Ireland, but his authority was very weak; and, within five months after his arrival, he departed out of Ireland without striking one blow, or building one castle, or planting one garrison among the Irish. Such was the conquest of Ireland by Henry II; which, as it was unjustifiable, so was it inefficient. As Sir John Davies observes, "though king Henry II. had the title of sovereign and lord over the Irish, yet did he not put those things in execution which are the true marks of sovereignty. For, to give laws unto a people; to intrude magistrates and officers over them; to punish and pardon malefactors; to have the sole authority of making war and peace, and the like, are true marks of sovereignty, which king Henry II. had not in the Irish countries; but the Irish lords did still retain all these

IRELAND.

these prerogatives to themselves: for they governed their people by the Brehon law; they made their own magistrates and officers; they pardoned and punished all malefactors within their several countries; they made war and peace one with another without controul; and this they did, not only during the reign of Henry II. but afterwards, in all times, even until the reign of queen Elizabeth." In fact, the Irish only acknowledged the superiority of Henry in the same way as the Welsh princes often did before their subjection; and in the same way as Henry himself did homage to the king of France, as his liege lord for the vast territories he held in France. Henry himself, in the treaty of agreement made in 1175, acknowledged Roderic as king of Connaught, and in his commission to William Fitz-Adelme gave the Irish lords the title and style of kings. It is unnecessary to enter into a detail of the petty wars between the English settlers and Irish chieftains, or of the jealousy entertained of the former by their sovereigns, who, though prevented by family distresses from going over, sent agents to watch and check them. Had Ireland been at this time subdued by a competent force, and the English laws introduced into every part of it, it would have contributed to the quiet and happiness of all classes; but as it was, the English settlers added to the confusion. Their only object appears to have been to acquire territories for themselves; and few crossed to Ireland except rude and barbarous warriors, little, if at all, superior to those amongst whom they went. In 1185, Henry sent John, his youngest son, whom he had previously made lord of Ireland, to that country. This young prince, being but 12 years of age, with a train of young noblemen and gentlemen to the number of 300, but not with any considerable army, arrived at Waterford, and was attended there by the Irish chieftains, who, disunited among themselves, and terrified by the representations of his force, flocked to Waterford to pay their respects and do homage, but the youthful courtiers about the prince were not calculated to conciliate; they treated their visitors with the utmost scorn and contempt, and so highly roused their indignation as to produce a general spirit of resistance. The original settlers, too, were ill used, and the English interest was with great difficulty maintained in the towns which they had fortified. Henry found it necessary to recal his son, and the government of Ireland was committed to John de Courcy, a valiant knight, who had already acquired considerable possessions in Ulster. "From this time forward," says that judicious writer Sir John Davies, "until the 12th year of king John, (which was a space of more than 30 years,) there was no army transmitted out of England to finish the conquest. Howbeit, in the mean time, the English adventurers and colonies already planted in Ireland did win much ground upon the Irish; namely, the earl Strongbow, having married the daughter of Mac Morrough in Leinster; the Lucies in Meath; the Geraldins and other adventurers in Munster; the Audelins, Gernons, Clintons, Ruffels, and other volunteers of Sir John de Courcy's retinue in Ulster; and the Bourkes (planted by William Fitz-Adelme) in Connaught. Yet were the English reputed but part owners of Ireland at this time, as appears by the commission of the pope's legate in the time of king Richard I, whereby he had power to exercise his jurisdiction in England, Wales, and *those parts of Ireland* in which John earl of Morton has power and dominion, as it is recorded by Matthew Paris." During this interval, not only the Irish chieftains frequently revolted, but some of the great English settlers assumed independence. This was particularly the case after the accession of John to the English throne, and the suppression of one of these was the avowed object of his visit to Ireland in

the year 1216. He brought with him a considerable force, though not perhaps sufficient for the complete reduction of the island, even if he had remained a sufficient time to perform so great an action. This, however, he did not, for he arrived in June and returned in September the same year. The Irish lords, for the most part, submitted themselves to him, as they had done before to his father; "which," says Sir John Davies, "was but a mere mockery and impotence; for his back was no sooner turned, but they returned to their former rebellion: and yet this was reputed a second conquest." At this time twelve counties were established in Leinster and Munster, and sheriffs appointed for them, and courts of judicature were also settled in Dublin, for the regular and effectual execution of the laws of England in that part of the island which acknowledged allegiance to the crown. Some castles were built upon the borders of the English colonies, but the king carrying back with him the army he had brought, the former settlers were left to defend their possessions, and increase them in the best manner they were able.

The long and turbulent reign of Henry III. was distinguished by no remarkable change in the state of Ireland. The families of Burgh and Fitzgerald received a large accession of power and territory, and the clergy, though themselves oppressed both by the king and the pope, were not deficient in turbulence and presumption. Edward I. an active monarch, was too much engaged in regulating the disordered state of England, and in reducing Wales and Scotland, to devote much attention to the affairs of Ireland. At the commencement of his reign, the English settlers experienced some heavy losses, and were nearly expelled from their southern possessions, but the Irish were not united, and the advantages gained in one year were often lost the next, through the dissensions of the conquerors. Many of the Irish were at this time anxious to share the protection of the English laws, for, to the disgrace of the English government, this advantage had been withheld, and whilst the murder of an Englishman by one of the *mere Irish*, as they were termed, was avenged with the utmost rigour, the murder of an Irishman was scarcely deemed a punishable offence. An application was made early in this reign to Ulster, the chief governor, offering the king 8000 marks, provided he would grant the free enjoyment of the laws of England to the Irish inhabitants. The petitioners must have been the Irish residing within what was called the "English pale;" for the rest were so much attached to their own Brehon laws, as to be averse to a change at a much later period; though it is probable that if the wise policy of assimilating *all* the inhabitants had been now adopted, the objection to it would have been less, than at the time it was actually attempted. The king was well inclined to comply with the request of the petitioners, but this did not suit those, whose violence and oppression would have been thus controlled, and whose influence was great enough to counteract the intended measure. Individuals, however, of the Irish race fled for, and obtained charters of denization, particularly on their intermarriage with the English. That such conduct irritated the old inhabitants cannot be surprising. "As long as they (the Irish) were out of the protection of the law," says Sir John Davies, "so as every Englishman might oppress, spoil, and kill them without controul, how was it possible they should be other than outlaws, and enemies to the crown of England? If the king would not admit them to the communion of subjects, how could they learn to acknowledge and obey him as their sovereign? When they might not converse or commerce with any civil men, nor enter into any town or city without peril

of their lives, whither should they fly but into the woods and mountains, and there live in a wild and barbarous manner? If the English magistrates would not rule them by the law which doth punish murder, and treason, and theft with death, but leave them to be ruled by their own lords and laws, why should they not embrace their own Brehon law, which punishes no offence, but with a fine or ericke? If the Irish be not permitted to purchase estates of freeholds or inheritance, which might defend to their children, according to the course of our common law, must they not continue their custom of tanistry, which makes all their possessions uncertain, and brings confusion, barbarism, and civility? In a word, if the English would neither in peace govern them by the law, nor in war root them out by the sword, must they not needs be prick'd in their eyes and thorns in their sides, till the world's end."

Sir John Wogan, appointed to the government in the year 1295, endeavoured to enforce the laws, and to keep in order the turbulent nobles of English extraction. For this purpose a parliament was summoned more regularly than such assemblies had hitherto been convened in Ireland. The regulations made by it, however, though calculated to check the disorders of the time, were either of little avail, or their effect of short duration; and the country still continued in a distracted state. The weak government of the second Edward left the great lords at full liberty to pursue their respective schemes of private interest, when an invasion by Edward, the brother of Robert Bruce, now established king of Scotland, supported by the chieftains of Ulster, reduced them to the greatest distress. Bruce was even crowned king of Ireland at Dundalk, and proceeded into Munster, carrying devastation wherever he went. His troops, however, walled away by pestilence and famine, were reduced to a small number, and in a battle, which he too eagerly fought, he was slain the third year after his landing in Ireland. On his defeat, matters reverted to the old channel, and so continued through the succeeding reign, until the appointment of Lionel, the king's second son, to be chief governor in 1361. Before notice is taken of his proceedings, it will be necessary to observe, that in the reign of Edward II, Maurice Fitz-Thomas of Desmond, being chief commander against the Scots, began that extortion of coin and livery, which is called, in the old statutes, a *dammable custom*, and the imposing and taking of them declared high treason. These words imply that he and his army exacted food for themselves and their horses, and money at pleasure, without any ticket, or other satisfaction. And this was, after that time, the general fault of all the governors and commanders of the army in Ireland, though some were more cruel in the exactation than others. "Besides," says Davis, "the English colonies, being dispersed in every province of this kingdom, were enforced to keep continual guards upon the borders and marshes round about them; which guards, consisting of idle soldiers, were likewise imposed as a continual burden upon the poor English freeholders, whom they oppressed and impoverished in the same manner. And because the great English lords and captains had power to impose this charge, when and where they pleased, many of the poor freeholders were glad to give unto these lords a great part of their lands, to hold the rest free from that extortion; and many others, not being able to endure that intolerable oppression, did utterly quit their freeholds, and returned into England. By these means the English colonies grew poor and weak, though the English lords grew rich and mighty; for they placed Irish tenants upon the lands relinquished by the English; upon them they levied all Irish exactations; with them they married, and fostered, and made

goffips; so as within one age the English, both lords and freeholders, became degenerate and mere Irish in their language, in their apparel, in their arms and manner of fight, and all other customs of life whatsoever."

Lionel, soon after created duke of Clarence, was, in right of his wife, possessed of a considerable territory in Ireland, and his first object seems to have been to recover parts of it from those who were now called *rebels*. His military proceedings were of no great moment, but he applied himself with zeal and diligence to the reformation of the English settlers. A parliament was summoned at Kilkenny, which was more respectable and numerous than any preceding one, and the result of the deliberation of which was that ordinance, known by the name of the Statute of Kilkenny; this was in 1397. The great object of this statute was to reduce the English colonies to obedience of the English law and magistracies. "The preamble of it recites," (to use the abstract given of it by Dr. Leland) "with a decision not without colour, but yet too general and indiscriminate, that the English of the realm of Ireland, before the arrival of the duke of Clarence, were become mere Irish in their language, names, apparel, and manner of living; had rejected the English laws, and submitted to those of the Irish, with whom they had united by marriage alliance to the ruin of the general weal. It was, therefore, enacted, that marriage, nurture of infants, and goffips with the Irish, should be considered and punished as high treason. Again, if any man of English race shall use an Irish name, the Irish language, or the Irish apparel, or any mode or custom of the Irish, the act provides that he shall forfeit lands and tenements, until he hath given security in the court of chancery to conform in every particular to the English manners. The Brehon law was pronounced to be a pernicious custom and innovated lately introduced among the English subjects. It was, therefore, ordained, that in all their controversies they should be governed by the common law of England; and that whoever should submit to the Irish jurisdiction, was to be adjudged guilty of high treason. As the English had been accustomed to make war and peace with the bordering enemy at their pleasure, they were now expressly prohibited from levying war upon the Irish without special warrant from the state. It was also made highly penal to the English, to permit their Irish neighbours to graze their lands, to present them to ecclesiastical benefices, or to receive them into monasteries or religious houses; to entertain their bards, who perverted their imaginations by romantic tales; or their news-tellers, who seduced them by false reports. It was made felony to impose or cease any forces upon the English subject against his will. And as the royal liberties and franchises were become sanctuaries for malefactors, express power was given to the king's sheriffs to enter into all franchises, and there to apprehend felons and traitors. Lastly, because the great lords, when they levied forces for the public service, acted with partiality, and laid unequal burdens upon the subjects, it was ordained that four wardens of the peace in every county should adjudge what men and armour every lord and tenant should provide. The statute was promulgated with particular solemnity; and the spiritual lords, the better to enforce obedience, denounced an excommunication on those who should presume to violate it in any instance." After observing that these institutions did not apply to any except the English settlers, Dr. Leland goes on to remark upon the want of equity and good policy towards the Irish. "Extensive views, liberal sentiments, and a generous zeal for public happiness would have prompted them to some measures for conciliating the affectionate as well as for subduing the petulant and posses-

fessions of the Irish; would have led them to demonstrate that they were the protectors and benefactors, not the arbitrary masters of those Irish natives whom they held in subjection; and to convince the most obstinate infurgents, that an honourable submission to the king of England was the only means of rescuing them from the miseries of their own petty fictions and tyrannies; a glorious exchange of the rudeness, the disorders, and dissolves of anarchy for the peace, the dignity, and the valuable advantages of social and civil life.¹⁷

The next attempt that was made to reduce Ireland was by Richard II. who, in 1304, went there with an army of 4000 men at arms, and 30,000 archiers, attended by a number of distinguished noblemen. The presence of such an army induced all the chieftains to make submission in a formal manner, with which Richard was contented. By this expedition he did not extend the English jurisdiction, nor add to his revenue; and he had no sooner departed than the Irish lords laid aside their masks of humility, and scorned the weak forces which the king had left behind him, began to infest the borders, and in defence of these, Mortimer, the king's lieutenant, and heir apparent of the crown, was slain. To revenge his death, Richard went to Ireland a second time with a great force; but during his absence, an insurrection took place in England, which terminated in his deposition. During the reigns of Henry IV. and V. nothing was attempted beyond the defence of the English pale, including four counties, viz. Dublin, Kildare, Meath, and Leath; and during the early part of the reign of Henry VI., so much had the Irish, and those English who had adopted their customs, increased in strength, that even the defence of those countries was become a matter of great difficulty. Towards the latter end of the reign of Henry VI., Richard, duke of York, was appointed chief governor, who, though he gained little advantage over the Irish, succeeded in attaching to himself not only the lords of the pale, but others of English race, numbers of whom engaged warmly in the support of his claim to the crown. An attachment to his descendants long continued to influence the Anglo-Irish, as was conspicuous in the reign of Henry VII. During the period of the civil wars, the state of Ireland was very bad, in consequence of the neglect of the English government; and the exaction of coin and livery, which grew excessive and intolerable. Such was the violence of faction, that the earl of Desmond, the most powerful nobleman in Ireland, was seized and beheaded under the pretext of offences which were generally committed with impunity. In 1474, the earl of Kildare, being lord deputy, formed an association of the principal noblemen and gentlemen within the pale for its defence against sudden invasions, called the "Brotherhood of St. George," and this continued till the tenth year of Henry VII. This prince, as soon as he found leisure to attend to the affairs of Ireland, was determined to break the power of those lords who, by their influence in the country, had hitherto managed every thing as suited their own private views. For this purpose he sent sir Edward Poyning as lord deputy, accompanied by an English chancellor and treasurer, and English judges. In a parliament held at Drogheda, by this deputy in 1495, most of the statutes of Kilkenny were revised and confirmed, with many others tending to lessen the influence of the great lords, and to reform the manners of the pale. Amongst others was a statute, which has since been the subject of much discussion, under the name of Poyning's law. This enacted, that no parliament should be held without the king's previous permission, and that no act should be passed until they had been previously sub-

mitted to the king and his council in England, approved by them, and returned under the great seal of that realm. Some alteration was afterwards made in the mode of preparing and transmitting the bills, but the effect of this law, which was to render the Irish government more dependent on England, continued until the reign of his present majesty, king George III. At the time, and long after, this law was considered by the English settled in Ireland as a desirable check on the chief governors, who had frequently summoned parliaments, and given assent to various acts, not only without communication with the sovereign or his English council, but even contrary to his interest, and to serve their own private purposes. The vigorous administration of the earl of Kildare effectually preserved the pale, and though an ignominious tribute, which had been long paid to many Irish chieftains, was not yet withdrawn, the hostilities of such chieftains were opposed and chastised. The superiority of the English government over the *cabole* of Ireland was once more asserted, and even some of the most ferocious chieftains became the avowed friends of the English power. On the other hand, the old English settlers had become so connected with the Irish as to be scarcely distinguishable from them; they adopted their language and customs, and were even more averse to the government than the native Irish. During the early part of the reign of Henry VIII. no material change took place in the state of Ireland, which Kildare, with some little interruption, continued to govern. The great possessions of this nobleman, and his connections in Ireland, especially with the house of Desmond, another branch of the Geraldine family, and with the great Irish sept of O'Neil, gave weight to his government, whilst his alliance to some powerful English families strengthened his interest at court. Francis I. of France, having, however, sent an agent to tamper with Desmond, with a view to distress Henry, and this having been discovered, Kildare was ordered to arrest that nobleman, but was either unwilling or unable to effect it. This displeased the king and involved him in difficulties, and the rashness of his son having involved him in open rebellion, all the members of his family were put to death, except a youth of twelve years old, who escaped to France, and was protected by cardinal Poie, notwithstanding the king's efforts to destroy him.

Whilst these disturbances took place in Ireland, the king, influenced by very unworthy motives, though his conduct was attended with the most happy effects, had thrown off the yoke of the pope, and had been declared by parliament, and by a convocation of the clergy, "supreme head, on earth, of the church of England." His new queen was partial to the reformation, and Cromwell, his prime minister, was active in promoting it. Henry was resolved to extend his new power to Ireland, and Browne, archbishop of Dublin, a creature of Cromwell's, was zealous in promoting his views. Ireland, however, was much less prepared for such measures than England had been. The continual hostilities in which all parties were engaged, prevented the progress of knowledge and civilization, even within the English pale, and the clergy, especially in remote parts, were amongst the most ignorant, and consequently the most bigoted, partisans of Rome. A decided opposition was therefore given to the acknowledgment of the king's supremacy, by the primate, and encouraged by the emulraries of Rome. Fear indeed induced the parliament to pass the proposition. Browne having pronounced those, who made any dissent of concurring with him, to have no right to be received, or treated as loyal subjects; but great resistance was offered to the carrying of it into effect. Lord Leonard Wood-

deputy, who had reduced the power of the Geraldines, now showed equal activity in suppressing the advocates of Rome, and by a great victory over O'Neil and his associates at Bellinagh, put an end for a time to open resistance. The suppression of the monasteries was carried into effect, and the most powerful and turbulent chieftains appeared earnest to express their attachment to the crown. Sir Anthony St. Leger assumed his charge as governor in 1541, with the fairest pre-views of tranquillity and public happiness. A parliament summoned by him declared Henry king of Ireland; this title, now first assumed, was acknowledged by O'Neil, and the other chieftains by indentures, and they at the same time renounced the papal authority in the fullest manner. Various regulations were passed for the government of Munster, where the laws of England, though formerly established, had been disused for 200 years. St. Leger also prevailed upon O'Neil, O'Brien, and the head of the Burkes called Mac William, to go into England, and present themselves to the king, who conferred on them the dignity of earls, and granted unto them their several countries by letters patent. He also granted to each a house and lands near Dublin, that they might, by frequent residence there, learn obedience and civility of manners. The reign of Edward VI. was chiefly occupied in endeavours to introduce the reformed liturgy, which was effected in Dublin and some other places, but was very generally disagreeable. On the accession of Mary, popery was restored without any difficulty, except that occasioned by the alienation of church property in the preceding reigns; but the regulations which the change required occupied much time and attention. The districts of Leix and Ophaly, which had been before reduced, were now made shires under the names of the Queen's and King's counties, and the native Irish were, in general, not averse to a government which favoured their religion. The reign of Mary, however, was short, and her successor Elizabeth was friendly to the reformation. Before we proceed to notice the more interesting transactions of this long reign, it will be useful briefly to consider the state of the country. The inhabitants have been classed in four divisions: 1. The native, or, as they were contemptuously called, the *mere* Irish. 2. The degenerate English, or those of English descent who had intermarried with the Irish, and adopted their customs and language, so as to be scarcely distinguishable from them. They were alike governed by the Brehon law, for an account of which see the article BREHON; and alike used the mode of succession called Tansistry, for which see TANSISTRY. 3. The English of blood, some of whom were possessed of large estates, and though the situation of the country did not allow of much refinement, yet their occasional intercourse with England, or with the English constantly coming over, enabled them to keep up an exterior appearance of English manners. Their estates resided within the pale. 4. The English of birth, sent over to fill the principal offices of state, and who generally acquiring property in the country, their descendants were continually forming an addition to the 3d class. These, who might have been called *mere* English, as they were ever disposed to sacrifice the interest of Ireland to that of England, were the persons countenanced and assisted by the English government. Spenser the poet, who resided in Ireland for some years in this reign, has described several of the Irish customs in his dialogue on the state of Ireland; and, though it must be remembered that he saw every thing through the eye of prejudice, yet a quotation or two may enable us to form a more correct idea of the licentiousness of manners of the Irish chieftains. Whatever opinion we may form of the impo-

licy and injustice of the English settlers and government on many occasions, it must be acknowledged that the Irish laws and customs were favourable to a savage wildness of manners inconsistent with the happiness of social and civil life. After noticing the barbarous manners of the Gallowglasses or infantry, of the Kernes or predatory cavalry, and of the horse boys, Spenser also describes two classes of men who contributed very much to the dissoluteness of the chieftains, *viz.* the Bards and the Carrows. "These Irish bards," says he, "are so far from instructing young men in moral discipline, that they themselves do more deserve to be sharply disciplined; for they seldom use to choose unto themselves the dealings of good men for the arguments of their poems, but whomsoever they find to be most licentious of life, most bold and lawless in his doings, most dangerous and desperate in all parts of disobedience and rebellious disposition, him they set up and glorify in their rhymes, him they praise to the people, and to young men make an example to follow." Then, having described the youth of one of these chieftains, he adds "in which, if he shall find any to praise him, and to give him encouragement, as those bards and rythmen do for little reward, or a share of a stolen cow; then waxeth he most insolent, and half mad with the love of himself and his own lewd deeds. And as for words to set forth such lewdness, it is not hard for them to give a godly and painted show thereunto, borrowed even from the praises which are proper to virtue itself. As of a most notorious thief and wicked outlaw, who had lived all his lifetime of spoils and robberies, one of their bards in his praise will say, That he was none of the idle milk-sops that was brought up by the fire-side, but that most of his days he spent in arms and valiant enterprises, that he did never eat his meat before he had won it with his sword; that he lay not all night slugging in a cabin under his mantle, but used commonly to keep others waking to defend their lives, and did light his candle at the flames of their houses, to lead him in the darkness; that the day was his night, and the night his day; that he loved not to be long wooing of wenches to yield to him, but where he came, he took by force the spoil of other men's love, and left but lamentation to their lovers; that his music was not the harp, nor lays of love, but the cries of people, and the clashing of armour; and finally, that he did not bewail of many, but made many wail when he died that deadly bought his death." At the same time, in answer to a question respecting these poems, "Whether they be any thing witty or well favoured as poems should be," this excellent judge replies, "Yea truly, I have caused divers of them to be translated unto me, that I might understand them, and surely they favoured of sweet wit and good invention, but killed not of the godly ornaments of poetry; yet were they sprinkled with some pretty flowers of their natural device, which gave good grace and comeliness unto them, the which it is great pity to see abused, to the gracing of wickedness and vice, which, with good usage, would serve to adorn and beautify virtue." These bards probably had as great effect in rousing a spirited opposition to the English as the Welsh bards, whom the policy of the first Edward led him most impudently to destroy. As to the Carrows, they are "a kind of people that wander up and down to gentlemen's houses, living only upon cards and dice, the which, though they have little or nothing of their own, yet will they play for much money, which, if they win, they waste most lightly, and if they lose, they pay as readily, but make reconence with one flesh or another, whose only hart is not, that they themselves are idle losses, but that, through gaming, they draw others to like lewdness

lowness and idleness. And to these may be added another sort of like loose fellows, who do pass up and down amongst gentlemen by the name of jokers, but are indeed notable rogues, and partakers not only of many ileaths, by setting forth other men's goods to be stolen, but also privy to many traitorous practices, and common carriers of news, with desire whereof you would wonder how much the Irish are fed."

Almost the whole of the two first classes, and the greater part of the English of blood, were zealously and blindly attached to the doctrines and discipline of the church of Rome, in which they had been educated, and were therefore easily incited to support Philip of Spain, a Catholic prince, to whom they had once been subject against their Protestant mistresses. In 1560, the first parliament in this reign was assembled for the purpose of re-establishing the queen's supremacy and the reformed worship. The house of commons consisted of only 76 members, from those parts where the English interest was strongest, yet the change was not effected without much clamour and opposition. Laws, however, were passed, restoring ecclesiastical jurisdiction to the crown, enforcing the use of the common prayer, and obliging all subjects to attend the public service of the church. But though the deputy succeeded with parliament, the measures were very unpalatable. "The numerous partisans of Rome inveighed against the heretical queen, and her impious ministers. The clergy who refused to conform abandoned their cures; no reformed ministers could be found to supply their places; the churches fell to ruin; the people were left without any religious worship or instruction. Even in places of most civility, the statutes lately made were evaded or neglected with impunity. The ignorant were taught to abominate a government, which they heard configned to all the terrors of the divine vengeance; were exhorted to stand prepared for a glorious opportunity of asserting the cause of religion; and assured of effectual support, both from the pope, whose authority had been profaned, and from the king of Spain, now particularly offended at Elizabeth."

Besides the disorder occasioned by these efforts to force upon the people a religion they detested, much uneasiness was occasioned to the government by the restless turbulence of Shane or John O'Neil, the most powerful chieftain in Ireland. Sir Henry Sidney, to whom Elizabeth entrusted the government for many years, and who deserved her confidence, succeeded in attaching to him several inferior chieftains whom O'Neil had injured, and with their aid completely subdued him. But scarcely was the northern disturbance allayed, than another broke out in the south, headed by the earl of Desmond, which was of longer continuance. Sir John Perrott, president of Munster, an office lately instituted, not only suppressed the rebellion, but enforced such a strict execution of English law, as to give an unusual appearance of peace, industry, and civility, to the whole province. Peace, however, was of short continuance, and an attempt of Sidney to raise a tax by order of council, without authority of parliament, excited a most determined opposition on the part of the nobility and gentry of the pale. These discontents were encouraged by the emissaries of Philip II.; a body of Spaniards landed in Kerry, who acted in concert with Desmond; and a protracted warfare was maintained, which, as usual, terminated in favour of the English. The enormous demesnes of Desmond were forfeited, and divided amongst a number of English Undertakers, as they were called, who entered into a stipulation to plant a certain number of English families on their estates, in proportion to the number of acres, a stipu-

lation frequently neglected to the great injury of the settlement. Amongst others who received portions, were Sir Walter Raleigh, who had served with reputation for bravery, though not without the stain of cruelty, and Edmund Spenser, the poet, who has introduced several allusions to Ireland into his Fairy Queen. In 1584, Sir John Perrott was sent over as chief governor, and as war and insurrection seemed to be then extinguished, he applied himself to the general extension of English law with considerable success. He nominated sheriffs for the counties of Connaught, and also for seven new counties instituted in Ulster, with other necessary officers; but his plans for more extensive improvement were thwarted in England from ill-timed economy, and notwithstanding all his exertions, a parliament, summoned by him in the following year, rejected almost every measure proposed to them. The oppression of the natives by the English settlers, which Perrott in vain endeavoured to repress, supplied new causes of discontent; and this active governor was at length obliged to leave Ireland. A more general spirit of insurrection than at any former period was now excited, and Elizabeth found it necessary to make uncommon efforts, lest England should be placed between the forces of Spain collected in the Netherlands, and their naval strength and armaments stationed in the harbours of Ireland. The misconduct of successive governors, especially of Elizabeth's favourite, the earl of Essex, who had an army of 20,000 men, increased the danger, and before the rebels were subdued, a Spanish army took possession of Kinsale, and a nuncio arrived from the pope to incite the friends of Rome to make every exertion. The abilities and exertions of Blount, lord Mountjoy, lord deputy, and of Sir George Carew, president of Munster, assisted by considerable reinforcements from England, at length effected the surrender of the Spaniards, and the complete reduction of all the lords and chiefs, who, until then, had ruled in the island, after a war which lasted about seven years. Elizabeth did not live to see this event, the final capitulation not having been signed until a few days after her death, though before the news of it had reached Ireland.

The reign of James I. was one of at least comparative tranquillity. All violent opposition to the authority of the English government and crown was put an end to. "The spirit of Irish resistance," to use the expressions of Sir John Davies, "was brayed, as it were, in a mortar, with the sword, famine, and pestilence altogether." Both the degenerated English and the native Irish were alike overcome. At the same time the power of the judges and of the English government was extensively fixed, the Irish laws and customs were abolished, and the English laws established in all cases, without exception, through the whole island. Numerous colonies were also sent from England and Scotland, especially from the latter, to occupy the forfeited estates, and seven entire northern counties were allotted to undertakers, which was called the "Plantation of Ulster," a measure which was certainly attended by the introduction of industry and order into that province. With a view to strengthen the Protestant party, great care was taken that these settlers should be Protestants, and they were chiefly Scotch Presbyterians, or English Puritans, the latter of whom found their situation at home uneasy, from James's zealous attachment to their adversaries. For the same purpose, many new boroughs were erected, so as to give a majority in parliament to the same party, which they could not otherwise have accomplished, as the county members were likely to be almost all Papists. It would have been at this time a wise and liberal policy to have completely united the two countries, so as to

have but one parliament, which might have been easily effected at that time. This would have rendered such extraordinary proceedings entirely unnecessary, and would in all probability have prevented much of the mischief which afterwards occurred; but the settlers were considered as a colony, dependent on the mother country, to whose interest they were to be subservient, without presuming to interfere in any but the petty regulations of their own island, and all but the colony were regarded as secret enemies, who could not be too carefully watched, or too strictly kept in subjection. In consequence, the distinctions which had subsisted amongst them were in a great measure done away, and they united in defence of a religion to which they were equally attached, and of rights which they conceived to be equally invaded. Such was the prevailing sentiment, when, after an interval of *twenty-seven* years, a parliament, summoned by Clivehiler, the deputy, met in 1632. The recusants, (as they were called, from their refusal to acknowledge the king's supremacy, and to attend the established worship,) were prepared to dispute every step, and were numerous in both houses. Such indeed was their resistance, that, although the bishops in the upper, and the new borough members in the lower house, gave government a majority, it was found necessary to prorogue them until the following year, when acts for acknowledging the king's title, for settling upon him a revenue, and for confirming the northern attainders, were passed. During the remainder of this reign, and for the early part of the succeeding one, the two contending parties often shewed their rancour without proceeding to extremities, whilst the period of peace was employed by some in active exertions for the establishment of manufactures, and the extension of cultivation. In 1633, lord Wentworth, better known by his later title of earl of Strafford, commenced his administration. He treated Ireland with severity, as a conquered country, the subjects of which had forfeited the rights of men and citizens, and depended solely on the royal grace. The recusants and the Puritans were equally offended by his measures; yet, by artfully plying one party against the other, he contrived to manage a parliament which he summoned, and to perform many acts of severity with a vigour beyond the law.

At length the time arrived when Ireland was to be once more involved in war and bloodshed. The impeachment of lord Strafford before the English parliament was one of the first steps to the overthrow of the royal authority. The severe restrictions imposed on the Catholic party, which, as before observed, included almost all the inhabitants, except the new settlers, led them to watch for an opportunity of revenge; and the distracted state of affairs in England affording a favourable opportunity, a general insurrection was planned, and carried into execution on the 23d of October 1641, an event productive of the most baneful consequences to the peace, union, and prosperity of Ireland. This civil war, or rebellion, as it is justly called, even admitting the palliations that have been urged, was begun by the native Irish, and they were afterwards joined by most of the Catholics. Happy would it be for the country if the acts of violence then committed could be for ever buried in oblivion. The writers on both sides are charged with partiality by their opponents; yet what they admit respecting their own parties is enough to shew that there was on both sides much to blame, and much to lament. For eleven years Ireland was a scene of confusion, there being no less than five different parties, of whom it has been said, that each, in the course of the war, at one time or other, fought against the faction with which it had formerly sided. At length, in 1652, Cromwell assumed the command of the parliamentary

army, to which he brought a considerable reinforcement, and soon completely reduced the whole island. The lands which had belonged to those who had been killed, or who were deprived of their possessions by force of arms, were now given to new colonists, many of whom had been officers in the victorious army. Limits were assigned to the Irish, beyond which they were not to come, and these continued to be strictly enforced till the restoration. The Protestant and English interest was now more completely established than at any former time; but though the Catholics had lost the power to injure, they retained their animosity. At this period, indeed, the interest and power of the old native Irish, as a distinct class of inhabitants, was entirely broken, their numbers being from that time much exceeded by those of the old and new inhabitants of the British race.

On the restoration it was hoped that the king would have overturned all the measures of Cromwell; but he confirmed all the grants, and the situation of the Catholics was little, if at all, amended. The duke of Ormond, who had great influence in Irish affairs, was a steady Protestant; and whatever might be the king's private wishes, no steps were taken in favour of the opposite party till near the conclusion of his reign, when his brother the duke of York appears to have had great influence over him. On the accession of James II. the Romish party in Ireland were inspired with the most extravagant expectations; they fancied themselves already restored to the estates of their ancestors, and possessed of every advantage to be derived from a king of their own religion. "At length," says Mr. Newenham, "the infatuated James, yielding to the impolitic counsels of men who, perhaps, might have governed a religious fraternity well, but who were utterly ignorant of the government of an empire; and taught to regard the Irish Roman Catholics as fit instruments for the accomplishment of his visionary and despotic projects, gradually raised, invigorated, and encouraged them. By the obsequious forbearance, or constrained acquiescence of Clarendon, and the indefatigable exertions of the zealous and plenipotent Tyrconnel, they were once more prepared to renew the terrible conflict; and animated by no ordinary combination of forcible motives, recurred to arms; after incautiously co-operating with their bigoted sovereign, in persecuting their Protestant countrymen without measure and without remorse; and thus, in some degree, justifying that severe retaliation which they themselves were soon after to experience.

—Eheu,

Quam temere in nosmet legem sancimus iniquam.

But England was not then, as on the preceding occasion, paralyzed by internal commotions. The prince who had ascended the abdicated throne was an experienced general, and a sound politician. The visionary James was greatly overmatched. The Irish Roman Catholics were, in consequence, completely vanquished; stripped of political power; hurled from every post of trust and emolument, and almost entirely dispossessed of their remaining lands. The work of vengeance, however, was not yet finished, nor could it perhaps have terminated thus, consistently with the weakness and wickedness inseparable from human nature. The Irish Protestants, still horrified by the remembrance of the ferocious massacre of 1641; recollecting the havoc and misery of the long war which succeeded that event; dreading a repetition of the tyrannical measures, the relentless, and, for the most part, unprovoked persecution from which they had been recently rescued; and a renewal of those bloody scenes which they had just survived; yielding, in short, to the united impulse of revenge and fear, and thereby hurried be-

IRELAND.

beyond the bounds of political honour and prudence, resorted in the following reign, when they were rather encouraged to do so, to every expedient which legislative ingenuity could supply, however likely to prove ultimately detrimental to themselves, with a view of reducing their inveterate enemies, the Roman Catholics, to absolute and irremediable political impotence. A code of defensive and preventive statutes, being the stamp of the passions by which it was originated, was in the end compiled: a code which was not merely limited to the preclusion of hostilities on the part of the Roman Catholics, but extended to the abolition of their venerated religion, which, in Ireland, had scarcely ever been fairly combated by the only weapons that ever should have been employed against it, the pens or tongues, and attractive examples of Protestants: a code which impeded the progress of the former in the paths of industry; thwarted every species of laudable ambition by which they might have been actuated; placed them on the footing of aliens in their native land; exposed them to vexatious outrages and spoliation; reduced them almost to the condition of slaves; obstructed matrimonial alliances between them and the Protestants, from whence, it is probable, the happiest effects might have flowed; and, worse than all, held forth incitements to filial contumacy, to a violation of one of the commandments of God; and introduced amongst them principles of duplicity and treachery. A code, which, while it oppressed, and seemed to overwhelm the Roman Catholics, facilitated the obstruction of those jealous measures, those commercial restraints which had long been the effect of retaining one of the fairest portions of the globe in a state of poverty and political insignificance. The massacre of 1641, which had been industriously exhibited in the most horrid colours, together with the cruel persecution experienced during the short reign of king James in Ireland, both still fresh in the recollection of the Protestants, necessarily heightened their animosity to the utmost; while repeated discriminations and disasters, and aggravated oppression, together with the accumulated misery produced by this revengeful code, certainly inconsistent with the principles of sound policy and true religion, naturally rendered the hatred of the Roman Catholics virulent beyond example. An unparalleled combination of irritating, maddening circumstances fomented, on both sides, the most rancorous malignity. The idea of a Protestant in the mind of a Roman Catholic, and that of the latter in the mind of the former, now became closely associated with every idea that could engender wrath, malice, and vengeance in the heart of man. Each abhorred the other; each longed for the extirpation of the other—"This among countrymen, among the friendly, cheerful, and hospitable people of Ireland, among Christians, among those who looked forward to eternal happiness through the mediation of the same Saviour, among those who adored the same Trinity, among those who agreed in all the essential points of religion, the maintenance of a few different speculative articles, and the observance of a few different rites, confessedly inoperative in social life, and consequently unworthy of serious notice, being unhappily combined with opposite interests, being coeval and concurrent with the most energetic principles of discord, serving as the tests, symbols, or distinctive characters of two parties inveterately and unappeasably hostile to each other, became at length, what in their natural unconnected state they could never possibly have become, alimentary to the most vehement detestation."

Though we cannot agree with the respectable writer of the preceding passage in all his remarks, especially in those which seem to think lightly of the difference between the Protestant

and Catholic faith; yet it, on the whole, contains so just and candid a representation of the unhappy differences between the parties, and is evidently written with such a desire of conciliation, that we have copied it without change, anxiously wishing that all the gentlemen of Ireland, of every sect, saw the matter in the same light, and were equally desirous of improving past evils to present harmony.

The events peculiar to Ireland, excepting the penal code, just remarked on, will not require much notice during the four reigns succeeding the revolution. The uniform policy was to keep Ireland in a state of dependency, and to prevent her manufactures or commerce interfering with those of England.

Encouragement was indeed given to the linen manufacture, and it proved a source of great benefit to the country, but the woollen manufacture was kept down, and the restrictions on commerce shewed a most unwarrantable jealousy. As the dependence of Ireland on England was never lost sight of, so some occasions occurred in which the parliament of the latter directly exerted its authority. In the reign of William acts were passed, by which Ireland was bound. In the year 1698, Mr. Molyneux published a pamphlet, entitled "The Case of Ireland being upheld by Acts of Parliament in England, stated," in which he called in question their right to do so, and his sentiments were known to be those of the Irish parliament and people. This book was condemned by the English parliament, which addressed the king on the pernicious assertions it contained, and on the dangerous tendency of the proceedings of the Irish parliament, and promised to give his majesty their ready concurrence and assistance to preserve and maintain the dependence and subordination of Ireland to the imperial crown of this realm. William promised on his part to fulfil their wishes, and notwithstanding the discontent of the Irish people, such was their divided state, and such the apprehension each party entertained of the other, that they were obliged to submit. Another cause of controversy occurred in 1719, in consequence of an appeal being carried from the Irish to the English house of lords. The barons of the exchequer, who had carried into effect the decree of the English house, were imprisoned by the Irish one, but the dispute terminated in a new act, by which it was enacted, "that the kingdom of Ireland is subordinate unto, and dependent upon, the imperial crown of Great Britain; and that the king's majesty, by and with the consent of the lords and commons of Great Britain, has full power and authority to make laws and statutes to bind the people and the kingdom of Ireland." Soon after this, in 1723, a circumstance occurred, which deserves notice, both on account of the example it set, that the united, determined, and persevering voice of a people might be ultimately successful, and on account of the active part taken by the celebrated dean Swift, then resident in Dublin. This was the well known affair of *Wood's halfpence*. A patent had been granted to a Mr. Wood, to supply Ireland with a certain quantity of copper halfpence and farthings for 14 years. It was alleged in Ireland, that this coin was greatly inferior in value to what it was made to pass for. The parliament of Ireland addressed the crown against the measure of sending the coin; and during their following biennial recess, great complaints continued to be made both by individuals and by public corporations. It would appear that though the badness of Wood's halfpence was the pretext, the dispute was, in reality, a question of rights and independence. Dean Swift contributed much to the public discontent, by a series of letters signed *A Drapier*, for discovering the author of the fourth of which, a reward of 300 pounds was offered. As such precautions

precautions had been taken, that no evidence could be procured against the author, the printer was indicted, but the grand jury, instead of finding the bill, approved the publication. The ferment was so great, that if ministers had persevered, a new civil war would probably have arisen, though it, like all preceding ones, would have only contributed, in all probability, to rivet the chains of Ireland more firmly. As it was, the patent was cancelled, and the ferment allayed. At this time the complaints of the people, on other accounts, were loud, of which dean Swift takes particular notice in his "Short View of the State of Ireland;" he compares this kingdom, in which a few placemen from England enjoyed plentiful salaries, to an hospital, in which all the household officers grow rich, while the poor, for whose sake it was built, are almost starving for want of food and raiment. Such are the principal events in Ireland, in the interval between the revolution and the accession of his present majesty to the throne in 1760. The Catholics were under the disabilities already stated, but the penal laws against them were seldom, if ever, enforced; and as the distance of time increased, the irritation occasioned by former events was considerably abated. Many of that body acquired wealth in the way of trade, and the nobility and gentry enjoyed their estates in quiet. The Protestants also gradually lost their apprehensions, and were taken up with the contentions against British sovereignty, which about this time gave a continual interest to the proceedings of parliament, where some able men distinguished themselves by their opposition to government. This parliament was unchanged during the life of the sovereign, and met every second year; and as the present mode of vacating seats was unknown, when a vacancy happened by death, the greatest exertions were used by the contending parties, and the election was usually decided by the majority of the house. The Irish government was peculiarly circumstanced. It was necessary that every act of parliament should have the sanction both of the British privy council, *i. e.* of the British ministry, and of the Irish parliament. It was therefore necessary for the former to be able to influence a majority of the latter. To do this, places and pensions were bestowed on those, whose powers of eloquence, or whose parliamentary interest made them serviceable; and besides this, the ministry were obliged to gratify the leading faction, by complying with such measures as were for their private advantage, although inconsistent with sound policy, and the true interest of Ireland. Hence a number of parliamentary grants, which have been justly stigmatized as jobs, and hence the undetermined conduct of the British ministry respecting Irish measures, even on occasions not long preceding the Union. The leading party in the Irish parliament must be gratified, because otherwise the public business would be at a stand. The lord lieutenant was not resident, except during the parliamentary session; and the management of affairs was, at other times, entrusted to lords justices, generally the primate, the chancellor, and the speaker of the house of commons; the two former invariably Englishmen, in whom confidence was chiefly placed, and the last, a man always possessed of great parliamentary influence from his talents and connections. The first step to a change was the rendering parliaments optional, which was moved by G. D. Lucas, and passed in 1768. The lord lieutenant now became constantly resident, and the sessions were held every year. The spirit of the Irish parliament increased; several men of great talents sprung up, and whilst the British ministry were engaged in their unhappy contest with America, they were obliged to yield to the people of Ireland first a free trade, and afterwards a repeal of the statutes which rendered Ireland de-

pendent. The volunteers, a body originally armed for the defence of the country against French invasion, probably contributed to these measures by the terror they occasioned to the ministry, whilst the agitation in England towards the close of the American war, and the unsettled state of administration between the resignation of lord North, and the appointment of Mr. Pitt, prevented that determined opposition which would have been made in a more settled state of affairs. In 1778 the grievances of the Roman Catholics began to receive attention, and that body was restored to many privileges, of which they had been harshly deprived. This was the commencement, and since that time all the most harassing disabilities have been removed, though some still remain, which are frequently the subject of parliamentary discussion. The events of the last 20 years are too recent to be enlarged on without that partiality from which human nature is scarcely ever exempt, and the detail would be perhaps unsuitable to a work of this general nature. Notwithstanding the misery occasioned by the rebellion of 1798, and the low state of many branches of trade and manufacture, Ireland has rapidly improved within that period, especially in agriculture, and should it be blessed with internal peace and union, it will soon, under the fostering care of the legislature, rise to a great degree of prosperity, and essentially contribute to the welfare and happiness of the *United Kingdom*. See UNION. Beaufort's Memoir. Pinkerton's Geography. Spenser. Cox. Davis. Hollinghead. Leland. Curry. Newenham's State of Ireland, &c. &c.

IRELAND'S EYE, a small island in the Irish sea, north of the hill of Howth, in the county of Dublin, Ireland, about a mile from the main land.

IRELAND, *New*, an island in the Pacific ocean, which is a long slip of land stretching from N.W. to S.E. about 270 miles, and separated from *New Britain* (which see) by a channel through which Capt. Carter passed in 1767, who gave its name to this island. This navigator found the nation very hostile, having lances headed with flint. Their faces were streaked with white, and their hair besprinkled with powder of the same colour. They are black, and said to be woolly-headed, but without the thick lips or flat nose of the negro. Some of the canoes of this island were 90 feet in length, formed out of a single tree. Bougainville also visited this country, and observed here the pepper-plant, and that singular insect, the walking leaf; among its numerous birds was the great crowned pigeon. To the west of New Ireland, and approaching New Guinea, a succession of little Archipelagos is found; in which are the Portland isles, the Admiralty isles, the Hermit and Eschequer isles; all of which present one principal island, the centre of the group, of which the circumference is formed by a number of flat islets linked together by reefs. The principal island of the ADMIRALTY *islands* (which see) is mountainous. The inhabitants are not very black. Their physiognomy is agreeable, and differs but little from that of the Europeans; they appear little sociable, and thieves; they have chiefs who exercise great authority; they are armed with darts headed with a volcanic glass. They wear at the extremity of the natural parts the shell "bulla ovum;" and are otherwise entirely naked. The women have only a garment about the waist. They live chiefly upon cocoa-nuts, of which these isles have abundance. Their hair is curly, and of a black colour, which they sometimes reddish with ochre mixed with oil; many parts of the body are also thus painted, and especially the face. In these islands it was once hoped to find *La Perouë*.

The Archipelago of *Hermitis* is scarcely 14 leagues in circumference; it produces Cytherean apples, "*ippondia cytherea*,"

Therea,' and many frisks of different species of "Eugenia," all good to eat. The natives appear more mild and pacific than those of the Admiralty Isles, though they seem to be more robust. They are wholly naked, not even wearing the shell. All these islands, and those about them, are covered with trees. Labillardiere, Pinkerton. The most southerly point of New Ireland is situated in S. lat. 4 59'. E. long. 152° 17'.

IRELAND, one of the Bermuda islands.

IRELLY, a town of Hindoostan, in Golconda; 25 miles E. of Hydrabad.

IRENEUS, in *Biography*, a native Greek, probably of Asia, and bishop of Lyons, in Gaul, in the second century. The time of his birth, and the precise place of his nativity, cannot be satisfactorily ascertained. Dodwell refers his birth to the reign of Nerva, A. D. 97, and thinks that he did not outlive the year 190. Grabe dates his birth about the year 108. Dupin says that he was born a little before the year 140, and died a martyr in 202. Tillemont thinks that he was born about the year 120, and died in 202. It is generally allowed that he was educated in the principles of the Christian religion, and that he was a disciple of St. Polycarp; and it has been supposed that he came to Rome with his master, in the time of Anicetus, about the year 157, and from thence passed into Gaul. He was first presbyter of the church of Lyons, and succeeded Pothinus, after his martyrdom in the year 177, as bishop of that church. Tertullian mentions him as one of the most considerable writers of the Christian church, and says of him that he was "a diligent inquirer of all sorts of opinions;" meaning, probably, that he had well studied the sentiments of the heathen philosophers, and of heretics, as well as the principles of the Christian religion. It has been commonly said that Ireneus died a martyr; but from the silence of Tertullian and Eusebius, and others, concerning the manner of his death, it is justly argued (says Lardner) by Cave, Bafnage, and Dodwell, that this supposition is not well founded, and that he closed his life in the ordinary course of nature. He was the author of many works, of which none are now extant besides his five books "Against Heresies," and fragments of some other pieces; and those five books, written by him in Greek, now exist only in an ancient Latin version, excepting some fragments preserved by Eusebius, and other Greek writers who have quoted them. In this large work "Against Heresies," Ireneus has shewn that he was well acquainted with heathen authors, and the absurd and intricate notions of heretics, as well as with the scriptures of the Old and New Testament, which he has frequently and copiously cited with peculiar and very distinguished respect. In his writings "we have full, express, and abundant testimony to the four gospels, the acts of the apostles, and twelve of Paul's epistles. The omission of the epistle to Philemon may well be ascribed to its brevity. He knew the epistle to the Hebrews, but was not satisfied that it was Paul's. As for the Catholic epistles, we have express quotations of the first of Peter, and the first and second of John; and the reason of not quoting the third may be well allowed to be its brevity. But to the epistle of James, the second of Peter, and the epistle of Jude, there are none, or very obscure references, hardly any that can be reckoned material. Nevertheless, on account of a general passage concerning the writings of the apostles, it may be questioned, whether he did not also know the epistles of James and Jude. The book of the Revelation is expressly ascribed to John, the disciple of the Lord. His testimony for this book is so strong and full, that, considering the age of Ireneus, he seems to put it beyond all

question, that it is the work of John the apostle and evangelist.

Ireneus appears to have been very humble and modest, and agreeable to his name (formed of *irene*, peace, a lover of peace. This is manifest in his letter to Victor, on occasion of the controversy about the time of keeping Easter. Although his writings may not be free from imperfections, he has given such proofs of learning, integrity, and good sense in the main, that all good judges must esteem him an ornament to the sect to which he belonged. The works of Ireneus were first published at Basil by Erasmus, in 1526, in folio; and they have since undergone various impressions. The most valuable of these are that of Grabe, published at Oxford in 1702, folio; and that of Maffius, a Benedictine of the congregation of St Maur, published at Paris in 1710, folio. Fabricius. Cave. Dupin. Lardner, in his Works, vol. ii.

IRENARCHA, *ἱρεναρχα*, composed of *irene*, peace, and *arche*, prince, from *αρχη*, command, a military officer in the Greek empire, whose business was to provide for the peace, security, and tranquillity of the provinces.

In Justinian's code it is mentioned, that irenarchæ are sent into the provinces to maintain the public peace, by punishing crimes, and putting the laws in execution.

Besides this there was another irenarchæ in the cities, to whom belonged the preserving of peace, and quelling sedition among the citizens. This officer was sometimes called *presertus urbis*.

The emperors Theodosius and Honorius suppressed the office of irenarchæ, on account of their abusing their trust, and distressing and persecuting the people, instead of maintaining peace among them.

IRENE, in *Biography*, empress of Constantinople, born in the year 752, was an Athenian orphan, but being distinguished by her great accomplishments she was married, at the age of 17, to Leo, son of the emperor Constantine V. This prince afterwards sat upon the imperial throne as Leo IV. and at his death, in 780, left his wife guardian of their son, Constantine VI. then but 10 years old. During his childhood, Irene most ably and assiduously discharged, in her public administration, the duties of a faithful mother; and her zeal in the restoration of images, has given her the title and honours of a saint, which she still holds in the Greek church. As the young emperor attained the maturity of youth, the struggle for power between him and his mother was carried on with the utmost ardour. He listened to his favourites, who shared his pleasures, and were ambitious of his power, and was convinced of his right, and of his ability to reign, and determined to reward the services of his mother by a perpetual banishment to the isle of Sicily. She, on the other hand, saw through his projects in time to frustrate, for the present, his plans. The contest, however, was not over; and the soldiers determining for the prince, he was proclaimed lawful emperor, and his mother was dismissed to a life of solitude. Here she excited a powerful conspiracy against Constantine, and, in 797, not only dethroned him, but most barbarously caused him to be deprived of his sight. After this she entered Constantinople in a chariot of state, attended by several patricians as her slave, and assumed the reins of empire. "But these patricians," says Gibbon, "were for the most part eunuchs; and their black ingratitude justified, on this occasion, the popular hatred and contempt. Raised, enriched, entrusted with the first dignities of the empire, they basely conspired against their benefactress: the great treasurer Nicephorus was secretly invested with the purple; her successor was introduced into the palace, and crowned at St. Sophia by
the

the venal patriarch. In their first interview, she recapitulated with dignity the revolutions of her life, gently accused the peridy of Nicephorus, insinuated that he owed his life to her unspurious clemency, and, for the throne and treasures which she had resigned, solicited a decent and honourable retreat. His avarice refused this modest compensation; and, in her exile in the isle of Lesbos, the empress earned a scanty subsistence by the labours of her distaff." In this forlorn condition she died in the succeeding year. Her zeal for orthodoxy, and her liberality to the church and the poor, have, in the eyes of ecclesiastical historians, almost wholly obliterated her savage cruelty and injustice towards her son. It is universally admitted that she was endowed with a strong understanding, and with great talents for government. Univ. Hist. Gibbon.

IRÉSINE, in *Botany*, is derived from *iris*, wool, because this plant, when it bears fruit, is covered with a sort of woolliness. *Erythraea* was the appellation of an olive-branch entwined with wool, such as was customary for the Greeks to hang up in their houses, in order to avert a vaine.—Linn. Gen. 521. Schreb. 687. Mart. Mill. Dict. v. 2. Browne Jam. 358. Swartz Obs. 376. Juss. 88. Lamarek Dict. v. 3. 202. Illustr. t. 813.—Class and order, *Diercia Pentandria*. Nat. Ord. *Holeraceae*, Linn. *Amarantibi*, Juss.

Gen. Ch. Male, Cal Perianth of two leaves, very small, acute, shining. Cor. Petals five, sessile, lanceolate, erect; nectary of five scales, the filaments being interposed. Stam. Filaments five, erect; anthers roundish. Female, Cal, and Cor. like the male. Pisl. Germen ovate, superior; stylenone; stigma two, roundish. Peric. none, except the permanent calyx. Seeds few, downy.

Ess. Ch. Calyx two-leaved. Corolla of five petals. Male, Nectaries seven. Female, Stigmas two, sessile. Seeds woolly.

Obf. Professor Swartz has remarked that he never found this plant but with hermaphrodite flowers. He is of opinion that the plant described by Browne might be a distinct species with diocious flowers. Swartz also says that *Irifine* is so closely allied to *Celosia*, that it almost appears to be a species of this latter genus.

1. *I. clostoides*. Linn. Sp. Pl. 1456. (Amarantus panicula flavicente gracili hololeucea; Sloan. Jam. v. 1. 142. t. 90. f. 2.)—A native of Virginia and the West Indian islands, particularly Jamaica.—Root perennial. Stems varying in height from two to ten or twelve feet, jointed, furrowed, divided at the top. Branches opposite, a little spreading. Leaves opposite, on foot-stalks, lanceolate or nearly ovate, acute, smooth. Panicles terminal. Flowers in a sort of spike, small, ovate, whitish, fealy at their base. Filaments shorter than the corolla; anthers yellow. The calyx resembles a capsule, inclosing one or more black shining seeds. A white wool is protruded from between the segments when the time of flowering is past.

We suspect that another species of this genus, with narrower leaves, is found in Jamaica.

IRETON, HENRY, in *Biography*, a celebrated commander and statesman of the parliamentary party in the civil wars of Charles I., was descended of a good family, and brought up to the profession of the law. In the contents of the period in which he flourished, Ireton joined the parliament army, and by his superior talents, and the interest of Cromwell, whose daughter he married, rose to the high office of commissary-general. At the famous battle of Naseby he was wounded and taken prisoner. By his address he soon obtained his liberty, and had a great share in all those political transactions which threw the parliament into the power of the army, and afterwards changed the consti-

tution from a monarchy to a republic. His councils had great influence with his father-in-law; and his education as a lawyer caused him to be employed in drawing up many of the public papers of his party. From his suggestion, Cromwell secretly called, at Windfor, a council of the chief officers, in order to deliberate concerning the settlement of the nation, and the future disposal of the king's person, and he had a principal hand in framing the ordinance for the king's trial, at which he sat as one of the judges. Through his instigation Fairfax put to death, by martial law, Lucas and Lisle, taken at the siege of Colchester. This unusual severity was loudly exclaimed against by all the prisoners. Lord Capel reproached Ireton with it; and challenged him, as they were all engaged in the same honourable cause, to exercise the same impartial vengeance upon all. Ireton accompanied Cromwell to Ireland in 1649, and in the following year was left by him in that island as lord-deputy. Having finished his military career with the capture of Limerick, he was seized with a peffilential disease in that place, of which he died in November 1651; sincerely lamented by the republicans, who revered him as a soldier, a statesman, and a saint. According to Hume, he was "ferce in his nature, though probably sincere in his intentions; he proposed, by arbitrary power, to establish liberty, and in the prosecution of his imagined religious purposes, he thought himself dispensed from all the ordinary rules of morality, by which inferior mortals must allow themselves to be governed." And again he was "much celebrated for his vigilance, industry, and capacity, even for the strict execution of justice in that unlimited command which he possessed in Ireland. He was observed to be inflexible in all his purposes, and it was believed by many that he was animated with a sincere and passionate love of liberty, and never could have been induced by any motive to submit to the smallest appearance of regal government. In gratitude for his great public services, the parliament voted an estate of 2000*l.* per ann to his family, and honoured him with a magnificent funeral at Westminster Abbey, a circumstance which, if he could have foreseen, says Ludlow, "he would certainly have made it his desire that his body might have found a grave where his soul left it; so much did he despite those pompous and expensive vanities; having erected for himself a more glorious monument in the hearts of good men, by his affection to his country, his abilities of mind, his impartial justice, his diligence in the public service, and his other virtues." Ludlow's Memoirs. Hume Hist. Life of Cromwell in the Biog. Brit.

IREW, in *Geography*, a town on the S.E. coast of the island of Timor. S. lat. 8° 45'. E. long 126° 5'.

IRGANONG, a town of Hindooistan, in Baglana; 2 miles S.E. of Saler Moular.

IRGISKOE, a town of Russia, in the government of Saratov, situated on the Irgis, which runs into the Volga, near Volk; 96 miles E. of Volk.

IRI, a town of Africa, in the kingdom of Congo.

IRJAB, a town of Candahar, taken by Timur Bec in 1398; 46 miles S.E. of Cabul. N. lat. 33° 50'. E. long. 69° 8'.

IRIARTE IGONACTO, in *Biography*, a Spanish painter of landscapes, of whom Murillo said, that he would only ascribe the beauty of his works to divine inspiration. He was secretary to the academy at Seville, where he died, in 1685.

IRIDES, in *Botany*, the 18th natural order in Jussieu's System, and the 8th of his 3d class. It is equivalent to the *Enfate* of Linnaeus, which latter appellation is properly, in our opinion, retained by Mr. Gawler (now Ker), in his

illustration of this order; see *ESAUZE*.—Its characters are thus given, the character of the claws being *monocotyledonous, with filaments inserted into the calyx or corolla*.

Corolla, which Jussieu terms *calyx*, suppuric, coloured, tubular at the base, its limb in six more or less deep segments, equal or unequal. *Stamens* three, inserted into the tube, opposite to three alternate segments of the flower, their filaments distinct, or rarely united into a tube embracing the style. *Germen* inferior; with a three-lobed and three-fold stigma. *Capsule* inferior, of three cells, and three valves, with many generally roundish seeds.

Root either fibrous, tuberous, or bulbous. *Stem* mostly herbaceous, leafy, rarely almost woody. *Leaves* alternate, flexible, mostly sword-shaped. *Flowers* growing out of sheaths, either solitary, or many together, which sheaths often consist of two valves.

The leading genera in Linnæus and Jussieu are *Syzyriacium*, *Iris*, *Lilia*, *Glaucium*, *Antholyza*, *Crocus*, &c. which Mr. Ixer has greatly subdivided. See *HESPERANTHA* and *GLADIOLUS*.

IRIDIUM, in *Chemistry*, is a simple substance, and a metal. It was discovered by Mr. Smithson Tennant in 1803, and an account of it was published in the *Phil. Transf.* for 1804. It appears that, previous to its publication, the same discovery was made, to a certain degree, by Defocitil, which was afterwards taken up and enlarged upon by Fourcroy and Vauquelin.

Mr. Tennant found that the small black scales existing in crude platina, and which are left after the platina has been dissolved, contained two metals which had not been previously noticed. (See *PLATINA*.) He subjected the above substance to the alternate action of potash and muriatic acid, by which means he obtained two solutions. The black scales are heated to redness in a silver crucible, with their own weight of potash. When the heated mass has water added to it, the potash dissolves in combination with one of the metals, the solution being of an orange colour. The residuum being treated with muriatic acid, a solution is obtained, which at first is blue, then becomes olive green, and ultimately of a red colour, consisting of the acid united to the oxyd of the other metal. By this alternate treatment, the oxyd of osmium, the other metal alluded to, is dissolved in the potash, and the oxyd of iridium in the muriatic acid. The acid solution, on being evaporated to dryness, affords crystals of an octahedral form, which is, no doubt, a pure muriat of iridium. The solution of these crystals is of a deep red colour. When a plate of zinc, or any other metal, having a greater affinity for oxygen than itself, is placed in the solution, a black powder is precipitated, which, on being heated, becomes red, and puts on metallic lustre. This metal, like gold and platinum, has so little attraction for oxygen, that it may be obtained by exposing the crystals of its muriat to a strong heat. In fact that it is deemed pure iridium. It is a white metal, having the appearance of platina. Owing to its great insolubility, we are not acquainted with some of its physical properties, such as its specific gravity and malleability. It has not been fused by Mr. Tennant or the French chemists. It has, however, since been made to assume the liquid form, by means of the very intense heat produced by the large Galvanic battery lately exhibited at the Royal Institution by Mr. Davy. This heat was so great, that at the same time the earths alumina and zirconia were fused, and charcoal was volatilized.

It forms malleable alloys with several of the metals, a presumptive proof that it is itself malleable. Mr. Tennant found that it did not combine with arsenic, but that it easily united with lead; from which, like the noble metals, it may

be separated by cupellation. It forms malleable alloys with copper and silver. Its alloy, with gold, differs little from pure gold, even when the iridium is in considerable quantity. It appears to stand next above gold and platina in its affinity for oxygen. It may be infused, from the change of colour in the acid solutions, that it admits of at least two stages of oxydation. When the metal is in its pure state, it is not acted upon by any acid except the nitro-muriatic, and even this acid, according to Fourcroy and Vauquelin, dissolves only a small portion of its weight. Its combinations with the stannic acids, and with combustible bodies, have not been attended to. See *OSMIUM*.

IRIJU, in *Geography*, a river of Guiana, which runs into the Atlantic, N. lat. 6° 58'. W. long. 51° 30'.

IRINON. See *IRIS*.

IRIS, in *Anatomy*. See *EYE*.

Iris, *Prolapsus*, or *Procidantia*, in *Surgery*, denotes a protrusion of a piece of the iris through a wound, or ulcerated opening in the cornea, after the escape of the aqueous humour. To this disease several writers have applied the name of *staphyloma*; though, in all probability, the influence of Scarpa will in future confine the latter term to a morbid thickening and projection of the cornea itself, a case which will be described in its proper place. See *STAPHYLOMA*.

The prolapsus of the iris is produced by full wounds and ulcers of the cornea as penetrate the anterior chamber of the aqueous humour, and sometimes by blows, which have been so violent as to rupture the transparent membrane investing the fore-part of the eye. If the lips of a wound of the cornea (as, for instance, those of the incision practised in the extraction of the cataract, or in opening an hypopygium) are not immediately put into reciprocal contact, so as to keep the aqueous humour from running out of the anterior chamber, as fast as it is secreted, the iris, drawn by the current of this fluid towards the wound in the cornea, is urged between the lips of the incision, and, becoming elongated, projects upon the preceding membrane in the form of a small tumour. The same accident happens, when the globe of the eye receives a blow, or is too much compressed with a bandage, while a disinfused wound of the cornea exists. In such a case, likewise, the prolapsus of the iris might be produced by a violent spasm of the muscles of the eye, excessive and long continued vomiting, or repeated coughing. A prolapsus of the iris arises even more frequently from ulcers which extend through the cornea, than from wounds of that membrane; and Scarpa assigns as a reason for this fact, the loss of substance always attending the former cases. The little swelling mult of course be of the same colour as the iris, namely, brown or grey; and its base is surrounded by a small opaque scale, formed by the cornea that has been for some time detached or divided.

It seldom happens that more than one prolapsus of the iris exists upon the same eye, since it does not often occur that the cornea should be wounded in more than one place. However, we need not imagine that the iris is never protruded in several places at once; Scarpa has seen three distinct protrusions upon the same cornea, in consequence of three separate ulcers of that membrane.

Small as the tumour may be, (and, indeed, it is sometimes not larger than a fly's head,) it is nevertheless apt to give rise to very severe symptoms. Nor are we to wonder at this circumstance, as the iris is supplied with numerous blood-vessels and nervous filaments; and that part of it which is protruded is further excessive irritation, as well from the friction of the eyelids, as from the action of the air, tears, and other matter upon it. Besides, it is a fact, that the projecting piece of the iris inflames and swells soon

After its protrusion, and consequently it suffers a great deal more from the compression and irritation. The patient at first complains of a pain like that of a thorn in the eye, and is also afterwards affected with an uneasy sensation of tightness or constriction of the organ. To these complaints are then added an inflammation of the conjunctiva and eye-lids, discharge of irritating tears, and an inability to bear the light. The protruded piece of the iris unavoidably drags towards it the rest of this membrane; and hence the shape of the pupil is changed from round to oval, and its situation undergoes an approximation to the wound or ulcer, through which the prolapsus of the iris has taken place.

When the disease has prevailed a considerable time, the severity of the pain, inflammation, and other symptoms, is sometimes lessened, instead of increased. Scarpa informs us of such an example in a man, fifty years of age, who for ten weeks had had a prolapsus of the iris twice as large as a millet-seed. The patient bore the disease with the utmost indifference, being merely troubled with a slight chronic redness of the conjunctiva, and a difficulty in moving the eye ball with freedom. The little tumour felt to the finger hard, and almost callous.

In the treatment of this disease, some practitioners have recommended pushing the iris back again into its natural situation, by means of a whale-bone probe; and, in case of this being found difficult of accomplishment, they have advised the wound or ulcer of the cornea to be dilated as far as necessary, in the same manner as the stricture of a strangulated hernia is divided, for the purpose of enabling the surgeon to reduce the protruded bowels. Others have suggested irritating the projecting portion of the iris, in order to make it contract and return into its proper place again; and, with the same intention, it has been proposed to expose the eye suddenly to a very vivid light. The experienced and judicious Scarpa, however, sets down all these methods as ineffectual, if not dangerous; for, says he, admitting that we could, in any of these ways, replace the iris, without lacerating or hurting it, still there would continue in the wound or ulcer of the cornea an opening, through which the aqueous humour would escape, and carry out with it again a fold of the iris.

It cannot be denied that a prolapsus of the iris is a most unpleasant kind of accident; but yet, as we are utterly unpossessed of any means whereby we can stop the escape of the aqueous humour through certain wounds and ulcers of the cornea, we ought, according to Scarpa, to consider the prolapsus of the iris a beneficial occurrence, and preventive of the total destruction of the eye, inasmuch as the protruded fold of this membrane, acting like a plug, prevents the entire loss of the aqueous humour, which soon collects again in the anterior chamber, and hinders a further protrusion of the iris, by separating this membrane from the cornea, and re-establishing the equilibrium between it and the other humours of the eye. Hence Scarpa reprobates the foregoing plans as useless and dangerous.

The principles laid down by this eminent surgeon tend to establish two chief indications, in cases of recent prolapsus of the iris: one is to diminish the extreme sensibility of the piece of the iris projecting out of the cornea; the other is to effect a gradual destruction of the protruded portion of the iris, to such a depth as will render the wound or ulcer capable of healing, but not so deeply as to break the adhesion which the iris has contracted to the bottom of the breach in the cornea.

Both these indications may be fulfilled by touching the projecting part of the iris with the antimonium nigratum, &c., with what is still preferable, the argentum nitratum.

An assistant, standing behind the patient's head, is to keep the upper eye-lid raised with Peller's elevator; and the patient is to hold his eye as steady as possible, by fixing it on one object. While the assistant raises the upper eye-lid, the surgeon is to depress the lower one with the index and middle fingers of his left hand, and with his right touch the protruded piece of the iris with the argentum nitratum, cut in the shape of a crayon. The caustic should be pressed upon the centre of the little tumour, so as to form an eschar of the proper depth. The pain suffered at this instant is exceedingly severe; but it quickly subsides, as soon as the eye has been bathed with warm milk. The caustic expeditiously destroys the sensibility of the protruded part of the iris, and the eschar prevents the effects of the friction of the eye-lids, and hinders the air and tears from causing any irritation of the projecting portion of that membrane. Hence the pricking and painful tension, previously felt in the eye, are diminished; as likewise are the ophthalmia and secretion of scalding tears.

The benefit thus produced lasts only as long as the eschar continues adherent to the tumour formed by the iris. Immediately the slough is detached, all the annoying complaints again come on, though in a somewhat mitigated degree, in consequence of the projecting part of the iris not being quite so prominent as it was before the caustic was applied. The eschar frequently separates on the second or third day; but whenever it happens, the painful symptoms recur; and the surgeon's duty is to use the argentum nitratum again without delay. The application is in this way to be repeated, until the protruded part of the iris is destroyed so deeply, that it can no longer hinder the wound or ulcer of the cornea from healing.

The employment of the argentum nitratum must not be continued, after the prolapsus of the iris has been sufficiently depressed; as we learn from Scarpa, that such a plan would bring on all the pain and inflammation again in an aggravated form. When the little tumour has been levelled as much as the indication requires, the caustic is not to be applied again; and the surgeon is simply to introduce between the eye and eye-lids a collyrium, containing sulphate of zinc and mucilage of quince-seeds, and afterwards insinuate a small quantity of the following ointment under the eye-lids, every morning and evening:

R. Adipis suille ʒʒ.
Tutivæ ppt.
Bol. Armen. subtilissimæ pulv. ā ā ʒij.
Calcis hydrarg. alb. ʒj. Misce.

This ointment must be at first weakened with twice or thrice its quantity of lard.

When the foregoing applications are not too stimulating, the ulcer is gradually diminished, and generally quite healed in about a fortnight.

As the union, which takes place in the course of the treatment, between the protruded piece of the iris and the internal edges of the wound, or ulcer, of the cornea, always continues after the cure is completed, the pupil must for ever remain of an oval shape, and a little inclined towards the cicatrix in the cornea. This must happen even when the treatment has been as successful as possible. It is pleasing, however, to learn from the experienced Scarpa, that such alteration in the situation and position of the pupil causes little or no diminution of the power of seeing the most minute objects, and occasions much less impairment of the sight than might be supposed, unless it unfortunately happen that the scar in the cornea is in the middle of it. Besides, we are also assured by the same distinguished surgeon, that

That the power of dilating the iris is the iris injured, inasmuch as the pupil, which was in the beginning of the disease narrow and oblong, becomes afterwards more capacious. This fact is likewise confirmed by Richter in his *Opf. Clair. facieul.* i. p. 82.

Scarpa has found the preceding treatment more successful than any other, not excepting the method of cutting off the protruded part of the iris with a pair of scissors. This last plan, he thinks, is only advantageous when the iris is strongly adherent to the internal lips of the wound or ulcer of the cornea, or when the prolapsus has existed a long while, and the projecting portion of the iris has become indurated and callous, while its base, constricted by the edges of the wound, or ulcer of the cornea, not only adheres to them, but has put on the appearance of a kind of pedicle. Scarpa, indeed, has seen one instance, where the little tumour fell off of itself in consequence of the compression made upon its neck by the edges of the ulcer of the cornea.

IRIS, Imperforate. See PUPIL, *Closure of.*

IRIS, in Botany, of the ancient Greeks, so named from the various, and somewhat concentric, hues of the flower, which give an idea of the rainbow. The modern Greeks call it *κίβω*, and the Turks *fusen*, both which words are synonymous with our *Iris*, and the French *lis*, or *flour-de-lis*—Linn. Gen. 27. Schreb. 36. Willd. Sp. Pl. v. 1. 224. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 1. 115. Sm. Fl. Brit. 41. Juss. 57. Lamarck. Illustr. t. 33. Gærtn. t. 13.—Class and order, *Triandria Monogynia*. Nat. Ord. *Enfilae*, Linn. *Irides*, Juss.

Gen. Ch. *Cal.* Spathas of two valves, separating the flowers, permanent. *Cor.* in six deep segments, united into a tube by their narrow bases; each oblong, obtuse; the three outermost reflexed, three inner erect and most acute. *Stam.* Filaments three, awl-shaped, lying on the reflexed segments of the corolla, and not half so long; anthers vertical, oblong, straight, depressed. *Pist.* Germen inferior, oblong; style simple, closely enfolded by the tube of the corolla; stigmas three, each with a petal-like, dilated, oblong appendage, keeled on the inside, furrowed at the outer, lying over each stamen, two-lipped, the lower lip small and notched, upper larger, cloven, slightly reflexed. *Peric.* Capsule oblong, angular, of three cells and three valves. *Seeds* several, large, more or less compressed and angular.

Eff. Ch. *Corolla* in six deep segments, alternately reflexed, superior. *Stigmas* with a petal-like two-lipped appendage.

Obf. Botanists have differed about the really efficient part of the stigmas of the *Iris*. The whole petal-like expansion was supposed by Linnaeus and his followers to be the actual stigma, or at least they had no precise idea of the exclusive action of any particular part. The late Abbé Cavanilles conceived the pollen to be received into a tubular opening between the base of each stamen and the extremity of the style, and there to perform its office. Kölreuter and Sprengel, with much more probability, believe the upper or inner surface of the small lower lip of the petal-like expansion, which is glandular in that part, to be the real stigma, and the latter has curiously explained the mode in which bees convey the pollen to this spot. See Sims and König's *Annals of Botany*, v. 1. 412. The stigma of several species of *Moraea* comes very near that of *Iris*, and there has always been some ambiguity between these two genera, which we shall endeavour to remove when we come to *MORAEA*.

Iris is a large and very natural genus. Tournefort subdivided it into several by the roots, which in some species are tuberosus, in others bulbous. Some moreover have the

upper surface of the reflexed segment of the corolla smooth, while in others that part is beautifully bearded.

In the *Species Plantarum* of Linnaeus are 22 species; in *Syst. Veg.* ed. 14. twice that number. Theuberger, who wrote a dissertation on this genus, having greatly augmented it. Pallas discovered many new species in the Siberian travels. Willdenow has 54 in all. Mr. Ker differs from the latter in the arrangement of many of them, even European ones, which he removes to *Moraea*, and 114 in all, as explicitly by Mr. Dryander in the new edition of the *Flora Rossica*. The whole is divided into 12 orders.

* *Root thick, foliil, horizontal. Flowers beardless.*
Of this the common English *I. setosa*, Linn. Bot. t. 578, less accurately figured by Curt. Lond. Bot. t. 3. 12, is an example. It grows in watery places, flowering in July, and like every known *Iris* is perennial. The flower is bright yellow, streaked with darker lines.

* *Root thick, foliil, horizontal. Flowers bearded.*

To this section belong many of our garden kinds, as *I. fufiana*, Curt. Mag. t. 91, or Chalcædonian *Iris*, so remarkable for its large flower, elegantly pencilled with black; *I. cristata*, Sm. Spicil. t. 13, found in America; as well as the well-known *I. variegata*, *fambucina*, *florentina*, and *germanica*, natives of the north of Europe.

*** *Root knobby. Flowers beardless.*

This contains only *I. tuberosa*, Fl. Græc. Sibth. t. 41, Curt. Mag. t. 531, known by its quadrangular leaves and singularly dark flower.

*** *Root bulbous. Flowers beardless.*

Here are found the pretty *I. Xiphium*, Curt. Lond. t. 686, which decorates many a cottage garden with its sweet blue and yellow blossoms; *I. perfoliata*, Curt. Mag. t. 1, more delicately coloured; and, to some persons, exquisitely scented, though to others it is scentless; and *I. Sibiricum*, Fl. Græc. Sibth. t. 42. Redout. Liliac. t. 29. The last is referred by Mr. Ker to *Moraea*.

IRIS, in Gardening, contains plants of the fibrous, tuberosus, and bulbous-rooted, showy, herbaceous, perennial kinds; of which the species cultivated are very numerous; but the following are some of the principal; the dwarf *iris* (*I. pumila*); the Chalcædonian *iris* (*I. fufiana*); the Florentine *iris* (*I. florentina*); the twice-flowering *iris* (*I. biflora*); the leafless *iris* (*I. aphylla*); the variegated *iris* (*I. variegata*); the German *iris* (*I. germanica*); the elder-scented *iris* (*I. fambucina*); the brown-flowered *iris* (*I. fqualens*); the crested *iris* (*I. cristata*); the trid-petalled *iris* (*I. tricuspis*); the bulbous-rooted *iris* (*I. xiphium*); the common yellow, or water-*iris* (*I. pseud-acorus*); the tinkling *iris* (*I. foetidissima*); the Virginian *iris* (*I. virginica*); the various-coloured *iris* (*I. versicolor*); the pale-yellow *iris* (*I. ochroleuca*); the spring *iris* (*I. verna*); the Persian *iris* (*I. persica*); the grass-leaved *iris* (*I. graminea*); the spurious *iris* (*I. spuria*); the Siberian *iris* (*I. sibirica*); the Martineo *iris* (*I. martinicensis*); the peacock *iris* (*I. pavonia*); and the snake's-head *iris* (*I. tuberosa*).

The first of these sorts has varieties with white flowers; with straw-coloured flowers; with pale-blue flowers; with bluish-coloured flowers; with yellow variable flowers; and with blue variable flowers.

The ninth sort has likewise varieties with blue standard's and purple falls; with pale-purple standard's; with white standard's; and with a smaller flower.

The eleventh species also varies greatly in the shape of the larger petals, as well as in the colours, as blue, purple, yellow, white, and spotted.

And the twelfth sort furnishes varieties with blue flowers; with violet-coloured flowers; with white flowers; with pur-

ple flowers; with yellow flowers; with blue standard petals and white falls; with blue standards and yellow falls; with striped flowers; the broad-leaved with blue flowers; the broad-leaved purple flowered; the sweet-scented blue flowered; the sweet-scented purple flowered, with variegated feet-feet flowers, and the double flowered.

The nineteenth fort, or Persian iris, is greatly esteemed for the beauty and extreme sweetness of its flowers, as well as for its early appearance in the spring, being generally in perfection in February or the beginning of the following month, according to the state of the season. And Martyn notices that, to raise the hyacinth and narcissus, it will blow within doors in a water-glass, but stronger in a fossil vat of sand, or sandy loam, and that a few flowers will feed a wick for a month.

Manner of Culture.—Most of the forts may be readily increased by parting the roots, or separating the offsets from the bulbs, and planting them out in the situations where they are to flower; the best fort in the autumn, or very early in the spring, and the latter in the close of summer, when the leaves decay, managing them in the same manner as the bulbous forts. As they increase and spread rapidly in their growth, they should be divided and taken off every two or three years.

New varieties of the different forts may be raised from seed, by sowing it in the autumn in a bed of light sandy mould. The plants come up in the following spring, and in the autumn may be transplanted where they are to grow. They flower a year or two afterwards in this climate.

The bulbous-rooted forts succeed best in such soils as are of the light, sandy, loamy kind; but will succeed in any that are dry.

The lill fort answers most perfectly in such aspects as are towards the east, the roots being prevented from going too deep in the ground.

As the second fort is liable to be injured by severe winters, a few should be planted in pots to have protection. This fort is well suited for forcing, in houses for the purpose.

When planted in the open ground, it requires a rather dry soil and situation to succeed in a proper manner.

The Cape forts should be maintained in the dry flow, and be propagated and managed in the same manner as other bulbous-rooted plants of the same kind.

All the forts are proper for affording variety in the borders, clumps, and other parts of pleasure grounds; and some of the more tender forts among potted plants of similar growth and habits.

Iris, in the *Materia Medica*. The *Iris florentina*, Florentine orris, or iris, is a native of Italy, and flowers in June; it was cultivated in England by Gerard in 1596, and is now constantly propagated by the florists; but the roots of the orris produced in this country have neither the odour, nor the other qualities of those of the warmer climates; so that for medicinal use they are commonly imported from Leghorn. In its recent state, the root is extremely acid, and when chewed, excites a pungent heat in the mouth, of several hours' duration. When dried, this acrimony is almost wholly dissipated. The taste is slightly bitter, and the smell is agreeable, approaching to that of violets. No essential oil has hitherto been obtained from this root; but spirituous tinctures of it contain more of its virtues than watery infusions. The fresh root is a powerful cathartic, and for this purpose its juice has been employed in the dose of a dram and upwards in droppings. It is now chiefly used in its dry state, and ranked as a pectoral or expectorant; though there is no evidence of its expectorant powers; and therefore it is now

considered as valuable only for the pleasantness of the perfume, and the flavour which it communicates.

The *Iris p'su-acorus*, *psylliris*, or *psylliris lutea*, *Acorus adulterinus*, yellow water-flag, or yellow water flower-de-luce, is common in marshes, and on the banks of rivers, and rendered very conspicuous by its large yellow flowers, which appear in the beginning of July. It had formerly a place in the Lond. Pharm. under the name of "*Clavibus luteis*." The root has no smell, but an acid styptic taste, and its juice, snuffed up the nostrils, produces a burning heat in the nose and mouth, accompanied with a copious discharge from these organs; and hence it is recommended by the ancients as an erethic and astringent. The root is much powerful astringent, that it has been used instead of galls in the making of ink, particularly in Scotland. For this purpose the common people cut some of the roots into thin slices, and either boil or infuse them in water till the liquor is highly tinged with blue; they then pour it clear off; and putting into it the blade of a knife, or any other piece of iron, they rub it hard with a rough white pebble, common there, and by degrees the liquor becomes black; they continue rubbing it till it is as deep a black as they require, and it is a tolerable good ink. (Phil. Trans. N^o. 117.) This root has also been used for the purpose of dyeing black; and from this quality it has been successfully employed as a medicine for the cure of diarrhoeas. When given with this intention, the root is to be well dried; for the fresh root and its juice are strongly cathartic, inasmuch that eighty drops of the latter produced repeated evacuations, after jalap, gamboge, &c. had failed, and by continuing its use in an increased dose, it cured an inveterate dropsy. Hence Bergius says, "*virtus recant. hydragoga, pungen. siccat. adstringens*." The expressed juice is likewise said to be an useful application to serpiginous eruptions and scrophulous tumours. (Woodv. Med. Bot.) The root of this plant is recommended by Brookes as a remedy for the tooth-ache.

IRIS, Rainbow, in *Physiology*. The word is Greek, *iris*, supposed by some to be derived from *iris*, *I speak, I tell*, as being a meteor, that is supposed to foretell, or rather to declare, rain. See RAINBOW.

IRIS is also applied to these changeable colours which sometimes appear in the glasses of telescopes, microscopes, &c. so called from their similitude to a rainbow. The same appellation is also given to that coloured spectrum, which a triangular prismatic glass will project on a wall, when placed at a due angle in the sun-beams.

IRIS is also a name given by some authors to a peculiar species of sprig crystal, remarkable for its giving the rainbow colours in reflection. This, however, being a property more or less found in all the kinds of sprig crystal, and thence much resembling one another, it became applied to sprig crystal in general; and iris, instead of being the name of a peculiar species, was understood as a synonymous term for common crystal.

IRIS Marina, the *Sea-rainbow*. This elegant appearance is generally seen after a violent storm, in which the sea-water has been in vast emotions. The celestial rainbow has great advantage over the marine one in the brightness and variety of the colours, and in their distinctness one from the other; for in the sea-rainbow there are scarcely any other colours than a dusky yellow on the part towards the sun, and a pale green on the opposite side. The other colours are not so bright or distinct as to be well determined, but the sea-rainbows are more frequent and more numerous than the others. It is not uncommon to see twenty or thirty of them at a time at noon-day. Observ. sur l'Asie, p. 292.

IRIS Plants, Petrified, in Natural History. In Dr. Grew's Catalogue of the Rarities of Gresham College, p. 274, he mentions a petrified iris-root; a stone somewhat flat, but radiated from the central part, the polished end of which, when wetted, shewed these radiations very fine: this extraneous fossil probably belonged to the coralline tribe, instead of being a root. In Dr. Lench's account of the fossil plants, found in the coal-pits at Burnley in Lancashire, he mentions iris: long narrow leaves, resembling those of flag, and so called in general, are common in coal strata; these kinds of leaves in the great-stone quarries in Derbyshire are often called swords, from the resemblance of their impressions in the stone to the point of a sword.

IRISH SEA, in Geography, the name of that part of the Atlantic ocean, which is between the coasts of Ireland and Great Britain.

IRISH Terms. See TERMS.

IRKINEEVA, in Geography, a town of Russia, in the government of Tobolsk; 160 miles E.N.E. of Eniseisk. N. lat. 58° 50'. E. long. 96°.

IRKUTSK, a town of Russia, and capital of a government, to which it gives name, on the Angara, near the lake Baikal, the see of a Greek archbishop, and a place of considerable commerce; the caravans which trade to China passing through it. N. lat. 52° 4'. E. long. 95°.

IRKUTSKOI, a government of Russia, containing all that part of Siberia which lies beyond the 107th degree of east longitude; bounded on the N. by the Frozen sea, on the E. by the N. Pacific ocean, on the S. by China's Tartary, and on the W. by the governments of Kélian and Tobolsk. It is the most extensive, but least populous of all the Russian governments, and is divided into the four provinces of Irkutsk, Nertchinsk, Yakutsk, and Ochotk, so called from the four principal towns.

IRMA-HASSAR, a town of Asiatic Turkey, in Natolia; 45 miles S.E. of Callamena.

IRNEE, a town of Hindoostan, in the circar of Mahur; 58 miles N. of Mahur.

IRNERIUS, in Biography, sometimes called Wernerius, a celebrated jurist of the twelfth century, was probably born at Bologna. He first taught philosophy in that city, and acquired much distinction by being the first who opened a school for lectures in the Roman law in Italy, after its interruption by the invasions of the barbarous nations. He also composed glosses upon the Roman law, not only upon the Code and Institutions, but upon the Digest. He obtained great reputation by his labours; and the name of Wernerius, in a plea of the counts Matilda, in 1113, stands before that of any other of the lawyers. The same circumstance is found in the pleas of the emperor Henry IV. from the year 1116 to 1118, which proves that he attended the court of that monarch in his professional capacity. In 1118 he accompanied Henry to Rome, where he was employed to persuade the Romans to the election of the anti-pope Burdina. He died about the year 1150; and is said to have introduced the degree of doctor into the university of Bayle.

IRON, Elyn, Germ. Fer, Fr. Ferrum, Lat. Ferro, Ital. Ferro, Sp. I. Hierro, Dan. Vas, Hung. Hierro, Span. Julazs, Russ. Ferro, Port. Sidero, Gr. ἴσχυρ (Bharzel, or Ferzel), H. b. Mars, Alchem.

The use of this metal is of very high antiquity, though no so remote, there is reason to believe, as that of either gold, silver, or copper. The inferior brilliancy of its colour may, perhaps, in some degree, account for this circumstance;

as well as the greater skill required to obtain it from its ores, and convert it to the purposes of art. It is mentioned frequently in the pentateuch; and was, in the time of the celebrated writer of that history, employed for the fabrication of swords, knives, and various other sharp-edged instruments. We may form some estimate of the value that was then attached to it, from an expression in the eighth chapter of Deuteronomy, where Moses tells the Israelites, in his descriptive eulogy of the Land of Promise, that it is "a land whose stones are iron, and out of whose hills they may dig brass." A circumstance, illustrative of the same fact, at a later date, is furnished about 400 years subsequent to that period, when Achilles proposed a ball of iron as one of the prizes to be distributed to the victors at the games instituted in honour of Peleoclus. (Pausan. 7.) The art of working it appears, in the course of a few succeeding centuries, to have arrived at considerable perfection; for, according to the information of Herodotus (Clio xxx.), a furnace of the metal, very curiously inlaid, was presented by Alyattes, king of Lydia, to the Delphic oracle, which, he says, "is of surpassing workmanship, and as worthy of observation as any of the offerings preserved at Delphi." The durability of iron, and its indispensable assistance in the preparation of every other metal, make it one of the most valuable possessions that has been bequeathed to the use of civilized man. "Without it," observes Fourcroy, "agriculture could not have existed, nor could the plough have rendered the earth fertile. The philosopher, while he studies the progress of the human understanding, and compares the fortune and state of the different nations established on various portions of the surface of the globe, will remark, that their iron-works seem, in some measure, to be proportioned to their intelligence, to the advancement of reason amongst them, and the degree of perfection to which the arts have arrived. When we consider it in this point of view, as the agent by which men, in the variety of its uses, and the numerous wants it supplies, acquire enjoyments which would be unknown to them if they did not possess these products of their industry, iron most singularly contribute to extend their ideas, to multiply their knowledge, and to conduct their spirit towards that perfectibility, which nature has given no less, as the character of the human species, than as the source of all the advantages it can enjoy." Syst. vol. 6.

Iron is a malleable and ductile metal, of a bluish-white colour; is susceptible of a very high polish, and of the specific gravity, according to the tables of Muschenbroeck, Swedenburg, and Brisson, of from 7.600 to 7.895, and even 8.166. It is soluble in moist acids, and precipitable from its combination with them, by various re-agents, which will be hereafter pointed out. With the Prussic acid it forms that beautiful pigment known in commerce, and the arts, by the name of *Prussian blue*; and in a variety of other ways, constitutes the basis of many valuable preparations. The combinations under which it is exhibited to us in nature are detailed in the following section.

§ 1. Ores of Iron.

Sp. 1. Native iron. Gediogen-eiszn. Fer natif. Ferrum nativum.

Its colour is steel-grey, passing to silver-white. Occurs only in a ramose form; the masses alluded to by Brochant and others being now considered of meteoric origin. Surface glittering. Internally it is intermediate between glittering and glimmering; and its lustre metallic. Fracture hackly. It is rather soft, is completely malleable, and flexible without being elastic. Sp. gr. 7.8.

A spe-

A specimen from a mine near Kaindorf, in Saxony, yielded, according to Klaproth,

Iron	92.5
Lead	6.0
Copper	1.5
	100.0

The varieties which contain nickel are meteoric.

It is found in detached masses, which are usually covered with an oxyd of a brownish colour.

The places of its occurrence are Kaindorf and Eibenstock, in Saxony; Oulle, near Grenoble, in France; and some others.

Sp. 2. *Iron Pyrites. Schwarz-filices. La Pyrite Sulfureuse. Ferrum Mineralisatum Pyriticum.*

This very abundant mineral is divided by Werner into five subspecies, common, radiated, capillary, hepatic, and cellular.

Subsp. 1. *Common Pyrites.*—Colour bronze-yellow, passing sometimes to gold-yellow. Occurs massive and disseminated. It is very frequently also crystallized. Its forms are the cube, either perfect or truncated, the octahedron, dodecahedron, and sometimes, though very rarely, the icosa-hedron. The crystals are in general small; except the cube, which is middle-sized. Their surface is either smooth or streaked, and varies from glimmering to splendid. Internally it is shining or glistering; and its lustre metallic. Fracture even; sometimes conchoidal. It is hard, brittle, rather easily frangible, and heavy. Sp. gr. from 4.600 to 4.831.

Exposed to the blow-pipe, it exhales a strong odour of sulphur, and burns with a blueish flame. It afterwards passes into a globule, obedient to the magnet, of a brownish colour; and treated with glass of borax, communicates to it a tint of a dark dirty green. It appears to be composed of about 52.5 sulphur, and 47.5 iron.

Its occurrence is almost universal, both with reference to geographic arrangement, and the mineral formations in which it is presented.

Subsp. 2. *Radiated Pyrites.*—Colour bronze-yellow, of a paler hue than the preceding; passing sometimes to brass-yellow. Surface tarnished. Is found massive and reniform, also uniform, globular, and crystallized. The shape of its crystals is cubic, and octahedral; the latter being sometimes truncated on the angles. The external lustre varies between splendid and glistering. Internally it is glistering and glimmering. Fracture usually radiated; sometimes uneven and fibrous. Fragments uniform. Occurs in coarse and large-grained distinct concretions, also lamellated and columnar. It is hard, brittle, very easily frangible, and heavy, but less so than the foregoing subspecies. Emits a sulphureous odour when struck, or rubbed. Sp. gr. from 4.698 to 4.775.

Before the blow-pipe it exhibits the same appearances as common pyrites, and is constituted of about 54 parts of sulphur, and 46 of iron.

It is considerably rarer than the preceding, and is found in veins, particularly those which contain lead or silver.

The places of its occurrence are, amongst others, Cornwall and Derbyshire, in England; Arendal, in Norway; and in various districts of Suabia, Saxony, and Bohemia.

Subsp. 3. *Capillary Pyrites.*—Colour bronze-yellow, inclining more or less to steel-grey. Occurs in very fine capillary crystals. Lustre shining or glistering; metallic. Brittle, and in a small degree flexible. The smallest of its

crystals prevents a more particular account being given of its character.

Its chemical properties are the same as those of common pyrites.

It is never met with but in very small quantity, and is the most rare of all the varieties of pyritic iron. It is most usually accompanied with quartz, lead-glance, or galena, and fluor and calcareous spar.

Is found at Annaberg, Schneeberg, and Johanngeorgenstadt, in Saxony; at Andreasberg, in the Hartz; and other places on the continent of Europe. The capillary pyrites, according to Klaproth's analysis, is not an iron-ore, but nickel, mixed with a small portion of cobalt and arsenic.

Subsp. 4. *Hepatic Pyrites.*—Its colour is intermediate between bronze-yellow and steel-grey, passing sometimes entirely to the latter. On exposure, the fresh fracture changes to a brown. It is found massive, and under a variety of other forms, as stalactitic, cellular, &c. also crystallized. The shape of its crystalline arrangement is prismatic, pyramidal, and tabular, each with six sides. Lustre glimmering, inclining to glistering; metallic. Fracture even, passing sometimes to uneven and imperfectly conchoidal. Fragments indeterminate, sharp-edged. Hard, rather inclining to soft, brittle, easily frangible, and heavy.

This subspecies is said to contain arsenic. It decomposes very easily on exposure to air, which renders it very difficult to be retained in mineralogical collections.

It occurs only in veins, and in those principally which contain red silver ore, galena, blende, common pyrites, and sparry iron-stone. The earthy minerals that accompany it are, for the most part, quartz, sulphat of baryt, and calcareous and fluor spar.

It is found in Derbyshire; at Joachimsthal in Bohemia; Annaberg and Freyberg in Saxony; and in various parts of Sweden, Norway, and Siberia.

Subsp. 5. *Cellular Pyrites.*—Colour bronze-yellow, a good deal inclining to steel-grey. Tarnishes by exposure, and then becomes of a grey tint. Occurs massive; but its most common appearance is cellular. Cells drusy on the surface. Lustre glistering. Fracture conchoidal. Fragments sharp-edged, indeterminate. Brittle, and in a slight degree flexible.

Its occurrence is in veins, where it is accompanied, according to the statement of professor Jamieson, with hepatic and common pyrites, lead-glance, sparry iron-stone, nickel, iron-ochre, brown-spar, heavy-spar, fluor-spar, and quartz.

Is found at Johanngeorgenstadt, in the electorate of Saxony.

Sp. 6. *Magnetic Pyrites. Magnetica. La Pyrite magnetique. Ferrum mineralisatum magnetico-pyritaceum.*

Colour copper-red, inclining much to bronze-yellow, and even to pinchbeck-brown. Tarnishes on exposure, becoming then brown. Occurs massive and disseminated: has never been found under any other form. Internal lustre glistering, or shining; metallic. Fracture uneven, and sometimes imperfectly conchoidal: when the latter, it has a lustre bordering on splendid. Fragments indeterminate, rather blunt-edged. Intermediate between hard and semihard. It is brittle, easily frangible, and very heavy. Is attracted by the magnet. Sp. gr. 4.516.

Treated by the blow-pipe, it emits a slight sulphureous odour, and melts with great facility into a greyish-black globule, which is attracted by the magnet, and colours borax black. It is composed of 36.5 sulphur, and 63.5 iron.

It occurs only in the class of rocks denominated primitive; and there only in beds. The minerals which usually accompany

accompany it are galena, magnetic iron-stone, arsenical pyrites and tin stone; with also quartz, garnet, stahlstein, hornblende, &c.

Its geographic distribution is rather extensive. Amongst many other instances, the following may be enumerated: Moel Eion, in Caernarvonshire, North Wales; Geyer, Breitenbrunn, &c. in Saxony; Bodenmais, in Bavaria; and in different parts of Norway and Siberia.

Sp. 4. *Magnetic Iron-stone. Magnetisförlin. Le fer magnétique. Fer magn.*

Werner divides this into two subspecies; namely, common magnetic iron-stone, and magnetic iron-land.

Subsp. 1. — *Magnetic Iron-stone.*—Colour iron-black, inclining sometimes to perfect black, and sometimes to steel-grey. Occurs massive, disseminated and crystallized. The form of its crystals is the cube, perfect or truncated; the octahedron, which is also sometimes varied by truncation; the garnet dodecahedron, and the rectangular four-sided prism, terminated by four planes, placed on the lateral edges, as in the hyacinth. These crystals vary much in size. The dodecahedrons and octahedrons have their faces smooth; but the planes of the four-sided prism are transversely streaked. Lustre externally shining; internally varying from glimmering to splendid. Fracture small and fine-grained, uneven, approaching sometimes to small conchoidal, and imperfect foliated. Fragments indeterminate, rather sharp-edged. Occurs sometimes in granular distinct concretions. It is semi-hard, passing to hard; brittle; when in crystals difficultly frangible, and heavy. Sp. gr. 4.200 to 4.939. It is attracted by the magnet; and is itself also magnetic.

Before the blow-pipe it becomes brown, and imparts a dark-green colour to borax. It is supposed to be an oxyd of iron, nearly in a state of complete purity.

This species is very common in primitive mountains, especially in those of gneiss and micaceous schistus. In these situations it arranges itself in beds; but sometimes composes the entire mass of distinct mountains. The strata, or secondary formations, as they are termed, are not free from it. It occurs in gneiss at Taberg; in hornblende in Smoland, and in basalt near Eisenach. It is usually associated with common hornblende, garnet, and granular limestone. Sometimes with actinote, albist, &c.; but is most frequently found in the vicinity of magnetic pyrites, arsenical and copper pyrites, and common pyrites.

It is found in one of the Shetland isles; in Bohemia, Hungary, Saxony, Italy, France, Switzerland, Siberia, and South America. Is very abundant in Sweden, where it is employed for the manufacture of the iron imported to this country for the supply of the Sheffield market.

Subsp. 2. *Iron-stone.*—Colour deep iron-black, which passes sometimes to ash-grey. Occurs in angular or roundish grains; and also in small octahedral crystals. Surface rough and feebly glimmering. Internal lustre shining, metallic. Fracture perfect conchoidal. Fragments indeterminate, sharp-edged. Streak greyish-black. Semi-hard, brittle, easily frangible, and heavy. Sp. gr. 4.600. Strongly attracted by the magnet.

Its chemical characters are as the foregoing subspecies. It occurs in the beds of rivers; and also imbedded in the rocks of basalt and wa-ke.

Is met with in the river Elbe, near Schandau, in Saxony; imbedded in float-trap, in Bohemia; and is found also at St. Domingo, Guadaloupe, in Norway, France, the Tyrol, Greenland, &c.

Sp. 5. *Iron-glance. Eisglanz. Le fer spéculaire. Fer-tum min. rãfatawa sp. glare.*

This is also divided into two subspecies; common iron glance, and micaceous iron-ore, or, as it is called by professor Jameson, iron-mica.

Subsp. 1. *Common Iron-glance.*—Colour steel-grey of greater or less intensity, and sometimes reddish. It occasionally passes into iron-black. Surface very often tarnished, and beautifully iridescent. Occurs massive, disseminated, and crystallized. The form of its crystals is various. The most common is the rhomboidal parallelepipedon; the cube, formed by the truncation of a double three-sided pyramid, and having three triangular faces instead of two of its angles opposite, and octagonal plates bounded by linear trapeziums, six in number, inclined alternately to different sides. Planes of the crystals sometimes smooth, and sometimes streaked. Externally it varies from glimmering to splendid; internally from glimmering to splendid; lustre metallic. Fracture compact and foliated. The compact varieties are uneven, and sometimes small conchoidal. The foliated have a fourfold rectangular cleavage. Fragments octahedral or pyramidal; sometimes indeterminate. Edges rather blunt. Generally unparafated. Gives a deep cherry-red streak. It is hard, opaque, brittle, more or less easily frangible, and heavy. Sp. gr. 5.0116 to 5.218. It is magnetic, but less so than the preceding species.

Before the blow-pipe it is infusible, alone; but becomes white when heated on charcoal; and yields a dirty yellow-coloured scoria, with borax. Stated by Kirwan to contain from 60 to 80 per cent. of iron.

This species appears to be confined to primitive, and the class called transition mountains. It has never been found in those of secondary formation. Its occurrence is in beds and veins, where it is usually accompanied with magnetic iron-stone, common pyrites, compact red iron-stone, hornstone, and quartz.

Sweden yields it very abundantly; as also does Norway. Some of the finest specimens are from the isle of Elba, where the ore is said to have been worked for upwards of three thousand years. It occurs in Bohemia, Saxony, Switzerland, France, England (in Lancashire and Cumberland), Hungary, South America, Siberia, &c.

The English specimens occur in cavities in compact red iron-stone. The crystals are usually small; and the lustre of their surface is particularly splendid.

Subsp. 2. *Iron-mica.*—Colour iron-black, passing sometimes to steel-grey, and sometimes to deep-red. The latter is rather the colour of it, when held under the form of thin plates, between the eye and the light. Occurs massive, disseminated, and crystallized. When the latter, it appears in thin tables with six sides. Surface smooth and splendid. Internally it is also splendid, and its lustre metallic. Fracture perfect curved foliated; cleavage simple. Fragments sometimes indeterminate, and sometimes tabular. The massive varieties occur in granular distinct concretions. Thin plates of it are translucent. Its streak is deep cherry-red. It is semi-hard, brittle, very easily frangible, and heavy. Sp. gr. 4.50 to 5.07.

Before the blow-pipe it exhibits the same appearances as the preceding subspecies, except in communication, an olive-green tinge to borax. The proportion of iron which it plus is from 70 to 80 per cent.

It is exclusively confined to primitive mountains, and is the most part to those of a newer formation. It is found, like iron-glance, in beds and veins, and is accompanied with other ores of the metal: calcareous and fluor spar, quartz, hornstone, &c.

Its geographic distribution is rather extensive. It occurs near Donkeld, in Perthshire; at Dartmoor, in Devonshire;

I R O N.

in one of the Shetland isles; in Norway, Sweden, Russia, France, Isle of Elba, and many districts of Germany.

Sp. 6. *Red Iron-stone. Roth-eisenstein. La mine de fer rouge. Ferrum ochraceum rubrum.*

Werner has divided this into four subspecies, which professor Jamieson, in conformity with the principles of the Wernerianomenclature, has denominated red iron-stone, ochry-red iron-stone, compact red iron-stone, and red hematite.

Subsp. 1. *Red Iron-stone.*—Colour deep cherry-red, sometimes blood-red and brownish-red, and even inclining to steel-grey. Utterly friable. Occurs sometimes massive and disseminated; and is composed of fealy parts which foil considerably. Lustre between glimmering and glittering; semi-metallic. Is greasy to the touch, and moderately heavy.

Exposed to the blow-pipe alone, it blackens without melting, and communicates a bright green colour to borax. According to Hany, it is constituted of

Iron	66.
Oxygen	28.5
Silex	4.25
Alumina	1.25
100.	

It occurs generally in veins in primitive and transition mountains, accompanied with other ores of iron, copper pyrites, quartz, barytic spar, &c.

Although a rare variety of this metal, it is found plentifully in the neighbourhood of Ulverston, Lancashire, and is also met with in Cornwall. It occurs too in Norway, the Hartz, Saxony, Silesia, Salzburg, Hungary, and South America.

Subsp. 2. *Ochry-red Iron-stone, or Red Ochre.*—Colour varies between blood-red and brownish-red. Occurs sometimes massive and disseminated, sometimes superficial, or coating other ores of the metal, but most usually friable. Lustre faintly glimmering, or dull. Fracture earthy. Fragments indeterminate, blunt-edged. Feels meagre. Soils more or less strongly. Is not very brittle. Easily frangible, and rather heavy. Sp. gr. 2.952.

It is rarely found alone; being generally accompanied with other species of iron-ore, and particularly with compact red iron-stone, and red hematite. It occurs in veins; and is distributed nearly as the two following subspecies.

Subsp. 3. *Compact red Iron-stone.*—Colour between brownish-red and dark steel-grey, passing sometimes to blood-red. Occurs massive, disseminated, and in various imitative forms, as reniform, cellular, &c. It is sometimes found crystallized, and appears either in cubes, or four-sided pyramids, the latter of which are truncated on their summits. The cube is found both perfect and truncated. Surface of the cubes smooth; of the pyramids rough and dull. Internal lustre between glimmering and dull; semi-metallic. Fracture for the most part even. It sometimes, however, passes into coarse-grained, uneven, and large conchoidal. Fragments indeterminate, rather sharp-edged. Streak blood-red. Between hard and semi-hard. Somewhat brittle, and more or less easily frangible, heavy. Sp. gr. 3.423 to 3.76.

It assumes a darker colour before the blow-pipe; but is infusible, even with the assistance of borax. This re-agent, however, is tinged of a yellowish-green by it.

Occurs in beds and veins with red hematite and the pre-

ceding subspecies; and is also accompanied with quartz, red-jasper, and hornstone.

It is found very abundantly in Lancashire; in the Hartz, Saxony, Bohemia, Hesse, Siberia, and France.

It is frequently smelted in this country; and principally in those works which fabricate the variety of iron denominated in the preceding part of this article, under the name of *ferregis*. The richer ores, in fact, are incapable of yielding the most highly carbonized descriptions of iron; partly, perhaps, because they contain too little earthy matter to afford a sufficiently plentiful *sluider*; and partly because the reduction is too immediate.

Subsp. 4. *Red Hematite.*—Colour intermediate between brownish-red and steel-grey; passing sometimes entirely to one or other of them, and even to blood-red. It is from the latter variety that the name of hematite (from *hæma, sanguis*) is derived. Occurs massive and reniform; also fibulatic, globular, uniform, &c. External surface rough and glimmering. Internally glittering, passing into glimmering, lustre semi-metallic. Fracture always fibrous. Fragments usually wedge-shaped; sometimes splintery and indeterminate. In angular granular distinct concretions. Streak a light blood-red. Hard, inclining to semi-hard. Rather difficultly frangible. Brittle, and very heavy. Sp. gr. 4.74 to 5.05.

It exhibits the same chemical characters as the foregoing subspecies, and yields in the large way about 60 per cent. of metal.

According to the recent analysis of M. D'Aubuisson, who has published a very interesting memoir in the 75th volume of the "Annales de Chimie," on the chemical constitution of certain iron ores which appear to have water as an essential ingredient, this mineral is composed of

Peroxyd of iron	90
Silex	2
Lime	1
Volatile matter	3
Loss	4
100	

The specific gravity of the specimens here submitted to examination was 4.8. Another specimen, the specific gravity of which was 5.0, yielded the following result:

Peroxyd of iron	94
Silex	2
Water	2
Loss	2
100	

Each of the above presented a trace of manganese, and the latter a similar evidence of lime.

Its geognostic situation is similar to the last.

Lancashire yields it very plentifully, as well as the neighbouring parts of Cumberland. It is found, too, in considerable abundance in Saxony; and in Bohemia, France, Silesia, the Hartz, Siberia, &c.

It is one of the most common varieties of iron ore, and is very frequently employed in the melting furnace.

Sp. 7. *Brown Iron-stone. Braun Eisenstein. La mine de fer brune. Ferrum ochraceum brunum.*

This, like the preceding, is divided into four subspecies, which have the same leading distinctions. They consist of brown iron-stone, ochry-brown iron-stone, compact brown iron-stone, and brown hematite.

Subsp. 1. *Brown Iron-stone*.—Colour varying between clove-brown and steel-grey. Occurs massive, superficial, and frothy. Is composed of fealy particles, which are glittering, and have a metallic lustre. Fragments indeterminate, blunt-edged. Intermediate between friable and solid. Soils strongly. Feels greasy to the touch. Is very soft, light, and sometimes even swimming.

It blackens before the blow-pipe without melting, and communicates a yellowish-green colour to borax.

It is generally found coating compact brown iron-stone, and brown hematite.

One of the Shetland islands affords it; and it occurs also in Saxony, the Hartz, Norway, Carinthia, Barenth, Carinthia, and Stiria.

Subsp. 2. *Ochre-brown Iron-stone*.—Colour yellowish-brown, inclining to ochre-yellow. Occurs massive and disseminated. Between solid and friable. Fracture earthy. Internally it is dull. Fragments indeterminate, blunt-edged. Soils considerably. Is more or less coherent, and heavy.

In part an olive-green colour to borax.

It accompanies the other subspecies; and is found in Norway, Saxony, Bohemia, Bavaria, and Salzburg.

Subsp. 3. *Compact Brown Iron-stone*.—Colour clove-brown of various intensities, passing sometimes to yellowish-brown. Occurs massive, disseminated, and in various imitative forms, as stalactitic, reniform, cellular, dendritic, &c. It sometimes, also, appears in pseudo-crystals, of which the cube, rhomb, and lens have been particularized. Madrepores and corallines, too, have it frequently for their base; as well as other extraneous fossils. Internally it is dull, or very rarely glimmering. Fracture usually even, sometimes earthy and small-grained uneven, and conchoidal. Fragments indeterminate, edges more or less blunt. Streak bright yellowish-brown, bordering on ochre-yellow. Is semi-hard, inclining to hard. Rather brittle. Easily frangible, and heavy. Sp. gr. 3.4771 to 3.551.

It darkens before the blow-pipe, in consequence of the loss of oxygen, and becomes magnetic. Borax receives an olive-green colour from it.

The proportion of its ingredients, as stated by M. D'Aubuisson, in the 75th volume of the "Annales de Chimie," is as follows:

	From Bergshern.	From Viedefoss.	From Verz.
Peroxyd of iron	84	81	10
Peroxyd of manganese	1		3
Silex	2	4	10
Alumina			3
Volatile matter	11	12	13
Loss	2	3	2
	100	100	100

The specific gravity of the specimen from Viedefoss was 3.4.

It is always accompanied with some of the other subspecies; and frequently with quartz, calcareous and heavy spar, and pyrites.

Occurs in Mainland, one of the Shetland isles; the Hartz, Saxony, Bohemia, Silesia, the Tyrol, France, Carinthia, &c.

Subsp. 4. *Brown Hematite*.—Its colour, internally, is clove-brown, which passes to yellowish-brown, and brownish-black. It is exhibited under a great variety of other shades, as bluish or iron-black, pitch-black-brown, bronze-yellow, and sometimes iridescent. Occurs rarely massive; usually in some

of the imitative forms before spoken of. It is sometimes found in pseudo-crystals of a pyramidal shape, with six acute-angled sides. Surface sometimes smooth, and sometimes rough and drusy. Lustre shining or glittering. Internally it is from glimmering to glittering; intermediate between silky and resinous. Fracture fibrous, passing sometimes to small conchoidal. Fragments usually splintery or wedge-shaped; rarely indeterminate. Occurs in distinct concretions. Streak yellowish-brown. Opaque. Semi-hard. Brittle. Very easily frangible, and heavy. Sp. gr. 3.951.

It blackens before the blow-pipe, but does not melt. With borax it enters into ebullition, and produces a dirty yellow-coloured compound.

Its constituent parts, according to M. D'Aubuisson, whose analyses were generally repeated two or three times, are as below stated:

	From Bergshern.	From Viedefoss.
Peroxyd of iron	79	82
Peroxyd of manganese	2	2
Silex	3	1
Volatile matter	15	14
Loss	1	1
	100	100

The specific gravity of the former was 3.8, and of the latter 3.9. The specimen from Viedefoss afforded a slight trace of alumine.

It occurs in the newest primitive, transition, and secondary mountains; but most frequently in the two latter, where it is found lining cavities in veins or beds. Its usual attendants are black and sparry iron-stone, calcareous spar, brown and heavy-spar, and sometimes, though rarely, quartz.

It is found in Veightland, the Fichtelgebirge, Franconia, Hessa, and Nassau.

This species, which is so very abundantly distributed in the German states, is of rare occurrence either in Sweden, Russia, Norway, or England. In the former, it furnishes materials for very extensive iron-works; and the wrought-iron produced from it is very valuable.

Sp. 5. *Sparry Iron-stone, Spatheisenschlein. Le fer spatheux. Ferrum oxarum spathiforme.*

Colour yellowish-grey, which passes into yellowish-brown, clove-brown, and blackish-brown. It tarnishes on exposure either to the air or heat, and then becomes brown or black, and sometimes iridescent. Occurs massive, disseminated, and crystallized. Its crystals are either rhombs, lenses, octahedrons, or garnet-dodecahedrons. They are seldom large or very small; commonly middle-sized and small. Their surface is sometimes smooth, sometimes drusy, and a little rough. Internally it varies from splendent to glimmering; like pearly. Fracture foliated. Cleavage triple. Fragments rhomboidal. Occurs in granular distinct concretions. The light-coloured varieties are translucent, especially on the edges; but the dark-coloured opaque. The former give a greenish-white streak; the latter a yellowish-brown. It is semi-hard, inclining sometimes to soft. Rather brittle. Easily frangible, and moderately heavy. Sp. gr. 3.300 to 3.810.

It blackens before the blow-pipe, and enters into ebullition with borax, to which it communicates a dirty yellow colour. It always effervesces more or less with acids. According to Bergmann, it is composed of

Oxyd of iron	-	38
Oxyd of manganese	-	24
Lime	-	19
Carbonic acid	-	10
Water	-	9
	-	100

but it is liable to great variation in the proportion of its ingredients. In a recent examination by Collet-Defcoitis, the following result was afforded :

Fragments of quartz	-	2.78
Red oxyd of iron	-	48.45
Brown oxyd of manganese	-	1.80
Lime	-	.54
Magnesia	-	1.68
Carbonic acid, water, and loss	-	44.67
	-	100.

Annales de Chimie, t. 58.

The specific gravity of the specimen analysed in this case was 3.693; and its colour was brownish-yellow.

It occurs in primitive and secondary mountains; in the former, in veins; in the latter, in b.d.s.

It is found sparingly in Britain; and not very abundantly in Sweden, Norway, Switzerland, Siberia, Bohemia, and Saxony. At Schmalkalden, in Hesse, however, there is a bed from 25 to 30 fathoms thick; and in different parts of Westphalia, Stiria, Carinthia, &c. it is very plentiful. A whole hill, in the province of Biscay, is composed of it, which is said to have been worked for several thousand years.

It is much used as an ore of iron, and the metal produced from it is considered to be peculiarly favourable for steel-making; but whether this is any thing more than a mere prejudice, seems greatly to be questioned.

Sp. 9. *Black iron-stone. Schwarz eisstein. La mine de fer noire. Ferrum ochraceum nigrum.*

This is divided into two sub-species; compact black iron-stone, and black hematite.

Subsp. 1. *Compact Black Iron-stone*—Colour between bluish-black, and dark steel-grey. Occurs massive, and in various imitative forms. Surface dull, or faintly glimmering. Internally it is bordering on glitening, and its lustre semi-metallic. Fracture commonly conchoidal, sometimes uneven. Fragments indeterminate, sharp-edged. Streak shining, but unchanged. It is semi-hard, brittle, easily frangible, and heavy. Sp. gr. 4.076, according to Wiedemann.

This mineral had for a long time been classed as an ore of manganese, and was removed to the present genus from some particular distinctions that were pointed out by Werner, between the compact grey manganese ore, of which it had usually been considered a variety, and the sub-species now under examination. M. D'Aubuisson, however, in the course of his late researches, has subjected a specimen of it to chemical analysis; and instead of finding iron to be its principal ingredient, has ascertained it to be almost wholly composed of manganese and silica. This would, perhaps, be a sufficient authority for transferring it to the latter genus again; but as the Wernerian classification has been uniformly adhered to in the present article, it has been deemed best to continue its enumeration here, and accompany the account of it with the particulars of M. D'Aubuisson's inquiry.

The specimen he examined came from Ra'chau, in Saxony, and was of a bluish-black colour mixed with grey. It had

a compact fracture, was semi-hard, approaching to hard, and of the specific gravity of 3.6. It consisted of

Peroxyd of manganese	-	64
Silex	-	13
Volatile matter	-	14
Loss (occasioned by an accident in drying some carbonat of manganese on the filter)	-	9

100

Annales de Chimie, t. 75.

Considerable difference is very likely to exist in the chemical constitution of this mineral, and the total absence of iron, in the present case, may certainly be regarded as rather an extraordinary circumstance. Indeed, Werner's judgment is much too accurate to admit the supposition, that the varieties which have come under his inspection were destitute of it; but from the very great produce of manganese in the above analysis, and the general character of the species, in imparting a violet-blue colour to borax, there can be little doubt that this, if not both sub-species of black iron-stone, are, properly, ores of the former metal.

Subsp. 2. *Black Hematite*.—Colour inclining more to steel-grey than the preceding sub-species. Occurs massive and reniform. Internally it is glimmering; lustre semi-metallic. Fracture delicately fibrous, passing into even. Fragments wedge-shaped. Occurs in granular dilucent concretions. In other respects agrees with the preceding.

Before the blow-pipe, both the members of this species melt with borax into a violet-blue coloured glass. No exact analysis has yet been made of the black hematite; but its chemical constitution is in all probability very much similar to that of the former sub-species.

Black iron-stone is found in primitive and stetz mountains, accompanied with brown and sparry iron-stone and quartz.

It occurs at Naila, in Barcuth; Ra'chau, in Saxony; Hesse, the Upper Palatinate, and the Harz.

Sp. 10. *Clay iron-stone. Thon eisstein. Le fer argileux. Ferrum ochraceum argillaceum.*

This widely distributed, and highly valuable mineral, is divided into seven sub-species; reddle, columnar clay iron-stone, lenticular clay iron-stone, jaspery clay iron-stone, common clay iron-stone, iron kidney, or kidney-shaped iron-ore, and pea ore, or pea-shaped iron-ore.

Subsp. 1. *Reddle*.—Colour light brownish-red. Occurs only massive. Principal fracture slaty, glimmering. Cross fracture earthy, dull. Fragments tabular, splintery or indeterminate. Streak lighter than the fracture surface, and more shining. Soils strongly, and may be written with. It is soft, and very soft, sectile, easily frangible; strongly adherent to the tongue, meagre to the touch, and moderately heavy. Sp. gr. 3.1391 to 3.931.

It decrepitates and blackens at a red heat, and, in a more elevated temperature, melts into a kind of pumice of a greenish-grey colour.

It most generally occurs in the newer clay slate; and is found in Thuringia, Saxony, Silesia, Salzburg, Hesse, and Siberia.

It is scarcely used for any other purpose than drawing.

Subsp. 2. *Columnar Clay Iron-stone*.—Colour brownish-red, passing sometimes to cherry-red. Occurs massive, and in pieces which are more or less angular. Surface rough and dull. Internally dull, and fracture earthy. It most usually occurs in columnar dilucent concretions. Streak blood-red. It is soft, very easily frangible, brittle, meagre to the touch, adheres slightly to the tongue, and is moderately heavy.

I R O N.

It blackens before the blow-pipe, and imparts an olive-green colour to borax.

It is but rarely met with, and appears to be, in some instances, of pseudo-volcanic origin. Its occurrence with porcelain Jasper, and other minerals which are evidently of that class, gives considerable colour to the silica; but there are cases, as the one observed by Reufs in Bohemia, where it appeared in the centre of a mountain of clay-slate, that are equally opposite in their evidence.

It is found in the *St. of Arran*, at Sobrufan, Hofelnitz, Delau, and near Probin, in Bohemia; at Dutweiler, in Saarbrücken; and Amberg, in the Upper Palatinate.

It yields too small a proportion of metal, even where the mineral is sufficiently abundant, to be at all worked as an ore of iron.

Subsp. 3. Lenticular Clay Iron-stone.—Colour brownish-red, varying to reddish and yellowish-brown, and greyish-black. Occurs massive. Internally it is strongly glimmering, sometimes glistening, and always semi-metallic. Fracture fine earthy, and sometimes flat. Fragments indeterminate, blunt-edged. Occurs in distinct concretions, which are frequently lenticular, but sometimes granular. The streak varies with the colour of the specimen: generally lighter. It is usually soft, sometimes very soft, and semi-hard. Sectile, inclining to brittle; very easily frangible, and heavy.

Its composition, according to Lampadius, is

Of oxyd of iron	64.
Alumine	23.
Silex	7.5
Water	5.
Loss	.5
	100

The black varieties, which occur only in the canton of Berne, are said to yield 90 per cent. of iron. The red ore, which is found very abundantly in Bohemia, affords 60 per cent.

It is distributed in transition and fletz mountains, and generally unmix'd with other minerals.

Besides the situations already noticed, it is met with in Suabia, the Netherlands, Bavaria, Franconia, and France.

It is melted as an ore of iron, and the brown varieties of it, which contain from 30 to 35 per cent. of metal, are much valued on account of the excellent quality of the metal that is produced from them.

Subsp. 4. Jaspersy Clay Iron-stone.—Colour brownish-red. Occurs massive. Internal lustre dull, bordering on glimmering. Fracture flat conchoidal; and sometimes even. Fragments rhomboidal, also cubic and trapezoidal. Lighter in the streak. Soft, brittle, easily frangible, and heavy.

It has, hitherto, been only met with in a bed which belongs to the secondary or fletz formation, between Vienna and Hungary.

Subsp. 5. Common Clay Iron-stone.—Colour light yellowish-grey, inclining to ash-grey, and passing into bluish and steel-grey, yellowish, reddish, and clove-brown, brick-red, and brownish-red. These colours, particularly the lighter ones, undergo a change on exposure to the air, generally becoming darker. Occurs massive, and in a variety of extraneous forms, especially of shells and vegetables. Internally it is dull. Fracture earthy, sometimes conchoidal and flaty. Fragments indeterminate, blunt-edged; soft; rather brittle; adheres a little to the tongue; is more or less easily frangible; meagre to the touch, and heavy. Sp. gr. from 2.030 to 3.471.

Exposed alone before the blow-pipe it blackens, but does

not melt. With borax it enters into a sort of ebullition, and produces a glass of a blackish olive-green colour. It varies considerably in the proportion of its ingredients. Some specimens of the mineral yield as much as 40 per cent. of oxyd of iron, whilst others do not afford more than 20 per cent., and many even less than that. The following, which will contribute to shew this, are the results of some analyses by Richter and Lampadius.

Oxyd of iron	20.1	33.9	39.	42.5
Oxyd of manganese	1.	1.1		3.
Silex	19.9	23.9	5.	13.8
Alumine	30.2	13.	40.	13.6
Magnesia			6.	
Carbonic acid	28.8	28.1		27.1
Water			9.	
Sulphur			1.	
	100	100	100	100

This subspecies is a very abundant ore, and occurs in beds in the secondary or fletz formation.

It is found very plentifully in different parts of England and Scotland; and is also met with in Westphalia, Bohemia, Silesia, the Upper Palatinate, Poland, Russia, Siberia, Italy, and Norway.

Subsp. 6. Reniform iron ore.—Colour yellowish-brown, varying in intensity in the same specimen. The centre is the lightest, and not unfrequently includes a small kernel of an ochre-yellow tint. Occurs in masses from the size of a walnut to that of a man's head, which are most commonly imbedded in clay or shale. Fractured towards the surface, even; in the interior fine earthy. Fragments indeterminate, rather sharp-edged. Internal lustre dull; externally glimmering, semi-metallic. It is composed of concentric, lamellar, distinct concretions, inclosing a nodule, which is often loose. Surface rough; external layers soft; those of the centre very soft; brittle; easily frangible; adheres to the tongue; is meagre to the touch, and moderately heavy. Sp. gr. 2.574.

It does not melt before the blow-pipe, when heated alone; but enters into fusion with borax, and communicates to it a dirty yellow colour.

Occurs in the newest fletz rocks, imbedded in the argillaceous strata that are incumbent on coal.

It is found abundantly in Derbyshire, and some of the neighbouring counties; in Scotland, Norway, Denmark, Bohemia, Silesia, Transylvania, France, and Siberia.

The greatest proportion of the iron manufactured in the midland districts of England, as well as in many parts of Scotland, is obtained from the two foregoing subspecies. The metal which they afford, too, is, generally speaking, of the best quality. This is principally referable to the liberal supply of earthy matter in their composition; for, without a sufficient production of scoria, or cinder, in the blast-furnace, the highly carbonized, and consequently most valuable, varieties of iron cannot be formed. These subjects will be more fully discussed in a succeeding section of the article.

Subsp. 7. Pissiform iron-stone.—Colour yellowish-brown, of different shades, passing sometimes to blackish-brown. This is its internal appearance. Externally, it varies according to the nature of the stratum in which it is imbedded, being reddish, yellowish, and liver-brown, and even yellowish-grey. Occurs in small spherical grains. Centre of the grain dull; lustre increasing towards the surface to glistening. Internal fracture fine earthy; externally, even. Fragments indeterminate, somewhat sharp-edged.

edged. Occurs in concentric, lamellar, distinct concretions. Streak yellowish-brown. It is semi-hard, passing to soft. Not very brittle; easily frangible. Sp. gr. 5.207.

It exhibits, before the blow-pipe, the same appearances as the last subspecies. Subjoined are the results of two analyses of it; the former by Vauquelin, the latter by Mallinckhof:

Iron	30	45
Oxygen	18	15
Alumina	31	13
Silex	15	12
Water	6	15
	<hr/>	<hr/>
	100	100

This mineral is supposed by Werner to occur in the second Metz lime-stone, and in clay-beds.

It is found in France, Switzerland, Franconia, Hesse, Swabia, the duchy of Wurtemberg, and Dalmatia. In the latter country, it is said to be used by the inhabitants instead of shot.

The greater part of the French iron is extracted from this subspecies. It yields, in the large way, from 30 to 40 per cent. of metal.

Sp. 11. *Bog iron ore. Rafeneseisenerz. Le fer limoneux. Ferrum ochraceum cespitium.*

Werner divides this into three subspecies; morafs ore, swamp ore, and meadow ore.

Subsp. 1. *Morafs ore.*—Colour yellowish-brown. It is sometimes friable, and sometimes approaching to coherent. When the latter, it occurs massive, corroded, and in grains. The former varieties consist of dusty particles. Lustre dull. Fracture earthy. Fragments indeterminate, blunt-edged. Soils considerably. Is meagre to the touch, and light.

Subsp. 2. *Swamp ore.*—Colour dark yellowish-brown, sometimes passing to yellowish-grey. Occurs corroded, vesicular, and amorphous. Lustre dull, sometimes slightly glimmering. Fracture earthy, passing to fine-grained, uneven. Fragments indeterminate, blunt-edged. Streak light yellowish-brown. Very soft; sectile. Easily frangible, and moderately heavy. Sp. gr. 2.944.

Subsp. 3. *Meadow ore.*—Colour, when fresh broken, blackish-brown, passing sometimes to yellowish-brown, and brownish-black. Occurs massive, in grains, tuberoso, perforated, and amorphous. Externally it is rough and dull. In the interior it varies from shining to glimmering; lustre resinous. Fracture conchoidal, passing sometimes to small-grained, uneven, and earthy. The conchoidal varieties have the brightest lustre. Fragments indeterminate, blunt-edged. Streak light yellowish-brown. Soft; brittle. Very easily frangible, and heavy.

Bog-iron ore in general blackens before the blow-pipe, without melting. It enters into ebullition with borax, and produces a glass of a dirtyish yellow colour. The only member of the species that appears to have been subjected to analysis is the meadow ore; and it is constituted, according to the information of M. D'Aubulison, of

Peroxyd of iron	61
Peroxyd of manganese	7
Silex	6
Alumina	2
Volatile matter	19
Phosphoric acid	2.5
Lime, sulphur, and loss	2.5

100 Annales de Chimie, t. 75.

The volatile matter, which so constantly forms a part of the results quoted from this chemist, almost exclusively consists of water; and it was with a view, indeed, of ascertaining the proportion of this ingredient, that his analytical labours were principally commenced. He supposes it to be an essential constituent of the different minerals he has examined, and proposes to arrange them under the class of *Lyntrats*.

The present species is melted in some of the countries that afford it, and yields, in the large way, from 30 to 35 per cent. of metal.

It occurs in the newest formations, and is conceived to be continually deposited in marshy places, from the evaporation of the water that has held it in solution. The preceding subspecies are products of this process at different stages; and the order in which they are arranged is indicative of the date of their formation.

It is found in different parts of the Highlands of Scotland, the Hebrides, Orkneys, and the Shetland islands. Poland and Prussia contain considerable quantities of it; as also do Brandenburg, Courland, Livonia, and Lithuania. Its occurrence is more frequent in the northern than in the southern countries of Europe.

Sp. 12. *Blue iron earth. Blue eisenerde. Le fer terreux bleu. Ferrum ochraceum ceruleum.*

Before it has been exposed to the air, its colour is greyish-white, but afterwards becomes indigo-blue of different shades, and sometimes smalt-blue. Occurs massive, and disseminated; and is composed of dull, dusty particles, which are friable and cohering. Soils slightly. Feels meagre, and is moderately heavy.

Before the blow-pipe, it becomes of a reddish-brown, and afterwards melts into a brilliant black glass, which tinges borax of a deep yellow. It is readily soluble in acids. Bergmann had supposed it to be a native *Prussian-blue*; and it has received a place in many mineralogical systems, under that name, from the same belief: but an analytical examination of it by Klaproth seems to prove it to be a compound of phosphat of iron and alumina.

It occurs in nests in clay-beds, amongst bog-iron ore, and incrusting turf and peat.

It is found, under the latter circumstances, in the Shetland islands; it also appears in Iceland, Saxony, Silesia, Swabia, Bavaria, Poland, Siberia, Russia, and Sweden.

Sp. 13. *Pitchy iron ore. Eisenpechereze. Fer phosphat.*

Colour pitch-black, passing sometimes into blackish-brown, and even deep reddish brown. Occurs massive. Surface earthy, and dull. Internally it is glimmering; lustre resinous. Fracture foliated, conchoidal, and sometimes fine-grained, uneven. Fragments indeterminate, tolerably sharp-edged. Opaque; semi-hard; brittle. Not very easily frangible, and moderately heavy. Sp. gr. 3.956.

It melts easily before the blow-pipe, and forms a black enamel. According to Vauquelin, it consists of

Phosphoric acid	27
Oxyd of iron	31
Oxyd of manganese	42
	<hr/>
	100

Is found near Limoges, in France.

Sp. 14. *Green iron earth. Grüne eisenerde. Le fer terreux vert. Ferrum ochraceum viride.*

This is divided into two subspecies; friable green iron earth, and coherent green iron earth.

Subsp. 1. *Friable green iron earth.*—Colour silken-green. Occurs massive, and disseminated; and consists of particles

which are without lustre. Fragments indeterminate; soils; is soft, and very soft. Sometimes friable. Meagre to the touch. Easily frangible, and moderately heavy.

Subsp. 2. *Cobernet green iron earth*.—Colour rather darker than the last subspecies. Occurs massive, and corroded. Internally dull. Fracture fine earthy, passing into even, and sometimes into splintery. Fragments indeterminate; soft. Rather brittle, and inclining to heavy.

Before the blow-pipe, it becomes first red, and then of a dark brown; but does not melt. It tinges borax of a yellow colour, inclining to olive-green. No exact analysis has been made of this species; but it is supposed by Werner to have iron and phosphoric acid for its principal ingredients.

It is a rare mineral, and has hitherto been only found at Braunsdorf and Schneberg, in Saxony, where it occurs in veins: in the former place, accompanied with quartz and pyrites; and in the latter, with quartz and native bismuth.

Sp. 15. *Cube-ore. Würflerz. Fer arseniat.*

Colour olive-green, of different degrees of intensity. Occurs massive, disseminated, and crystallized in small and very small cubes, which are sometimes flattened and truncated at the angles. Planes of the crystals smooth and splendent. Internally it is glistering, and its lustre between pearly and adamantine. Fracture imperfect foliated. Fragments indeterminate. Occurs in granular distinct concretions. It is translucent; soft; brittle, and gives a streak of a straw-yellow colour. Sp. gr. 3.000. It appears sometimes in the form of a reddish-yellow powder, which is thinly distributed over the surface.

Before the blow-pipe it swells up, and emits an arsenical odour; melting afterwards into a grey metallic globule, slightly tinged with yellow. From the analysis of Chenevix, it appears to be composed of

Arsenic acid	- -	31.
Oxyd of iron	- -	45.5
Oxyd of copper	- -	9.
Silex	- -	10.
Water of crystallization		10.5
		<hr/>
		100
		<hr/>

It occurs in veins, accompanied with some ores of copper, quartz, mica, and feldspar.

The only places that have, hitherto, afforded it, are the mines of Carrarach and Murrell, in Cornwall.

Until the account published of this mineral by the count de Bournon, and Mr. Chenevix, in the Philosophical Transactions for 1801, it was mistaken for an arseniat of copper.

§ 2. *Assay and Analysis.*

Since the metal contained in every ore is of so much greater specific gravity than any other of its accompanying ingredients, it will be easy to form a tolerable idea of the value of an iron-ore by the weight of a given bulk.

Previously to working any iron-ore it should be very minutely assayed, both in the humid and dry way. By the humid process we shall ascertain the exact proportions of its constituents, without which it would be a mere work of chance to attempt to extract the iron in the metallic form.

When we are acquainted with the nature of the earthy matter in combination with the ore, we know with the greatest certainty what substances we ought to add in the crucible, for the purpose of eliminating the metal. All such substances are called fluxes, merely because they form fusible

compounds with the earthy matter of the mineral. It is to this treatment of a small quantity of the ore that we give the name of assaying.

The process by which the component parts are ascertained, consists in subjecting a small quantity of the ore in fine powder to the action of an acid, and sometimes to an alkali. By this means the whole is dissolved, and the different materials of which it is composed are separately precipitated by different chemical re-agents. The process, however, varies considerably with the nature of the ore to be examined.

Iron ores, as subjects of analysis, are divided into three heads; namely, sulphurets, oxyds, and salts.

The first are distinguished by their general bronze colour, but more particularly by the suffocating smell of sulphureous acid gas, which they afford by being heated to redness in the open air. The second consist of iron united with oxygen, and are by far the most common of all. Nearly the whole of the iron-ores in use are of this kind, containing also different proportions of earthy matter in their composition.

The third division comprehends such as consist of the oxyd of iron combined with some acid, and hence are called fluxes. The principal varieties of these are the phosphats, sulphats, arseniats, and carbonats.

The apparatus employed in the humid analysis will be a lamp fitted up with different-sized sliding-bearers, a silver crucible, and small portable furnace, with a sand-bath, and one of water, for drying precipitates; capsules of glass and porcelain; precipitating glasses, funnels, and filtering paper. For reducing the ore to powder, a mortar of hardened steel will be first necessary, and afterwards one of agate, to grind it very fine. Accurate weights and scales will be highly requisite, with cups of silver or platina.

The re-agents wanted will be sulphuric, muriatic, and nitric acids. Pure potash, soda, and borax, in the solid form. Solutions of the same, and also the pure aqua ammonia. The fully saturated carbonats of all the alkalis, and the subcarbonats of the same. The triple prussiat of potash and iron; and, when merely used as a test, prussiat of lime will answer. The analyst should, also, have in his possession powders or solutions of all the separate substances of which the mineral is supposed to consist, for the purpose of comparing real results with those obtained in his experiments.

If the ore to be analysed be a pure sulphuret, 100 grains, or any other given weight, may be reduced to powder, observing to weigh it after the operation, to see if any of the mortar has been abraded, which, when the ore is very hard, is to be expected; and the increased weight must in that case be noted down.

Let this powder be boiled with nitric acid in a long narrow-beaked glass vessel, which should be very thin at the bottom, to avoid cracking. By this method the sulphur of the ore will be converted into sulphuric acid; part of the nitric acid will be decomposed, and most of the remainder fly off, so that the resulting fluid will principally consist of the iron dissolved in sulphuric acid.

To this solution add the muriat of barytes, till a precipitation ceases to take place. When the precipitate has subsided, and the fluid is become perfectly clear, gently pour off the liquor, which is a solution now of iron in the muriatic acid. Let the precipitate, consisting of sulphat of barytes, be repeatedly washed with hot distilled water, till the liquid gives no precipitate with nitrat of silver, and afterwards add the washings to the fluid first poured off. After this white powder has been dried on the steam-bath, which is an apparatus constructed for this particular use, let it be weighed, and for every 100 grains of the substance allow 21.3 of sulphur. To the liquid parts which contain the oxyd of iron, add

add a clear solution of the sub-carbonat of potash. Let it boil for a little time, and the oxyd of iron will subside. Wash it and dry it as above, afterwards weighing the product. The quantity of oxygen in the oxyd of iron thus obtained, may be known by the quantity of iron obtained from it in the process of assaying, which we shall afterwards give. If the ore consist of oxygen and iron only, it may, without any previous treatment, be referred to the dry process. When, however, earthy matter is combined with it, the humid analysis should be referred to, which requires a different mode of proceeding to that already given.

Let 100 grains of the ore be reduced to a fine powder, as above directed, observing to weigh it afterwards, for the purpose of ascertaining whether any of the materials of the mortar be mixed with it. The matter so added, if it be acquired from the agate mortar, may be deemed pure filix.

To this powder add 300 grains of dry potash, in a silver crucible, capable of holding about six or seven ounces. Pour to the mixture a very little water, just sufficient to moisten the whole. Apply a gentle heat in the first instance, to prevent the mass from swelling too much, and gradually increase the temperature till the crucible is red-hot. The mass will now be in a state of fusion more or less perfect, according to the quantity of filix contained in the ore. If, from a great proportion of alumine being present, the fusion should be very imperfect, more potash must be added, and the heat continued and raised as high as the crucible will bear. When the crucible, with its contents, are sufficiently cooled, let both together be put into a capsule of porcelain, and nearly filled with distilled water. The whole should then be set upon a sand-bath, and boiled for some time, taking care to stir it very frequently. This will detach the matter adhering to the crucible, and if any filix remain unacted upon, it will be dissolved by the potash.

Let the whole be now saturated with muriatic acid, and even added a little in excess; and then gently boiled till all the liquid is evaporated. During this, the mixture must be constantly stirred; and particularly at the time the mass is becoming dry.

To this residuum let a large quantity of distilled water be poured. All the substances soluble in the acid will be now taken up. If it contain filix that will be left at the bottom. Let the whole be decanted into a narrow tall glass vessel, to suffer the filix to subside. Carefully pour off the clear liquor, and then add fresh hot distilled water, and continue to do so till the fluid does not cause a precipitate with nitrat of silver; observing to save all the washings which are acted upon by that salt. The remaining water may now be evaporated from the filix, and the powder, being heated red-hot in a crucible of silver or platinum, should be then weighed. If it be pure, it will be of a delicate white colour, not adhering to the fingers, as is the case with some of the other earths.

The solution containing the remaining substances should be evaporated to as small a quantity as possible, so that the fluid remain liquid and clear. To this let a saturated solution of the subcarbonat of potash be added, and afterwards boiled a few minutes. By this means, the whole of the ingredients will be precipitated together, and when all of them have perfectly subsided, decant off the liquor, repeatedly washing it with hot water. The first decanted liquor, with the washings, may be thrown away. Lastly, evaporate the remaining water, till the solid matter is of a pulpy consistence. To this, in a capsule of good porcelain, add a solution of pure potash. The alumine will be thus dissolved, while all the other substances will remain un-

touched. Let this fluid be poured off, and fresh water mingled with it, to take away all the alumine. Then, to the mixture containing the alumine, add not only as much water as will saturate the potash, but also a quantity sufficient to dissolve the alumine, when the liquid will be quite clear. Lastly, to this pour in carbonat of ammonia, till no more precipitate falls down. The precipitate, when washed and dried as above directed, and heated to redness in a silver crucible, may be considered as pure alumine.

The residuum from which the alumine was last taken is now to be dissolved in sulphuric acid, diluted with a large quantity of water, the acid being slightly in excess. This solution may contain magnesia, iron, and probably manganese. If lime were present, it will be left insoluble at the bottom of the vessel, in the state of sulphat of lime. The small portion of this substance dissolved by the fluid, may be precipitated by the addition of alcohol. The powder, when collected and dried at a dull red heat, must be weighed; allowing for every 100 parts 42 of pure lime. The solution from which the lime was separated, must next be saturated with a solution of the neutral carbonat of potash. In a few minutes the iron will be precipitated in the state of oxyd, while the magnesia and manganese will be dissolved by the carbonic acid. The iron must be separated, dried, and weighed. If with the solution containing the magnesia and manganese a solution of hydrosulphuret of potash be mingled, the latter will be precipitated in the form of a sulphuret; and this being washed and heated till the sulphur is driven off, the oxyd of manganese will be left in sufficient purity.

The magnesia still held in solution may be precipitated by adding a sufficient quantity of pure potash. The product must be heated to redness, and weighed. The weights of the different substances being added together, will, if great care has been used, be within one or two per cent. of the quantity originally submitted to experiment. If the deficiency be considerable, some mistake must have been made, and it will be necessary to repeat the analysis.

In the examination of salts of iron, nothing more is requisite than to disengage the acid with which the iron is combined. The arseniat of iron, for example, must be boiled with potash, which will separate the arsenic acid, and leave the oxyd of iron but very little acted upon. The arsenic acid may be afterwards precipitated by nitrat of lead; allowing for every 100 parts of the arseniat of lead, when dried, 33 parts of arsenic acid.

If the ore be a pure carbonat, to 100 grains in powder, add an equal quantity of sulphuric acid, in a glass vessel which can be placed over a lamp. Heat the mixture for some time, stirring it with a glass rod. The carbonic acid will be thus expelled, and its quantity will be indicated by the loss of weight sustained. Care should, of course, be taken that the heat be not too great, otherwise the evaporation of fluid matter may create error in the experiment. The iron may be afterwards treated as in the analysis of the earthy ores, and its quantity ascertained, by the methods there described. Having learned the exact proportions of the ingredients united in the ore, we may, with some degree of certainty, proceed to the assay by the crucible and fluxes. If the ore consist of oxyd of iron simply, nothing more is necessary than to introduce it into a crucible with about half its weight of charcoal powder, and any substance susceptible of vitrification, so as to keep off the air. This may be either pounded glass, or equal parts of lime and clay. But perhaps the best substance that can be employed, is the most fusible part of the blast furnace cinder, which is the least coloured with oxyd of iron. This may be employed in quantity amounting

amounting to about half the weight of the mineral to be assayed.

The earthy iron ore must be treated according to the result of the humid analysis; such earth being added as a flux, as will make the most fusible compound with that found by analysis to be present. The carbonaceous matter may be from $\frac{1}{4}$ to $\frac{1}{2}$ the weight of oxyd of iron.

The furnace best calculated for these experiments is called an assay furnace, and is capable of producing a great heat. See FURNACE.

The crucibles should be very small, not capable of holding more than three fluid ounces; and they should be provided with covers turned to them in a lathe before they are burned. The assay may be deemed finished when the whole is in a state of fusion, and the metallic button separated, which, being weighed, will give the *per centage* of iron in the ore.

§ 3. Reduction of Ores, and Manufacture of Pig-iron.

Although iron in its pure state is almost an infusible substance, it is capable of assuming the liquid form, by being combined with other matter. With sulphur it forms a fusible mass, of which we shall treat hereafter. It is also rendered fusible at a temperature something higher than that required to melt copper, by being combined with about $\frac{1}{2}$ of its weight of carbon. It is to this compound in different proportions that the name of pig-iron is given, and it is so denominated, because it is cast into masses of a semi-cylindrical shape, called *pigs*.

The fusibility of this compound of iron and carbon, enables us to extract the metal from the ore to the greatest advantage. It is now common, particularly in our own country, to obtain the iron in this form, previous to making it into bar, or malleable iron. Formerly cast metal was not much in use, except for the manufacture of bar-iron and steel; while in the present day, a much greater proportion of it is consumed in that state than in any other; and the majority of our furnaces, too, are solely employed for this branch of manufacture.

The process by which pig-iron is obtained from the different iron ores is called *smelting*; and the furnaces employed for the purpose are called *smelting*, or *blast furnaces*. See BLAST FURNACE, and BLOWING.

The ores of iron require different treatment in the smelting process, according to the quantity of heterogeneous matter with which the metal is combined.

In all the ores the iron is in the state of oxyd, and would at least require a strong heat in contact with combustible matter for their reduction. In most, the oxyd of iron is combined with a considerable proportion of earthy matter, and they are then denominated *iron-stones*. These may be generally divided into two classes; the one called argillaceous, from abounding with excess of alumine, or clay; and the other calcareous, from lime being their principal earthy constituent. The former of these iron-stones is by far the most abundant in this country.

But, besides the earthy matter and oxygen in this class of metallic minerals, many of them contain sulphur, which is doubtless combined with the iron in the state of pyrites. Arsenic and manganese are also sometimes united with them. Of the above, the arsenic and sulphur are extricated, previously to smelting, by the process called *roasting*. For this purpose, the stone is stratified with refuse pit coal, and burnt in large heaps in the open air. The heat is sufficient to dissipate the greatest part of the above volatile materials, leaving behind the earth and oxyd of iron; and also the manganese, when the ore abounds with that metal.

In the process of smelting, two things are absolutely essential to the separation of the iron. First, the metal itself must be rendered fluid, which will then, by its great specific gravity, descend to the lowest parts of the furnace, and some other compound mud, at the same time, be eliminated in a liquid form, so as to float upon its surface, and defend it from the influence of the blast. If the ore consisted of iron and oxygen alone, the carbon of the coke would combine with the oxygen; and an excess of carbon would also unite with the iron to render it liquid at that temperature; but here would be a deficiency of the fluid vitreous matter necessary to the defence of the iron from the oxygen of the blast. Hence it will be necessary to employ some substance with such iron-ore, which shall be capable of forming a liquid scoria, or cinder, for the preservation of the carburetted iron when once obtained. So far as observation has dictated, it would seem that the cinder cannot be too perfectly fluid. The principles on which the fusibility of the cinder depends, are not simply confined to the materials used in the smelting of iron, but refer to all compound fusible matter with which we are acquainted. It may be observed, in general, and, indeed, almost without exception, that the fusibility of an alloy of two metals is fusible at a temperature much less than the arithmetical mean between the fusing points of the metals themselves. For instance, an alloy of lead and tin is more fusible than either of the metals composing it, and a similar mixture of copper and silver may be used as a solder for either silver or copper separately. This property is not less conspicuous in the earths. None of them in their *pure* state can be fused in our hottest furnaces; nor scarcely with a stream of oxygen gas; although certain proportions of them are, together, fusible at the heat of a moderate air-furnace. Lime and clay, when separately taken, may be considered as incapable of fusion at any degree of heat, yet produced in furnaces; and lull, in certain proportions, they are too fusible to be made into even bricks or crucibles. It will appear, from these facts, that the iron-master cannot pay too much attention to the subject of the relative fusibility of the earths in different proportions. Most of the iron-ores of this country are argillaceous; that is, consist, besides oxyd of iron, of a small quantity of silic or flint, and a large proportion of clay. Limestone has always been employed for such ores, and, by combining with the clay and flint, as well as with a small portion of the oxyd of iron, forms a scoria or cinder, easily capable of fusion. Since, however, the proportions of these earths in the ore cannot be uniform, the quantity of limestone to be added ought to vary according to circumstances. We may hence infer, that if the fusibility of the cinder depends upon the particular proportions of the earths present, the iron-maker ought to possess a very perfect knowledge of the relative fusibility of different combinations of these bodies, and being at the same time aware of the component parts of the ore to be reduced, he will not be at a loss what should be added in the furnace, for the purpose of producing the most fusible cinder. But it will be proper here to observe, that the earths present, however accurate may be their proportions, will not of themselves form a cinder of sufficient fusibility, without the united aid of the oxyd of iron. This fact will be very familiar to those who have had experience in the use of fire-bricks. Clays which are free from that ingredient do not burn of a red colour; and hence the white appearance of fire-bricks is a tolerable test of their goodness. But those, on the contrary, which exhibit a redness on being fired, are easily fused, and unfit, consequently, to be used in those situations which are exposed to great heat. The proportions of lime, clay, and oxyd of iron, necessary to constitute the most fusible compound,

found, has not, as we have yet heard, been directly ascertained by experiment. An inquiry, undertaken with this view, would, however, be of great importance to the iron-maffer. It might be effected in two ways; first, by mixing different proportions of the materials employed; and, fecondly, by a direct analysis of the moff fusible part of the blaft-furnace cinder, and that with which the belt and moff carbonated iron has been produced. The cinder which fuses at the loweft temperature will be belt known by its fracture after cooling. It may, in general, be deemed good in proportion to its earthnefs when fold, and particularly fhould the outer cruft appear glaffy and transparent. A reafon may be given for this appearance, by reference to fome facts announced by fir James Hall and Dr. Hope, in accounting for the opacity of the whin-ftone. They found that when common flint-glafs, which is more fusible than the blaft-furnace cinder, was allowed to cool flowly, the mafs became opaque, and put on a ftony appearance. They hence concluded, that the whin-ftone might have been transparent, and have poffeffed a glaffy fracture, had it been cooled rapidly. The inference to be drawn from this will be obvious; for the more fusible the cinder, the longer it is in cooling, and confequently the more opaque. What ftrengthens this idea, too, is, that the exterior of a mafs of cinder is more transparent, almoft conftantly, than the interior; and the centre of that in particular, under which the belt iron is made, having a ftony fracture, with a thin vitreous fhell furrounding its outside. In beginning to work any new ore of iron, the firft ftep is to analyfe it, both in the dry and humid way. By the firft, we get the *percentage* of iron in the ore; and by the fecond, we become acquainted with the quality and proportions of its earthy matter. The next ftep is to analyfe the coal to be employed, for the purpofe of afcertaining the quantity of carbon it contains, and alfo the nature and proportions of its earthy refidua. Thefe facts being clearly made out, there will be nothing neceffary but to add to thefe materials a proper mixture of fuch fubftance as will make the moff fusible cinder. If the ore be argillaceous, or, in other words, if clay predominate, lime is to be the material employed. Indeed, ores of this defcription are fo very common, that lime has been thought the only fubftance to be ufed, under all circumftances, for the purpofe of a flux; and fo completely ignorant have the iron-maffers been of the philofophy of the procefs, that it has even been attempted to be added when the ore has already abounded with calcareous ingredients.

Keeping in view the principles we have juft laid down, the management of the calcareous ore will be equally eafy with the mode of working the argillaceous; fince, in fuch cafe, we have only to employ clay for the flux inftead of lime. But the belt method would, perhaps, be, if the component parts of an argillaceous and a calcareous ore were fufficiently well known, to mix the two together in proper proportions.

Whatever may be the fubftance employed, whether it be limestone for an argillaceous ore, or clay for a calcareous ore, it fhould be very minutely analyfed, as thofe fubftances are fearcely ever found in a ftate of purity. The lime fhould, if poffible, be the bell limestone. At all events, the magnesian ftatun fhould be avoided, fince that fubftance tends much to leffen the fusibility of earthy compounds. Some fubftances, fo which we give the name of clay, frequently confift of a large proportion of fome other earth.

Another thing to be attended to, alfo, is the ftate of oxydation in which we find the iron-ore.

If it be highly oxydated, more of the carbonaceous matter will be required for its reduction, and in all probability a

longer time; but, befides this, a greater quantity of the oxyd of iron will combine with the earthy matter, which, although it may contribute to the fusibility of the cinder, a large portion of the iron will be loft. On the contrary, when the iron is in a low ftate of oxydation, the whole of the iron may be apt to combine with the carbon, and the earthy matter may not get a fufficient quantity of the oxyd to render it, in a proper degree, fusible. In fuch cafe, it would be neceffary to add fome oxyd of iron, which might more eafily vitrify and enter into the compofition of the cinder.

The coal employed in the fmelting of iron, for the purpofe of being coked, is commonly laid in heaps in the open air, and afterwards fet on fire. When the combustion has gone on to a certain degree, the fire is checked by covering it with duft and preventing all poffible access of air. For farther particulars, fee COKE.

It is effential that the coke fhould be harder than it can generally be made in the open air without confiderable wafte; and we recommend, therefore, the method employed in making the cokes for melting steel. The coal, which is very foft, is piled up in ovens of the fhape of an erect fruftum of a cone. The air is let in at an aperture near to the bottom, which is contracted in fize as the combustion becomes rapid, and ultimately clofed. The whole mafs will at this time have acquired fuch a degree of heat, as not only to drive off all the volatile matter, but to render the coke extremely hard. There is a confiderable faving in this mode of coking, and the coke is not only more compact, but better adapted for the generality of ores of iron.

In fmelting the argillaceous ore, the proportions of the roasted ore, and the limestone, are governed entirely by the coke employed. The latter is always a fixed quantity, and the ore and limestone are varied according to the quality of the iron to be made and the working order of the furnace. In proportion as more or lefs of lime and ore are added to the ftandard quantity of coke, the furnace is faid to carry a greater or lefs burthen.

It would be ufelefs to give any precise proportions of the ore and limestone to a given quantity of the fuel, fince they are found to vary with the nature of the coal in ufe; and, what is not a little remarkable, the proportions will frequently vary in two furnaces working with the fame coal, and even in the fame furnace at different times.

The burthen of the furnace will alfo vary with the quality of iron to be made, that is, as it is required to contain more or lefs carbon. In making the dark-grey iron called N 1, and which contains the greateft proportion of carbon, the burthen muft be lefs than that required to make the lefs carburetted iron, commonly called white iron, or *forge-pig*.

To give a general idea of the proportions of the materials, we fhall prefent in detail, the quantities ufed at a blaft-furnace, making in general good melting iron, which is of an intermediate quality between N 1 and the *forge-pig*. The ore is argillaceous, containing about 27 *per cent.* of iron; the coal rather foft, but having a good proportion of carbonaceous matter; and the limestone good, being of the fhaly kind before fpeaken of. The furnace is about 45 feet high, and 12 feet diameter in the widelt part. It works with a bright *layers*, and receives from the blaft about 2500 cubic feet of air in a minute, through a circular aperture of 24 inches in diameter.

The average charges of coke *per day*, as it is termed, or in the fpace of 12 hours, are 50 (each 24 *cwt.*), or nearly feven tons. The calcined ore for good melting iron is about the fame quantity, and for *forge-pig*, or the leaft carburetted

variety, six of coke to seven of ore. The limestone unburnt, under the same circumstances, is to coke as four to eleven; and for melting metal, retains a similar ratio. With the above charge per day, that is, for 12 hours, this furnace makes on the average about 40 tons of melting iron per week.

Some furnaces carry so little burthen as not to yield more than 13 or 14 tons weekly; whilst others, particularly in South Wales, produce, with the same sized furnace, as much as 60 and even 70 ton in an equal time. The burthen of these furnaces is very great, the ore to the coke being in some cases as 13 to 7; and the quality of the iron is uniformly inferior. Since the cavity in the furnace is constantly kept full of the above materials, it may easily be conceived that the whole must be in many intermediate stages, from the fully melted iron to the unchanged ore. At the point where the greatest heat is produced, which will be a little above the level of the blast, every thing capable of fusion will be assuming the liquid form. We cannot, however, for a moment suppose, that the iron at this point is in a state of oxyd, since it would of necessity be all vitrified, and enter into the composition of the cinder. If the iron, even in its carburetted form, were to remain long at so great a temperature, and within the influence of so much oxygen, it would first lose all its carbon, and ultimately pass into the state of vitreous oxyd. As, however, the oxygen of the blast rises in the furnace, it comes in contact with the carbon of the coke, and is very soon converted into carbonic acid gas. That point in the furnace, therefore, where the whole of the oxygen has entered into combination with carbon, may be denominated the commencement of cementation, or the point where the oxyd of iron is first deprived of oxygen, and ultimately saturated or cemented, as it is termed, with carbon. From this point to the top of the furnace the process of cementation is going on with different degrees of rapidity, proportionate to the temperature. It is found by experiment, that if a piece of iron-ore, particularly any of the oxyds that contain but little earthy matter, be exposed in a close vessel in contact with carbon, it will first lose the whole of its oxygen, and afterwards become so saturated with carbon, as to be capable of fusing into the best pig-iron. Hence it appears that the reduction of the ore, so far as relates to the deoxydation and carbonization of the iron, may take place at a temperature below fusion, and without the mass of ore changing its form. The ore exposed to the carbonaceous matter in the cementing part of the furnace, must as completely undergo a similar change as if it were in the closest vessel; for the oxygen is excluded by the presence of carbonic acid gas. When the carbonized, but yet solid, iron, in the form of the ore, falls below the cementing point, or perhaps short of that, it begins to fuse. The earthy matter of the ore, being in contact with lime, begins also to assume the liquid form; and whilst the melted metal is exposed to the oxygen of the blast, a small portion of oxyd of iron is produced, which will enter into the composition of the cinder, and thus tend to increase its fusibility. The liquid iron now drops into the chamber of the furnace called the *heart*; and the liquid cinder, being of less specific gravity, floats upon its surface, completely defending it from the oxygen of the blast. Hence we see that the column of the blast-furnace may be divided into three portions; the upper portion, or cementing part; the middle, or melting part; and the chamber, or heart, where the metal is preserved till it is in sufficient quantity to be run out into pigs. The cementing portion is by far

the most extensive, and will vary in its extent with the strength of the blast.

Since the combustion must be in proportion to the quantity of oxygen consumed in a given time, the heat of the furnace will depend upon the quantity and velocity of the air blown into it to a certain extent. If the blast should have too great a velocity, the oxygen would pass through a greater space in the furnace than is desirable before it was disposed of, and the cementing portion would be lessened in consequence. On the contrary, if the velocity were too little, the heat would be confined to the vicinity of the tuyere, and the cementing, as well as the melting processes, would be retarded for want of heat.

When the blast is sufficient to generate the necessary heat for melting the cinder and the metal perfectly, the extent of the cementing portion will depend upon the height of the furnace. This gives us one very satisfactory reason, why a furnace is required to be higher for the use of coke, than when it is heated with charcoal; since the carbon of the latter enters into the composition of the iron with much more facility than that of the former.

According to experiment, it appears that the facility with which carbon enters into combination with iron, in a close vessel, is inversely as its aggregation or cohesion. Hence it is found, that the carbon obtained from animal substances, which is soft and porous, is best calculated to convert iron into a carburet.

It will appear from the last observation, and from what has been said on the nature of coke, that the carbon employed for cementation should be mechanically different from that required to generate the great and permanent heat necessary to the fusion of the materials. The one in the cementing portion should, therefore, if it were practicable, be surrounded with coke of the softest kind, whilst the materials within the influence of the blast, and occupying the melting portion, should be supplied with such as is harder.

In making the most highly carbonized iron, or what is called N^o 1, it sometimes happens that a portion of the iron unites with a great excess of carbon, forming a substance, which, when cold, appears in bright shining scales. It is found to possess most of the properties of plumbago, differing from that substance only in containing less carbon. This carburet is no doubt in the liquid form in the furnace, and being of much less specific gravity than the iron, floats upon its surface. It is so much more infusible than the metal, that before the iron enters the moulds of the pig-bed it is seen swimming at the top in the scaly form, before mentioned.

This substance is called by the workmen *kyb*; and whenever it appears, is a certain sign that the furnace is working on the best sort of iron. So surely, indeed, is it the case, that N^o 1, or the most highly carburetted metal, has received the epithet of *kyb*, because *kyb* is the common attendant on its production.

The most remarkable and anomalous circumstance presented in the smelting of iron, is the difference in quantity and quality of the iron made in winter and in summer, when all other things are equal. It is a fact well ascertained, that in order to make the same quantity and quality of iron in summer as in winter, the furnace will not carry so great a burthen, and, at the same time, the means of generating heat requires to be increased.

Various opinions have been given to explain this curious fact. Some have supposed that the proportion of the oxygen was less in the atmosphere in summer than in winter. Others,

that the excess of moisture contained in the air in summer above that in the winter, might explain the phenomenon. Whatever may be the cause of this difference in the blast-furnace, the flame may equally be referred to common fires, which, it is well known to every one, are much hotter in winter than in summer. If the Lavoisierian doctrine of combustion were true, we should not expect that the power of air to generate heat would vary with the temperature, since the flame caloric which had contributed to dilate the oxygen in summer, would be given up when the oxygen combined with the carbon. Unfortunately for that doctrine, however, we find that the quantity of heat generated during the combination of oxygen, is directly as the quantity of oxygen, whatever may be its state, whether solid, liquid, or aeriform.

It appears from general observation, that the difference in the quantity and quality of the iron made in winter and summer may be, in a great measure, referred to changes arising from variation of temperature. The average result of this atmospheric influence is different with different blast-furnaces, and, indeed, with the materials employed; but in general the quantity varies in winter and summer from $\frac{1}{4}$ th to $\frac{1}{2}$ th, besides the alteration of quality, which in some furnaces cannot be prevented by any change in the burthen.

If the whole of this difference depend upon the temperature of the blast sent into the furnace, we must expect to find it either in the increased rarity of the air, or in the presence of moisture, which exists more abundantly in the atmosphere in summer than in winter; or, perhaps, it may be attributable to both these circumstances.

Soon after the constituent parts of water were discovered, some iron-masters attempted to produce combustion by blowing steam into the furnace. But, notwithstanding the great proportion of oxygen existing in aqueous vapour, their expectations were far from being realized, and the scheme was given up by them under a firm conviction that it never could succeed.

This experiment, however, served to shew that no more mischief might be expected from the vapour of water in the atmosphere, than its merely excluding a portion of oxygen. Conceiving it, therefore, to have no other influence in the furnace, we will submit some calculations to the reader, in order to shew the absolute difference in the quantity of oxygen sent into the furnace in winter and in summer, and to ascertain what share of the defect may be attributed to this circumstance, or whether the whole may not safely be referred to it.

We have much to regret that we are not in possession of more experiments as to the temperature of the air sent into the furnace at different times of the year. The mere temperature of the atmosphere is not sufficient for this purpose, since the air gives out much heat by compression in the blowing cylinder. In a former part of this work (see *BLAST-FURNACE*), a table of some observations was given, on which, as far as they go, reliance may confidently be placed. In this table the temperature of the air was stated when it entered the blowing cylinder, and after it had been compressed into a vault, from which it passed into the furnace. If we take the temperature on its entrance into the furnace in winter at 50°, and in summer at 100°, the difference will be 50°, and the variation in the quantity of oxygen will be inversely as the increased volume of the air. It is found that elastic fluids are augmented in bulk by one degree of Fahrenheit .00208 of the whole. Therefore, the quantity of oxygen at 50° will be to that at 100° as 1 + (100 -

50) × .00208 : 1; and the oxygen, consequently, in summer will be .104, or little more than $\frac{1}{10}$ th less than in winter.

The defect arising from the relative quantities of moisture contained in the air in winter and summer will be very trifling, except where the water-regulator is employed instead of the air vault or common regulator. (See *BLAST-FURNACE*.) When the air does not come in contact with any thing moist after entering the blowing cylinder, in order to learn the quantity of water present, we have only to ascertain the relative proportions of vapour existing at the respective temperatures of the atmosphere in winter and summer. It appears from a theorem, which we have founded upon Mr. Dalton's ingenious experiments upon evaporation and the force of vapours, that the quantity of water in air at 32°, at which temperature we suppose it to enter the furnace in winter, is equal to 2.04 grains in each cubic foot. This, in weight, is $\frac{2.04}{561}$; and in bulk, vapour being

to air at 32° as 274 to 561, equal to $\frac{2.04}{274}$ of the whole, or .0075. The summer air, which we take at 55°, contains 5.32 grains in a cubic foot; a quantity amounting in weight to $\frac{5.32}{524}$, and in bulk to $\frac{5.32}{274}$, or .019 of the whole. The difference .0115 is the deficiency of common air in summer, arising from the presence of aqueous vapour; and makes the total variation in the quantity of oxygen between summer and winter equal to .1155 = $\frac{23}{200}$, or $\frac{1}{8}$ th nearly.

We here consider water as producing injury merely by displacing a certain proportion of oxygen, and not being prejudicial in itself, as is supposed by the generality of iron-masters. The reason given for its bad effects does not appear intitled to much weight. The opinion commonly entertained is, that the carburetted hydrogen set at liberty, carries off a greater quantity of heat than the nitrogen of atmospheric air. An effect which, if even true, is inadequate to explain the appearances. When the air is received into a water-regulator, as is the case in many blast-furnace works, a much larger quantity of moisture may be expected to enter the furnace, than with the ordinary apparatus. In the above calculation, if the air had been received over water, we should find that its temperature in the receiving vessel in winter and summer would be 50 and 100°. The vapour in the former amounts to 4.67 grains in a cubic foot: in the latter, to 18.95 grains in the same quantity.

Hence, air at 100° will contain less oxygen than that at 50°, by .055 of the whole; which is a little more than $\frac{1}{2}$ th. This added to the loss by increased temperature alone, will be .159, or nearly $\frac{1}{6}$ th.

We may from this conclude, that the extra-quantity of moisture admitted by using the water-regulator, will at any rate increase the difference in the amount of oxygen from $\frac{1}{4}$ th to $\frac{1}{6}$ th, or thereabouts; which, in all probability, will more than counter-balance the good effects arising from its uniform pressure. There does not appear to be, in the present state of our knowledge, any means of effectually remedying this evil. Some good might accrue from admitting the exterior air as cold as possible, and not allowing it to come in contact with water after entering the blowing-cylinder. This may be done to a certain degree, by causing the

the air to ascend from a deep pit, by a pipe communicating with the blowing cylinder. This contrivance, however, should be laid aside whenever the air of the atmosphere becomes colder than the average temperature of the earth.

With regard to the defect arising from increase of volume of the air in the furnace months, the heat caused by the friction of the blowing piston will be found to contribute much to the evil. The air by this means gets an additional elasticity, and if the same quantity of air be thrown into the furnace it must be effected by decreasing the pressure of the blast, or by increasing the aperture of the *noze-pipe*. If the compression of the air could be effected by any means which would avoid the friction of machinery, it would no doubt be a desideratum in the process of blowing. It will appear from these facts, that in summer, when the quantity of air is deficient from increase of volume, and from the presence of water, that a larger quantity of air should be made to enter the furnace, partly by increasing the velocity, and partly by using a *noze-pipe* of greater diameter. If the deficiency were made up by the increase of pressure only, the velocity would be too great for producing a maximum of combustion, where it is immediately wanted, independent of the mechanical evil it would be liable to produce. If, on the other hand, the aperture of the *noze-pipe* were increased in summer, to make the quantity equal to that of winter, the air would enter in a state of greater rarity, and the combustion would, from this cause, be of less intensity. This circumstance alone, perhaps, is sufficient to prevent a complete remedy of the evil, and will go far to explain the difference between the fractions resulting from calculation and experiment.

We shall conclude our account of this department of iron-manufacture with some general observations upon the nature and properties of pig-iron, as it is applied to different purposes.

When the iron has combined with its full dose of carbon, constituting what is called in the trade, grey, or smooth-faced iron, and also N^o 1, it is admirably fitted for making the lighter and finer sort of castings, such as grates and other ornamental work. It is from iron of this quality that the cast-iron cutlery is manufactured, since no other would run sufficiently fluid for articles so small as the prongs of forks, and the bows or rings of scissors. This iron, however, is not the best for larger castings where strength and hardness are desirable; as in large wheels, for example, beams, pillars, railways, &c. The metal employed for these purposes contains a lesser proportion of carbon than the former, and is generally called melting-iron, or N^o 2.

That species of pig-iron, however, which is combined with the smallest dose of any, is almost exclusively employed for making malleable iron, and is called, for that reason, *forge-pig*. We have given, in the next section, an account of the proportion of carbon present in the different varieties; and it will appear from thence, that of all the combinations of iron and carbon, steel contains the least, and grey, or N^o 1, pig-iron, the most of any of the compounds we are yet acquainted with.

As a proof that pig-iron only requires to lose its carbon to become malleable, we have at present in this country manufactures upon a large scale, for converting cast metal goods, such as nails, cutlery, &c. into iron perfectly malleable, without even changing the figure given to them by casting. Nails produced in this way are so malleable, even when cold, as to bear the hammer, and are capable of being bent to a right angle in a *vice*.

But a still stronger proof that this metal assumed the form of iron is from the great heat it will bear. The

prongs of a common fork made by this process can be welded together with the greatest facility. Pig-iron, until lately, has been considered a much more complex body than experience has warranted. We have heard of its being supposed to contain silica, or, according to Mr. Davy, silicium, to which it owes some of its crude qualities. But the process just mentioned is sufficient to refute the assertion. Iron masters, even at this day, however, will talk about oxygenated pig-iron, meaning that which is full carbonated; but it must be clear to every one acquainted with the chemical qualities of those bodies, that the presence of carbon and oxygen in a liquid mass is perfectly impossible, as they are incapable of existing together uncombined at any such elevated temperature. Hence we must regard pig-metal as a compound of iron and carbon only. Manganese may perhaps sometimes be present in it, when particular ores are employed for smelting, but its union must be considered as accidental.

To make pure iron, therefore, we have, from these conclusions, only to extricate the carbon. This may be done, in small masses, by stratifying the articles in a close vessel with some substance containing oxygen. The poorer iron ores, which are free from sulphur, are used in powder for this purpose; and after the materials have been exposed to a heat just short of the fusion of the metal, the air being completely excluded, the carbon will become dissipated, and the iron left in a state of purity. See CASTING and FOUNDRY.

§ 4. Conversion of Pig-iron into malleable Iron, and Steel.

1. *Bar, or wrought Iron*—Iron, as obtained by the reduction of its ores in the blast-furnace, contains, as we have before stated, a certain proportion of carbon, which renders the metal unfit for the various purposes of forging, but constitutes its principal value as applicable to the use of the founder. To deprive it of this ingredient certain processes are gone through, the object of which is, by the concurrent action of heat and air, to dissipate the carbon under the form of an elastic compound. The kind of iron chosen for the conversion is that denominated by manufacturers *forge-pig*. It is the lowest quality made for the purposes of art; and, in consequence of its being combined with a smaller dose of carbon than any other, which thus causes it to bear a less price in the market, is doubly preferable for the end required.

The price of *forge-pig* is almost exclusively determined by the quantity of carbon which is in combination with it. The varieties usually distinguished are N^o 1, otherwise called *grey, smooth-faced, or lumpy*, metal; N^o 2 and 3, and *forge-pig*. The proportion of carbonaceous matter present in these varieties is differently stated by different experimentalists. Clouet makes the highest proportion to amount to $\frac{1}{4}$ th; but from the results obtained by Mr. Mather in combining iron *directly* with the doses of charcoal requisite to produce its various sub-carburets, $\frac{1}{16}$ th appeared to be the *maximum*. Of this, the following table, published by him in the 13th vol. of the Philosophical Magazine, will afford the necessary proof.

Soft cast-steel	-	-	-	-	-	-	-	-	$\frac{1}{16}$
Common ditto	-	-	-	-	-	-	-	-	$\frac{1}{8}$
Same, but harder	-	-	-	-	-	-	-	-	$\frac{1}{4}$
Ditto, too hard for drawing	-	-	-	-	-	-	-	-	$\frac{1}{2}$
White cast-iron (same as before called <i>forge pig</i>)	-	-	-	-	-	-	-	-	$\frac{1}{2}$
Mottled cast-iron (N ^o 2.)	-	-	-	-	-	-	-	-	$\frac{1}{2}$
Black cast-iron (N ^o 1.)	-	-	-	-	-	-	-	-	$\frac{1}{2}$

The first step in the process of decarbonization, according to the more common mode of operating, is to expose the iron in a

Furnace, called by some a *refinery*, but by others, to distinguish it from one hereafter to be described, a *run-out furnace*. It consists of a vessel open at the top, imbedded in stone or brick work, about two feet three inches long, two feet wide, and ten inches deep. This is generally, in part, constructed of cast iron; and, when so made, has an outer case about two or three inches distant from the inner one, which is constantly supplied with a stream of cold water to prevent the apparatus from melting. The iron to be decarbonized is placed in this receptacle, and kept in a continual state of fusion for three or four hours by the aid of a coke fire, which is heaped to a considerable height above the level of the vessel, and extended proportionally on the hearth that surrounds it. The size of the hearth is mostly about three yards in length, and from two to three wide, and is completely covered by the funnel of the overhanging chimney. Bellows of considerable size are employed to carry on the process; and the current of air which issues from them is directed immediately on the surface of the iron by one or more *tuyeres*. These *tuyeres* are double, like the case, and continually cooled by the application of the same means. When the decarbonization is completed, the metal is let out at an opening in the side, which has been kept close during the operation by a *stopping* of sand. It flows into a groove about 18 inches wide, and six or seven feet long, constructed of stone in the floor that surrounds the furnace. The bottom of the vessel is so placed as to be nearly on a level with the floor; the only elevation given to it being what is merely sufficient to let the iron run out with facility. A considerable quantity of vitreous oxyd is formed during the process; and the loss in the weight of metal, which is stated to amount to from $\frac{1}{4}$ th to $\frac{1}{3}$ th, is principally referable to this circumstance. The total quantity of carbon which the iron contains originally is not estimated at more than $\frac{1}{4}$ th; and yet the approach of it to the pure state, or, in technical language, to the state of *bar* or *wrought iron*, after this operation, is very inconsiderable.

The cake of metal procured by these means is broken into lumps of a convenient size, and subjected, in a furnace of another description, to a process known in the art by the name of *puddling*. The furnace, which is also distinguished by the same term, is a variety of the reverberatory; and at the immediate point where the flame strikes upon the hearth, a shallow concavity is worked out, in which the melted iron is exposed. Opposite to it is a door, and through this the metal is kept in continual agitation, by means of a sort of rake, for the purpose of exhibiting fresh surfaces perpetually to the influence of the air. Water is likewise occasionally thrown in, which in some degree contributes to the decarbonization. With the loss of carbon, the iron also loses its fusibility, and about the middle stage of the operation appears in the form of small detached lumps, which scarcely seem to exert any affinity for each other. At length, however, by much stirring, and frequently pressing them together, they cohere into a pulpy mass; and being gathered into pieces of a convenient size, are carried under rollers, where, after passing through four pairs, in succession, of a gradually diminishing gauge, they are produced into plates seven or eight inches wide, and three feet or more in length. Considerable quantities of matter are squeezed out in the rolling, which principally consist of a vitreous kind of oxyd. This is, for the most part, to be referred to the action carried on in the furnace; but some portion of it is, in all probability, created by the combustion of small pieces of fluid metal, which, engaged amongst the particles of the *puddled* mass, are hurled through the air in a state

of vivid inflammation, by the compressive violence of the rollers. The total loss thus sustained is estimated at from $\frac{1}{4}$ th to $\frac{1}{3}$ th. The plates obtained by this treatment have a very compact appearance; and if attempted to be worked in the state they are then presented under, would crumble almost wholly into small granulated lumps. To impart to them the necessary closeness and solidity, they are again heated in another kind of furnace, and beaten forcibly with a heavy hammer, which is raised by machinery.

Previously to being thus treated, they are broken up into cakes of small size, and placed upon circular slabs of stone from 8 to 12 inches in diameter. The size of the cakes is in a great measure determined by a particular effect of the last pair of rollers that they are passed through; ribs, of a diamond shape, girding either one or both of them, on the whole extent of their surface, which leave a deep indentation on the plates, so as to render them easily frangible in that direction. The height to which these cakes are piled on the circular slab just spoken of, is generally about 12 inches; and when so prepared, they are placed on the hearth of a reverberatory furnace, which differs but little in form from that employed for *puddling*, except in being flat at the bottom instead of concave. The furnace is denominated a *balling furnace*; and the piles of metal, *pies* or *balls*. They are continued in this situation until they have arrived at a welding heat, and are then removed by large tongs under the stroke of the hammer. Near to the place a smith's forge is kept in blast, where long bars of iron are also urged to the welding point; and, after the first stroke or two of the hammer, united to the *ballied* masses, to afford greater convenience in turning them. The masses are heated out into ingots of about three feet in length; and the bar last mentioned being separated, they are divided deeply by an instrument termed a *fit*, to facilitate their being afterwards broken; and the process is then completed. They are in this state called *blooms*, and have yet to undergo another operation, for the purpose of being made into bars or plates. Much loss is sustained by the last treatment, and principally from the same formation of oxyd as was noticed in the preceding case. The quantity thus lost, added to the waste occasioned in the *blooming*, which comes next to be described, is usually considered as equal to $\frac{1}{3}$ th of the metal obtained by *puddling*; which will make the total deficiency, by all the operations, as nearly equivalent to $\frac{1}{2}$. The ingots or *blooms*, which are received from the hammer, after being broken, over a small wedge-shaped block of iron called a *top*, are placed in a species of reverberatory, very similar to the *balling furnace*, and denominated a *blooming furnace*, or *bloomingery*. They are here heated to welding, and then submitted to the requisite pressure under rollers, which are either plain or grooved, according as the iron is wished to be obtained in plates or in bars. This completes the whole of the processes necessary for making the best malleable iron; and it results from the observations which have been premised, that, in order to procure one ton of it, five-and-thirty hundred weight of *forge-pig* is previously required.

Two other modes of operating are at present in use; one of which omits the *puddling*, and the other, that part of the foregoing process that concerns the fabrication of *blooms*. In the former, iron is exposed to the heat of a charcoal fire, in a species of furnace precisely similar to the one before described as a *refinery*, or *run-out furnace*; and is continued in that situation, until the metal is thought to be sufficiently decarbonized. It is very frequently stirred during the operation; and when brought into nature, (to use the technical expression,) is collected into masses, and removed by

Yongs under a large hammer, denominated, *as* applied to this particular use, a *flashing Lammor*, where it is beaten into cakes, which are afterwards broken up, and treated in the *balting furnace* as before described. This is the old mode of working, and the iron obtained from it is by many conceived to be of very superior quality. The heat produced is considerably inferior to that afforded by coke in the *run-out furnace*; and the iron is less surrounded by the fuel than in the case just mentioned. The present charcoal fire is properly a *refinery*, and not the one which is used merely as a preliminary to the process of *puddling*. Here, the business of decarbonization is at once completed; and the resulting metal is in the same state of purity as that yielded from the rollers, after it has been *puddled* by the other method. *Balling* and *blooming* follow in regular succession, and plates or bars are produced exactly as before.

According to the second mode of treatment, in which *blooming* is omitted, the masses obtained from the *balting furnace* are reduced under the hammer into the form of solid, cubical blocks; and when their temperature is too much lowered to be capable of any further working, they are again heated in a fire called a *chafery*, which is urged by a powerful pair of bellows, and scarcely differs from a common smith's forge, except in being larger, and the coles upon it being heaped up to the unusual height of at least two feet. In this situation they are raised to the point of welding, and afterwards hammered out into ingots of a flattened shape. Iron bars are united to them very shortly after they are brought from the *balting furnace*, to afford a greater facility of management, in the same manner as was described in the making of *blooms*; and these, as before, are detached, when the ingot is sufficiently formed. The iron produced in this way is not considered so good as that afforded by either of the other processes, and is employed, for the most part, in the commoner services of art. Repeated rolling, or hammering, is the only means of imparting the fibrous texture so necessary to good bar iron; and as this treatment is less frequent in the present mode of operating, the deficiency of value in the material obtained may very probably be referable almost exclusively to this circumstance.

The above include the whole of the *important* variations that are presented in the manufacture of bar iron. Other shades of disagreement may be traced in different works; but they are of a nature too trifling and unimportant to merit any particular enumeration. The art is still in its infancy; and the light of chemical science, by being brought to a focus here, cannot fail to disclose many improvements in the present modes of procedure, which will greatly abridge the expence now incident to this valuable branch of national industry. That the mere abstraction of about 4 *per cent.* of carbon should require a sacrifice, in effecting it, of above 40 *per cent.* of iron, appears monstrous beyond example; and as those who are connected with the art become more scientific in their views, we shall unquestionably find that it will be much more economically accomplished.

When iron has been completely freed from carbon, and has acquired its highest degree of malleability by repeated hammerings, it is by far the most tenacious of all the metals, and is capable of being drawn into the finest wire.

The tenacity of iron, as well as of all the rest of the malleable metals, varies considerably according to its softness. After iron has been kept in a red heat for some time, and suffered gradually to cool, it becomes remarkably changed in point of softness. By being hammered, drawn into wire, or rolled, it increases in hardness to a certain extent; but, at the same time, partly loses its malleability.

By this mechanical treatment, when cold, its strength or tenacity increases; and it may be taken at one point, when it will require a far greater weight to break it, than if it were hammered either more or less.

All the experiments yet published relative to the tenacity of iron, and the other metals, are on this account very defective. The writer of this article has seen an iron wire, when newly annealed, break with a weight of 50 pounds; but, after being drawn through two holes of a wire plate, bear above twice that weight, without sustaining injury. Iron, when properly annealed, will bear more bending backwards and forwards before it breaks, than in any other state: but the strength, or that power which resists a weight, exerted longitudinally to break it, is jointly as the last property and its hardness. Hence the reason why its strength is increased with a certain degree of hammering. The specific gravity of malleable iron, according to Briffon, is 7.788; that of pig iron being 7.207. Iron, in a state of purity, requires a great heat for its fusion, that the best crucibles are nearly ready to melt with it. It has, however, been fused, and cast into an ingot. It is said to liquify at 153° of Wedgwood. Its malleability is greatly increased by heat; and by raising it to a very high temperature, it becomes exceedingly soft, and may be brought so near to absolute contact with another piece similarly heated, that they unite firmly together. This process is called *welding*. Its great affinity for oxygen, when heated to a welding point, would very soon reduce it to an oxyd, if it were not for the vitreous matter fusing upon its surface; and it may be still more completely defended, by dipping it in powdered glass and sand. See *Description of Plates* at the end of the article.

2. *Steel*.—This substance, which is a compound of iron and carbon, but in less proportion than that of pig iron, is of such distinguished importance in most of the arts, that no other substance could be substituted, capable of supplying its united properties of hardness, tenacity, and elasticity. After the pig iron is totally deprived of carbon, and becomes malleable, the metal can be re-impregnated with that substance to a certain extent, without losing much of its malleable property.

It is curious to remark, that although we have made iron of excellent quality in this country, for all the nice purposes to which it is capable of being applied, yet, in attempting to convert it into steel, we have always failed; the steel being red-short, and otherwise bad. It, of late, however, has been so great a desideratum to obtain steel from British ore, in consequence of our want of communication with Sweden and Russia, that several efforts have been lately made to bring about this desirable object, and not altogether without success. We may yet entertain a hope, therefore, that the time will arrive, when we shall not be dependent on other countries for this useful commodity.

The only steel at present, on which perfect reliance can be placed, is made from some of the best marks of Swedish iron. The bars are stamped with certain letters or characters, well known to the steel-makers; and some of them have preserved their character for making good steel during a long series of years.

The size of the bars varies from 3 inches broad and $\frac{1}{2}$ inch thick, to about 2 broad by $\frac{7}{8}$ thick.

Nothing more is necessary to impregnate the bars of iron with carbon, by which they become steel, than to stratify them with powdered charcoal in a close vessel, called a cementing pot; exposing the same to a degree of heat as little short of what would fuse the steel as possible.

The furnace in which the process of cementing bar iron is performed is called a converting furnace.

The pots are made of a peculiar stone called fire-stone, from its joint property of not being liable to crack by the heat, and its little disposition to enter into fusion. It is a fine grit, and occurs abundantly in the neighbourhood of Sheffield. The interior of these pots is in dimensions from 12 to 15 feet long, and from 2 feet to 30 inches square. Every furnace contains two of them; and they generally hold about 5 tons of iron each. The metal is stratified with the charcoal dust, in such a way that each bar may be completely covered; and the last stratum, which should be thicker than the rest, is kept close with a mixture of clay and sand, so as to prevent the charcoal beneath it from entering into combustion with the outer air.

The fire is then gradually applied, and the exterior surface of the pots constantly enveloped with flame, till the whole mass has become of the heat required. This heat is kept up for a considerable time, so that from the commencement of firing to the maximum is about seven days. The same pace is afterwards required to allow the mass to cool. This rule, however, is not sufficient to tell when the cementation is perfect. A hole is generally left in the front of the furnace, passing through the wall to the interior of the pot. One or two bars are laid with their ends projecting into the opening, which is loosely filled with powdered charcoal. When the process is supposed to have gone on long enough, one of these bars is drawn out and examined.

All bar iron must, owing to the manner in which it is made from the pig, contain a small portion of oxyd of iron, as well as some remains of iron not completely deprived of its carbon. The long continued heat which this process requires, cannot fail to cause an union between the oxygen and carbon, accidentally existing in the bars; and we may expect, in consequence, that an elastic fluid will be formed, which must be either carbonic acid or the carbonic oxyd; but since the oxyd is in the state of finery cinder, we should rather conceive it to be the latter; and we believe experience warrants the conclusion.

This elastic fluid, when the metal is so near the fusing point, causes the surface of the bars to be covered with blisters, which are a sure sign that the cementation is complete; and it is from the number and size of these blisters, that the workmen know when to cease adding fuel to the furnace.

Steel is made of different degrees of hardness, by giving it more or less carbon; and this is effected by keeping up the heat a longer time, still having regard to the quantity and size of the blisters.

The steel used for coach-springs contains the smallest quantity of carbon; a somewhat greater proportion is required for table knives, forks, carpenters' tools, and agricultural implements; and the largest dose of all is wanted for files, which can scarcely be too hard, if the steel be sufficiently malleable to work.

Steel, in the state it comes from the cementing furnace, is called *blistered steel*, from the appearance we have just described. It is not used but for common purposes, although formerly we had no other kind. The bars of iron being formed under the forge hammer, and produced in a country not remarkable for the excellence of its machinery, the metal is found to abound with numerous seams and shells, which good workmanship might in a great measure avoid.

This evil is, however, very happily remedied, by making

the blistered-steel into what is called *shear-steel*, and *cast-steel*.

Shear-steel has derived its name from the advantage with which it has been applied in the manufacture of sheep-shears. Its admirable property of welding to iron, without the other qualities it possesses being injured, renders it of great importance in all cases where the body of the edge-tool is constructed of iron, and the edge merely steel.

From having been first made at Newcastle-upon-Tyne, it has also been called *Newcastle steel*. The apparatus used for its manufacture consists of a pair of bellows, or other blowing machine, and a fire place similar to that of a smith's hearth, but upon a larger scale. The hammer for drawing the bars is larger than a tilting hammer, but smaller than the one employed at an iron forge.

In order to make shear-steel, a number of bars of the best blistered-steel are laid together, and temporally fastened. In this state they are introduced into the fire, and heated to a welding temperature; after which they are firmly united by means of the hammer, and drawn. At a second heat these masses are beaten down into bars about 1½ inch broad and ½ of an inch thick. By this process the loose parts and seams of the bars are closed together, and the steel is rendered susceptible of a polish, of which before it was not capable. But these are not the only advantages. The additional hammering so far improves its malleability, that the tenacity it enjoys is much greater, while its hardness is very little less.

This steel is particularly adapted for springs of every description, and for all edge-tools requiring great tenacity rather than hardness.

Cast-steel is entirely free from the mechanical defects which belong to blistered-steel, and even, in some degree, to shear-steel; since it consists of the latter variety completely fused, and cast into ingots.

The furnaces employed for this purpose should possess all the advantages which can be given to air-furnaces, on account of the great heat requisite for the process. (See FURNACE.) The crucibles, in which the steel is melted, are made of Stourbridge clay, mixed with a small quantity of powdered coke, which makes them less liable to crack in the heating or cooling; and, at the same time, gives to them a considerable degree of stiffness in the fire, when raised to the very great heat required. These crucibles are furnished with covers, which are of rather more fusible clay than the body of the vessel, and, on that account, are soon partially vitrified; by which means they become closely luted at the time the steel is at a temperature sufficiently high to be destroyed by the oxygen of the atmosphere.

The fuel employed for melting steel, consists of the hardest coals, and in all cases where long continued and high temperatures are necessary, coals of this description should always be employed. Two advantages attend the use of them; for although the soft coals produce a very great heat during a short space, yet the length of time required for melting steel would oblige the workman to charge the furnace too often; so that he would ultimately get a greater heat by the permanence of the hard coals; and the specific gravity of the latter is so much greater than the soft, that the fuel is more condensed, and hence, allowing for the difference of cohesion, will give more concentrated heat, if the supply of air be sufficient.

The crucibles are of a size sufficient to hold about 30 lbs. of steel; and, in general, each will bear charging three times, or even four: some would remain found still longer than that, if the fires were continued; but they are seldom kept

kept in more than twelve hours in the day, and this will not allow of more than three heats. For the best possible cast-steel, the bars of the best blistered-steel are broken into small pieces, it being, on coming from the cementing furnace, sufficiently brittle for this purpose. An inferior kind of cast-steel is made from the scraps, which consist of the waste of the manufactories. The heat required to melt steel is very great; and inversely as the quantity of carbon combined with it. Before cast-steel making was brought to great perfection, the quantity of carbon given to it was greater, in order to effect its more easy fusion. The crucibles and furnaces, however, are now so much improved, that the steel can be melted with much less carbon, and it is, in consequence, so *kind*, to use a technical phrase, as to weld with iron, and even to be capable of uniting two pieces of it together.

After the steel has become sufficiently fluid, it is poured into cast-iron moulds, which form it into ingots of an octagonal shape; and are about 30 inches long, each weighing about 3 cubs. Formerly, the great secret of making cast-steel was said to consist in using some peculiar flux. No substance, however, from what has been observed, can increase the fusibility of the steel, but an additional dose of carbon, which is improper after a certain quantity has been united with it. The only substance, therefore, which can be employed to any advantage, must be some fusible vitreous matter, capable of floating upon the surface of the metal, and defending it from the contact of air.

The flux at present used, and the most proper for this purpose, is the blast-furnace cinder. But pounded glass, or any vitreous substance which fuses a little before the metal melts, will answer equally well.

The ingots of cast-steel, as well as the bars of blistered-steel, and shear-steel, are drawn into rods ready for forging into various articles, by a piece of machinery called a *tilt*, or *tilting-mill*. (See *TILTING-MILL*.) By this hammer, the cast-steel can be drawn down to the size of $\frac{1}{4}$ inch square. But in reducing smaller than that, it would be liable to be injured in its fabric. It is drawn into rods of small size by hand, for the purpose of making gravers, and watch-makers' tools: and for still more delicate articles, it is manufactured into wire. The blistered-steel will not bear drawing to a small size, on account of the looseness of its texture.

Steel is of a mean specific gravity between wrought and pig-iron; and, like the former, it increases its property in this respect by hammering. Like iron, too, it becomes softer on being annealed, but never becomes so soft as that metal. When of good quality, and at a certain degree of hardness, it is stronger than iron; that is, when stretched longitudinally by a weight; but, by sudden bending or twisting, it is more liable to break short. In working it with the hammer, it will not bear so great a heat as iron; since the temperature iron and its combinations sustain without melting, is inversely as their dose of carbon.

This property of bearing heat, is, however, in a still less ratio in cast-steel. This is owing to its having entirely lost its fibrous form in the melting. Hence there is less danger in heating it after it has been hammered.

In welding steel to iron, or steel to steel, the fire ought to be very free from sulphur, or other extraneous matter; and the heated parts of the rods should be frequently supplied with either sand, or sand mixed with the scales which come from the hammered iron. This fuses upon the surface and keeps off the air. See *FORGE*.

The most singular property which belongs to steel, is that of its hardening by being heated red-hot, and cooling rapidly. This change is greater the hotter the steel, and the

colder the fluid into which it is plunged. (See *CUTLERY*.) Water, in general, is employed for this purpose; and spring-water is better than any other. If the water abound with animal or vegetable matter, the hot steel cools more slowly. This is occasioned by a film of the matter in solution forming and remaining upon the surface, and, being a bad conductor of heat, prevents the steel from cooling. File-makers say, that the salt which is inevitable in their hardening water, makes the steel harder, and they sometimes put sulphuric acid into it for the same purpose.

In hardening steel in thin plates, such as saws, particularly when of cast-steel, quenching in water would cause them to crack, and make them so hard as not to be useful. They have, in consequence, recourse to some substance which is not so good a conductor of heat. Oil, with tallow, bees' wax, and resin dissolved in it, is generally employed for these articles. (See the article *SAW*.) If the steel be heated red-hot, it mostly returns to its original state. This, however, is sometimes not the case with thin plates of cast-steel. In giving various degrees of heat from the hard state, it becomes more soft and less elastic. See *CUTLERY*.

This curious and valuable property which it possesses might, at first view, appear to be caused by an increase of density; but the specific gravity of hardened steel is less than before it is hardened. It has been said to depend upon a certain crystalline arrangement of its particles; but this is a mere apology for ignorance. The most plausible theory we have heard of is mentioned in one of Dr. Darwin's notes to his "Botanic Garden," and was the idea of a very ingenious friend of that celebrated author. This theory was equally applied to the singular property possessed by the glass toys known by the name of *Prince Rupert's Drops*. It is as follows. When the heated steel or glass is plunged into water, the exterior stratum becomes so hard and solid, as not to be capable of shrinking; and every succeeding layer is to a certain degree placed in the same situation. When caloric leaves a body slowly, it contracts in its dimensions, until it assumes something near its original volume. But if any force prevent the parts from approximating, the molecules will attract each other with a power equal to the repellent energy of the caloric that caused the expansion. So soon, however, as the outer stratum is broken, the whole of the others are destroyed in succession. This is most glaringly the case with the glass drops before spoken of, and, to a certain extent, with unannealed glass, and hardened steel.

With respect to the latter, however, it is confined to large masses, and particularly of cast-steel. The rollers employed by jewellers and others are of cast-steel, and are very liable to break in the hardening, although about half the mass in the middle is pure iron. They do not always crack at the time, but at different periods afterwards, and frequently, when no violence is applied to them, some have been known to fly six months after being finished. Sometimes they break with great report, and what strengthens the above opinion as to the cause is, that the figure of the roller is frequently changed from a round to an elliptical shape. For farther particulars, see *STEEL*.

§ 5. *Chemical Properties.*

When a piece of polished iron is exposed to the air, it soon loses its lustre; and if the atmosphere be humid, it becomes covered with red spots called *rust*. When it is exposed at 400 degrees of Fahrenheit, it changes to a yellow colour. The temperature being increased, the colour gradually turns to a brown, and at the heat of about 600 it becomes of a beautiful blue tint. This change of colour arises from the combination of oxygen; the

the quantity increasing with the temperature. If the surface be defended by a coating of chalk and a solution of glue, no change of colour takes place when the heat is applied. In the art of blueing steel, advantage is taken of this method to make the blue ornamental.

In a higher temperature the surface becomes covered with a fealy crust, which is composed of oxygen and iron; and in the heat of a smith's forge, it combines with oxygen so rapidly as to burn, throwing off sparks in bright corrufications. If small iron wire be exposed in pure oxygen gas, the end being ignited with a bit of greased cotton, the metal enters into brilliant combustion, and a globule of melted matter is formed at the end of it. The iron so burnt loses all its metallic properties, by combining with the oxygen; and during this change the phenomena of burning take place. The globule is so brittle as to be capable of being reduced to powder, and is called the black or vitreous oxyd of iron.

Iron has so great an attraction for oxygen, that it decomposes water even in the cold. When filings of that metal are mixed with water in a vessel connected with a pneumatic apparatus, an elastic fluid is evolved, which is found to be hydrogen. The iron loses its metallic lustre, and ultimately is converted into the black oxyd before spoken of.

If this mixture be in a retort, and the boiling heat applied, the iron combines with the oxygen of the water with much greater rapidity; and, of course, a much greater quantity of hydrogen is eliminated. This method has been employed to obtain the black oxyd of iron, which was formerly called *Martial Ethiops*. Iron decomposes water with very great rapidity, when the sulphuric or muriatic acid is present. The acid takes up the oxyd as it is formed by the agency of the water, and a new surface is constantly presented. A large quantity of hydrogen is in this process disengaged, and it is by the present method that this gas is procured for firing aeroflatic machines, and for other purposes. If the oxyd which is taken up by the acid be precipitated by an alkali, and dried instantly, it will exhibit a similar appearance to that obtained by the action of water alone. When first separated it has a green appearance, which it owes to the presence of water; and this being dissipated by heat, it is left of a dark-grey colour. This oxyd, formed by either of the above processes, is called the prot-oxyd of iron, because it is combined with the *first* or smallest dose of oxygen. According to Proust and Lavoisier, it consists of 73 of iron, and 27 of oxygen.

If the prot-oxyd of iron be exposed to the air in a red heat for a length of time, it assumes a red colour, and constitutes the substance known in the arts by the names *crocus* and *colcothar*. This change of colour is found to have been caused by its combining with an additional dose of oxygen, and the product is denominated the peroxyd, consisting, according to Proust, of 52 iron, and 48 oxygen. From the best chemical authorities, it appears that iron unites with oxygen only in two fixed proportions, constituting the prot-oxyd and the peroxyd; although it has been held by some that there are more varieties.

If a bar of iron be heated red-hot, and a stick of sulphur applied to it, a fluid substance will drop from its end, which is found to be compounded of sulphur and iron, and in chemistry is called fulphuret of iron. The fusion of sulphur and iron-filings, in a crucible, gives a similar product. The attraction between these substances is so great, that their union in nature is very common.

Iron-filings, mixed with sulphur, and made into a paste with water, in a certain time become very hot and even produce flame. The mixture is sometimes buried under ground to produce an artificial volcano. This phenomenon, how-

ever, does not depend upon the immediate combination of the fulphur with the iron. The water, which is a considerable agent, is decomposed; the oxygen uniting with the iron to form an oxyd of iron, and with the fulphur to form the sulphuric acid, while the hydrogen combines with another portion of the fulphur producing fulphuretted hydrogen, which occasions the flame in the experiment.

When iron-filings are heated with sulphur, even where oxygen is not present, at a little short of the temperature of redness, they combine and produce flame. We are indebted to the associated Dutch chemists for this fact, as well as a similar experiment with sulphur and copper.

The artificial compound of fulphur and iron, from the experiments of Proust, is composed of

62.5 fulphur

37.5 iron

100

The native fulphuret is found to contain a greater proportion of sulphur. When heated in a close vessel, some of the fulphur sublimes, and may be collected in a proper apparatus. By this treatment, it is reduced to the state of common fulphuret, and loses 20 per cent. of its weight. It is hence composed of

50.6 fulphur

49.4 iron

100

According to some experiments made by Mr. Hatchett, however, these proportions are not regular in specimens where the crystalline form varies. This ingenious chemist has found a native species agreeing in the proportion of its constituents with the artificial fulphuret. It is what has been called magnetic pyrites; and is by this test of the magnet distinguished from the common pyrites, which does not possess that property. It has also another peculiar character. If dilute sulphuric or muriatic acid be poured upon it, a rapid action takes place, and fulphuretted hydrogen is evolved. This is not the case with the super-fulphuret till it has been exposed to heat, when it loses its excess of fulphur. The common fulphuret of iron has been employed to make artificial magnets. Mr. Hatchett found that not only the sulphurets, phosphurets, and carburets, were separately magnetic; but suspects that certain proportions of all these may constitute a *maximum* of magnetic virtue.

It is highly probable, that the iron is the only substance possessing magnetism; and that the facility with which these compound substances become magnetic, may arise from the greater ease with which the particles of iron assume the peculiar arrangement on which this curious property depends. That some arrangement, though perhaps equally mysterious with crystallization, may be the cause of magnetism, there is much reason to believe. By mixing iron-filings with melted resin, and inclosing them in a brass tube, if a magnet be brought near to the tube, while the mats is still liquid, the whole, when cold, will become a magnet. During the touching of a piece of steel to make it magnetic, there is little doubt but that a new and peculiar disposition takes place amongst the particles, notwithstanding the solid state of the metal. The particles of bodies appear to be free to motion in the solid form. We find that iron combines with carbon, while both bodies are in that state; and what is still more curious, the compound assumes a different crystalline structure, according to the proportions of the two bodies. Oxygen appears, in some instances, to alter the internal arrangement of solid bodies. If brags, for example, were to be kept in a damp room, but more particularly where the fumes

of acids are present, the metal, although previously very tenacious and ductile, becomes fo brittle, as not to bear bending to a right angle; at the same time that the broken surfaces exhibit a crystalline fracture. That species of form, therefore, under which magnetism exists, may be brought about by various means. All iron instruments, kept in one position for a length of time, become magnetic; especially if that position coincide with the magnetic meridian. We regret that so little is known on this interesting subject; and for farther particulars refer to the article MAGNETISM.

Iron combines with several of the metals forming alloys, none of which have very striking or useful properties. The alloy of iron and gold has been examined by Mr. Hatchett, who found that 11 parts of gold to 1 of iron formed a malleable alloy, remarkably ductile, fo as to roll into plates, and be capable of being stamped into coin. The colour was of a pale yellowish-grey, and it was of the specific gravity of 16.885. The most singular property of this alloy is its increase of volume by combination. Before the union, the bulk was 2799; and afterwards, 2843. The very contrary is the case with most of the other alloys of metals, and agreeably to Berthollet's doctrine of affinity, we find that the mean specific gravity of bodies by experiment, is greater than the arithmetical mean, directly as the affinity of the bodies. We should, therefore, in this instance conclude, that either the affinity of the metals is trifling, or that the above law is not general.

The alloy of pure iron with platina has not been effected from the great infusibility of the two metals. Dr. Lewis alloyed cast iron with platina, as well as steel. The specific gravity of this alloy, contrary to the last, was greater than the arithmetical mean. It was very hard and tenacious, possessing some degree of ductility.

After being kept ten years, it was little tarnished. Iron is easily alloyed with silver. In equal parts they form a compound of considerable ductility, of the colour of the latter metal, but much harder; and is attracted by the magnet. The metals separate, in some degree, when kept in fusion; but, according to the experiments of Morveau, not completely; the silver retaining some of the iron, and the iron some of the silver, by which its quality, as a metal, is much improved. Iron is not easily combined with copper in large quantity. We find, however, that these metals are capable of uniting, and the alloy is, in some degree, magnetic. Indeed, in forming certain instruments of brass, where the magnetic needle is employed, they are frequently defective from this circumstance. To free copper entirely from iron, it should be redissolved in an acid. The oxyd, after precipitation, should be dissolved in aqua ammonia, and the alkali then distilled from it. This being afterwards treated in a close vessel with some inflammable matter, the metal will be obtained pure. The alloys of tin and iron, and that of iron with zinc, may be formed by mixing clean iron-filings, or turnings, with those metals while in a state of fusion. These compounds are not of any use. Iron may be foldered with several of the metals. Copper, gold, and silver, unite to it with great facility; but require the presence of borax to keep off the air.

The most permanent folder for iron is the carburet of the same metal, called N 1, pig-iron. The pig-iron loses some of its brittleness, and the malleable metal becomes much harder. It does not appear improbable that steel might be formed by uniting these two substances together in certain proportions.

We have next to treat of the salts of iron, or its combinations with acids.

Sulphat of Iron.—Sulphuric acid does not combine with iron in its metallic form; in conformity with the general law that no acid unites with a metal till the latter is previously oxydated. Iron is but slightly acted upon by this acid in the cold; but with a degree of heat far short of boiling, the iron takes from it a portion of oxygen, converting it into the sulphurous acid, which escapes in the form of gas. The iron, thus oxydated, combines with another portion, and forms the sulphat of iron.

When water is added to the iron and the acid, a much more rapid action takes place. The metal seizes the oxygen of the water; hydrogen is evolved; and the acid unites with the oxyd forming the salt in question. When the product obtained by this means is more than the water can dissolve, it assumes the form of green crystals, which, when separated, are the same with those known in commerce and the arts by the names of *green vitriol* and *copperas*.

In the action of iron upon the concentrated sulphuric acid, it appears anomalous, that the metal should not be oxydated with more facility by this acid, when water is so rapidly decomposed, the elements of which have so strong an attraction for each other. It may appear equally strange that the water is not decomposed when the acid is not present. When it is recollected, however, that the oxyd of iron is not soluble in water, nor sulphat of iron in the acid, it will appear very clear that the two substances are both essential to the effect; the acid promoting the decomposition of the water by taking away the oxyd, and the water taking up the salt, which would be equally obstructive to the process.

This salt is not commonly obtained by the above process. The sulphuret of iron, above described, already consists of two of its elements, namely, sulphur and iron; the oxygen and water of crystallization being alone wanting to complete the salt under inquiry. For this purpose, the natural combination of it, or pyrites, is first roasted, and then exposed in large heaps under sheds. These heaps are frequently moistened with water, by which, together with the presence of the air, the iron and the sulphur become oxygenated, and crystals of the sulphat begin to form. The water, which is thrown on from time to time, dissolves the salt, and runs into large reservoirs, which are also under sheds, to prevent the rain falling into them. This solution, however, does not contain the salt in a fit state for crystallization, being too highly charged with oxygen. The liquor is transferred into large boilers, and pieces of old iron put into it, which, by taking up the excess of oxygen, change the solution from a red to a green colour. When the evaporation has gone on to a certain point, the salt crystallizes, and the green crystals being separated, are fit for sale.

When the crystals are obtained from a clear solution, and are well defined, exhibiting transparent rhomboidal prisms, the specific gravity of which is 1.8, the salt may be deemed in a state of purity. It dissolves in $\frac{1}{3}$ ths its weight of boiling water, and twice its weight of water at 60°. When kept dry, it is not liable to change in the air; but if moistened it becomes covered with red spots by the absorption of oxygen, and if it be dissolved in water, it returns to the state in which it existed before boiling with the metallic iron. When the crystals are heated, the salt at first fuses, then assumes the form of white powder, by losing its water of crystallization. At a red heat the acid begins to fly off; and ultimately a fine red oxyd is left behind. It is in this way the *crocus* of commerce is prepared.

According to the analysis of Bergmann, this salt is composed of

Acid	-	-	39
Protoxyd of iron	-	-	23
Water	-	-	38
			100

According to Kirwan :

Acid	-	-	26
Oxyd	-	-	28
Water	-	-	46
			100

It is decomposed by the alkalies and alkaline earths ; and by all the salts forming infoluble compounds with fulphuric acid.

Oxy-fulphat of Iron.—This salt consists of the fulphuric acid united to the peroxyd of iron. Its solution in water is of a deep reddish-brown colour. It is infusceptible of crystallization. Hence, the green crystals separated in making coppers are perfectly distinct in their nature from the salt which is left in the remaining liquid. When the fulphat is exposed in a state of solution for a length of time, it assumes a red colour, and is converted into this salt ; so that we never find the common fulphat in mineral waters, but the oxy-fulphat. This change may be more speedily brought about by heating it with nitric acid. A quantity of nitrous gas is evolved, and, according to Mr. Davy, ammonia also ; the former from the decomposition of the acid, the latter from the decomposition of both the acid and the water. The fluid gradually assumes a deep brown colour. It has a strong astringent taste, much resembling the juice of sloes. When this salt is formed without the addition of water, it is exceedingly heavy, and concentrated, and of a deep brown tint, approaching to blackness. If concentrated fulphuric acid be poured into it suddenly, it loses its brown colour, and becomes of a clear white, having the consistence of thick cream. It is so soluble in water, that when evaporated slowly, instead of crystallizing, it assumes the form of syrup. If too much heat be applied, however, the oxyd either precipitates, or it assumes the form of a sub-salt, and becomes infoluble.

Since the oxy-fulphat differs from the fulphat in the proportion of oxygen only, several substances reconvert it into that salt, by abstracting the excess of oxygen. If it be kept, for instance, for some time in a close-stopped bottle with iron-filings, the metal becomes oxidized, and the whole is changed to the simple fulphat.

Gay-Lussac has lately shewn that the quantity of acid in any metallic salt is in proportion to the quantity of oxygen in the metal. (Memoires d'Arcueil, t. ii p. 159.) Hence no additional acid is required in converting this salt into the fulphat.

Tin, and several other metals, produce the same effect. The excess of oxygen may instantly be taken away by passing sulphuretted hydrogen gas through the oxy-fulphat. This gas reduces the oxyd exactly to a minimum of oxydation, to the state of protoxyd ; and hence the reason why this gas does not precipitate iron from its solutions.

The oxy-fulphat may be easily separated from the fulphat ; the former being soluble in alcohol, which the latter is not.

From the method required to form this oxy-salt, it will appear that there are several substances which may be employed to give their oxygen to the fulphat of iron. Of these are the nitric and oxy-muriatic acids. And by pouring a

solution of gold into a solution of this fulphat, the oxy-fulphat is produced, and the gold becomes metallic.

Dr. Thomson enumerates several triple salts, formed by the fulphuric acid with iron and other metals.

1. Sulphat of iron and copper.
2. Sulphat of iron and zinc.
3. Sulphat of iron and nickel.

The former of these sometimes exists in the blue vitriol of commerce, which is a very great evil to colour-makers. The iron precipitates with the copper, and destroys the beauty of the latter. In order to ascertain whether iron be present in blue vitriol, dissolve a small quantity in a wine-glass, and add aqua ammonia till it smells strong of the latter. The oxyd of copper will be dissolved, and the oxyd of iron left at the bottom. By standing for some time, the precipitate becomes yellow and very conspicuous. It is even said that some of these salts have triple bases. The two hitherto observed are as follows :

1. Sulphat of iron, zinc, and nickel.
2. Sulphat of iron, copper, and nickel.

Sulphite of Iron.—Berthollet has given us an account of a compound of iron with the sulphurous acid. When iron is exposed to the action of this acid, it becomes speedily oxidized ; but what is singular, not at the expense of the water ; as is the case with the fulphuric acid ; but it appears that the acid is decomposed, the oxygen uniting with the iron, while the sulphur combines with the salt. Hence this fulphat of iron is always contaminated with sulphur. The sulphurous acid has a less affinity for iron than the fulphuric ; and if the latter be added to the fulphat, its acid is disengaged in the form of gas.

Nitrat of Iron.—The nitric acid has very violent action upon iron, and an abundance of the red fumes of nitric oxyd are disengaged. The same thing in some measure takes place with this acid, as has been remarked with regard to the sulphuric. If it be more than a certain strength the action is feeble, until a certain portion of water is added. The same explanation will answer in both instances. The nitric acid does not dissolve the nitrat as first formed, the presence of which interrupts the future progress of the operation. When the solution is made with much water the iron is oxidized to a minimum, and the salt formed is the proper nitrat. It is of a pale green colour. The vessel in which this solution is made should be kept in water as cold as possible, else it will absorb too much oxygen, and pass to the oxy-nitrat.

Oxy-nitrat of Iron.—When iron is acted upon by the less diluted acid, and with heat, the salt formed is the oxy-nitrat. The solution is of a deep brown, resembling the oxy-fulphat. It has a strong astringent taste, and turns vegetable blues red. When the solution is boiled the oxyd is partially precipitated ; nor will it afterwards dissolve in the nitric acid. This has furnished one means of separating iron from other substances in the analysis of minerals.

We are indebted to Vauquelin for a method of obtaining this salt in a crystallized state. The method he recommends is to keep the black oxyd of iron and strong nitric acid together for a length of time, till the crystals appear. They have an acid taste, and are deliquescent. The form of them is that of a four-sided prism.

The alkalis precipitate the oxyd of iron from this salt of a fine yellow colour, and yield a product which is valuable to painters.

Muriat of Iron.—The muriatic acid, like the sulphuric and nitric, acts feebly upon iron, except it be diluted to a certain extent with water. It differs from the latter, and

agrees with the former, in not being decomposed; but merely takes up the oxyd formed by the oxygen of the water, the hydrogen being given out in the state of gas. The solution is of a green colour; and, on evaporation, it affords crystals presenting the same appearance. Mr. Davy has given us several useful facts relative to this salt. It was employ'd by him to great advantage in making some eudiometrical experiments. He found that a solution of it absorbs a large quantity of the nitric oxyd gas, which, in this situation, is better fitted for absorbing oxygen than by mixing the two gases together. By absorbing this gas it assumes a brown colour, and acquires an astringent taste. When the compound is heated, it appears that the gas is decomposed as well as a portion of water; since the iron becomes more highly oxydized, and ammonia is formed. Mr. Davy recommends an infallible method of forming this salt, by adding muriatic acid to sulphuret of iron. The sulphuretted hydrogen prevents the muriat from becoming oxy-muriat, which has not the property of absorbing the nitric oxyd. Muriat of iron is very soluble in water and in alcohol. It is decomposed by the alkalis and alkaline earths, and all salts, the bases of which form insoluble compounds with muriatic acid; such as silver and mercury.

Oxy-muriat of Iron.—The muriat of iron, like the sulphat and nitrat, is converted into the oxy-muriat by the oxyd of iron passing from the state of prot-oxyd to that of per-oxyd. It slowly undergoes this change by exposure to the air; and rapidly, by the agency of those bodies which afford oxygen with greater facility, as the nitric and oxy-muriatic acids. The solution is of a deep brown, but does not afford crystals by evaporation. It has a powerful, astringent taste, and a peculiar odour. When this salt is distilled it affords oxy-muriatic acid, leaving in the retort the prot-oxyd of iron.

If the heat be applied rapidly, the salt sublimes; not in the state of oxy-muriat, but of muriat of iron.

There is also a triple salt formed by the muriatic acid with iron and ammonia. This may be prepared by adding iron-s filings to muriat of ammonia. It may either be obtained in crystals by evaporation, or it may be sublimed. In the latter state it is known in medicine by the name of *Flores Maris*.

Phosphat of Iron.—The phosphoric acid has little action upon iron; but the acid unites with the prot-oxyd, and forms this compound.

It is prepared by adding a solution of sulphat of iron to a fluid mixture of phosphat of potash. The salt precipitates in the form of a blue powder, which is insoluble in water, and does not lose its colour by exposure to the air.

The substance known by the name of native Prussian blue, is a phosphat of iron; but, what is remarkable, it has little colour when dug out of the earth, becoming deeper on exposure to the atmosphere. A crystallized specimen, lately brought from Brazil, has been analysed by Vauquelin, and is composed of

Acid	21
Protoxyd	45
Water	34
	<hr/>
	100

Oxy-phosphat of Iron.—This salt is formed by taking advantage of some oxy-salt of iron and phosphat that is soluble; as, for instance, by adding together the oxy-sulphat, or oxy-muriat of iron, and the phosphat of soda or of potash, a white powder will be precipitated, which is the oxy-phosphat of iron.

This salt is insoluble in water, but dissolves in the muriatic or sulphuric acids; from which it may be precipitated, unchanged, by pure ammonia.

Sub-oxy-phosphat of Iron.—The salt above described is not decomposed by the alkalis like the metallic salts in general. The alkali combines with a portion of the acid only, leaving the salt with an excess of base, which is the sub-oxy-phosphat of iron. This sub-oxy-phosphat does not dissolve in water, or scarcely in acid; but it has the singular property of dissolving in albumen, or the white of eggs; and if an alkali be present, which is the case with the albumen in the serum of blood, it assumes a reddish-brown colour, and is supposed, therefore, to be the principal colouring matter of the red blood of animals.

Fluat of Iron.—The liquid fluoric acid attacks iron, or rather takes its oxyd, which is formed by the oxygen of the water, while hydrogen gas is evolved. It has no striking properties, or any which it may be important to describe.

Borat of Iron.—This salt, being insoluble in water, is obtained by mixing solutions of borat of soda and sulphat of iron together. It appears in the form of a yellowish powder, and melts into glass before the blow-pipe.

If the oxy-sulphat of iron be employed, an oxy-borat will be obtained.

Carbonat of Iron.—When iron-s filings are mixed with the liquid carbonic acid, and suffered to remain for some time, the water will acquire a perceptible taste of iron. If it be exposed to the air, a precipitation takes place, either from the gas flying off, or from the salt assuming the state of sub-carbonat. The precipitate is of a yellow colour. This salt is frequently found in mineral waters, to which it gives a peculiar odour. The water, by standing a little while, is not sensible to any of the tests of iron; but a yellow precipitate is found at the bottom of the vessel.

When a solution of neutral carbonat of potash is added to a solution of sulphat of iron, a large quantity of iron is dissolved by the carbonic acid, giving to the fluid a strong inky taste.

This salt is also found native in the solid form, of which we have already spoken in the mineralogical part of this article.

The common rust of iron, formed by exposing iron to the air, may be proved to be a carbonat of this metal by its perseverance with acids. It is, no doubt, from the solubility of this salt, that iron becomes so perishable by exposure to the weather.

The sub-carbonat of this species, according to Bergmann, is composed of

24 acid
76 oxyd
<hr/>
100
<hr/>

It appears from some experiments of Bucholz, that the native carbonat, by heating red-hot, becomes magnetic.

Acetat of Iron.—The acetic acid, when of moderate strength, added to iron-s filings, causes the iron to be oxydated by the decomposition of the water, while the hydrogen is set at liberty. The solution has a sweetish, though inky taste, and emits the odour of vinegar. The best way of forming this salt is by mixing acetat of lead and sulphat of iron together. The sulphat of lead becomes insoluble, and the acetat of iron remains in the liquid. Mr. Davy obtained this salt by digesting the sulphuret of iron with acetic acid. It afforded to him crystals in small prisms.

Oxy-acetat of Iron.—If the oxy-sulphat of iron be used instead of the sulphat with the acetat of lead, the salt is

of lead is precipitated, and an oxy-acetat is held in solution of a beautiful reddish-brown colour. This salt does not afford crystals. It has the smell of vinegar; and, when in solution, affords an excellent test for arsenic. The arsenic forms an insoluble compound with the iron, of a brilliant orange tint. The pyrolignic acid, which is an impure acetic acid, unites with iron, and yields a very cheap acetat of iron, which is used by dyers and calico printers as a mordant.

Succinat of Iron—When the solutions of fuccinat of potash or soda, and sulphat of iron are mixed together, a brownish-red insoluble precipitate is formed, which is the fuccinat of iron. The soluble fuccinat may hence be employed to separate iron from other substances.

It is composed of

Acid and water	61.5
Oxyd - - -	38.5
	<hr/>
	100

The *oxalat, tartarat, citrat, malat, benzoat, and suberat of iron*, are but little known. They are all, however, soluble in water.

Gallat of Iron.—When the gallic acid is added to any solution of iron, the oxyd being at a *minimum* of oxydation, a fine purple precipitate will be produced. If the acid be entirely freed from tan, the purple colour is much more conspicuous. The pure gallic acid, therefore, is much better as a test for iron, than the mere infusion of galls.

The tan may be separated from this acid by means of gelatine, which does not precipitate the gallic acid. By this treatment a solution may be obtained colourless and limpid.

If the gallic acid be added to a salt of iron, in which the oxygen is at a *maximum*, the precipitate is a very complete black; but the oxyd soon separates, and falls to the bottom in the form of a red powder. This property renders these salts of iron unfit for making writing ink. When the oxyd is in the state of prot-oxyd, the combination is permanent; and although it is not so black when first used, it soon becomes dark by exposure to the air. We may hence learn, that while ink is in use, it should not be kept exposed to air; since it passes to the state of oxy-gallat, and the oxyd will fall down.

Pruissiat of Iron.—When the triple prussiat of potash and iron is poured into a solution of the latter substance, the oxyd being at a *minimum* of oxydation, a white powder is precipitated, which is the prussiat of iron. If this powder be exposed to the air, it changes to a blue; and in this state is called the oxy-prussiat of iron.

Oxy-prussiat of Iron.—This salt is formed by the same soluble prussiat being added to the oxy-sulphat of iron, and constitutes the beautiful blue pigment, known by the name of *Pruissiat blue*. It is generally, however, adulterated with alumine. See PRUSSIAN BLUE and PRUSSIC ACID.

Arseniat of Iron.—The native arseniat has been already described in the mineralogical part of this article. Arseniat of potash, or ammonia, being added to the sulphat of iron, an insoluble powder precipitates, which is the artificial arseniat of iron.

Oxy-arseniat of Iron.—The arseniat of iron, in common with all the other salts of this metal, combines with an extra dose of oxygen, constituting the oxy-arseniat. The precipitate formed by the arsenic acid and the oxy-acetat of iron is of a bluish-white colour.

The oxy-arseniat of iron, from the analysis of Chencvix, is composed of

Acid	42.4
Oxyd	37.2
Water	20.4
	<hr/>
	100

Arsenite of Iron.—The arsenious acid, or the common white arsenic of commerce, forms with iron peculiar compounds, which have been but little examined. It does not take the oxyd of iron from the sulphat, but decomposes the acetat, forming with the protoxyd a substance of a greenish-yellow colour; the precipitate from the oxy-acetat being of a bright orange. If either of the acetats contain the least portion of the sulphat of iron, it prevents the precipitation of the arsenite.

Chromat of Iron.—See CHROME.

Most of the other acids combine with iron; but they form compounds which are but little known. Certain alkaline salts act upon iron, and produce triple compounds, which have not received a particular examination. When the nitrat of potash is fused in contact with that metal, the acid is decomposed, and the iron oxydized to a *maximum*. This melted mass, after the acid is completely dissipated, is of a red colour. If, before it becomes deliquescent, which takes place from the presence of the alkali, it be thrown into water, the alkali dissolves a quantity of iron, forming a solution of a deep splendid purple tint. The colour remains permanent for some time, if the air be excluded; but, if exposed in an open vessel, it changes quickly to a green, and the oxyd ultimately precipitates, leaving the liquid clear and colourless. The precipitated oxyd is of a deep red colour.

Description of Plates.

Plate I. *fig. 1*, a plan of an iron forge; *fig. 2*, an elevation of the same. In *fig. 1*, A is a water-wheel, which gives motion to the stamping hammer E; G, the mill-dam; H, the tail water course; I is a small water-wheel, to give motion to the blowing machinery; L, *fig. 1*, is another water-wheel, which works the hammer o, for drawing the balls, &c. into bars; K is the mill-dam for supplying all the wheels.

Q, in *fig. 1*, is a refinery, technically called a *furny*; in *fig. 2*, is the elevation. It is blown by the double blowing cylinders, e, e. R, the *chafery* for heating the masses of iron a second time after hammering; S, S, plans of blowing furnaces, and similar to the puddling furnace.

Plate II. *fig. 1*, is a front view of the finery, as seen *fig. 2*. Plate I.; *fig. 2*, being a side view. K, the hearth on which the pig-iron and charcoal is placed; G H, the chimney; f, the air-pipe; g, a cock to regulate the blast; h, a leathern pipe connecting the main-pipe with the nose-pipe; i, *fig. 3*, an enlarged view of the tuyere-iron, into which the nose-pipe i is inserted, and which enters the hearth at a, *fig. 1*; m and n are two iron pipes, terminating in, and forming a part of the tuyere-iron. The pipe m communicates with a cistern of water, which conveys a stream of cold water, for the purpose of keeping the tuyere-iron cool, and which is discharged at n, into the cistern o, *fig. 4*, where the whole of this apparatus is seen. The furnace called the *run-out furnace* is very similar to the finery. The hearth of the finery is surrounded with cast-metal plates, having a cavity under the bottom plate, to throw water from time to time to keep the bottom plate cool. The *run-out furnace* differs from this, in being surrounded on three sides with water. This furnace, and its use, has already been described. The chafery is also similar to the finery,

finery, except in the hearth being more like the smith's forge.

Fig. 5. exhibits tongs for taking the balls from the furnace to the hammer; and fig. 7. an iron ladle, employed to throw water into the puddling furnace, to oxydate the iron.

Fig. 8. the face of the stamping hammer, which is made to be taken out occasionally.

Fig. 9. the face of the hammer employed for drawing out the bars; *b* is the part used to extend the bars in length with more expedition; the part *a* being employed for smoothening or finishing the bar.

Figs. 10. and 11. are different views of the balling furnace: *a* is the fire-grate; *b*, the hole where the fuel is admitted; *d d*, the roof made of fire-brick; *e*, the door through which the balls are admitted; and *b b*, the hearth on which the balls are laid to be heated, by the flame which is carried by the draught of the chimney *G*. This furnace is bound on all sides by bars of iron, secured by bolts.

The puddling furnace is so nearly similar to this, as not to require a separate drawing. The hearth is more concave opposite the door, for the purpose of containing the metal which is liquid, previous to its assuming its malleable state. The door of this furnace, for heating the balls, consists of a frame of wrought iron, containing fire-bricks, to prevent the escape of heat. It shuts and opens upon the hole, by being attached to the end of a lever; its weight being counterpoised at the other end. See fig. 1. Plate IV. where *R* is the lever; *b*, the door; and *f*, the part by which it is raised.

The door of the puddling furnace consists of a solid piece of cast-iron, about 3 inches thick, having a small hole through it, for the purpose of inspecting the process, and introducing the puddling instruments.

Plate III. figs. 1 and 7. are views of the reverberatory furnace, used by the cast-iron founders, for melting large quantities of metal at once. This furnace, like the last, is heated with flame from its fire place *a*, the fuel being introduced at *B*; *c d* is a sloping hearth, on which the pigs or other pieces of metal are laid; *b*, the door where it is introduced; and *g*, the chimney. The melted metal runs down to the part *o*, where it is accumulated, and is let out at *f*; or a door may be opened at *e* above, and the melted metal carried out in ladles, to be poured into the moulds.

Fig. 2. is a section of a cupola, in which *a* is the interior of the furnace containing the metal and cokes; *e*, the tap hole; *b*, the nose-pipe; *d*, a leathern pipe connecting the air-pipe, which comes from the blowing cylinder, with the fame; *c*, a stop-cock to regulate or turn off the blast.

It generally consists of four plates of cast-iron, firmly bolted together; the interior being lined with fire-brick. This furnace is generally employed for the best kind of work, and will melt many charges in a day, according to the nature of the metal exposed in it.

Plate IV. figs. 1. and 2. are two views of forge-hammer machinery, erected by the celebrated Smeaton. *A* is the water-wheel; *H*, a fly-wheel; *D*, wheel-work to open the shuttle by a little at once, for the purpose of adjusting the quantity of water; *F*, a cog-wheel to give motion to the wheel *G*; at the other end, *I*, are a number of cogs, which lift the hammer *K*, fig. 2, by passing under its shaft, or helve, as it is sometimes termed; *L*, a large beam of wood inserted into the post *M*, and passing horizontally over the hammer. Into the posts, *M* and *N*, is inserted a piece of ash-wood *o*, against which the hammer *K* strikes in its ascent, and by its elasticity re-acts upon the hammer, and

gives it a greater descending velocity than would be produced by gravity alone. *Q* is a number of heavy pieces of metal laid upon the beam *L*, to increase its *vis inertiae*, and will, in consequence, receive less motion from the hammer. (See MILL-WORK and WATER-WHEEL.) The hammer here described has been much improved, so far as regards the spring at *o*.

That already mentioned in the plate is much preferred. The whole of it is made of cast-iron, and its weight is about 35 cwt. It acts simply by its gravity; its extra force, therefore, over the common one, consists in its greater quantity of matter. It is made exceedingly massive near the centre of motion, by which means its centre of oscillation is thrown nearer to that point, and it consequently descends with greater velocity. Although this is an advantage with respect to the number of strokes in a given time, it is a disadvantage in another way; since the centre of oscillation is also the centre of percussion, or the point where the greatest stroke is made. Could the velocity be obtained without this evil, the advantage would be material. See TILTING-MILL.

IRON, in the *Materia Medica*, is said to have greater virtues than any of the other metals, which is not to be wondered at, as being the only one that is in a manner soluble in the human body. All the other metals, whether hard or soft, poisonous or salutary, may even fluid mercury itself, swallowed in their crude state, pass out of the body again unaltered; but this is not the case with iron, its crude filings are often taken as a medicine, and are always so much acted upon by their juices, as to produce considerable effects. It is so easily wrought upon out of the body also by fire, and by different menstrua, that it becomes an aperient or astringent, as it is differently treated; and is, under proper management, greatly superior to all other medicines in chronic cases.

Iron or steel, that is, the *ferrum* or *chalybis*, may be employed indifferently, as Cullen suggests, in the preparation of the rubigo; but he thinks that, upon the whole, the preference is due to the iron in its soft malleable state, or in that which is called "forged iron." As iron, says this medical writer, like all other metals, in its solid and entire state, is not active with regard to our bodies, without being corroded or dissolved by saline matters, he is of opinion, that it is rendered active only by being combined with acids. It has indeed been common to give the entire metal, brought by filing into a fine powder, and with very good effects, as a medicine. But this he does not consider as an exception to his general rule; because he is persuaded that there is constantly present in the human stomach a quantity of acid capable of dissolving iron; and as a proof of it he alleges that he never knew iron given in its metallic or slightly corroded state, without producing a blackness in the stools, which affords a presumption of a previous solution of the iron in acids. As this combination with acids is necessary, physicians and chemists have diversified this combination in a variety of ways; Dr. Cullen observes, that he has not known a preparation of iron for the purpose of medicine, that has not been prepared by a combination with acids, or by bringing the iron into a state that rendered it readily soluble by the acid of the stomach, and Dr. Lewis very properly remarks, that Prussian blue, though truly containing a quantity of iron, as it is not soluble in any acid, is the least promising of all the medicinal preparations.

Its virtues internally were not unknown to the ancients; Dioscorides attributes both an astringency and aperieny to it, and prescribes it in hæmorrhages. He also recommends its rust, or *crocus martis*, in suppressions of the menses; though

though he, on the other hand, prescribes wine or water, in which red-hot iron has been quenched, as an astringent in dysenteries, diarrheas, and weaknesses of the stomach.

Iron combined with acids becomes an astringent substance; and hence its great medicinal virtue is caused by its tonic and strengthening qualities; for by increasing the tone of the vessels, it increases their vigour and activity. It produces a slight and gentle irritation of the fibres, the effect of which is to constrict the sensible organic parts upon which it acts, and to increase their force and elasticity. Iron particularly acts upon the fibres, and the vessels of the stomach and intestines; hence it produces excellent effects in all diseases which proceed from laxity and inactivity of the digestive organs. Such are crudities, bad digestion, accompanied with diarrhoea, flatulencies, flatulent colics, &c. &c. in diseases which proceed from the former, as many hysterical, hypochondriacal, melancholic affections, intermittent fevers, tertians and quartans, &c. In those cases iron quickens the circulation and raises the pulse; renders the blood more florid, and as it were expands and rarefies the juices, promoting, when they are deficient, and retarding, when in moderate, the secretions that are made from the blood, as perspiration, urine, and the uterine purgations. By the same corroborating power, which renders it serviceable in promoting deficient, and restraining redundant discharges, where the suppletion or flux arises from debility and relaxation, it increases, on the contrary, fluxes, and confirms obstructions, when they proceed from tension, rigidity, or spasmodic strictures of the vessels. Where either the circulation is quick, or the habit plethoric, by increasing the velocity of the blood, and the plethoric symptoms, it produces heaviness, dulness, vague heats and flushings, or kindles more dangerous fevers or inflammations, or bursts some of the over-distended small vessels. In some constitutions, where iron is proper and salutary, particularly in hysterical and hypochondriacal cases, and where the stomach is very weak, it is apt at first to occasion great sickness and perturbation: to remedy these inconveniences, Sydenham advises, to begin with very small doses, and to administer it for a while at bed-time, in conjunction with a slight opiate. In other circumstances, it is commonly taken in the morning and afternoon, and moderate exercise used to promote its action. In all cases the dose should be small and repeated; a grain, or half a grain of the metal dissolved, or in a soluble state, is generally a sufficient dose. Its effects are known by odorous eructations, and by the alvine feces being tinged of a black colour.

Stahl, and several other modern chemists and physicians, acknowledge only the tonic and strengthening qualities of iron. The cases in which iron has produced a relaxing and aperient effect are those, in which the obstructions, and the defect of secretions and excretions, have proceeded from weakness and relaxation of the fibres and of the vessels, rather than from a crassitude of humours, as in the chlorosis, in some kinds of jaundice, and other diseases of the same sort.

The same preparation, as Dr. Lewis has judiciously observed, may sometimes exert an aperient, and sometimes an astringent power, according to the state of the body to which they are applied. *E.g.* If a retention of menses depends upon a weakness in the vessels of the uterus, chalybeate medicines, by invigorating the force of the vessels, may cure the disease, and may thereby appear to be aperient; and, on the contrary, in a menorrhagia, when the disease depends upon a laxity of the extreme vessels of the uterus, iron exhibited, by restoring the tone of these vessels, may

shew an astringent operation. However, it is probable, that in the cases of suppletion depending upon a constriction of the extremities of the vessels of the uterus, the same tonic powers may not be so properly employed. By considerations of this kind, the utility or propriety of the medicinal preparations of iron may be determined. In all cases of active hemorrhagy they must be hurtful; and in cases of hemorrhagy from external violence, Dr. Cullen would judge them to be useless, if not hurtful. In cases of a general acidity, as it is frequently marked under the title of "Cachexy," and in all cases of evacuations from laxity, whether faecal or serous, they are likely to be the most effectual remedies. The good effects of the preparations of iron, as Dr. Cullen apprehends, have been often misapprehended by their being given in too small doses. The saline preparations, in large doses, are ready to irritate the stomach; and for this reason, and some others, it must be always proper to begin with small doses, and to increase them by degrees; but he has often found, that no great benefit is to be obtained but when large quantities, either by the size of the doses, or by the long continuance of them, have been thrown in. He says, that he has found the simple ruit as effectual as any other preparation, and the stomach has borne it better than any other. He begins with a dose of five grains, but gradually increases it to what the stomach easily bears. Some are said to have given it to the quantity of six drams in one day; but he has hardly found any stomach that would bear the third part of that quantity without much sickness. He thinks that the stomach bears it better by joining with it some aromatic.

The preparations of iron that have been in more frequent use, and some of which are at present continued under different names, are, 1. The crude filings reduced to an impalpable powder; this is an excellent form for administering iron in female disorders, in which the body is weak, languid, and full of acidities; the dose of the filings is from two or three grains to a scruple or more. 2. "Mars saccharatus," which is the filings candied with sugar, by dissolving two parts of fine sugar in water, and boiling it down to a sandy consistence, and adding, by little and little, one part of the cleaned filings in a kettle over a gentle fire; the vessel being continually shaken, that the filings may be crufted over with the sugar. In order to prevent the mixture from running into lumps, a little starch is previously mixed with the sugar, in the proportion of a dram to a pound. 3. "Lima-mars Martis preparata," or "Chalybis rubigo preparata," is formed by moistening the filings with vinegar or water, and exposing them to a moist air, or occasionally moistening them afresh, which soon change in great part into ruit; this ruit may be separated from the uncorroded part, by grinding and washing over the fine powder with water. This is given in the same dose as the crude filings.

This preparation, which was denominated "chalybis rubigo preparata" in the London Pharmacopoeia of 1745, and "ferri rubigo" in that of 1787, is now called "ferri carbonas," or carbonate of iron. It is formed of sulphate of iron, eight ounces; sub-carbonate of soda, ten ounces; and a gallon of boiling water. Dissolve the sulphate of iron and sub-carbonate of soda separately, each in four pints of water; then mix the solutions together, and set by the mixture, that the precipitated powder may subside; having poured off the supernatant liquor, wash the carbonate of iron with hot water, and dry it upon bibulous paper in a gentle heat.

There are two oxys of iron, both of which are combined with acids, and form different modifications of the same salt, a distinction that ought to be particularly regarded

in medicine; they have been named, from their colour, black and red oxids; the former, which is black, or (if formed as in the present instance, by precipitation from water) greenish, consists of iron 73, and oxygen 27, according to Lavoisier. It may be formed in various ways: as by exposure of a paste of iron-filings and water to the air; by heating together one part of red oxyd of iron, and two parts of iron-filings; and by adding a solution of alkali to one of green sulphate of iron, and drying the precipitate quickly without exposure to air; and it is kept as a separate article in the Edinburgh Pharmacopæia, under the name of "Ferri oxydum nigrum purificatum." The latter, or red oxyd, consists, according to Proust, of iron 52, oxygen 48, and in its relation to black oxyd is composed of 66.5 of that oxyd, and 33.5 of additional oxygen. Some chemists have supposed the existence of other gradations of combination of iron and oxygen, but the above are all that are generally admitted, or that require particular notice; this latter is also kept in the Edinb. Pharm. under the name of "oxydum ferri rubrum." Salts containing the black oxyd, on exposure to air, pass to the state of red oxyd, by attracting oxygen from it, and in the process of drying, the same change happens here to the oxyd in the sub-carbonate, which, at the time of its first precipitation, is a black oxyd. The same substance, more imperfectly prepared, constituted the rust of iron (*ferri rubigo*) of the former Pharmacopæia, for which, in all the processes into which it entered, this precipitate is now substituted. The red oxyd of the Edinburgh college is the old "Colcothar vitrioli," and formed by exposure of common sulphate of iron to a strong heat, sufficient to drive over its sulphuric acid, when the red oxyd remains behind, as in the process which was formerly in use for obtaining that acid. Sub-carbonate of soda is preferred for the precipitation to that of potash, on account of the greater solubility of the sulphate of the former than of the latter alkali, and the consequent facility with which it may be washed away. The salt is a sub-carbonate, but as only one of the compounds is kept, the relation is not expressed. The dose of the "ferri carbonas" is from two to ten grains.

4. "Mars sulphuratus," prepared by mixing iron filings with twice their weight of flower of brimstone, and as much water as will make them into a paste, which in a few hours swell up, and is then pulverized, and put into a heated crucible to deflagrate, and kept constantly stirring with an iron spatula, till it falls into a deep black powder: this powder urged longer in the fire, becomes red, and is called, 5. "Crocus martis aperientis et astringens." 6. The salt or vitriol of iron, "ferrum vitriolatum," called "Sal martis" This is now diffused. See *Crocus Martis*.

This is the "ferri sulphas," sulphate of iron, of the Lond. Pharm. of 1809; and is composed of iron and sulphuric acid, of each by weight eight ounces, and four pints of water. The sulphuric acid and water are mixed together in a glass vessel, and the iron is added; then, after the effervescence has ceased, the solution is filtered through paper, and evaporated, so that crystals may form as it cools. The water is afterwards poured away, and the crystals are dried upon bibulous paper. Upon a large scale this salt is formed from native sulphuret of iron (*pyrites*) by roasting, and exposing it to the open air. The sulphate of iron is afterwards dissolved in water and crystallized by evaporation. Sulphuric acid will unite either with the black or red oxyd: the first of these is the salt here intended for internal use, and upon this point great stress ought to be laid; as the last is the state in which the sulphate of trade is usually found, and which, for medical purposes, is a very distinct and inferior

thing. Its crystals are transparent rhomboidal prisms, of a light green colour; its taste is astringent and strong, and it reddens vegetable blues. One part is soluble in two of cold, and in three-fourths of boiling water. It is insoluble in alcohol, in which menstrum the red sulphate is soluble, and this affords a method of ascertaining the existence of the latter with the former, as also of separating it. On exposure to air it is gradually converted into red sulphate: it consists, according to Kirwan, of acid 26, iron 28, and water 46, parts. Heat drives off the water of crystallization, and the salt remains white: if urged farther, it drives over the acid, and leaves first a red sulphate, and at last a red oxyd of iron. The dose of the "ferri sulphas" is from one to five grains. 7. "Tinctura martis in spiritu falis," P. L. 1745, "Tinctura ferri muriatis," P. L. 1787, or "Tinctura ferri muriatis," tincture of muriate of iron, P. L. 1809. This is formed by pouring the muriatic acid, in the proportion of a pint, upon half a pound of carbonate of iron in a glass vessel, and shaking it occasionally for three days: then letting it by, that the faces, if there be any, may subside; pouring off the solution, and adding three pints of rectified spirit. This salt appears to be an oxy-muriate of iron, the red oxyd of iron employed being, on its combination with the acid, black oxyd, and giving over its superabundant oxygen to the muriatic acid. This appears to be its state, because sulphuric acid added to it detaches oxy-muriatic acid, and heat drives over oxy-muriatic acid; and in the latter instance, although the red oxyd was used for its preparation, the black oxyd remains behind. The salt, evaporated to dryness, yields an orange-coloured mass, which is uncrystallizable, deliquesces on exposure to air, and is soluble in alcohol. The tincture has a brownish yellow colour, and very astringent taste. 8. "Flores martiales," P. L. 1745, flowers of iron (see *Flores*), "Eus Veneris," P. L. 1720, "ferum ammoniacale," P. L. 1787, or "ferum ammoniacum," ammoniated iron, P. L. 1809, is composed by intimately mixing carbonate of iron and muriate of ammonia, of each a pound, and subliming by immediate exposure to a strong fire, and, lastly, reducing the sublimed ammoniacal iron to powder. This substance consists of red muriate of iron, mixed by sublimation with muriate of ammonia. It is orange-coloured, with a smell resembling saffron, is deliquescent, and soluble in alcohol. The residue, which is deliquescent, consists also of red muriate of iron, and was formerly kept under the name of "lixivium martis." The dose is from three to fifteen grains. 9. "Tinctura florum martialium," P. L. 1745, "Tinctura martis Myrsinchi," P. L. 1720, "Tinctura ferri ammoniacalis," P. L. 1787, or "Tinctura ferri ammoniaci," tincture of ammoniated iron, P. L. 1809, is formed by digesting four ounces of ammoniated iron in a pint of proof spirit, and then straining. This is an elegant chalybeate, and may be given in doses of a tea-spoonful. 10. "Ferrum tartarizatum," or tartarized iron, P. L. 1787, and 1809, called also "Mars solubilis," and "Chalybs tartarizatus," consists of iron, a pound, super-tartrate of potash, powdered, two pounds, and a pint of water. Rub them together, and expose them to the air in a broad glass vessel for eight days, then dry the residue in a sand bath, and reduce it to a very fine powder. Add to this powder a pint more of water, and expose it for eight days longer; then dry it, and reduce it to a very fine powder. This is a triple salt, in which the iron is first oxydized by being massed and exposed to air, and then combines with the superabundant acid of the super-tartrate of potash; and it is therefore a tartrate of potash and iron. It may be dissolved in water and crystallized. This elegant and useful chalybeate may be given either in a solid or liquid form, from five

grains to a scruple. It has been usually distinguished in the shops by the name of its inventor, Dr. Willis. 11. "Liquor ferri alkalinus," or solution of alkaline iron, is composed of $2\frac{1}{2}$ drams of iron, two fluid-ounces of nitric acid, six fluid-ounces of distilled water, and six fluid-ounces of the solution of subcarbonate of potash. Having mixed the acid and water, pour them upon the iron, and when the effervescence has ceased, pour off the clear acid solution; add this gradually, and at intervals, to the solution of subcarbonate of potash, occasionally shaking it, until it has assumed a deep brown-red colour, and no farther effervescence takes place. Lastly, set it by for six hours, and pour off the clear solution. This preparation was first described by Stahl, and called "tinctura martis alkalinæ," and it is for the first time introduced into the London Pharmacopœia of 1809, as affording a combination of iron distinct from any other, and often applicable to practice. It seems to be a triple salt, formed by the union of nitric acid with red oxyd of iron, and with potash. Dr. Lewis has observed, that alkaline solutions of iron are ill adapted for medicinal use; and on that account, he says, they have been wholly neglected in modern practice. 12. "Vinum ferri," wine of iron, P. L. 1787 and 1809, "Vinum chalybeatum," P. L. 1745, consists of two ounces of iron filings mixed in two pints of wine. The mixture is set by for a month, occasionally shaking it, and it is then filtered through paper. Lewis Mat. Med. Cullen Mat. Med. London Pharmac. 1809. See *Chemical Properties of IRON, Chalybeates, and Minerals, &c. WATERS.*

IRON, Case-hardening of, a process by which a superficial hardness is given to various articles made of iron. It is found by experience that pure iron is not susceptible of a very fine polish, and that, when it is exposed to the air, it very soon changes. All iron utensils, therefore, such as fire irons, and many other articles, having the appearance of polished steel, are case-hardened, for the purpose of giving them a finer polish, as well as rendering their colour more permanent. The goods to be case-hardened should be finished with the exception of polishing, since, if the process be well managed, the most delicate workmanship will not be injured. A box of wrought iron must be provided, which is perfectly found in every part, having a lid of the same metal, to fit very tight. In this box the articles are to be stratified with powdered carbon, that of animal substances being the best, for reasons given in the article IRON, in the section on Steel. The box being perfectly filled with these materials, let the lid be fitted on, and luted all round with a paste made of equal parts of pipe-clay and Calais sand. The whole is now to be surrounded by bricks loosely built up, a little higher than the top of the box, leaving about four inches on each side for fuel. This may be done either upon a smith's hearth or in the open air. The most proper fuel is the refuse-cokes from any fires where pit-coal is burnt. The fire being kindled, and the space filled up with this fuel, the heat will be applied gradually, owing to the smothered combustion. As soon as the box appears of a light red heat, let it remain about half an hour, or more time if the box be large, in the same temperature. The lid may now be taken off, and the box inverted and its contents emptied over a cistern of cold water. If the box be suffered to cool without being opened, the goods will be perfectly white and metallic when taken out. If they are now heated red-hot, and quenched in cold water, they acquire the same hardness as if turned out of the box red-hot into the water. If the articles are very delicate, so as to be injured by the air in heating a second time, they may be preserved, by dipping them into a mixture of a saturated solution of salt (muriate of soda) with any vegetable matter to give it a pulpy consistence. During the time of

heating it red-hot, the salt fuses upon the surface of the metal, defending it from the oxygen, so that after it is quenched in the water, and brushed, it will be perfectly clean.

The size of the iron box should not be very large; it is better to do the work at two or three processes. Charcoal is a very bad conductor of heat, and if the mass to be heated were large, those articles near the sides would be over done, by combining with too much carbon, while those in the middle would be too little carbonated.

People in the habit of case-hardening, have generally some secret receipt for the process, on which they get great value. All, however, agree in using carbon, the only thing necessary: some add to this salt-petre; others sal ammoniac, and other articles, to which they very knowingly attribute their relative success. We can, however, assure the most fastidious of these persons, that if they make their box perfectly air-tight, by the rules above given, stratifying the articles with animal carbon alone, they will, with proper heat and time, produce the greatest possible effect.

Animal carbon may be produced from most animal substances: among these are blood, hoofs, and leather. These substances should be pressed into an iron pot, which can be heated red-hot, covered close, with a small open tube inserted into the cover. The volatile matter that escapes may be set on fire, which will in a great measure destroy the smell; or a receiver may be adapted, and the crude ammonia distilled off. When the volatile substances have come over, the residuum will be fine animal carbon, which requires only to be reduced to powder.

This animal carbon is so fitted for combining with iron, that if it be made into a pulp with a saturated solution of salt, and laid upon the surface of iron; upon being heated red-hot, and quenched in cold water with this coating upon it, the surface will become hard. Any part of an iron article, not wished to be case-hardened, may be prevented from undergoing the change, by covering the part with pipe-clay.

IRON, Harping. See HARPING.

IRON-liquor, in Calico Printing and Dyeing, is a solution of iron in the acetic acid, used as a mordant for certain colours. It is employed as a substitute for the sulphat of iron, and is preferred, in those processes, to the last salt. The oxyd of iron, which is the essential ingredient, is more easily attracted by the stuff from the acetic than the sulphuric acid, and, besides, the texture is not so liable to be injured by the acetat as the sulphat of iron. In order to make this substance cheap, the acid distilled from wood, called pyrolignic acid, and now found to be impure acetic acid, is used as a substitute for vinegar. See *PYROLIGNIC Acid*, and the last section of the article IRON.

IRON moulds are marks or stains produced on substances, particularly linen and cotton, by the oxyd of iron. The affinity of these vegetable substances for the oxyd of iron is so great, as not only to take it from the surface of iron, but from any acid with which it may be combined. We find, hence, that very few acids are capable of removing iron-moulds. From the well-known fact that the attraction of acids for oxyds of metals is more feeble as the latter contain more

more oxygen, we are enabled to account for iron-moulds being easier to remove, as they are more recent. The stain soon acquires an orange-red colour, by absorbing oxygen, and is with more difficulty extracted. Various means are employed by the laundresses for removing stains of iron, the most general of which is the citric acid, commonly called salt of lemons. The muriatic acid is frequently employed by the bleachers, and it is by far the most rapid and effectual process; but the great caution necessary, in suddenly washing the spot after the stain has disappeared, lessens its utility for domestic use. When the spot is dipped into the clear muriatic acid, the iron almost instantly disappears, and it is at that instant the part should be plunged into a quantity of clean water, and washed as quick as possible; the washing being continued for a considerable time.

In order to render the oxyd of iron more easily soluble by any acid, let the part stained be steeped for some time in a solution of sulphuret of potash, or what is more easily obtained, sulphuret of lime, rinsing it afterwards in clean water. The oxyd will be deprived of some of its oxygen, and may be removed by almost any acid, when it is so dilute, even, as not to injure the stuff, however long it may remain in it.

It may be proper here to observe, that the tartaric and oxalic acids remove iron-moulds equally well with the citric acid.

When the substance iron-moulded is printed calico, and of a buff colour, or any other colour in which iron is employed as a mordant; it will be found that, in removing the iron-mould, the proper colour will also disappear. In this case there is no effectual remedy.

Moss of the iron-moulds are produced in the washing, for want of sufficient caution. In those utensils in which metal is at all necessary, copper or zinc should be employed instead of iron. With care, however, iron vessels may be safely used. When they are not in use, the surface of the iron should, after being made clean and dry, be smeared over with oil or tallow, and rubbed dry at the time they are used.

Iron-moulds, yellow lumps of earth or stone, found in chalk-pits about the Chilterns, in Oxfordshire, and elsewhere, being in reality a kind of pyrites, or indigested iron-ore.

Iron-spot, in *Mineralogy*, is a term applied by Mr. Jamsón (*Geognos.* vol. iii. p. 47. 159.) to such rocks and stones as are coloured or clouded by the oxyds of iron. Ferruginous is a more common name for this very common appearance in the strata.

Iron-sick, a *Nautical Term*, signifying the decay of the iron fastenings by its corrosion with the sea water, by which the continuity of the parts is gnawed away by degrees, whereby the vessel is not only rendered weak, but leaky.

Iron-stone, is that species of iron ore which abounds with a considerable proportion of earth, such as lime, or alumine, and is the ore most common in this country. See *Iron*.

The manner of getting iron-stone is divided into three departments: 1. By *fall-work*: 2. By *bell-pits*: and 3. By *open-work*. The first of these methods is employed when the stone lies at a considerable depth. After sinking a shaft to the lower part of the stratum, the ground is excavated in an horizontal direction, leaving at intervals certain parts standing to support the roof of the excavation. The spaces between these pillars are called *falls*.

The *bell-pit* is employed when the iron-stone lies at some distance from the surface, and where the ground is not sufficiently firm to bear a *fall-work*. These pits, when first opened, are narrow, but become wider below, assuming the shape of a bell.

The third method, or the *open-work*, is made use of when the stratum containing the stone is nearly horizontal, or is very near to the surface. The earth is first removed, laying the stratum containing the ore bare, and the stone is got out as from an open quarry.

The argillaceous iron ores are generally called iron-stones, and abound in many of the coal districts. In Mr. Farey's *Agricultural and Mineral Report on Derbyshire*, vol. i. p. 217, a list of seventy-five places in and near that county is given, where iron-stone has been dug, or where the rakes of iron-stone, as they are there called, have been worked.

Iron-wood, in *Botany*. See *SIDEROXylon*.

Iron-works, in a *Ship*, denotes all the pieces of iron, of whatsoever figure or size, which are used in its construction; as bolts, boom-irons, which are composed of two rings, nearly resembling the figure of 8, nails, spikes, chains, and chain plates, block-trops, cranks, braces, pintles, and goodings.

Iron-works, a name given to the establishments for the manufacture of pig-iron. (See *ELAST-furnace* and *IRON*.) The most proper situation for iron-works is on the side of a hill, from which a perpendicular descent could be formed nearly equal to the height of the blast-furnace. The upper ground by this means is on a level with the mouth of the furnace, where all the materials are introduced, and is therefore the situation where the ore is roasted, and the coals prepared; the lower ground being the most proper for the rest of the works.

Where such local advantages do not exist, the materials are drawn up on an artificial inclined plane, by appropriate machinery.

Iron-warts, in *Botany*. See *GALEOPSIS* and *SIDERITIS*.

Iron Island, in *Geography*, a small island in the East Indian sea, near the coast of Siam. N. lat. 12 35'. E. long. 98°.

Iron Lough, a lake of Ireland, in the county of Westmeath, through which the river Inny passes. It is about five miles N.W. from Mullingar.

Iron Mountains, a chain of American mountains, in Tennessee, extending from the river Tennessee to that of French Broadtown, S.W. to N.E. and constituting the boundary between Tennessee and North Carolina, and reaching from near the lead mines, on the Kanaway, through the Cherokee country, to the south of Chota, and terminating near the source of Mobile. This chain abounds with caverns and cataracts.

IRONDEQUET, a bay on the fourth side of lake Ontario.

IRONSIDE, GILBERT, in *Biography*, an English prelate, was born at Hawkbury, in Oxfordshire, in 1388, and educated at Trinity college, Oxford. Soon after he entered upon holy orders, he obtained the rectory of Winterburn, in Dorsetshire. At the restoration he was made bishop of Bristol. He died in 1671. He was author of "Questions on the Sabbath," and a sermon. Wood.

IRONY, derived from *iron*, *dissemblance*, in *Oratory*, a figure in speech, whereby we plainly intend something very different from what our words express; as when we seem to praise a person at a time when we evidently rally and discommend him.

Quintilian calls this figure *disserpationem*, *dissemblatam*, and *ill-iron*; and observes that it may be known by the manner of the pronunciation, or from the nature of the person or the thing. The fallacies of irony are veils and follies of all kind; and it has thus been used by the most grave persons on proper occasions. Socrates used it so much as to acquire the name of *the iron* or *the droll*. It was also used by the pros-

phet Elijah, 1 Kings. xviii. 27, by Solomon, Ecclef. xi. 9, and by our Saviour himfelf, Mark, vii. 9.

IROQUOIS. See *Six Nations*.

IROQUOIS, National Mufic. Claude Perrault, an unbeliever in the harmony or counterpoint of the ancients, tells us, in his "Physical Effays," that Louis XIV. near the end of his reign, when fome of the Iroquois nation were brought into France, wifhing to hear them fing, that he might form fome idea of their mufic, many of them fung their wild melodies in unisons and octaves, while others accompanied them in grunting like pigs; regularly, however, marking the meafure by a violent jolt. And thus they attuned the acute voices by the mixture of the *grave* *grants* and rhytmical pulsations of the others.

Perrault imagines, from the defcription which Caffiodorus gives of harmony, or finging together, which the ancients called *symphony*, that Roman harmony resembled that of the Iroquois.

IRRADIATION, fignifies an emanation or fhooting out of rays, or fubtle effluvia, from any body. See **EMANATION, RAY, EFFLUVIA, and QUALITY.**

IRRATIONAL NUMBERS, the fame as *fad numbers*. See **SURD and NUMBERS.**

IRRATIONAL Quantities. See **RATIONAL Quantities.**

IRRATIONAL Soul. See **SOUL.**

IRREDUCIBLE CASE, in *Algebra*, is an expreffion arifing from the folution of certain equations of the third degree, which always appears under an imaginary form, notwithstanding it is, in fact, a real quantity, but the reduction of it to a rational, or irrational finite expreffion, has at prefent refitted the united efforts of many of the moft celebrated mathematicians of Europe. Every cubic equation may be reduced to the form $x^3 + ax = b$; and then, according to the common rule,

$$x = \sqrt[3]{\frac{b}{2} + \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}} + \sqrt[3]{\frac{b}{2} - \sqrt{\frac{b^2}{4} + \frac{a^3}{27}}}$$

See **EQUATIONS.**

Now, when a is negative, $\frac{a^3}{27}$ is alfo negative; and, there-

fore, when $\frac{b^2}{4} < \frac{a^3}{27}$, the quantity under the inferior radical,

viz. $\sqrt{\frac{b^2}{4} - \frac{a^3}{27}}$, is imaginary; becaufe we cannot extract the fquare root of a negative quantity; and this is what conftitutes that which is generally called the irreducible cafe.

This difficulty foon prefented itfelf to Cardan, after Tartalea had communicated to him his method for the folution of cubic equations, which rule is now commonly, though very improperly, attributed to the former. Cardan informs Tartalea, in a letter dated Auguft 4th, 1539, that he underftood the folution of the equation $x^3 + ax = b$, and alfo of $x^3 - ax = b$, when $\frac{b^2}{4} > \frac{a^3}{27}$; but when $\frac{b^2}{4} < \frac{a^3}{27}$ his attempts always failed; and he therefore begged of Tartalea to clear up his difficulty, by fending him the folution of the equation $x^3 - 9x = 10$. Tartalea was himfelf perfectly aware of this difficulty, but he was by no means fatifhed with Cardan's conduct, whom he at that time fufpected to be about publifhing as his own the rules he had taught him; and, therefore, inftead of giving him an explicit answer, he writes to him in the following terms:—"M. fignorino, I have received your letter, in which you write, that you underftand the rule for the cafe $x^3 - ax = b$,

when $\frac{b^2}{4}$ is greater than $\frac{a^3}{27}$, but when $\frac{b^2}{4}$ exceeds $\frac{b^2}{4}$, you

cannot refolve the equation; and, therefore, you request me to fend you the folution of the equation $x^3 - 9x = 10$. To which I reply, that you have not ufed a good method in that cafe, and that your whole procefs is entirely falfe. As to refolving your equation you have fent, I muft fay that I am very forry that I have already given you fo much as I have done; for I have been informed by a credible perfon, that you are about to publifh another algebraical work, and that you have been boating through Milan of having difcovered fome new rules in algebra. But take notice, that if you break your faith with me, I fhall certainly keep my word with you, nay, I even afure you to do more than I promifed." (Dr. Hutton's Mathematical Dictionary, article ALGEBRA.) Tartalea, however, notwithstanding what he fays in this letter, was himfelf well aware of the difficulty in queftion, as appears from fome of his private memoranda; and from that time to the prefent, which is near 300 years, the fame impediment remains, notwithstanding the repeated attempts of many very diftinguifhed mathematicians; in fact, there is great reafon to fuppofe, independently of the failure of fo many ingenious attempts, that the formula is in-expreffible in any other finite form, than that under which it naturally arifes by the folution. See **EQUATIONS.**

Notwithstanding, however, that no analytical folution can be given to the cafe in queftion, every equation of this form has three real roots, which are obtainable by other methods, fuch as by means of a table of fines and tangents, infinite feries, continued fractions, and a new method lately publifhed by Mr. Barlow in the Mathematical Repository, which feems by far the readieft and moft accurate of any that has been at prefent difcovered; the rationale of which is as follows;

1. Every cubic equation may be reduced to the form $x^3 + ax = \pm b$, by the known rules in algebra; but when the equation is in the irreducible cafe, this ambiguous form ceafes, and the equation becomes $x^3 - ax = \pm b$; the folution of which, by the following method, is the fame for either fign of b ; only when b is pofitive, the root firft found will be pofitive, and when b is negative, the root will be negative alfo; it will, therefore, be fufficient to confider the cafe $x^3 - ax = b$, in which $\frac{b^2}{4} < \frac{a^3}{27}$, as we have before feen.

Now, every equation of the form $x^3 - ax = b$, may be transformed to another dependent equation, in which the co-efficient of the fecond term fhall be unity; that is, to another of the form $y^3 - y = c$. For make $x = \frac{y}{z}$, then the

equation becomes $\frac{y^3}{z^3} - \frac{ay}{z} = b$; or $y^3 - az^2y = bz^3$;

now take $az^2 = 1$, or $z = \sqrt[3]{\frac{1}{a}}$; and, confequently, bz^3

$= \frac{ba^{\frac{2}{3}}}{a}$; whence we have $y^3 - y = \frac{ba^{\frac{2}{3}}}{a}$; or putting $\frac{ba^{\frac{2}{3}}}{a}$

$= c$, it becomes $y^3 - y = c$, as required.

And the value of y being found in this reduced equation, we immediately obtain that of x , in the original one, by means of the expreffion $x = \frac{y}{z}$, or $x = y \sqrt[3]{\frac{1}{a}}$.

Now, the original equation being by hypothefis of the irreducible form, the transformed equation muft neceffarily be fo

IRREDUCIBLE CASE.

for its wife; and, consequently, $\frac{c^3}{4} < \frac{1}{27}$, or $c < \frac{2\sqrt[3]{3}}{9}$, or $c < .38491$; affording this, therefore, as the maximum value of c , we find that the greatest value of y can never exceed 1.1549, nor can the least be less than unity; so that all possible values of y lie between the limits 1 and 1.1549; and if, therefore, we have a table containing all the values of c to those of y , between the above limits, we shall have by inspection the solution of every equation of the irreducible case, when converted into the form $y^3 - y = c$; and hence also of every irreducible equation of the form $x^3 - ax = b$, because $x = y\sqrt[3]{a}$.

The following is a table of this description, the value of y being arranged in the leading column, except the last digit, which is found in the upper horizontal line, and the respective values of c are found in the other columns, being exactly the form that is usually given to the common tables of logarithms; and the finding of any value of y , corresponding to a given value of c , is performed exactly the same as that of finding the natural number to a given logarithm. Thus, for example, giving $y - y = .3837$ to find y : in the table the number corresponding to $.38369912$ is 1.1543; that is, $y = 1.1543$. It is obvious, therefore, that, from bare inspection, the value of y may be found true to five places of figures, but these are extended to 8 or 9 places *true*, by taking proportional parts as in logarithms; thus, find the next greater and less tabular number to that proposed; and then say, as the difference of these is to .0001; so is the difference between the least of them and the number proposed, to the part which is to be added unto the least value of y ; and this proportion may be safely carried to four places at least, and thus the value of y will be known to eight places. This may be demonstrated as follows: the proportional part that is thus added unto y , is always less than .0001, and, therefore, less than the $\frac{1}{10000}$ th part of y , and hence it may be said to be very small with regard to y . Now, I say, that if a and b be both very small with regard to a third quantity y , that the following proportion is very nearly true; *viz.*

$$\frac{(y+a)^3 - (y+a)}{(y^3 - y)} : \frac{(y+b)^3 - (y+b)}{(y^3 - y)} :: a : b;$$

for, by rejecting all those powers of a and b higher than the first, this proportion becomes precisely

$$(3y^2 - 1)a : (3y^2 - 1)b :: a : b;$$

and since, in this case, a and b are less than .0001, (or at least neither of them ever exceed this,) by rejecting the squares and cubes of these quantities, we cannot have affected the fourth place of figures in the result, and therefore the pro-

portion may always be depended upon to four places. And thus, the following rule may be deduced for every irreducible cubic equation, $x^3 - ax = b$; *viz.*

Find $\frac{b\sqrt[3]{a}}{a^2}$ in the following table, and take out the corresponding value of y ; then will $y\sqrt[3]{a} = x$ be the root sought. Let us, for instance, take the example proposed by Cardan to Tartalea; namely, $x^3 - 9x = 10$, to find x

$$\text{Here } \frac{b\sqrt[3]{a}}{a^2} = \frac{30}{81} = .37037037.$$

Tab. n. .37057828, corresp. n. 1.149937037037 given n.
next less .37028164 ——— n. 1.1498137028164 left tab.

As 29664 : 1 :: 08873 : 2991
Therefore $y = 1.14982991$
 $3 = \sqrt[3]{a}$

and $x = 3.44948973$ as required.

Ex. 2.—Required the value of x in the equation
 $x^3 - 7x = 9$.

$$\text{First } \frac{6\sqrt[3]{7}}{7^2} = .32396054;$$

Tabula n. .32398835, corresp. n. 1.1359 32396974
Next less .32370267, ——— n. 1.1338 32370267

As 28568 : 1 :: 26687 : 9342

Therefore the value of y is 1.13389242;

and $y\sqrt[3]{7} = 1.13389342 \times 2.6457513 = 2.999999999$, as will be found by the operation; which answer is true to the 10th place, the real root being 3, as is obvious from the equation. It will be unnecessary to give any other examples, as the same method is pursued in all cases, and the same accuracy may be depended upon in the results. The reader who will trouble himself to compare the rule here laid down, with any other that has been before given by other writers, will soon be convinced of the immense labour that is saved by the following table; at the same time, that the number of figures in the result are nearly double those that can be safely obtained by the tables of sines and tangents.

For the method of finding the other two roots after one is obtained, see EQUATIONS; for the solution of cubic equations by the trisection of an angle, see BONNYCAILLE'S Trigonometry; and for the method by infinite series, see Philo-
sophical Transactions, vols. lxxviii. and lxxx.

IRREDUCIBLE CASE.

IRREGOLARE, *Ital.* in *Ecclesiastical Music*. Modes are called irregular in canto fermo, when the compass is extended beyond its usual limits, or its regular scale is in some unusual manner, violated.

A cadence, or clofe, used to be termed irregular when the harmony did not clofe on the key note. (See *Disappointed CADENCE*.) But Rameau has given this title to a particular cadence of his own system, in which the fundamental base rises a 5th, or falls a 4th after the chord of the ♯ to the 4th of the key. See **CADENCE**.

IRREGULAR, something that deviates from the common forms or rules.

Thus we say, an irregular fortification, an irregular building, &c. See **BUILDING**, **FORTIFICATION**, **BASTION**, and **PLACE**.

IRREGULAR Figure, in *Geometry*, is that whose sides and angles are not equal. See **REGULAR**.

IRREGULARS, in *Grammar*, are such inflexions of words as vary from the general rule, or pattern.

IRREGULAR, among the *Casuals*, is applied to a person who is unqualified for entering into orders, as being a bastard, maimed, &c. or to an ecclesiastic, who is interdicted, suspended, or censured, and by that means rendered incapable of holding a benefice, or discharging any of the sacred functions.

IRREGULAR Bodies, are solids not terminated by equal and similar surfaces.

IRREGULAR, in the *Art of Building*, is applied not only to the parts of an edifice which deviate from the proportions established by antique monuments, and confirmed by architects; as when a Doric column is made nine modules high, or a Corinthian eleven; but also to the places and figures of buildings, where the angles and sides are made unequal, as in most of the ancient castles; where, without any necessity or confinement from the situation, they effected such irregularity.

A column is also said to be irregular, not only when it deviates from the proportions of any of the five orders, but when its ornaments, whether in the shaft, or the capital, are absurd and ill chosen.

IRREGULAR Leap, in *Music*. See **LEAP**.

IRREGULAR Temperament, or irregular douzeaves, or systems of twelve notes in the octave, are such as have more than two kinds of tempered fifths, or where the wolf, resulting or bearing fifth, does not fall between ♯ G and ♭ E, as Mr. Farey has shewn in the *Phil. Mag.* vol. xxxvi. p. 39 and 47. The systems of lord Stanhope, M. Kirnberger, Mr. Hawke's douzeave, and many others, are irregular systems: a former division of the systems of temperament used to be into equal and unequal, but as there could be but *one* equal temperament, such a division answered little purpose: the equal temperament is a regular douzeave, wherein the wolf is equal to each of the temperaments of the fifths, as shewn in the 6th scholium, in Mr. Farey's paper above referred to.

IRREGULAR Diatonic Intervals, are such as, when expressed in any notation by three very small other intervals, and arranged in a table, do not increase pretty regularly in each of their three terms.

IRREGULAR Measures, in *Mining*, are variable measures or strata in thickness, sometimes called *Girdls* (see that article); and according to Mr. William Martin (*Outlines*, p. 171.) include also strata that take a different direction in their dip from that of their attendant strata: in which latter case, we apprehend, that observers have mostly overlooked some *fault* which ranges between the irregular strata and their attendant strata, and have detached and altered

their positions, or that the strata, or folia (of which this author takes no notice), that often cross beds of stone oblique to their strata-seams or way-boards, have been mistaken for the latter, as often has happened. Numerous instances of variable or irregular measures have been noticed by Mr. Farey in his Survey of Derbyshire and its Environs, and are particularized in his *Agricultural and Mineral Report* to the Board of Agriculture, vol. i. p. 176. 238. 276, &c. Others have been observed by Mr. James Keir, in Shaw's *History of Staffordshire*; and in Mr. Wedgorth Forster's *Treatise* on a section of strata. They are indeed very important geological phenomena.

IRREGULARITIES in the *Moon's Motion*. See **MOON**.

IRREPLEVIABLE RETURN. See **RETURN**.

IRREPLEVIABLE, or **IRREPLEVABLE**, in *Common Law*, signifies what may not be replevied, or let at large upon sureties.

IRRIGATION, in *Agriculture*, the art of covering meadow or grass-lands with water, so as to render them more highly productive and beneficial. It may be noticed, that there are two methods of effecting improvements on lands by covering them with water; one of which is by applying it so as to cover the surface when in the state of grass or sward; the other by communicating it to the soil of such grounds as have been broken by means of cultivation. The first is the method that has been principally introduced into practice in this kingdom, and which, by a late writer, has been termed the "European practice of irrigation." But though the history of the origin of this means of improvement is involved in much difficulty, and not capable of being easily traced; it was probably introduced at a very early period from eastern countries, where the practice of covering the lands with water, in order to protect them from the injurious effects of excessive heat, has prevailed for ages; yet by some it is thought, to have been brought to the attention of the farmer in this country in another way, for the benefit of natural floods, to the grass-lands which they occasionally overflowed, being evident, and in some instances great, the means of producing artificial floods, and of spreading them over lands, not liable in their natural situation to be overflowed, would become, of course, it is supposed, a desirable object. And that as the most obvious effect of floods, or the overflowings of rivers and brooks on the lands over which they spread, is that of depositing their feculent particles; thereby operating as a vehicle of manure; it is likewise evident to common observation, that foul waters, as those of floods, let fall their feculencies, most freely, in a *flagnant state*. Further, that "it is also equally evident, that the state of stagnation of the waters of floods, or a state that approaches it, is caused by some obstruction of the current below the place of stagnation." And that "from these circumstances being seen, and they could not well be missed by any one who gave the subject a second thought, the means of manuring lands with water, artificially, were given; in situations it is meant which would admit of the requisite obstructions." And it is further suggested, that "the bottoms, dips, or valleys, which abound, more or less, in every part of the kingdom, would naturally be the most apt subjects for flooding artificially with foul waters, on the principle of manuring the land with their sediment." For on "a bank, or dam, being made across the valley, below the part to be manured, the rivulet which generally accompanies a valley of this kind, especially after heavy rains, the only time when flooding on this principle could be practised, would of course be obstructed; and its waters, fouled, perhaps, with the richest

IRRIGATION.

particles of arable lands, be spread over the bottom of the valley, to an extent proportioned to the height of the bank, and its own flatness: a valve or flood-gate being fixed in the bed of the rivulet to let off the waters, when the *suble* of their foulness were deposited: thus gaining a principal advantage over natural flooding; in which the grosser particles only are let fall; the finer, and perhaps most valuable escaping to the river, and thence to the sea, before they be precipitated or let fall upon the land." It is conceived that on these principles, it is evident, some of the meadow-lands of the midland districts have formerly been flooded; and that it is not probable, that so evident a method of improving meadow-lands should have been confined to a particular district; but may have been common to other parts of the island. And it is further stated by the same writer, that the *anient* method of meliorating grass-lands, by the means of *floignant* water, could no longer prevail, than until the superior effects of running water, on such lands, were discovered and ascertained. And that this important discovery must have been made by *observation*, on the comparative effects of running and standing water, in the natural and artificial flooding spoken of above; and must have been ascertained by a long course of *experience*: as it is not likely that *reason* should have had any share in striking out the modern method of improving grass-lands by running water. For even now, when the reality of the improvement appears to be fully established, there seems to be no full or satisfactory *theory* to account for it: though many of the effects thus produced have lately been more clearly explained and better understood, as will be seen below. The *warmth*, communicated by running water to the grass it flows over, is one great reason adduced for the good effect of running water on this sort of land. But even after this discovery was made, and the effect fully established, it would be some length of time before the art arrived at its present high degree of perfection. As it may, in its present state, be safely deemed the most useful and scientific operation, that has entered into the common practice of husbandry. And the memory of the inventor, or inventors, deserves the highest praise and admiration.

It has likewise been remarked, that the great degree of verdure and luxuriance which almost immediately succeeds the occasional covering of grass-lands with water, sufficiently demonstrates the power which it possesses in promoting vegetation: and that it is a means of fertility that has been employed for ages in more warm climates, with the most beneficial consequences in increasing the quantity of vegetable produce. But that although it has been long in use in other countries, and of late more particularly attended to in this, the principle on which it produces its effects are not yet fully explained.

In considering manure as the nourishment or food of plants, some of the properties of water, that may be beneficial in the vegetable economy when absorbed or taken up by the fibrous roots of plants, have been mentioned; and there are other ways in which it may be advantageous in forwarding the growth of grass herbage when applied over the surface. It is conceived that in climates where the heat is considerable, it may be of much utility, not only by keeping the fine fibrous roots of the grass or other plants in a moist patulous state, the most proper for the purposes of absorption, but in such a temperature or state of heat, from the cooling effect produced by the constant evaporation that is taking place near the surface of the ground, as is the most suitable for their healthy and vigorous growth. It is probably in this way that garden plants are principally benefited by the application of water in the hot summer seasons in our own

climate; as when the waterings are not constantly kept up injury rather than good is mostly experienced. But that another and more beneficial way in which grass produce may be immediately increased, and the fertility of the lands more permanently improved in this country by the floating or covering them with water, is from the waters of the rivers or brooks that are turned upon them, containing, either in the state of solution or diffusion, a variety of different sorts of enriching materials which they gradually and evenly deposit upon the surface while they rest upon or slowly flow over it. This must, it is imagined, be the case in all those instances where the rivers or streamlets either at, or in their course flow through or over beds of chalk, marble, or other calcareous strata; as in their passage they become highly impregnated with the fine particles of these different substances. And where they are fed by the small runlets which receive the waters that proceed from the higher and more elevated lands, they must often, especially after heavy rain, be loaded with a large proportion of fine rich materials of the animal, vegetable, or other kinds, which they deposit in a regular manner in their tardy trickling course over the surfaces of the fields below.

It would appear that waters thus impregnated produce the most beneficial effects, particularly when not in flood, upon the lands that are the nearest to the sources whence they become principally impregnated with their fertilizing principles; as when they have flowed to some distance they have, in a great measure, deposited and let fall such enriching substances, and are become too pure for affording advantage in the way of deposition. It is only in the time of floods that they can produce much utility in this way at any great distance. It was found by an able philosophical writer, Dr. Darwin, that the water of the Derwent, though it flows for several miles near Matlock, through calcareous strata, contained no impregnation of this sort on its reaching Derby, although the springs in that neighbourhood had a large proportion of it in their composition. And the same author has ingeniously suggested another mode in which water may prove serviceable in floating grounds in this climate, which is that already stated of protecting the grass or other plants from the too severe effects of cold during the winter, or early spring season. In this view it is observed, that the water of strong springs, which in this country have constantly the temperature of forty-eight degrees of Fahrenheit's thermometer, is to be preferred to that of rivers, where it can be procured in a sufficient proportion, as the degree of cold in these is in the same ratio with that of the atmosphere, till it declines to the freezing point, or that of thirty-two. Though both, when spread out, forming a thin sheet of ice on the surface of the land, are beneficial in defending the roots of the grass plants from too intense degrees of cold, and of thus preserving them in a more healthy condition; and it is added, that those of some sorts of grasses are supposed even to vegetate beneath the ice, as the rein-deer moss in Siberia mostly vegetates beneath the snow, in a degree of heat of about forty, which is the medium between that of the inferior surface of the dissolving snow, or that of thirty-two, and that of the common heat of the internal parts of the earth, which is forty-eight; and in this manner the grass produce in this cold country be considerably increased, so as, under proper management, to nearly double the usual annual quantity under other circumstances.

In further illustration of these principles it may be observed, that the water issuing from springs where they abound with particles of gravel, or a stony, mouldering kind of rock, containing a large proportion of calcareous earth, are known from experience to be better adapted to the purpose

IRRIGATION.

pose than that which arises from others that do not contain such materials. The difference in the effects, often so visibly produced, has been accounted for, from watering one field from a spring issuing out of a chalky soil, over those which take their rise in another, similar in every respect and management, except that the water applied arises in, or flows through, a swamp or morass, composed chiefly of peat earth, or proceeds from situations known to contain none of these substances. However, the fact is unquestionably established, that the water of rivers which run through comparatively level and fertile countries, is not only better than that of such as have their courses through mountainous, unproductive tracts, but superior to all others, as every different streamlet adds a new accession of fertilizing materials, which, being dispersed over the surface of the meadows, in their fine and attenuated state, cannot avoid adding a considerable degree of improvement to the lands.

It is conceived by Mr. Marshall, that if the art, as it now stands, were struck out on principle, it must have been on that of animal circulation; to which the operation of meliorating grass-lands with water, through the means of floats and drains, is perfectly analogous. The floats are arteries, conveying the circulating fluid to every part of the subject, imbuing every atom: the drains, veins, collecting the scattered fluid, and conveying it back to its natural channel. But that, in less figurative language, the floats may be considered as trenches, receiving, by the means of flood-gates, as occasion requires, the water of a river, brook, or rivulet, and conveying it along the upper margin, and upon the tops of the natural or artificial swells of the field of improvement—the drains, counter-trenches, stretching along the lower margin, and winding in the dips and hollows, to receive the waters spread over the surface by the floats.

Each set of trenches, whether of floats or drains, bears more or less resemblance to a tree, with its trunk and branches; the branches of the floats increasing in number, and diminishing in size, as they proceed from the river or other source; those of the drains, on the contrary, diminishing in number, and increasing in size, as they approach the receptacle or place at which the water is to be discharged. And it is further remarked, that when the water is at work, as it is properly enough termed, the entire surface, supposing the operation to be perfect, is covered with one continued sheet of living water, purling slowly and evenly over every part, an inch or more deep. If the grass be very short, the water is seen, and has a beautiful as well as a profitable effect: if not, it steals, unseen, among the herbage, or shews itself, partially; it being impossible, in practice, to render the sheet throughout of an uniform depth or thickness, as it must naturally pass off quicker in some situations than others.

From this general idea of the method of watering grass-lands, on the modern principle, it is clearly shewn that a dead flat, a perfect level, is, of all others, the least adapted to the practice. A perfect level, however, seldom occurs in nature; inequalities, sufficiently to promote a circulation of water on the turf surface, may generally be discovered, if judiciously sought. In the midland counties, Mr. Marshall has seen in the practice of a superior manager a beautifully simple expedient practised, to find out the inequalities of a piece of ground nearly flat: which is that of covering it with water, and preserving the level by the means of leveling pegs, stumps or piles driven down in various parts to a level with the surface of the water; so that, after the water was let off, the level still remained. The parts last covered were, of course, the proper ground for the floats; the parts left free for the drains; art being used, where wanted, to

give additional advantage to the natural inequalities which may be present. But situations in general (water-formed lands excepted), abound, he thinks, sufficiently with inequalities of surface: either natural, as the swells and hollows of lands, lying out of the way of floods, and having never been ploughed: or artificial, as those which have been raised by the plough into ridge and furrow: in this case the ridges receive the floats, the furrows the drains: in that, the plummet is the guide to the floats; the water they throw out, to the drains or cuts to be formed.

The same writer adds, that, in the above district, he has seen the side of a hill watered with rain-water, from a road running along the top of it: the same trench, in this case, acting as float and drain, running a zig-zag along the face of the slope, the lower folds catching the water spread out by the upper; and that he has likewise observed several instances of ridges and furrows being watered from similar sources. In these cases, whether the natural descent of the lands was little or great, the floats were opened upon the ridges with clods of turf cut out of the trenches, placed at distances proportioned to the descent, to check the current sufficiently, to force the water out of the trench above, yet leaving it a sufficient passage, to suffer it to carry down a supply to the parts below. He has also met with one or more instances in which ridges and furrows have been levelled at an excessive cost, by paring off the turf, throwing down the ridges by hand, and replacing the turf, giving the surface one regular gentle descent; and thus, notwithstanding it is allowed by those who may be styled maulers in the art, that the quicker the circulation the more beneficial the effect. Upon the whole, it appears pretty evident, that the operation, though scientific, can seldom be rendered mechanical. Straight lines and plain surfaces can seldom be had, but at a great, and, frequently, an unnecessary expense. The given situation of the ground should be consulted and maturely studied before the work be set about. Every feat may be said to require a different arrangement of trenches. Of course, no man ought to set about a work of so difficult a nature until he has studied its principles, and made himself master of its theory; nor then, without the assistance of practice in himself, or others whom he can employ for the purpose.

It is conceived that to expatiate on the utility of watering grass-lands would be a waste of words. In situations where a sufficient supply of water, of a fertilizing quality, can be commanded at all seasons, it ranks indubitably among the highest class of improvements. Much, however, it is supposed, depends on the quality of the water; not on its colour or clearness, but the specific quality of the suspended particles. Waters, in their natural state (not purified by distillation), more especially spring waters, though perfectly transparent and pure to the eye, are as various in quality as soils, owing to earthy and other particles being suspended in them imperceptibly to the eye, requiring the aid of chemistry to detect them; hence hard water, soft water, wholesome waters, medicinal waters, &c. The effects of clear spring water have been found strikingly evident in various cases of this sort of management in different places in this country.

But although very much depends on the quality of water for the purpose of meliorating grass-lands, much also depends on the quantity; on having a sufficient supply at all seasons. With this there are, perhaps, few waters which might not be rendered beneficial to grass-land, if thrown over it at proper seasons, and in proper quantity. Without it, the benefit, it is possible, may not be adequate to the expense. The most obvious advantage of watering grass-

IRRIGATION.

lands, it is conceived, arises in a dry season; and if the supply fail in such seasons, as frequently happens in many situations, the intention is in part frustrated; the winter and early spring waterings being in this case all that can be commanded for the purpose. This is given by way of caution; and as a discouragement to the practice. There are, it is not observed, in this island, situations innumerable, in which the advantages arising from the practice, properly conducted, would far exceed the expence of obtaining them; and to ascertain them is an object of the first magnitude to the owners and occupiers of grass-lands, and in many instances, probably in those of the arable kind likewise.

Hence it may be safely concluded, that this mode of improving grass, or other lands, where it can be had recourse to, is of the greatest importance, and of the most valuable kind; and it is probably capable of being applied in a greatly more extensive manner than has yet been the case, by the persons employed in conducting the business fully availing themselves of the various occasional falls of rivers, streams, and, in particular seasons, of canals, as in this way water may often be provided for the purpose of distributing over extensive tracts of land that have hitherto been thought incapable of admitting of such means of melioration and improvement. In other circumstances and situations, by having recourse to damming up the water, and the occasional use of wooden pipes in the conveying it where necessary, it may be easily raised to heights sufficient for conducting it over many elevated lands, and by such means promote their vegetation and produce to a degree that cannot be easily calculated or conceived.

And, from what has been already done in this way, it is evident that, on heathy moors, and other mountainous tracts, it may often be applied with the prospect of great advantage. In traversing such hills, instances are daily occurring of little rivulets or rills, which are insufficient to form a regular course, spreading their waters on particular parts, and thus providing a most beautiful verdure; which affords sufficient proof of what may be effected by the judicious application of water in such situations. The same principles may be applied, in many situations, in conveying the rich liquors collected in ponds and reservoirs about the farm yards and buildings, that are too frequently wasted by evaporation or other means, over the adjoining fields, as has been practised in Cheshire by Mr. Fenja.

To this system of improving grass-lands, the chief objection is, the first expence of the work; but if it be conducted in a judicious manner, and by persons acquainted with the business, this will seldom be so considerable as is commonly supposed, or form any material impediment; as the increase of produce, which is almost immediately the consequence, will amply repay the improver. It has been objected to by some on the ground of cutting the land, but this is of little consequence if additional supplies of food be thereby afforded for the support of live stock, and the gradual improvement of the soil at the same time effected.

It may be stated that winter and spring are the two seasons when grounds of the grass kind are usually irrigated or watered, as from the month of November till the beginning of March. The experience of the operator must, in a great measure, regulate this proceeding as to the length of time they should remain under water. In some districts it is the practice to allow the water to flow over the fields for several weeks together, with only the interval of a day or two occasionally; while in others the custom is to cover them alternately each other week. When frosts set in, the work is usually suspended; but it has been remarked, that

in such cases the succeeding crop of grass is less plentiful. As the spring season advances, much less floating is found to be requisite. However, in every case where floating is performed to advantage, the land should be laid dry between every time of covering it with water.

It has been advised in the beginning to lay the water on in the early part of November, suffering it to overflow from 10 to 14 days, and then taken off; repeating the same process in the two following months; giving in February also two waterings of from five to seven days each; and in March three, of from three to five days each, according to the state of the weather, constantly permitting the water to continue longer upon the land in cool than warm weather; and it is likewise generally advised, that on the sandy, gravelly, and drier kinds of lands, the water should not remain so long at a time as in those of the heavier kinds; and in the latter sorts, Mr. Wright considers three weeks as long enough; but Mr. Boswell thinks it may continue on a month, or even six weeks in the first waterings, about November, and a something shorter time for those of the former sort of lands. Mr. Wright also recommends, in December and February, the land to be let dry, for the purpose of air for a few days, and that in February particular attention is necessary, not to permit the water to flow over the ground many days together, without being taken off, as there may be danger from white scum being formed; and by the land being left exposed to frost in its wet state, it may be injured that way. These inconveniences, it is supposed, however, by Mr. Wright, may be avoided by taking the water off in the day, and turning it upon the lands only during the night time. But Mr. Boswell, who has had extensive experience in this way, does not seem to apprehend any danger from this circumstance to the land.

Towards the beginning of the spring, as about March, and sometimes sooner, there is usually a sufficient bite of grass to admit the lands to be fed by stock. The water should in this case be turned off for a fortnight or more, in order to give it a sufficient degree of firmness before the animals are turned upon it. During the following months, it is observed that the grass may be eaten close, but not later; as continuing it even for a few days in May would greatly injure the hay produce which is to be obtained, both in quantity and quality. In this month, when the grass has been fed down, the water should, according to Mr. Wright, be again turned over the lands for a few days, by which they are so moistened as to produce a full crop of hay. It is not improbable but that, with less close feeding, two crops of hay from such watered lands might frequently be taken with benefit. It is remarked by this writer, that the first crop of hay from watered lands, when cut sufficiently early, is equally good with that of most other sorts, but that when let stand too long, it becomes coarse and unfit for the purpose of fodder.

A late philosophical writer has suggested, that where the flooding of lands is continued some time, the water should only be suffered to trickle or flow over it gently from the higher parts, and not stagnate upon it; as, in the latter case, the grass roots are soon destroyed in the spring, and that when such materials begin to decay underneath the water, a white scum arises in consequence of the air set at liberty by the beginning putrefaction, which has been suspected as prejudicial to the grass, but which is rather the effect than the cause of the mischief, and demonstrates that the water has remained too long in a stagnant state upon the ground, and requires to be removed, or to have a fresh supply from the stream; but the former is probably the better practice. The necessity of continuing the irrigation,

or watering of land, after it has been once begun in hot climates and seasons, has been already shown, and it is suggested that there may be injury done to the grass plants by the sudden application of much water under such circumstances in some cases.

It is usefully inculcated by a late writer that, before any serious expence is incurred in works of this kind, the nature and effects of the water that is to be employed should be fully ascertained by the establishment of trial grounds, which, if it be proper and beneficial for the purpose, will be shewn by the superiority in the growth, verdure, and general appearance of the grass towards the latter end of March, or the beginning of the following month. The quantity of water and extent of ground that can be covered by it must likewise be jointly taken into consideration before any improvement of this sort can with propriety be undertaken. And in every instance it is advised that due estimates, and a calculation of profit, be formed on the following principles. First calculating the probable advantages that may arise every year from hay and pasturage, and an annually increasing supply of manure and dung; then taking the interest at six per centum on the estimated cost of the works that may be requisite to produce them, together with the amount of the estimated annual expence of labour, and necessary repairs.

A great number of interesting instances of successful irrigation, or application of water over lands, in the midland districts, have been related by the same author. And in this case, as in many others, Mr. Bakewell stands first as an improver of grass-lands. It is stated that, formerly, a fruit meadow, lying by the banks of the Soar, received considerable benefit from the water of the river being spread over them judiciously in the time of floods. But now, not only these meadows, but near an hundred acres, he believes, of higher lands lying entirely out of the way of natural floods, are watered on the modern principle.

And it is remarked that the ingenious improver just noticed, like a man of experience in business, before he set about this great work, studied the art in the principal scene of practice, the west of England, where he spent some days with the ingenious Mr. Boswell, who, not many years ago, published a treatise on the subject. And that the great stroke of management in this department of his practice, which marks his genius in strong characters, is that of diverting to his purpose a rivulet or small brook, whose natural channel skirts the farthest boundary of his farm, falling, with a considerable descent, down a narrow valley, in which its utility, as a source of improvement to land, was confined. This rivulet, being turned at the highest place that could be commanded, and carried, in the canal manner, round the point of a swell, which lies between its natural bed and the farmery: by the execution of this admirable thought, not only commanding the skirts of the hill, as a source of improvement by watering; but supplying, by this artificial brook, the house and farm-offices with water: filling, from it, a drinking-pool, for horses and cattle; a wash-pool, for sheep; and converting it into a multitude of other purposes: acquisitions which, Mr. Marshall says, many other situations in the island are capable of affording. One of these purposes is worthy of being mentioned as deserving the attention of the practical farmer. After endeavouring to invent a flat-bottomed boat or barge, to navigate upon this canal; for the purpose, most particularly, of conveying his turnips from the field to the cattle-sheds; and finding it not easily practicable, his great mind struck out, or rather caught, the beautifully simple idea of launching the turnips themselves into the water; and letting them flow down singly with the current.

"We throw them in," says he, "and bid them meet it at the barn's end!" in which situation he was then (October, 1789) contriving a reservoir, or dry dock, for them to fall into: with a grate at the bottom, to let out the water, and retain the turnips; which will there be laid up, clean washed, and freight-free, as a supply in frosty weather.

The improvements effected in this department of rural affairs, by this able improver, are, it is observed, not only extensive, but highly interesting, and are rendered the more striking, by "proof pieces," (a good term for experimental patches,) left in each locale of improvement.

In the art of irrigating or watering grass-lands, on the modern principle, Mr. Paget, of Ibbotock, is also mentioned. This improver, it is stated, cuts a considerable quantity of hay, annually, from lands which have received no other manure than water, during the last forty years. A striking instance, it is supposed, that water is not merely a stimulus or force, as some men conceive it to be, but communicates some real nutriment to the herbage or grass plants. In the practice of this improver, one circumstance occurred, which ought to be mentioned by way of caution. He found that in watering an orchard with the washings of the street and yards of a neighbouring village (a desirable species of water) the fruit-trees were greatly injured. A similar circumstance also took place in the practice of Mr. Bakewell. It is well known that surface water is in all circumstances highly injurious to fruit-trees of the apple kind. Also, near Appleby, in Yorkshire, Mr. Moor has executed a considerable work of this kind in a judicious manner, cutting a fresh channel on one side of the site of improvement, for a rivulet which wound through its middle; in order to prevent its overflowing at an improper season; and converting the old channel, (partially filled up) into a main float; an expedient which may be frequently practised with good effect, in different situations. The same species of improvement has likewise been carried on with much spirit and success by Mr. Wilks of Meeham; and in other instances the practice has not been attended with less success, though under different circumstances.

According to the agricultural survey of the county of Devon, Mr. Templer, of Stover, has experienced from this method of husbandry very considerable beneficial effects on a tract of marshy land on the borders of his canal. It had formerly produced from five to ten shillings an acre. After having it drained and levelled, by forming conductors for the overplus water of the canal during the winter floods, and distributing it by well arranged sluices, so as to throw the enriching particles upon the surface, he converted these marshes into valuable, verdant meadow-land. The method that was adopted in constructing the distributing sluices was by having a number of trunks placed at various distances, to each of which a plug was fitted, and when the flood swelled the canal above the level requisite for navigation, the plugs were taken out, and the water immediately overflowed the surface of the meadow-lands, being at any time capable of being easily restrained by replacing the plugs; similar success is likewise ascribed to have attended a like process on lands in the upper line of the canal.

Besides these, in Yorkshire, Cheshire, Wales, and the more northern parts of Scotland, as well as in the different districts in which the practice of irrigation has been long common, various improvements have been effected by the application of water to the surface of grass-lands, which will be particularly noticed under the proper head, and also the most approved methods of accomplishing the business under different circumstances of soil and situation. See *Watering of Land*.

IRRIGABILITY, in *Physiolog.* &c. &c. in its most general,

neral sense, the capability of being irritated or excited, or that property by which living parts are enabled to execute their functions: when thus employed, it is synonymous with excitability, and may be regarded as denoting the most characteristic peculiarity of living matter. It is very commonly employed, in a more limited acceptation, to express the property by which muscles are enabled to contract, either in obedience to the will, or to any mechanical or chemical stimuli. In either case, this word is to be understood as signifying merely a property of living bodies, the real nature of which is as entirely unknown to us as that of attraction or chemical affinity. All the speculations which have been entertained on the subject of its nature, supposing it to be a peculiar subtle matter like those (whose existence, be it observed, rests also on supposition) of electricity common or Voltaic, of magnetism or light, or considering it as identical with oxygen, may be dismissed without any formal refutation, as they are completely gratuitous assumptions. See LIFE, MUSCLE, and NERVE.

IRRITATION, in *Medicine*, signifies a state of feverishness and inquietude, in which the functions are impeded, and the strength gradually impaired, arising either from internal or external causes, but principally from the former. It is synonymous with the *ερεθισμ*, *ερεθισμος*, of the Greek writers. Irritation is produced, in different instances, by extraneous substances in the cavities or organs of the body, as calculi in the bladder, kidneys, or ureters; worms in the stomach or intestines, &c.; or by chronic disease in the viscera, such as scirrhus of the liver, of the mesenteric glands, &c.; or slow inflammation in any part; or by the prevalence of any depressing passion, as grief and anxiety; or by long watching; and various other causes. In febrile diseases, from whatever origin, a state of irritation is more readily produced; *i. e.* the same stimuli which excite little effect in the state of health, tend to aggravate the feverish symptoms, such as external heat, strong light, noises, muscular or mental exertion, and the like: whence, in every fever, whether idiopathic or symptomatic, the removal of every source of irritation is an indication constantly to be kept in view.

IRRSUMIT, in *Geography*, a town of East Greenland. N. lat. 61 10'. W. long. 45 35'.

IRSOA, a small island near the coast of Portugal, on the fourth side of the mouth of the Minho. N. lat. 41 50'. W. long. 8 36'.

IRTISCH, or IRTYSH, a river of Russia, which rises in the Chinese Soongoria, flows through the lake Norisnfan, in N. lat. 46 30', then enters the Russian territory, and after meandering through a large tract of country, throws itself, in N. lat. 61', and E. long. 56', into the Ob. In its way it takes up several smaller rivers, and forms several islands, of which some occasionally disappear, and their places are supplied by others; and the intervals in which it is navigable are perpetually changing. Its water in the inferior regions is whitish and light, so that it should seem to flow over a bottom consisting chiefly of calcareous marl. It swarms with fish, and its sturgeons have a peculiar delicate flavour.

IRVINE, or IREWINE, a sea-port town and royal borough in the bailiwick of Cunningham, and county of Ayr, Scotland, is seated on the northern bank of the river Irvine, the estuary of which forms the harbour. On the southern side of the river is a row of houses uniformly built; and these, with others, are hamlets to the parish of Dundonald. The town appears to have been chartered at an early period; for in a grant from Alexander II., reference is made to previous charters. The magistracy of this town

had formerly extensive jurisdiction, but this has been abridged; but it still derives an ample revenue from a large tract of land near the town. Here is a commodious harbour, which has 10 or 12 feet of water on the bar at spring-tides. Several vessels, called buffes, were formerly employed in the herring-fishery: at present the coal-trade is the chief object with the inhabitants. Above 24,000 tons have been shipped from this port in one year. Attached to the town is a dock-yard for ship-building, a large tan-yard, rope-ground, and a bleach-field. Many of the inhabitants are also engaged in the manufacture of carpets, muslins, silks, lawns, and other articles. In the year 1800, the town contained 729 houses, and 4584 inhabitants; though its population was estimated, in 1790, at 3500. The town is 61 miles W. by S. from Edinburgh. The church is described as a prominent object of beauty and interest in the town. Bowtree hill, in the vicinity of Irvine, is a feat of the honourable Mr. Hamilton; and near it is an old castle, belonging to the earl of Eglington, who has a feat in the neighbouring parish of Kilwinning. In the parish of Irvine it is said that a religious sect called Buchanites, from the name of the founder, had its origin. Sinclair's Statistical Account of Scotland, vol. vii. p. 169, &c. by the Rev. James Richmond.

ISA, in *Hindu Mythology*, one of the thousand names of Siva, the personification of the destructive or regenerative power of the deity. (See SIVA.) With the epithet *Maha*, or *great*, prefixed, Mahesa is formed, another of Siva's names. In this form, the name of his consort or fakti (see SAKTI) is Ili. Under these names for William Jones recognizes the Osiris and Isis of Egypt. Iwara seems but another mode of writing and pronouncing Isa; and the deduction of Osiris from that found is no strained etymology, especially when confirmed by many historical and characteristic coincidences. Iia and Iii are both personifications of the moon; for with the Hindus, that luminary is both male and female: and here we find Parvati (of whom Iii is only another form and name) again corresponding with the Diana of the Greeks, one of whose names is Luna.

ISAAC, in *Scripture Biography*, the son of Abraham and Sarah, was born at Gerar, in the country of the Philistines, B. C. 1896, when his father was 100, and his mother 90 years of age. His birth was previously announced to Abraham, as the son of covenant and promise, in whose seed all the nations of the earth should be blessed. His name, according to its Hebrew etymology, which denotes "he has laughed, or shall laugh," expresses the pleasure with which his parents received the prediction of his birth, and augured the honour that awaited his posterity. A circumstance, however, occurred, which tended to abate their joy; and this was a divine command to offer Isaac as a sacrifice. (See ABRAHAM.) At the age of 40 years, Isaac married Rebecca, the daughter of Nahor, Abraham's brother; and by her he had two twin-sons, Esau and Jacob. (See their articles.) This venerable patriarch, for whose history we refer to the book of Genesis, ch. xviii—xxxv. died at the age of 180 years, B. C. 1716, and was buried with his parents in the cave of Machpelah.

ISAAC I. COMENUS, in *Biography*, emperor of the East, son of Manuel, was the first of the noble family of Comeni who arrived at the imperial throne. Isaac and his brother John were bequeathed by an affectionate father, conscious of his own defects in the service of his country, to the gratitude and favour of his sovereign. The noble youths were carefully trained in the learning of the times, the arts of the palace, and the exercises of the camp; and had become extremely popular with the people and the army. On the elec-

vation of Michael VI., the discontent of the soldiery was openly manifested. The generals, who considered themselves insulted by the election of Michael, secretly assembled in the fanctuary of St. Sophia, and would have chosen the venerable and valiant Catacalon, if the modesty of the veteran had not suggested the importance of birth as well as merit in the choice of a sovereign. Upon his refusal of the dignity, Isaac Comnenus was approved by general consent. Comnenus, then in Paphlagonia, soon learnt the decision of the military synod; and invetted with the imperial insignia, marched to Nice, which he took by surprize; but being encountered in the neighbourhood of that city by Michael's generals, he entirely defeated them, and proceeded to Constantinople. The dethroned emperor resigned his dignity, and retired to a monastery; and Isaac was solemnly crowned, September 1, 1057. His short reign was undisturbed by foreign enemies: he fell into a declining state of health, which he took as an admonition to retire from the world. John, whom he would gladly have invetted with the imperial purple, refused to accept the toil, and it was conferred upon Constantine Duca; and Isaac ended his reign of two years and three months in a monastery. Isaac in a great measure recovered his health, and survived two years his voluntary abdication. At the command of his abbot, he observed the rule of St. Basil, and executed the most fervile offices of the convent; but he was gratified by the frequent and respectful visits of the reigning monarch, who revered in his person the character of a benefactor and saint. Gibbon. Univer. Hist.

ISAAC II. ANGELUS, emperor of the East, was raised to that dignity by the fall of Andronicus, the last of the Comnenian family who reigned at Constantinople. The revolution which hurled him from the throne, saved and exalted Isaac Angelus, who descended by the female line from the same imperial dynasty. "The successer of a second Nero," says the historian, "might have found it an easy task to deserve the esteem and affection of his subjects; nevertheless they sometimes had reason to regret the administration of Andronicus." Isaac abandoned himself to frivolous amusements and luxurious indulgences, and oppressed his people by the lavish expences of his household. "Isaac," says Mr. Gibbon, "slept on the throne, and was awakened only by the sound of pleasure: his vacant hours were amused by comedians and buffoons, and even to these the emperor was an object of contempt: his feasts and buildings exceeded the examples of royal luxury; the number of his eunuchs and domestics amounted to twenty thousand." His generals were successful in expelling the Sicilian invaders; but Isaac disgraced himself by the cruelty with which he treated the captives. Constantinople was besieged, and the weak emperor put all his trust in an image of the Virgin Mary, and the prayers of the monks. A revolt of the Bulgarians proved a lasting injury to the empire; and it became necessary to suffer them to establish an independent kingdom. Isaac drew upon himself various acts of hostility from Frederic Barbarossa, who was the friend and ally of the Crusaders. At length the perfidy of his own brother Alexius was more fatal to him than foreign violence. In 1195, he seized upon the throne, during the absence of Isaac on a hunting party; and obtaining possession of his person, deprived him of his sight, and shut him up in a lonely prison. His son Alexius escaped, and engaged the western powers in his behalf; who, in 1203, took Constantinople, and replaced Isaac upon the throne in conjunction with his son. Another revolution, in 1204, effected by Alexius Duca, deprived them of their seat; and the

death of Isaac very soon followed, or perhaps preceded, the murder of his son. Univer. Hist. Gibbon.

ISAAC, HENRY, a German composer of great renown in Italy, during the fifteenth century, under the name of Arrigo Tedesco; by which title he is celebrated by Pelitian. Quadrio, tom. ii. p. 321. says that he was maestro di cappella of the church of San Giovanni, in Florence; and the first who, in different ballad-airs, set the songs of Lorenzo il Magnifico, in three parts, for a professional masquerade. He flourished about 1475. Glareanus, in his "Dodecachordon," says that "Henry Isaac chiefly cultivated the church style; and in his works may be perceived a natural force and majesty, superior, in general, to any thing that can be found in the compositions of our times; though his style may be said to be somewhat rough. He was fond of long notes in some one of his middle parts, while the rest of the voices were in a manner playing round it, as the wind plays when it puts the waves in motion round a rock."

ISABAD, in *Geography*, a town of Persia, in the province of Irac; 50 miles S. of Hamadan.

ISABE, a town of Japan, in the island of Nippon; 50 miles N.W. of Jedo.

ISABEL, ST., one of the islands of Solomon, in the Pacific ocean, 200 miles in circumference, S. lat. 7° 30', about 160 leagues west of Lima, discovered by Mendana in 1567. The inhabitants are cannibals, and worship serpents, toads, and other animals. Their complexion is brown, their hair woolly, and they wear no covering but round their waist. They are divided into tribes, and are constantly at war with each other.

ISABELLA, in *Biography*, queen of Castile, born in 1451, was the daughter of John II. She passed the early part of her life in great obscurity, and without any prospect of a crown; but the Castilians having conspired against her brother Henry IV., obliged him to declare Isabella heiress to the kingdom. In 1469 the married Ferdinand king of Arragon; and upon the death of Henry in 1474, they were conjointly declared king and queen of Castile. They were proclaimed at Segovia, amidst loud acclamations; and the fidelity of their new subjects enabled them to defeat all the designs of their enemies, who had declared in behalf of Joanna, the supposed daughter of Henry. Alphonso IV., king of Portugal, espoused the person and the cause of the latter, and took up arms in her defence and his own. The defeat at the battle of Toro, in 1475, was fatal to his pretensions; and by a peace concluded in 1479, the right of Isabella and her husband was fully acknowledged, and Joanna retired into a monastery. In this same year, the crown of Arragon fell to Ferdinand; and from that period the kingdoms of Castile and Arragon were inseparably united, comprising the whole of Spain not possessed by the Moors. (See FERDINAND.) Religious zeal was a leading feature in her character; and the desire of propagating the Christian faith in parts of the world where it was yet unknown, was the chief motive of the encouragement she gave to the projects of Columbus, which eventually added so much to the Spanish monarchy. Her merits towards the church were rewarded by the title of "The Catholic," conferred by Innocent VIII. on both the royal partners, and their successors in the Spanish crown. Isabella died with the great regret of her subjects, in November 1504, in the 54th year of her age. Univer. Hist. Robertson's Hist. of America.

ISABELLA, in *Conchology*, the name given by the French naturalists.

naturalists to the beautiful pale-brown voluta, so much esteemed in the Dutch cabinets.

ISABELLA, in *Geography*, a small island near the coast of Brazil: 25 miles S.W. from the mouth of the river St. Francisco.—Also, a town on the north coast of the island Hispaniola, built by Christopher Columbus in the year 1493. N. lat. 19° 55'. W. long. 73° 0'. Isabella Point forms the N.E. side of the bay of the same name. Here Columbus formed the first Spanish settlement, naming it after his patroness queen Isabella. He was driven hither by a tempest in the night.

ISABELLA, *St.*, a town of Brazil, in the government of St. Salvador, near the coast. S. lat. 11° 10'.

ISACHNE, in *Botany*, from *ισος*, equal, and *αχνη*, a husk. Brown. Prodr. Nov. Holl. v. 1. 196. Class and order, *Triandria Digynia*. Nat. Ord. *Gramina*.

Ess. Ch. Calyx of two equal, membranous, obtuse valves, two-flowered. Florets equal, bivalve, of a paper-like texture; the outer male, inner female. Two scales beneath the germen. Stigmas feathery. Seed enclosed in the hardened calyx. *Brown*.

A genus of smooth grasses, growing in watery places. Leaves flat, their sheaths bearded at the top. *Flowers* panicled.—They have great affinity to *Panicum*, and the aspect of *P. coloratum*. It appears by Hermann's herbarium that his *Menertiana*, Fl. Zeyl. 24, is of this genus.

The only New Holland species given by Mr. Brown is *I. australis*. "Panicle lanceolate, simple. Branches and flower-stalks zig-zag. Stem erect." Native of Port Jackson, New South Wales.

ISEUS, in *Biography*, an orator of Chalcis, in Eubœa, who flourished about the end of the Peloponnesian war, the fourth century before the Christian era. When he came to Athens, he put himself under the instructions of the orator Lyfias, from whom he obtained the same purity, accuracy, conciseness and perspicuity of style, which distinguished his matter, with more force and vigour. He was celebrated for popular eloquence, and had the honour of being the instructor of Demosthenes. It has been said that he was dissipated in early life, but that as he attained to years of maturity, he became illustrious by the practice of the opposite virtues. He lived to the time of king Philip. He was author of sixty-four orations, of which ten only are now remaining, which are to be found among the *Oratores veteres Græci*. These have been translated by Sir William Jones, and were given to the world in 1779. There was another Greek orator of this name, who came to Rome in the first century of the Christian era, and who is mentioned with great applause by Pliny the younger, who observes that he always spoke extempore, and wrote with elegance, unlaboured ease, and great correctness.

ISAGO, in *Geography*, a country of Africa, N.W. of Benin.

ISAGON, in *Geometry*, is sometimes used for a figure consisting of equal angles.

ISAIAH, or the *Prophecy of Isaiah*, a canonical book of the Old Testament. Isaiah is the first of the four greater prophets; the other three being Jeremiah, Ezekiel, and Daniel. This prophet was of royal blood, his father Amos being brother, as some have said, to Azariah, or Uzziah, king of Judah.

The first appointment of Isaiah to the exercise of the prophetic office is supposed to have taken place in the last year of Uzziah's reign, or 758 B.C., at which time he is supposed to have been about 35 years of age; and if he lived to the reign of Manasseh B.C. 696, by whole order,

according to a tradition of the Jews, he was fawn afunder, the duration of his office must have extended to 61 or 62 years. But this Jewish tradition is uncertain; and one of their principal rabbins (Aben Ezra, Com. in II. i. 1.) seems rather to think that he died before Hezekiah, which opinion is received as the most probable. It is certain, however, that he lived at least to the 15th or 16th year of Hezekiah; and this makes the least possible term of the duration of his prophetic office, about 47 or 48 years; so that he prophesied in the reigns of Uzziah, Jotham, Ahaz, and Hezekiah. The time of the delivery of some of the prophecies is either expressly marked in, or easily deducible from, the history to which they relate; that of a few others may, with some probability, be inferred from expressions, descriptions, and circumstances interwoven in the predictions themselves. The prophecy contained in the first chapter stands single and unconnected; and contains a severe remonstrance against the corruptions prevailing among the Jews of that time; powerful exhortations to repentance; grievous threatenings to the impenitent; and gracious promises of better times, when the nation shall have been reformed by the just judgments of God. The expression is upon the whole clear; the connection of the several parts easy; and in regard to the images, sentiments, and style, it gives a beautiful example of the prophet's elegant manner of writing; though perhaps it may not be equal in these respects to many of the following prophecies. The prophecy contained in the second, third, and fourth chapters, makes one continued discourse. The first five verses of the second chapter foretel the kingdom of the Messiah, the conversion of the Gentiles, and their admission into it. From the 6th verse to the end of the 2d chapter, is foretold the punishment of the unbelieving Jews for their idolatrous practices, their self-confidence and distrust of God's protection; and moreover the destruction of idolatry, in consequence of the establishment of Messiah's kingdom. The whole third chapter, with the first verse of the fourth, is a prophecy of the calamities of the Babylonian invasion and captivity; with a particular amplification of the distress of the proud and luxurious daughter of Sion. Chapter iv. 2—6, promises to the remnant, which shall have escaped this severe purgation, a future restoration to the favour and protection of God. The prophecy was probably delivered in the time of Jotham, or perhaps in that of Uzziah. The 5th chapter is unconnected with that which precedes, and with that which follows it; and the subject of it, like that of the first chapter, is a general reproof of the Jews for their wickedness; but it exceeds that chapter in force, in severity, in variety, and in elegance; and it adds a more express declaration of vengeance, by the Babylonian invasion. The vision in the 6th chapter seems to contain a solemn designation of Isaiah to the prophetic office, and it is therefore thought by most interpreters to be the first in order of his prophecies. Bishop Lowth, however, conjectures that this may not be the case; because Isaiah is said to have prophesied in the time of Uzziah; but as Isaiah's prophecies are not placed in exact order of time, the 2d, 3d, 4th, and 5th chapters seem to be antecedent to the 1st chapter, and to suit the time of Uzziah, or the former part of Jotham's reign, whereas the 1st chapter can hardly be earlier than the last years of Jotham. Accordingly this might be a new designation, to introduce more solemnly a general declaration of the whole course of God's dispensations in regard to his people, and the fates of the nation; which are even now still depending, and will not be fully accomplished till the final restoration of Israel. The 7th chapter begins with an historical account of the occasion of this prophecy; and then

then follows a prediction of the ill success of the designs of the Israelites and Syrians against Judah; and a denunciation of the calamities to be brought upon the king and people of Judah by the Assyrians, whom they had now hired to assist them. The 8th chapter is closely connected with the foregoing, and contains a confirmation of the prophecy before given of the approaching destruction of the kingdoms of Israel and Syria by the Assyrians, of the denunciation of the invasion of Judah by the same Assyrians; together with a repeated general assurance, that all the designs of the enemies of God's people shall be in the end disappointed and brought to nought, concluding, after admonitions and threatenings, with an illustrious prophecy of the manifestation of the Messiah, the transcendent dignity of his character, and the universality and eternal duration of his kingdom. This prophecy concludes at the 6th verse of the 9th chapter. The whole passage from chapter ix. 7. to chapter x. 4. contains a distinct prophecy, and a just poem; remarkable for the regularity of its disposition and the elegance of its plan; it is addressed exclusively to the kingdom of Israel, and the subject of it is a denunciation of vengeance awaiting their enemies. The 5th verse of the 10th chapter begins with a new and distinct prophecy, which is continued to the end of the 12th chapter. It appears that it was delivered after the taking of Samaria by Salmanser, in the 6th year of the reign of Hezekiah, and as the former part of it foretells the invasion of Senacherib, and the destruction of his army, which makes the whole subject of this chapter, it must have been delivered before the 14th year of the same reign. Then, according to Isaiah's usual method, he takes occasion, from the mention of a great temporal deliverance by the destruction of the Assyrian army, to launch out into the display of the spiritual deliverance of God's people by the Messiah, to whom this prophecy relates. (See Rom. xv. 12.) The hymn in the 12th chapter seems, by its whole tenor, as well as by many expressions in it, much better calculated for the use of the Christian church, than for the Jewish in any circumstances, or at any time, that can be assigned; and the Jews themselves seem to have applied it to the times of the Messiah. The 13th and 14th chapters (excluding the five last verses of the latter, which belong to a quite different subject) contain one entire prophecy, foretelling the destruction of Babylon by the Medes and Persians; delivered probably in the reign of Ahaz (see Vitringa, i. 380.) about 200 years before the completion of it. The former part of this prophecy, says bishop Lowth, is one of the most beautiful examples, that can be given, of elegance of composition, variety of imagery, and sublimity of sentiment and diction in the prophetic style; and the latter part consists of an ode of supreme and singular excellence. The 15th and 16th chapters, which ought not to have been separated, taken together, make one entire prophecy, delivered, most probably, soon after the foregoing, in the 18th year of Hezekiah, and accomplished in his 4th year, when Salmanser invaded the kingdom of Israel. The prophecy in the 17th chapter comprehends the kingdom of Samaria and the Israelites, confederated with Damascus and the Syrians against the kingdom of Judah. It was delivered probably soon after the prophecies of the 7th and 8th chapters, in the beginning of the reign of Ahaz, and was fulfilled by Tiglath-Pileser's taking Damascus, (2 Kings, xvi. 9.) overthrowing a great part of the kingdom of Israel, and carrying a great number of the Israelites also captives to Assyria; and still more fully in regard to Israel, by the conquest of the kingdom, and the captivity of the people, effected a few years after by Salmanser. The prophecy in the 18th chapter is in all its circumstances obscure and

doubtful. In the 19th chapter the prophet seems to have had in view the conquest of the Persians by Alexander, which was in fact a deliverance to Egypt, together with other preceding and collateral incidents, and the favour granted to the Jews by Alexander and the Ptolemies. The 20th chapter refers to the taking of Assidol or Azotus, and warns the Jews against depending too much on the assistance of Egypt. The ten first verses of the 21st chapter contain a prediction of the capture of Babylon by the Medes and Persians; the remaining prediction is obscure. The prophecy, ending with the 14th verse of the 22d chapter, foretells the invasion of Jerusalem by the Assyrians under Senacherib, or by the Chaldeans under Nebuchadnezzar. Vitringa thinks that the prophet had both in view; that of the Chaldeans in the first part, verse 1—5, and that of the Assyrians in the latter part, v. 8—11. The prophecy in the 23d chapter denounce the destruction of Tyre by Nebuchadnezzar. From the 13th chapter to the 23d inclusive, the fate of several cities and nations is denounced; of Babylon, of the Philistines, Moab, Damascus, Egypt, Tyre. The prophet then proceeds, in the 24th and three following chapters, to declare the judgments impending upon the people of God themselves, for their wickedness and apostacy; and the desolation that shall be brought on their whole country. The particular subject of the 24th chapter has been differently assigned by interpreters; some refer it to the desolation occasioned by the invasion of Salmanser; others to the invasion of Nebuchadnezzar; and others to the destruction of the city and nation by the Romans. Vitringa is singular in referring it to the persecution of Antiochus Epiphanes. Bishop Lowth thinks it may have a view to all the three great desolations of the country by Salmanser, by Nebuchadnezzar, and by the Romans, especially the last. The 25th chapter contains a song of praise, dictated more by the prospect of future mercies, than by the recollection of past evils. The subject of the 27th chapter seems to be the nature, the measure, and the design of God's dealings with his people. The prophecy in the 28th chapter, as far as the fifth verse, relates to the Israelites, and manifestly denounces their destruction by Salmanser. It then turns to the two tribes of Judah and Benjamin, the remnant of God's people, who were to continue a kingdom after the final captivity of the Israelites. It begins with a favourable prognostication of their affairs under Hezekiah; but soon changes to reproofs and threatenings, for their intemperance, disobedience, and profaneness. The subject of the 29th and four following chapters is the invasion of Senacherib; the great distress of the Jews while it continued; their unexpected and sudden deliverance by God's interposition in their favour; the subsequent prosperous state of the kingdom under Hezekiah; interpersed with reproofs and threatenings, and also with promises of better times. The 34th and 35th chapters make one distinct prophecy; an entire, regular, and beautiful poem, consisting of two parts; the first containing a denunciation of divine vengeance against the enemies of the people, or church of God; the second describing the flourishing state of the church of God, consequent upon the execution of those judgments. The 36th chapter contains a history of the invasion of Senacherib, and of the miraculous destruction of his army, as a proper introduction to the prophecy in the 37th chapter, which is the answer of God to Hezekiah's prayer, which could not be well understood without it. The narration of the 38th and 39th chapters seems to be in some parts an abridgment of that of 2 Kings, xx. The course of prophecies which follow from the 40th chapter to the end of the book, and which, taken together, constitute the most elegant part of the writings of the Old Testament,

tament, interperfed alfo with many paffages of the higheft fublimity, was probably delivered in the latter part of the reign of Hezekiah. They are chiefly of the confolatory kind; and therefore they are opened with the promife of the reftoration of the kingdom, and the return of the people from their captivity, by the merciful interpofition of God in their favour. The prophet, however, extends their views to the fulfilment of God's promifes of eftablifhing a more glorious and an everlasting kingdom, under the Mefiah to be born of the tribe of Judah, and of the family of David. He connects thefe two events together, and hardly ever treats of the former without throwing in fome intimations of the latter.

Ifaiah has been, with peculiar propriety, denominated the "evangelical prophet," on account of the number and variety of his prediétions concerning the advent and character, the miniftry and preaching, the fufferings and death, and extenfive permanent kingdom of the Mefiah. His prediétions are, indeed, fo explicit and determinate, as well as fo numerous, that no one can be at a lofs in applying them to the mifion and character of Chrift, and the events that are cited in his hiftory by the New Teftament writers. The whole book of Ifaiah, fome few paffages excepted, which, if brought together, would not at moft exceed the bulk of five or fix chapters, is confidered by bifhop Lowth as poetical. (See the article *PROPHETIC POETRY*.) "He abounds," fays this learned critic, "in fuch transcendent excellencies, that he may be properly faid to afford the moft perfect model of the prophetic poetry. He is at once elegant and fublime, forcible and ornamented; he unites energy with copioufnefs, and dignity with variety. In his fentiments there is uncommon elevation and majesty; in his imagery the utmoft propriety, elegance, dignity, and diversity; in his language uncommon beauty and energy; and, notwithstanding the obfcurity of his fubjects, a furprizing degree of clearnefs and fimplicity. To thefe we may add, there is fuch fweetnefs in the poetical compofition of his fentences, whether it proceed from art or genius, that if the Hebrew poetry at prefent is poffeffed of any remains of its native grace and harmony, we fhall chiefly find them in the writings of Ifaiah: fo that the fayng of Ezekiel (xxviii. 12.) may moft juftly be applied to this prophet:

"Thou art the confirmed exemplar of meafures,
Full of wifdom, and perfect in beauty."

Ifaiah greatly excels, too, in all the graces of method, order, connection, and arrangement; though in afcerting this we muft not forget the nature of the prophetic impulfive, which bears away the mind with irrefiftible violence, and frequently in rapid tranfitions from near to remote objects, from human to divine: we muft alfo be careful in remarking the limits of particular prediétions, fince, as they are now extant, they are often improperly connected, without any marks of difcrimination, which injudicious arrangement, on fome occafions, creates almoft infuperable difficulties." Bifhop Lowth has felected as a fpecimen of the kind of poetry in the language of which Ifaiah delivers his prophecies, the prediétion contained in the thirty-fourth and thirty-fifth chapters; and pointed out the beauties that eminently diftinguifh the fimple, regular, and perfect poem, as he denominates this prophecy. The latter part of the book, commencing at the fortieth chapter, is, perhaps, fays the fame excellent judge, "the moft elegant fpecimen remaining of inspired compofition, and yet, in this refpect, is attended with confiderable difficulty. It is, in fact, a body or collection of different prophecies, nearly allied to each other as to the fubject, which, for that reafon, having a fort of connection, are not to be feparated but with the utmoft difficulty. The general

subject is the reftoration of the church. Its deliverance from captivity; the deftruction of idolatry; the vindication of the divine power and truth; the confolation of the Ifraelites, the divine invitation which is extended to them, their incredulity, impiety, and rejection; and the calling in of the gentiles; the reftoration of the chofen people; its glory and felicity of the church in its perfect ftate; and the ultimate deftruction of the wicked, are all fet forth with a fufficient refpect to order and method. If we read thefe paffages with attention, and duly regard the nature and genius of the myftical allegory; at the fame time remembering, that all thefe points have been frequently touch'd upon in other prophecies promulg'd at different times, we fhall neither find any irregularity in the arrangement of the whole, nor any want of order and connection as to matter or fentiment in the different parts. Grotius calls Ifaiah the Demofthenes of the Hebrews, and bifhop Lowth ranks him with Homer. (See *JEREMIAH*.) As a commentator on this book, the learned are under great obligations to Vitringa in his excellent commentary in 2 vols. fol. Amongft the Englifh tranflations, the firft place will be allowed to bifhop Lowth for his admirable work, abounding fo much with learned criticifm and correct tafte, entitled "Ifaiah; a new Tranflation, with a Preliminary Difertation, and Notes, critical, philological, and explanatory," firft publifhed in 1778, 4to. in which the author has perfued the metrical arrangement. The late Michael Dodion, efg. alfo publifhed in profe "A New Tranflation of Ifaiah; with Notes fupplementary to thofe of Dr. Lowth, late Bifhop of London, and containing Remarks in many parts of his Tranflation and Notes, by a Layman," 1790, 8vo. We have lately had a valuable tranflation of the prophecies of Ifaiah by Dr. Stock, bifhop of Killala. See the works already cited, and Lowth's *Prælectiones de Sac. Poef.* Heb. N^o xx—xxi.

ISAKLU, in *Geography*, a town of Afatic Turkey, in Caramania; 12 miles N.W. of Akhehr.

ISAKOVA, a town of European Turkey, in Moldavia; 60 miles N.E. of Jaffy.

ISAKZI, a town of European Turkey, on the Danube; 26 miles W. of Iffail. N. lat. 45° 18'. E. long. 29° 9'.

ISAMBLUCIS, in *Natural Hiftory*, the name of a genus of foftils of the clafs of the *felenite*, but of the columnar, not the rhomboidal kind.

The *felenite* of this genus confift of fix fides, and two obtufe or abrupt ends; and all their fides being very nearly of the fame breadth, they much refemble broken pieces of the columns of fpring-cryftal.

The bodies of this genus, as well as the reft of the columnar *felenite*, are fubject to a longitudinal crack, which fometimes admitting a fmall quantity of clay, fhapes it into the figure of an ear of grafs. Hill's *Hift. of Foff.* p. 121. See the article *SELEXITES*.

ISANDORA, in *Geography*, a town of Angola, on the Coenza; 25 miles S. of Loanda.

ISANI, in *Mythology*, one of the many names of the Hindoo deity, Siva; alfo of his fakti, or confort Parvati; it feems nearly fimilar with Ifa. (See under thofe articles.) The Hindoos reckon eight of their principal deities, as regents or fupporters of the eight cardinal and intermediate points of the heavens. Of thefe regents, called Maruts, or winds, Indra is the chief, and rules the East. (See *INDRA* and *MARUT*.) Iffai or Siva, in that form, is by fome mythologifts, but not by all, reckoned another, and ruler of the north-eaft. See Moor's *Hindoo Pantheon*, under *Indra* in the index.

ISANTHUS, in *Botany*, fo called by Michaux, from *isant*, equal, and *anthus*, a flower, becaufe this plant, unlike moft

rich others of the class *Didymia*, has a regular corolla.—Michaux Amer. v. 2. p. 3. 1. 56. Clafs and order, *Didymia Gymnospermia*. Nat. Ord. *Ferriacollae*, Linn. *Lobatae*, Juss.

Gen. Ch. *Cal*. Perianth bell-shaped, rather spreading, cloven half way down into five, nearly equal, lanceolate segments; the two lower ones, especially after the corolla has fallen off, more clove than the rest. *Cor.* Nearly equal with the calyx, almost regular; tube fringed, fifth, narrow cylindrical, limb somewhat wheel-shaped, five-cleft; each segment oval and similar, with two spots at the base. *Stam.* Filaments four, nearly equal, a little shorter than the corolla, perfectly erect; anthers oblique, closed below; cells ovate, diverging nearly at a right angle.—*Pist.* Germen superior, four-cleft; style the length of the filament, recurved at top; stigmas two, recurved and much spreading, linear tongue-shaped; the lower one rather the longest. *Peric.* none, except the permanent, spreading tube of the calyx. *Seeds* four, obovate, rugged and reticulated, connected only at their base, filling the calyx.

Eff. Ch. Calyx five-cleft. Corolla nearly equal, five-cleft. Stamens erect. Anthers with divaricated lobes.

1. *I. ceruleus*. Blue Ianthus.—Michaux Amer. v. 2. p. 30. A native of Virginia and Carolina, in a chalky soil. The whole plant is rather viscid and hairy. *Root* annual. *Stem* about a foot high, erect, round, branched. *Leaves* opposite, on short stalks, ovate, acuminate, ribbed or nerved, fringed. *Flowers* of a pale blue.

We are only acquainted with this plant from the description and figure of Michaux. It is without doubt very nearly allied to the *Asperifolia*, though we have followed that author in referring it to the class *Didymia*.

ISARIA, in *Geography*, a town of Naples, in Calabria Ultra; eight miles E. of Nicastro.

ISARRIA, a town of Naples, in Calabria Ultra; 11 miles S. of Squillace.

ISATIS, in *Botany*, is the *Isatis* of Dioscorides, and *Isatis* of Piny, but its derivation is totally unknown. *Wood*. Linn. Gen. 344. Schreb. 435. Willd. Sp. Pl. v. 3. 420. Mart. Mill. Dict. v. 2. Sm. Fl. Brit. 693. Ait. Hort. Kew. v. 2. 406. Tournef. t. 100. Juss. 242. Lamarck Illust. t. 554. Gertn. t. 142. Clafs and order, *Tetradynamia Siliculosa*. Nat. Ord. *Siliquifera*, Linn. *Crucifera*, Juss.

Gen. Ch. *Cal*. Perianth of four, ovate, spreading, coloured, deciduous leaves. *Cor.* of four petals, cross-shaped; petals oblong, obtuse, spreading, by degrees attenuated into claws. *Stam.* Filaments six, slightly spreading, the length of the corolla; two of them shorter; anthers of long, lateral. *Pist.* Germen superior, oblong, two-edged, compressed, as long as the shorter stamens; style none; stigma obuse, capitate. *Peric.* Pouch oblong, lanceolate, obtuse, compressed, two-edged, of one cell, not gaping, two-valved, deciduous; the valves are boat-like, compressed and carinated. *Seed* solitary, ovate, central.

Eff. Ch. Pouch lanceolate, one-celled, single-seeded, deciduous, with two boat-like valves.

1. *I. tinctoria*. Wood.—Linn. Sp. Pl. 936. Engl. Bot. t. 97. Mart. Fl. Rusl. t. 41.—“Radical leaves crenated, stem-leaves arrow-shaped. Pouch oblong, smooth.”—Rather a scarce plant in Britain, flowering in July, and found in fields. It was not originally a native of this island, but has become naturalized from its frequent culture for the purpose of dyeing blue. It is also a basis for several other colours. Pliny says the ancient Britons flamed their bodies with wood, but from the circumstance of this plant having been introduced into this country from the shores of the Baltic, Spain, Italy, &c. Mr. Miller concludes that

Wood (*Rosid's Lutescens*), and not Wood, was used by our ancestors for the purpose above-mentioned. If this plant in question can be identified with Pliny's, it is undoubtedly a native. *Root* bicoloral. *Stem* erect, branched, furnished with alternate, somewhat succulent leaves; the radical ones flange on long foot-stalks, and are crenated. *Calyx* as well as the *corolla* of a yellow colour. *Seeds* few, dark brown. *Stem* and *leaves* occasionally besprinkled with few hairs.

Linnaeus enumerates three other species of *Isatis*, *Isatis arvensis*, and *isotica*. The last of which is very properly removed by Willdenow to *Cabula* of Gertn. r. *Isatis* and *Allion* mention another species under the name of *alpina*. This genus was very unaccountably placed by Linnaeus in his order of *Siliquifera*, together with *Daucus* and *Crucifera*; but its near affinity to *Draba*, *Lepidium*, &c. in the shape and size of its pouch, sufficiently warrant professor Schreber's placing it among the *Siliculosa*.

ISATIS, in *Zoology*. See *LAGORUS*.

ISATODES, a word used by Hippocrates, and some other of the old writers, to express a greenish colour of the bile discovered in the stools, which resembled the colour of the herb *isatis*, or wood. This was esteemed an indication of a highly depraved bile.

ISAURIA, in *Ancient Geography*, a town of Asia Minor, near Pisidia. Its inhabitants were merely occupied in plunder, when Servilius made war upon them and conquered them. Hence he obtained the name of the “Isaurian.” Its chief town was “Isaura,” or “Isauropolis,” which were repeatedly destroyed and rebuilt. Under the Greek emperors, Isauria became a considerable province at the expense of the neighbouring provinces. Hierocles, in his “Notitia,” reckons in it 23 episcopal towns, and Leon-Sage enumerates 29.

ISBARTEH, in *Geography*, a town of Asiatic Turkey, in Natolia, the residence of a Pacha; and in the faubourgs are four Greek churches; 92 miles S. of Kiutaja. N. lat. 37° 44'. E. long. 30° 56'.

ISBASTER, one of the smaller Shetland islands. N. lat. 60° 34'. W. long. 0° 58'.

ISCA, or ISCA DAMNORUM, in *Ancient Geography*, a town of Albion or England, the capital of the Damnonii, and most probably Exeter.

ISCA SILURUM, the capital of the Silures, now Caerleon in Monmouthshire. Here the second legion of the Romans, which had contributed greatly to the reduction of the Silures, was placed in garrison (as some antiquaries have imagined) by Julius Frontinus, to keep that people in obedience. It is certain, however, that this legion was very early and very long stationed at this place. Ica Silurum was, in the time of the Romans, a city not only of great strength, but also of great beauty and magnificence. This appears from the description which is given of its ruins by Giraldus Cambrensis, in his topography of Wales, written in the 12th century, soon after it had been destroyed and abandoned.

ISCALES, a town of Britain, in the country of the Belgae, generally placed at Ichelier in Somersetshire.

ISCARIOTH, a place of Judea, in the tribe of Ephraim, whence Judas, who betrayed our Saviour, is supposed to have derived his surname.

ISCHEMUM, in *Botany*, from *ischos*, to repress, and *aimos*, blood, because it was supposed to possess the virtue of stopping hemorrhages from recent wounds. In this sense the name was originally applied to the *Panicum sanguinale* of Linnaeus, called, for the same reason, *Sanguinaria* by some writers; and is now retained for a genus of grasses bearing some resemblance to that, but the reputed virtue above-mentioned can scarcely be thought to have any founda-

tion. Linn. Gen. 542. Schreb. 718. Mart. Mill. Dict. v. 2. Brown. Prod. Nov. Holl. v. 1. 204. Juss. 30. Lamarck. Illust. t. 839. Clafs and order, *Polygamia monœcia*, or rather *Triandria Digynia*. Nat. Ord. *Gramina*.

Gen. Ch. Cal. Glume two-flowered, of two cartilaginous nearly equal valves, situated tranſverſely; the outer almoſt ovate, tumid, cloven and acute at the top, the upper part of the back flattened, ſtriated, bordered; inner oblong, boat-like, pointed or awned at the top, furnished with a longitudinal dorsal membrane below the extremity. Florets ſhorter than the calyx, the outer one male, inner hermaphrodite. Qor. (in the hermaphrodite floret) of two thin, membranous, pellucid glumes; the outer ſwelling, either beardless or awned, cloven to the infertion of the awn, acute; awn long, ſlender, bent, twiſted in the lower part; inner glume lanceolate, acute, its margins folded together; (in the male floret) of two rather firmer, pellucid, ſomewhat coloured glumes; the outer oblong, ſwelling, contracted upwards, acute, beardless; inner oblong, obtuſe, concave at the back, thinner and acute at the margin; Nectary in each of two ſmall, ſpatulate, abrupt, notched leaves. Stem. Filaments three, capillary, ſhort; anthers oblong, cloven at each end. Piſt. (in the hermaphrodite floret) Germen oblong; ſtyles two, capillary, erect, ſhorter than the corolla; ſtigmas oblong, feathery, ſpreading, prominent. Peric. none, except the unchanged calyx and corolla. Seed (in the hermaphrodite floret) ſolitary, oblong, linear, convex at one ſide.

Eſſ. Ch. Calyx of two valves, two-flowered, placed in pairs, laterally, on a jointed ſtalk; outer valve flattened. Corolla of two valves, ſhorter than the calyx. Stigmas feathery. One floret male, or neuter.

Linnæus defines two ſpecies only, *I. muticum*, Sp. Pl. 1487, and *I. arifolium*. Ibid. The firſt is delicate of awns, and is the *Tagadi* of Rheede Hort. Mal. v. 12. 91. t. 49, found in every kind of ſoil in Malabar, but not of any particular uſe, except as a graſs in general. The root is perennial. Stems about a foot high, round, ſmooth, reed-like, leafy. Leaves lanceolate, pointed, broad at the baſe. Spikes terminal, double, ſhort, cloſe, ſhining. *I. arifolium*, diſtinguiſhed by its awns; was gathered by Oſbeck in China, and has narrower leaves.

I. riggiæ, Salſ. Ic. 1. t. 1. Hort. 27.—“External barren glumes tranſverſely rugoſe; one of the fertile ones, whether male or female, awned.”—Found by Koenig in the borders of rice fields in the Eaſt Indies. This is very remarkable for the ſtrong wrinkles or furrows of its glumes. Linnæus was inclined to make it a ſteu genus by the name of *Cicadaria*. Mr. Salſbury cultivated it in his ſtove at Chapel Alerton before 1799.

Mr. Brown in his Prodrum has added ſix new ſpecies to *Iſchæmum*, and alſo juſtly refers to this genus the *Collada* of Cavanilles, Ic. v. 5. 37. t. 460.

ISCHENIA, 1724, in *Antiquity*, anniversary ſports celebrated at Olympia, in memory of Iſchenus, the grandfather of Mercury and Hercules; who, in a time of famine, devoted himſelf to be a ſacrifice for his country, and was honoured with a monument near the Olympian ſtadium.

ISCHIA, in *Geography*, a volcanic iſland, ſituated at the eaſtern entrance of the gulf of Naples, about 18 miles in circuit; the ſee of a biſhop, ſuffragan of that of Naples, and containing three pariſhes, and a convent of nuns. The volcanic ſubſtances of which this iſland is internally compoſed, prove, beyond the poſſibility of doubt, ſays Spallanzani, that it owes its origin to fire. The caſtle of the city of Iſchia, as it is called, is built on a rock ſurrounded by the ſea, and a little more than a quarter of a mile in circuit. The two component ſubſtances of this rock are lava and

tufa. About a mile to the weſt is a torrent of lava, called the “Arfo” or burnt ground, which is the moſt recent of any in the iſland, ſince it flowed in 1302. This lava, though it flowed five centuries ago, is abſolutely ſterile; producing not a ſingle blade of graſs, and only affording, in ſome places, a few arid and uſeleſs plants of the lichen, or liverwort. On the ſurface, and for a little depth, it is light and ſpongy, and eaſily crumbles; but deeper, it becomes denſe and harder. This lava is of the hornſtone baſe, and has an earthy ground; varying in colour from that of iron to a reddiſh-black, and having incorporated in it very numerous feltſpars. M. Dolomieu ſays, that the eruption of the Arfo, though it continued two years, never produced any pumice, but only black ſcoriæ; but Spallanzani obſerves, that the hornſtone, by a violent fire, may be changed into a true pumice. Though this tranſmutation rarely happens, no part of the iſland, however, abounds ſo much with pumices as the Rotaro, a mountain ſituated between Cafamicola and the city of Iſchia. This mountain is of a conical ſhape, and compoſed of tuſa, pumices, and enamels. The extent of the pumices is more than a mile. The Rotaro is the only place in Iſchia which affords enamels. The mountain of St. Niccola, which in earlier times was called Epeoco, and which is in the centre of the iſland, was, as Spallanzani ſays, without doubt, the firſt that towered above the waves. The conſtituent ſubſtances of this mountain are of various kinds. The fulphate of alumine (alum) was formerly extracted in Iſchia for commercial purpoſes; and the manufacture was principally carried on at Catrico, a place ſituated above Laeco, on the higher eminences of the Epeoco. But a careful obſerver has not been able recently to diſcover any remaining veſtige of this ſubſtance. Spallanzani concludes from experiments on different lavas, that this valuable ſubſtance might ſtill be obtained at Iſchia. This ingenious naturaliſt coaſted the iſland and examined various mountains that occupy the lower part of it. He began with the Vico, which is partly formed of tuſa, and partly of two currents of lava, which deſcend into the ſea. The baſe of both theſe lavas is hornſtone, and they abound in feltſpars. He then proceeded to Monte Zaro, formed, towards the ſea, by a river of lava, extending a mile in length, and nearly two in breadth. The baſe of this lava is hornſtone, and it contains mica and feltſpars. From the termination of Monte Zaro to the commencement of Monte Imperatore, is a long and ample tract, almoſt entirely tuſaceous, ſcattered over with fragments of pumice. The Monte Imperatore preſents different ſeris of lava, the baſe of which is hornſtone, intermixed with abundance of feltſpars. In many parts of the iſland our author found a ferruginous ſand, which not only moves the magnetic needle, but is ſtrongly attracted by the loadſtone. This iſland, our author apprehends, when it was firſt produced by conflagrations in ancient, and to us unknown, times, muſt have been of much greater extent than it is at preſent. Time has alſo produced a great alteration in the interior parts of the iſland. From the ſummit of Epeoco, a number of conical eminences may be ſeen; but their internal craters no longer exit; nor can be found in Iſchia inextinguible traces of a ſingle one, ſince thoſe depths and ample cavities, thoſe reſemblances of theatres and amphitheatres, which may be every where obſerved, may be equally the effect of fire or water. The ſubſtances, our author conceives, which have furniſhed aliment to the different conflagrations of Iſchia, have had their centre in the ſe arſilicaceous rocks, which, by the above-mentioned eruption in 1302, flowed that they were not then exhausted. See Spallanzani's Travels in the Two Sicilies, &c. vol. 1.

Along the coaſt of this iſland a few pretty villages are diſperſed;

dispersed; and detached habitations are scattered over the surface of the whole island, and are to be found even at an elevation where the culture of the soil must cease. The white colour of the houses forms an agreeable contrast with the verdure of the vines and gardens in which they are embosomed. At the summit of the mountain, which forms this island, a hermitage, composed of a chapel, and three cells, has been excavated out of the volcanic rock. The cells are inhabited by as many hermits. One of them goes his round through the island twice a week, and brings back bread, oil, eggs, and every thing necessary for the service of the altar. The inhabitants give him alms with joy, and recommend themselves to his prayers. They make a pilgrimage annually to this chapel.

This island enjoys a propitious climate, and the sky is seldom obscured with clouds. The winters are mild, the reptiles harmless, and the springs cure various diseases. The government is likewise mild, and the island is exempt from taxes. The king pays it a visit every year, and gives portions to the indigent young females.

An hospital is established here at the expence of a charitable society at Naples. Some hundreds of sick receive attendance and relief during the bathing-season. Several barks are solely employed in removing the convalescents to Naples, and bringing back other patients to the hospital. The lame, who are cured of their infirmities, leave behind them their crutches, which they consecrate to the Madonna, or to some particular patron. The trees, shrubs, and plants which prefer volcanic soils, thrive surprisingly in this island. Here and there are seen groves of oak and chestnut trees; which are suffered to grow only to years. The orange, pomegranate, fig, Neapolitan medlar, and arbutus, are the most common trees in the gardens. Of wild shrubs, the myrtle and the mastic are the most numerous. The inhabitants have something peculiar in their language, their figure, and their dress. In their conversation, they scarcely ever use the word *man*, that of *Christian* being substituted for it; and with them *Christian* is synonymous with *Catholic*. In their pious expressions they seldom soar higher than the Mother of God. It is to our Lady they recommend you, when they leave you, and they wish you a *holy night* (*Santissima notte*). To her they apply when afflicted with disease. At the death of an adult they pray for the repose of his soul. The death of a child is regarded as a happy event. Religious festivals are with them days of rejoicing. N. lat. 40 50'. E. long. 13° 46'.

The soil feeds no animals besides asses and goats. The roots of the houses throughout the island are flat, and are used for drying fruits and other purposes.

ISCHLADICUS MORBUS, in *Surgery*. See *Disease of Hip-joint*.

ISCHIAS. See *Disease of Hip-joint and Sciatica*.

ISCHIATIC, in *Anatomy*, an epithet applied to certain parts of the body situated near the ischium; as the ischiatic artery and nerve. See **ARTERY and NERVE**.

ISCHIATOCELE, in *Surgery*, a hernia taking place at the ischio-schiatic foramen. See **HERNIA**.

ISCHIM, in *Geography*, a town of Russia, in the government of Tobolsk, on the river Ichim, which runs into the Irtysh, N. lat. 57 45'. E. long. 90°; 108 miles S. of Tobolsk. N. lat. 56 10'. E. long. 69 14'.

ISCHIMSKOI, a town of Russia, in the government of Tobolsk, at the conflux of the Ichim and Oby; 112 miles E. of Tobolsk.

ISCHIO-CAVERNOSUS, in *Anatomy*, a name given by Winlow and others to the erector penis muscle. See **GENERATION**.

ISCHIOCELE, in *Surgery*, a hernia between the ischium and ischium.

ISCHIO COCCYGEUS, in *Anatomy*, a name for the coccygeus muscle; which see.

ISCHIM, one of the divisions of the os innominatum. See **EXTREMITIES**.

ISCHIM *Os*, *Fracture of*, in *Surgery*. See **FRACTURE**.
ISCHNAMBUCUS, in *Natural History*, the name of a genus of mollus of the class of the *slugs*, but one of those which are of a columnar form, not of the common rhomboidal one.

The word is derived from the Greek, *ισχνη*, thin, and *βου*, blunt or oblique, and *σκια*, a column, and expresses a body in form of a thin flattened column, with obtuse ends. The bodies of this genus are of an octahedral figure, consisting of six long planes and about two broken ends. The top and base planes are broader than the rest. The crack which runs through the whole length of bodies of this genus is often filled with clay, which spreads itself into the form of an ear of some grasses; of this genus there are only four known species. Hill.

ISCHNOPIHONIA, in *Medicine*, from *ισχνη*, thin, and *φωνη*, the voice, a term which seems to have been used originally to denote a certain tenuity or smallness of the voice; but the most common acceptation of the word is in the sense of *hesitation of speech*.

ISCHURIA, from *ισχνη*, I stop, and *ουρα*, urine, signifies an entire suppression or retention of the urine.

The discharge of urine may be altogether prevented or suppressed for a time, from four different sets of causes; whence Dr. Cullen has, with great judgment, arranged the forty-three varieties of *ischuria*, described by Sauvages after Cullen, under four heads or species. There are, 1. *Ischuria renalis*, in which the impediment to the excretion of urine is in the kidneys themselves; 2. *Ischuria ureterica*, in which the impediment consists in an obstruction of the canal of the ureters, through which the urine should pass into the bladder; 3. *Ischuria vesicalis*, in which the urine, secreted by the kidneys, and transmitted through the ureters, is retained in the bladder from disease in that receptacle itself; and, 4. *Ischuria urethralis*, in which the impediment is occasioned by some obstruction in the canal of the urethra, through which the contents of the bladder are discharged. See Cullen. *Synops. Nosol. Method. Class. iv. Ord. 5.* Sauvages, *Class. 5. Ord. 3.*

The *renal ischuria*, in which there is little or no secretion of urine effected by the kidneys, is to be distinguished by the following circumstances: It supervenes upon some previous affection of the kidneys, and is accompanied by pain or an uneasy sense of weight in the region of the kidneys, while, at the same time, there is no tumour in the hypogastrium, or lower portion of the belly, such as a distended bladder would occasion, nor any desire to make water. The *ischuria*, from obstructed ureters, is accompanied by singular symptoms, except that the pain or uneasiness is felt in the course of the ureter; it is likewise urine accompanied by hypogastric tumour, or desire to pass urine. The most frequent causes of these two forms of retention of urine are inflammation of the kidneys or of the ureters, or the presence of calculous concretions in those parts; but other causes have been occasionally observed to produce the disease, such as grumous blood, impeded in the same parts, and purulent matter, or mucus, obstructing the passages. It may be remarked, that some writers have confined the term *retention of urine* to the renal form of the disease, as if they would assert, that, when the urine was not secreted, it was retained in the blood; and they designate the other form

of the disease by the term *suppression of urine*:—a false hypothesis, but the terms may be retained as expressing the facts. When the retention is connected with inflammation of the kidney or ureter, its cure will depend upon the removal of that salutary state. (See NEPHRITIS.) And when it originates from impeded excretion, it must be treated with the remedies referred to in other analogous cases. See NEURALGIA.

The two other species of ischuria, originating from impediments to the excretion of the bladder, by diseases of that organ itself, or of its outlet, the urethra, are to be distinguished by the extent of the inflammation of the hypogastrium, above the pubes, and by the frequent urging to make water, accompanied with pain in the neck of the bladder, in the one case, and in some part of the urethra in the other. The causes which give rise to the vesical suppression of urine, are inflammation of the neck of the bladder; stone in the bladder; spasm of the sphincter; rally extending to the bladder; over-dilatation of its fibres, from retaining the urine too long; purulent matter, mucus, or grumous blood, lodged in the neck of the bladder; and tumours of the neighbouring parts compressing the neck of the bladder. Such as hardened feces in the rectum, or calculeous concretions, flatulency, inflammation, abscess, or hemorrhoidal swellings in the same bowel, and also the gravid uterus, or other enlargements of that viscus. The causes of impediment in the canal of the urethra, which occasion suppression of urine, are inflammation of that passage; pus, mucus, or grumous blood impacted in it; stricture; tumours in the perineum; phimosis, &c.

The means by which these causes of suppression of urine are chiefly to be removed, and the disease to be cured, are principally surgical. See *Suppression of URINE*.

ISCHURIA, in *Surgery*. See *Retention of URINE*.

ISETHIORD, in *Geography*, a large bay or gulf of Denmark, on the N. coast of the island of Zealand; the mouth of which lies in N. lat. 55° 59'. E. long. 11° 50'.

ISELASTICS, ISELASTICA, a kind of games, or combats, celebrated in the cities of Greece and Asia, in the time of the Roman emperors.

The victors at these games had very considerable privileges conferred on them; after the example of Augustus and the Athenians, who did the like to the conquerors at the Olympic, Pythian, and Isthmian games. They were crowned on the spot, immediately after their victory; had pensions allowed them; were furnished with provision at the public cost; were carried home in triumph, and made to enter their cities through a breach in the walls; whence their appellation from *isethiasthai*, to enter.

ISEL N. JAMES CHRISTOPHER, in *Biography*, an eminent philosopher and divine, was born at Basel in 1681; and having had a good foundation in grammar learnt; he was admitted to his academical course as early as the age of 13, and at 15 he distinguished himself by a Latin poem on "The Passage of the Rhine" by the French, which obtained for him great applause. In 1701 he was ordained minister, and on that occasion published a dissertation on the Behaviors of the Revelations, in answer to the bishop of Meaux. In 1704 he accepted the chair of eloquence and history in the university of Marburg, which he occupied with great reputation for two years. In 1706 he was appointed professor of history and antiquities at Basel, and in 1711 he was made doctor in theology, and appointed to teach that science. He was invited to settle at Paris, which he declined, and the French academy elected him to the place of honorary member, vacant by the death of Cuper. This honour was conferred upon him in return for the pains

he had taken to comply with the king's request of obtaining for him copies of the acts of the council held at Basil in the fifteenth century. He died in 1737, and his memory was honoured by a great number of eulogies in Latin and German. The works of M. Iselin consist of orations, dissertations, and detached tracts on a variety of subjects, philosophical, theological, and miscellaneous. Moreri.

ISELIN, ISAAC, was born at Basil in 1728. He received his academical education at Cottingen, where he paid great attention to jurisprudence and statistics under the most able professors. He undertook the task of reducing the jurisprudence of the Swiss confederation into a system, of which he published a specimen in his thesis, when he obtained the degree of doctor, under the title of "Tentamen Juris publici Helvetici." When he had completed his studies he went to Paris, and obtained the acquaintance and friendship of the most eminent men of letters in that capital. After his return, he applied with great diligence to the study of jurisprudence, and in 1756 he was appointed to the important office of secretary to the grand council of his native city. Soon after he published his first work, entitled the "Dream of Mankind," which has gone through many editions. He next gave the world a work, entitled "Free Thoughts on the Depopulation of my native City," in which he recommended the admission of new citizens. But his most important work was his "History of Mankind," in which he traces the progress of the human mind from a state of rudeness to that of refinement, and shews in what manner nations have emerged from obscurity, and have been completely civilized by the introduction of arts and manufactures. Iselin was the author also of a periodical work, entitled "Ephemerides of Mankind." He carried on an extensive correspondence both in Switzerland and foreign countries, and he wrote many excellent critiques in the "Deutsche Bibliothek," which are said to be distinguished by their acuteness, modesty, and adherence to truth. He died in the year 1782, at the age of 54. Iselin's writings abound with exalted ideas and ingenious thoughts, and display great knowledge of human nature, ardent patriotism, and a strong vigorous mind. Gen. Biog.

ISEN, in *Geography*, a town of Bavaria; 24 miles E.N.E. of Munich.

ISENBURG, UPPER, *County of*, a principality of Germany, situated in the Wetterau, about 30 miles long and 10 broad. The territory of Isenburg is divided into several branches, taking their surnames respectively from towns on the estate.

ISENSBURG, Lower, a county of Germany, in the circle of the Lower Rhine, formerly governed by counts of its own, as a fief of the electorate of Treves.

ISENSBACH, a town of Germany, giving name to the county, situated on the Ilr, and surrounded with sharp rocks, on one of which is a castle built by Charlemagne; 10 miles N. of Coblenz. N. lat. 50° 30'. E. long. 7° 35'.

ISENBURG, M., a town of Germany, in the county of Isenburg, founded by French refugees; 3 miles S. of Frankfurt on the Main. N. lat. 50° 3'. E. long. 8° 38'.

ISENHAGEN, a town of Westphalia, in the principality of Linauburg; 24 miles E.N.E. of Zelle.

ISEO, a town of Italy, in the department of the Benaco, on a lake to which it gives name, through which the river Oglio takes its course: the town was anciently called "Sabino"; 12 miles N.W. of Brescia.

ISER, a river of the Tyrol, which rises about 5 miles N. of Inspruck, and, passing by Munich, Landshut, Landau, &c. runs into the Danube, 2 miles below Deckendorf.

ISEKE, a river which rises in the Alps, about 12 miles from

from mount Cenis, in a mountain called "Iferan," in the duchy of Savoy, and, after entering France, passes by Grenoble, &c. and joins the Rhone, about 3 miles above Valence; navigable for boats as far as Montmelian.

ISERE, formerly *Griffaudan* and *Vivonia*, one of the 11 departments of the eastern region of France, so called from the river Isere, which crosses it; situated in N. lat. 45° 30', W. of Mont Blanc: containing 452 square leagues, and 441,208 inhabitants, and divided into four districts, *viz.* Vienne, including 104,689 inhabitants; Tour-du-Pin, having 99,053; Grenoble, 109,623; and St. Marcellin, 67,843 inhabitants. Its number of cantons is 44, and that of communes 558. The annual contributions amount to 3,546,809 francs, and the expenses charged upon it to 3,388,804 francs 37 cents. This department consists of barren and marshy plains, deep vallies, and high mountains partially wooded. The chief products are grain, hemp, roots, some good wine, and excellent pastures. It has mines of iron, copper, lead, coal, quarries, and mineral springs. Its capital is Grenoble.

ISERINE, in *Mineralogy*. See **TITANIUM**.

ISERLOHN, or **LOHN**, in *Geography*, a town of Germany, in the county of Mark, inhabited by Lutherans, Calvinists, and Roman Catholics, who are allowed their separate worship. Its manufactures are considerable in iron, tin, ribbons, velvets, silks, fluffs, &c.; 32 miles N.E. of Cologne. N. lat. 51° 18'. E. long. 7° 40'.

ISERNIA, a town of Naples, in the Molise, situated at the foot of the Apennines, the see of a bishop; 12 miles W.S.W. of Molise. N. lat. 41° 38'. E. long. 41° 2'.

ISERTIA, in *Botany*, was so named in honour of Mr. Hiert, a German botanist, and surgeon in the Danish service, on the coast of Guinea.—Schreb. 234. Willd. Sp. Pl. v. 2. 225. Mart. Mill. Dict. v. 2. Vahl. Ecol. p. 2. 27. Lamarck Illustr. t. 256. (Guettarda; Juff. 207. Aubl. Guian. v. 1. 317.) Class and order, *Hexandria Monogynia*. Nat. Ord. *Rubiaceae*. Juff.

Gen. Ch. Cal. Perianth of one leaf, superior, cordate, four or six-toothed, permanent. *Cyp.* of one petal, round-shaped; tube long, cylindrical, slightly curved; and divided into six, lobovate, rather erect, villose segments. *Stam.* Filaments six, very short, within the throat of the corolla; anthers linear, united to the back, erect. *Pist.* Gynia inferior, reniform; style three-angled, surrounded by a glandular tube; stigma six-cleft. *Pedic.* Fruit pulpy, somewhat glandular, crowned by the calyx, six-cleft; the cells of the cells brittle. *Seeds* numerous, small, angulate, rough.

Ess. Ch. Calyx superior, six-toothed. Corolla funnel-shaped, six-cleft. Stigma six-cleft. Fruit six-celled, many-seeded.

1. *I. coccinea*. Willd. n. 1. (Guettarda coccinea; Aubl. Guian. v. 3. t. 123.)—Leaves lanceolate-elliptical, clothed with hairy pubescence, acuminate, acute at each end. Flow. pedicels branched, bifid. A notice of woods in Guinea, flowering and bearing fruit at all seasons.—This tree rises to the height of ten or twelve feet, is clothed with erect, knotty, square branches. Leaves opposite, large, ovate, acute, green above, downy beneath, dark-coloured, with reddish nerves. *Stipules* long, broad, acute, deciduous. *Flowers* racemose, erect, terminal; their pedicels opposite, furnished with two little scales. *Calyx* purplish. *Tube yellow*. *Fruit* red.

2. *I. parviflora*. Willd. n. 2.—"Leaves oblong, the lower ones somewhat heart-shaped at the base. Bunch of flower ovate." Found in the island of Trinidad.—Leaves generally smooth, sometimes rather villose beneath.

ISSETSK, in *Geography*, a town of Russia, in the government of Tobolsk, on the Iset, which runs into the Tobol, near Yalutorovsk; 44 miles W.S.W. of Yalutorovsk.

ISGAARD, a town of Denmark, in North Jutland, situated on a peninsula in the Baltic; seven miles E.N.E. of Aarhus.

ISGAUR, **ISGURIAH**, or *Iskuria*, anciently called "Diocuria," and "Sackopolis," a town of Mingrelia, on the E. coast of the Black Sea, with a road for ships, which in summer is tolerably good. In 1672 it was burned down by the Abkhaz, who were invited by the prince of Mingrelia to assist him against the Turks. N. lat. 43° 18'. E. long. 40° 32'.

ISHMAELITES, in *Ancient Geography and History, the descendants of Ishmael, the son of Abraham by Hagar, his Egyptian bond-maid. Ishmael was born in the year B.C. 1916, and his name, founded on a circumstance which afforded relief to his mother, when she was wandering from her master's house towards Egypt, her native country, is derived from the Hebrew *ישמעאל*, formed of *שמעאל*, *shama'al*, to hear, and *אל*, *el*, God, and denoting "the Lord hath hearkened!" The heavenly messenger who appeared to Hagar in the wilderness, and instructed her by what name to call her future son, predicted also that he and his posterity would prove fierce and warlike, engaged in repeated hostilities, and yet able to maintain their independence. Hagar, deriving encouragement from this circumstance, returned to the house of Abraham, and was soon delivered of her promised son. The father regarded Ishmael as the heir of his wealth, till Sarah had the promise of her son Isaac. After the birth of Isaac, Abraham was persuaded by his wife to dismiss Hagar and her son; and the patriarch probably provided for their subsistence in some distant situation, where they could not encroach on the patrimony of Isaac. Having wandered for some time in the wilderness of Beer-sheba, they proceeded farther to the wilderness of Paran, which bordered on Arabia, and here Ishmael arrived at maturity, and became an expert archer, or a hunter and warrior. In process of time his mother procured for him a wife out of a family by whom he had twelve sons, who eventually established themselves as the heads of so many distinct Arabian tribes. Accordingly the descendants of Ishmael are mentioned in history, under the general name of Arabians and Ishmaelites. Of Ishmael's personal history, we merely learn from the sacred writings, that he joined with his brother Isaac in paying the last tribute of respect to the remains of their father; and that he died at the age of 137 years (B.C. 1773.) Gen. xxv. 9. 18. His descendants, according to the scripture account, spread themselves "from Havilah to Sinar, that is before Egypt, as thou goest into Assyria." From this brief statement, we may conjecture how far their territory extended; for Havilah, according to the generality of writers, was situated near the confluence of the Tigris and Euphrates, and Sinar, on the isthmus which separates Arabia from Egypt, now called the isthmus of Suez. From thence we may well imagine, that they spread themselves on both sides to far as to have taken possession of the greatest part of Arabia; and, indeed, Josephus (Antiq. l. i. c. 13.) does not scruple to style their progenitor the founder of the Arabian nation. See **ARABIA**.*

ISI, in *Hindoo Mythology*, is a name of the goddess Parvati, consort of Siva, in her form of *Ishy*; which see.

ISIA, *Istus*, feats and sacrifices anciently solemnized in honour of the goddess Isis.

The Isia were full of the most abominable impurities; and for that reason, those who were initiated into them

were obliged to take an oath of fecrecy. They held for nine days fuceceffively, but grew fo fcandalous, that the fenate abolifhed them at Rome, under the confulate of Pifo and Gabinus. They were re-eftablifhed by Auguftus, and the emperor Commodus himfelf affifted at them, appearing among the priefts of thofe goddeffes with his head fhaven, and carrying the Anubis.

ISIAC TABLE is one of the moft confiderable monuments of antiquity, being a plate of copper or brafs, difcovered at Rome, in 1525, and fupported by the various figures in bas relief upon it, to represent the feafts of Isis, and other Egyptian deities.

With regard to the hiftory of this monument, we may obferve, that the copper or brafs ground was overlaid with a black enamel, artifiially intermixed with fmall plates of filver. When, in the year 1525, the count de Bourbon took the city of Rome, a lockfmith bought it from a foldier, and then fold it to cardinal Bembo, after whose death it came into the hands of the duke of Mantua, and was kept in that family till it was loft at the taking of that city by the Imperialifts in the year 1630, nor has it been ever heard of fince. By good fortune it had been engraved in its full proportion, and with all poffible exactnefs, by *Aenes Vico* of Parma. This tablet was divided into three horizontal compartments, in each of which were different fcenes, containing different actions. Thofe compartments are, as it were, different cartouches, diftinguifhed fometimes by fingle ftrokes only, but oftener by a very large fafcia, which is full of hieroglyphics, that is, of that myfterious writing, confecrated by the ancient Egyptians to the myfteries of religion. The four fides of the table were inclofed with a border, filled up, like the ground, with feveral figures of the Egyptian gods, and with a great number of hieroglyphics. There have been various opinions as to the antiquity of this monument: fome have fuppofed that it was engraved long before the time when the Egyptians worfhipped the figures of men and women. Others, among whom is bifhop Warburton, apprehend, that it was made at Rome, by perfons attached to the worfhip of Isis. Dr. Warburton confiders it as one of the moft modern of the Egyptian monuments, on account of the great mixture of hieroglyphic characters which it bears.

It has been alfo a queftion, whatever may be thought of the antiquity of this tablet, whether it only represents the myfteries of Isis, whose figure, placed in a fort of niche, occupies the centre; or whether it contains the principal points of the Egyptian theology, fince all their gods are here reprefented. Pignorius, Kircher, and Cluffier, have offered their various conjectures concerning the defign and meaning of this monument. The abbe Baumer (in his "Mythology, &c." vol. i. p. 567.) declares it to be his opinion, that it was a votive table, which fome prince, or private perfon, had confecrated to Isis, as an acknowledgment for fome benefit which he believed he had conferred upon her. That goddeffes occupies the principal place in it, and the defign of varying her attitudes and fymbols, muft have been to point out to us, in how many different modes fhe was represented, as well as the different facrifices that were offered to her. Accordingly, three forts of thofe are there to be obferved, one of animals, another of plants, and a third of libations. Perhaps the perfon who had confecrated this table to Isis, had offered to her all thefe forts of facrifices, either for having been cured of fome fevere difeafe, or for having been delivered from fome great danger, to which he had been expofed by fea; for that goddeffes was equally invoked in difeafes, and when people were entering upon a long voyage; fince the epithets of "Salutaris" and

"Pelagia" were added to her name. Nothing was more common than the votive tables, confecrated to Isis. All the temples of this goddeffes were full of them; and works of that fort procured a living to great numbers of painters, as we learn from Juvenal (Sat. 18.):

"Et quam votiva tellantur fano tabellâ
Plurima, Pictores quis nefcit ad Iſide pasci."

ISIACI, priefts of the goddeffes Isis. Diofcorides tells us, that they bore a branch of fea-wormwood in their hands inftead of olive. They fing the praifes of the goddeffes twice a day, viz. at the rifing of the fun, when they opened her temple; after which they begged alms the reft of the day, and returning at night, repeated their orifons, and flut up the temple.

Such was the life and office of the Ifiaci; they never covered their feet with any thing but the thin bark of the plant papyrus, which occafioned Prudentius and others to fay they went bare-footed. They wore no garments but linen, becaufe Isis was the firft who taught mankind the culture of this commodity. See Diodorus Siculus, and Plutarch's Isis and Ofiris.

ISIDORE of Pelufium, in *Biography*, a celebrated difciple of St. John Chryfoftom, and diftinguifhed in the Greek and Roman calendars by the epithet of "Saint," was by birth an Egyptian; and flourifhed, as the contemporary of Nonnus, and, according to Cave, about the year 412. As his name does not occur after the year 433, he probably died before the middle of the fifth century. He embraced the monaftic life at Pelufium, and acquired, by his austerities and indefatigable application to literary ftudies, high reputation for fanctity, learning, and eloquence, fo that he was honoured by the Greeks with the appellation of "the famous." Facundus fays, that he wrote 2000 epiftles for the edification of the church; and Suidas afcribes to him 3000, explanatory of the fcriptures. Of thefe there are ftill extant 2012, in five books; of which Mofheim fpeaks in terms of high commendation: faying of them, that though they are fhort, they are admirably written, both with refpect to the folidity of the matter, and the purity and elegance of their ftyle. He adds, that they manifelt more piety, genius, erudition, and wifdom, than are to be found in the voluminous productions of many other writers, and that they call a confiderable degree of light upon feveral parts of fcripture. Dr. Lardner, citing a difertation of Dr. Heumann on Ifidore of Pelufium (apud Primitias Gottingenfes, Hanover, 1738, 4to.), informs us, that this learned writer argues, that moft of Ifidore's letters are fictitious, and not a real correſpondence; and fays Lardner, he feems to have proved what he advances. Ifidore has largely quoted all, or moft of the canonical books of the Old Teftament; but he very feldom quotes any apocryphal books. He alfo often cites the four gofpels, the acts of the apoftles, and all St. Paul's epiftles, except that to Philemon. He likewife quotes and explains paſſages of the epiftle of James, the firft and fecond epiftle of Peter, and the firft epiftle of John. He explains the 8th verſe of the fecond epiftle of John, and there is no reafon to doubt his having reſcued the other. He explains a paſſage of the epiftle of Jude; and uſes feveral expreffions that feem to have been taken from the book of Revelation; fo that, upon the whole, his ſenſon of ſcripture was the fame as our's. Ifidore had a great refpect for the ſcriptures, and often recommends the perufal of them. The beft edition of his works was published at Paris, in Greek and Latin, 1638, folio. Cave. Dupin. Mofheim. Lardner.

ISIDORE of Seville, was an eminent bifhop of this city in Spain

Spain for 40 years, from the year 507 or 506 to 636. He was the son of Severianus, governor of Cartagena, and brother of Leander, bishop of Seville, who had the care of his education. He presided at a council held in Seville in 619, and at another in Toledo in 653; in which measures were adopted that served to reform the lax state of ecclesiastical discipline and manners in Spain. He was a voluminous writer, and his works are enumerated by Dupin and Lardner; and the best edition of them was published at Paris, in 1601, by father James du Breuil, a Benedictine monk, in folio. As a writer, he is characterized more by learning and pedantry, than by judgment, taste, or accuracy. Mosheim reckons him among those authors, who gave rise, by their collections, to that species of divinity, which was afterwards distinguished by the Latins under the denomination of "positive theology." Dupin, though he represents him as a prodigy of learning, and an orator, admits that he wanted genius, and a discriminating judgment; and that his opinions are often false, and his remarks trivial, and frequently erroneous; and that his style is rather perspicuous than eloquent or polished. Isidore received all the same books of the New Testament which we receive; and he speaks of them with great respect, stating that they contain the precepts of life and the rule of faith, and that they may be profitably read by all sorts of men. This Isidore is sometimes called "the younger," to distinguish him from Isidore, bishop of Cordova, in the fifth century, who wrote "Commentaries on the two Books of Kings," which he dedicated to Paul Orosius, the disciple of St. Augustine. Cave. Mosheim. Dupin. Lardner.

Isidore was a man of great and extensive learning, but particularly, it is said, in geometry, music, and astrology, which, in the time of Isidore, was another name for astronomy.

His book on the holy offices contains the principal points of discipline and ecclesiastical polity. He is frequently ranked among musical writers. In his treatise on the divine offices, much curious information occurs concerning cantos fermo, and music in general; but particularly its introduction into the church, the institution of the four tones by St. Ambrose, and the extension of that number to eight by St. Gregory. In treating of secular music, he has a short chapter on each of the following subjects: of music, and its name; of its invention; its definition; of its three constituent parts, harmonies, rhythm, and metre; of musical numbers: of the three-fold divisions of music; 1st. Of the harmonical division of music; 2dly. Of the organic or instrumental division; 3dly. Of the rhythmical division.

These chapters are very short, and contain little more than compressed definitions of musical terms. In enumerating the seven liberal arts, cap. ii. he ranks them in the following manner: grammar, rhetoric, logic, arithmetic, music, geometry, astronomy. Isidore died in the year 636, and is buried among the saints of the Roman calendar.

ISIDORE, MERCATOR, or PICTOR, the name given to the author of a collection of epigrams, which for some time were attributed to Isidore of Seville, is supposed to have flourished towards the close of the eighth century. This collection contains the pretended decretals of more than sixty popes, which are followed by the canons of the councils which were held in Greece, Africa, France, and Spain. They are generally considered as spurious, of which there is abundant internal evidence, arising from the style, the incorrectness of their dates, and from many historical, geographical, and chronological errors. They were invented for the purpose of strengthening the already overgrown power of the church, and to enforce the belief that the

bishop of Rome was constituted and appointed by Jesus Christ as supreme legislator and judge of the church universal; and that, therefore, the bishops derived all their authority from the Roman pontiff, nor could the councils determine any thing without his permission and consent. Though the forgery was manifest to every thinking person, yet with the great mass of the people it produced the intended effect, and contributed to enrich and aggrandize the Roman pontiffs, and exalt them above all human authority and jurisdiction. Moreri. Mosheim.

ISIDORE of Charax, a Greek author, in the time of Ptolemy Lagus, about three centuries before the Christian era, composed several historical works, and a description of Parthia, which has been published by Hevelius, and likewise at Oxford, among the collection of the lesser geographers. It is entitled "Methoos Parthica."

ISIDORO, *Str.* in *Geography*, a town of California; 30 miles N. N. W. of Loreto.

ISIGNY, a town of France, in the department of Calvados, and chief place of a canton, in the district of Bayeux; 29 miles W. N. W. of Caen. The place contains 1826, and the canton 13,951 inhabitants, on a territory of 240 kilometres, in 29 communes. N. lat. 49 19. W. long. 1.—Also, a town of France, in the department of the Channel, and chief place of a canton, in the district of Mortain; 9 miles W. of Mortain. The place contains 358, and the canton 5768 inhabitants, on a territory of 75 kilometres, in 11 communes.

ISUKOVA, a town of Japan, in the island of Niphon; 20 miles S. S. W. of Kanazava.

ISIMA, a town of France, in the department of the Dora; 10 miles E. of Aolla.

ISIME, a town of Thibet; 25 miles E. of Harachar.

ISINDI, in *Ancient Geography*, an episcopal town of Asia, in the second Pamphylia.

ISINDUS, or ISINDA, a town of Asia, in Ionia.

ISINGLASS, a name given to Muscovy talc, and to *Ichthyocolla*; which see. See also GLUE.

ISINGLASS *Fish*, in *Ichthyology*. See ACUPENSER and HYO.

ISIS, in *Ancient Geography*, *Yebrook*, a river of Asia, in the Colchide, which, according to Arrian, was *ναγισκος*; and he places it between the mouth of the Acmalis and that of Mogra, about 90 *stadia* from the one and the other.

ISIS, in *Geography*, a name frequently given to the river Thames, before it joins the Thame at Dorchester; but this river is only a branch of the Thames, which rises near Minchinhampton in Gloucestershire, and joins the main stream near Lechlade.

ISIS, in *Mythology*, a goddess of the ancient Egyptians, worshipped by them and many other nations.

ISIS, according to some, is synonymous with *παλαια*, ancient or aged, an expression which, in the Egyptian theology, was appropriated to the moon, on account of her eternal birth. According to others, and particularly Jablonki, (*Pantheon Egypticum*, vol. ii.) Isis, in the Egyptian language, signified "the cause of abundance;" and it was applied by the Egyptian priests to the moon, because they supposed, in consequence of attention to the phenomena of nature, that the moon has a direct influence on the atmosphere, the winds, and the rains; and therefore they regarded it, like the sun (which they called Osiris), as one of the sources of the inundation of the Nile. Hence they were led to characterize this beneficial effect, by denouncing the cause of it Isis. This is said to have happened 220 years after the exodus of the Israelites; at which period they bestowed surnames on the sun and moon, proper to their discoveries, and presented the people with a new theology.

logy. According to Herodotus and all the ancients, Isis and Isis were the two great divinities of the Egyptians, and the most generally worshipped in the whole country; and, indeed, almost the whole mythology of those ancient people is comprehended under what their priests fabled about her. The Greek and Latin authors extend it still farther; the Egyptian mythology concerning Isis and Osiris, since, according to them, they comprehended all nature, and all the gods of that ancient people. According to Herodotus, the Egyptians took Isis for Ceres, and believed that Apollo and Diana were her children, and that Latona had only been their nurse; differing from the Greeks, who regarded her as their mother. According to the same author, Apollo and Orus, Diana and Bubastis, Ceres and Isis, are the same; and hence it is, he says, that Æschylus makes Diana the daughter of Ceres. Moreover, the mythologists assert, that Isis and Osiris included, under different names, all the gods of paganism; since, according to them, Isis is Terra, Ceres, Juno, the Moon, Minerva, Cybele, Venus, Diana, and, in one word, all nature; and hence, as they pretend, this goddess was called Myrionyma, that is, who has a thousand names. Osiris also, in their opinion, is Bacchus or Dionysius, the Sun, Serapis, Pluto, Ammon, Pan, Apis, Adonis, &c. It is difficult to ascertain the real origin of Isis amidst these mythological fables. Some have pretended that the fable of Isis came originally from Greece; and they have confounded that goddess with Io, the daughter of Inachus, king of Argos. The fable of Io is recited by Ovid in his "Metamorphosis," (l. 38.) and this fable has been differently understood and explained by various authors. It is allowed that there was in Greece a princess named Io, the daughter of Inachus, or, as Pausanias says, of Jasus; and the Greeks took occasion to confound Isis and Io, in consequence of the introduction of the worship of Isis into Greece, especially into the city of Argos. Inachus taught the Greeks to pay honour to Isis, and hence they looked upon her as his daughter. Jablonski says, that the Egyptians, from remote antiquity, worshipped the moon, under her proper name of "Ioli," which, in the Egyptian language, signifies the moon; and that Inachus, the first king of Argos, carried this worship into Greece, nearly 300 years before the birth of Moses. It is there, says Eustathius, that a cow is the symbol of Io, or the moon; for in the Argian language, the moon is called Io. The Grecian fable, on the other hand, makes Io cross the sea from Greece, metamorphosed into a cow, and conducts her into Egypt, where she receives the name of Isis. Accordingly, Lucian, well versed in ancient mythology, puts these words into the mouth of Jupiter, "Conduct Io to the banks of the Nile, across the waves of the sea. Let her become Isis; let her be the goddess of the Egyptians; let her augment the waters of the river, and let loose the winds." As the Nile began to increase at the new moon which follows the solstice, the Egyptian priests, who regarded this planet as the mother of the winds, decreed to her the honour of this phenomenon. "Isis," says Servius, (Obs. on the Æneid. l. 8.) "is the genius of the Nile. The sistrum she bears in her hand indicates the increase and the flowing of the waters; the vase she holds in her left marks their abundance in all the canals." Temples were erected to her in the different provinces, and the had altars and sacrifices throughout the whole country. "Coptos," says Eustathius, "is a city of the Thebais, where Io is adored under the name of Isis. It is on her festivals that they celebrate with the sistrum the increase of the Nile." The people, from the allegorical language of the priests, imagined that they owed this bounty to the tears of that divinity. The Egyptians, according to

Pausanias, were persuaded that the tears of Isis had the virtue to augment the Nile, and to make it rise up into the country. Savary, in his "Letters on Egypt," says, that the Copts are not yet cured of this superstition.

Notwithstanding the fabulous pretensions of the Greeks with regard to the origin of Isis, and their attempts to identify her with their Io, the Egyptians, according to Diodorus Siculus (l. i.) and Plutarch (De Is. et Osir.) assert that this princess was born in their country; that the married Osiris, that they lived together in perfect harmony, and that they concurred in their endeavours to polish and civilize their subjects, to teach them agriculture, and several other necessary arts of life. Diodorus adds, that Osiris, determining on an expedition to India for purposes of civilization, settled Isis regent of his kingdom. (See Bacchus.) On his return to Egypt he found that his brother Typhon had formed a party against the government. Typhon, however, resisted the gentle means used by Osiris for subduing his ambitious spirit, and, under a pretence of hospitality, confined him in a chest exquisitely wrought, and threw it into the Nile. When Isis heard of her husband's tragical end, she made diligent search for the corpse, and having found it in Phœnicia, was allured by the king of Byblos to carry it off to Egypt. Having lamented over it, she at length caused it to be interred at Abydos, a town situated to the west of the Nile. In the mean time Typhon was contriving to secure his new empire, but Isis, being recovered from her distress, collected her troops, and placed them under the conduct of Orus, her son, who pursued the tyrant, and vanquished him in two pitched battles. (See ΤΥΦΩΝ) Isis, having died some time after her son's victory over Typhon, the Egyptians paid adoration to her with her husband Osiris, as to divinities; and because they had applied themselves, during their reign, to teach agriculture, the ox and the cow became their symbols. Festivals were instituted to their honour, in which various infamous rites were afterwards introduced. Thus the infamous image of the Phœnician king, who was consecrated, was carried in procession, and it became the symbol of fruitfulness, though in its original institution it had only been the mark of Isis's passion for Osiris her husband. Diodorus Siculus has recorded the following inscription on an ancient monument, by which Isis was characterized. "I, Isis, am the queen of this country. And I had Mercury for my prime minister. None had power to hinder the execution of my orders. I am the eldest daughter of Saturn, the youngest of the gods. I am the sister and the wife of king Osiris. I am the mother of king Orus. I am the who resides in the dog-star. The city of Bubastis was built in honour to me. Rejoice, O Egypt, thou that hast been to me instead of a nurse, and mother." The following inscription, according to Plutarch (De Is. et Osir.) was engraved upon the pavement of Minerva's temple. "I am all that has been; that is, and that shall be, and none among mortals has hitherto taken off my veil."

The Egyptians, having called the moon Isis, or the cause of abundance, applied this epithet to the earth, as the mother of fruits. We know, says Macrobius (Saturn. l. i.), that Osiris is the sun, and Isis the earth. Isis, in the Egyptian language, adds Servius, means the earth. In this point of view, she has a striking affinity to the Ceres of the Greeks; and this agrees with the account given of her by Herodotus (l. ii.). Plutarch informs us, that the priests honoured only with the name of Isis that part of Egypt which was watered by the Nile, and in allusion only to her fecundity: he adds, that, in the sacred language, they termed the inundation, the marriage of Osiris with Isis.

Isis is reported by Diodorus Siculus to have invented many excellent

excellent medicines: and hence, says he, after she was received among the number of the duties, she was applied to for the cure of diltempers; and frequently indicated remedies by dreams. Galen takes notice of some plaisters which bear her name. Banier's Mythology, vol. i. Savary's Letters on Egypt, vol. ii. See *BRÆASTIS*, *ORUS*, *OSIRIS*, and *SOTHIS*.

ISIS, in Zoology, a genus of Zoophytes of a ramose or plant-like form, the stem and branches of which are composed of stony articulations, longitudinally striated, united by spongy or horny junctures, and covered, when living or in a recent state, by a soft porous cellular flesh or bark; and the mouths beset with oviparous polypes. The species of this family are entirely of the marine kind, and mostly inhabitants of the Indian seas.

Species.

HIPPIRIS. Joints white with black junctures. *Isis hippuris*, Linn. *Sertularia ramosissima*, &c. Hort. Cliffort. *Isis*, Pallas, Ellis, &c. *Hippuris fasciata*, Clavius. *Accabarium album*, Rumpf. *Litophyton*, &c. Gualt.

A native of the Indian seas, where it is found growing to rocks, and is from six inches to two or three feet in height. The flesh, when recent, is bright orange or red, the bone or stony part, as in the dried state, whitish. A variety is described by Esper under the name of *Isis elongata*.

DICHOTOMA. Stem coralline, with smooth joints and decorticated junctures. Gmel. *Isis articulata filiformis*, &c. Pallas. *Hippuris coralloides cornu capensis*, Petiver.

This species is somewhat flexible, about six inches in height, with flesh-coloured joints, and flesh of a cinnamon colour, beset with convex papillæ. It inhabits the seas of India and Ethiopia.

CHIRACEA. Stem coralline, with decorticated joints and orbicular junctures. Gmel. *Litobryon*, &c. Hort. Cliffort. *Isis articulata paniculato-dichotoma ramosissima explanata, cortice hinc papilloso*, Pallas. *Isis*, &c. Soland. *Corallium rubrum indicum*, Ellis Phil. Transf. *Accabarium rubrum*, Rumpf. *Pseudocorallium croceum*, Ray. *Hippuris fasciata fulvo-rubra canariensis*, Moris. *Accabaar seu corallodendron vulgare rubrum*, Seba.

Inhabits the seas of the East Indies; the colour deep-red, or sometimes white, with the junctures brownish-yellow; the stem irregularly grooved, the branches numerous, dichotomous and spread, the joints connected by yellow spongy knobs; flesh yellow, with numerous stellated mouths, the habitations of polypes, each of which is furnished with eight claws.

ENTROCHA. Stem testaceous, round, with orbicular perforated joints and verticillated dichotomous branches. Gmel.

Stem about three quarters of an inch in thickness, with crowded flat orbicular joints, perforated in the centre, the perforations pentangular, with the disk somewhat striated from the centre, the outer bark unequal and surrounded with a row of tubercles: branches thin, dichotomous, continued and not jointed. Inhabits the ocean.

ASTERIA. Stem testaceous, jointed, pentagonal; the branches verticillated with a terminal dichotomous star. Gmel. *Encrinus capite stellato ramofo dichotomo pentagono equistiformi*, Ellis Phil. Transf. *Palma marina c Martinitica*, Guettard Act. Paris.

Found in the seas about the island of Barbadoes. Neither this nor the species preceding, though retained under the genus *Isis*, upon the authority of Gmelin, can with propriety be considered as pertaining to that genus, or perhaps to any other, at present established among naturalists. They unquestionably belong to a race of creatures whose manners,

and even structure, are not at this time very clearly understood.

COCINEA. Stem jointed, slender, very red, and somewhat striated; joints united by short yellowish spongy junctures; flesh on the outside covered with small scarle: prominent cells, each furnished with a mouth. Solander.

A diminutive kind of coral, with irregularly spreading branches, and which rarely exceeds the height of two or three inches. It is a native of the Indian ocean, and is sometimes found entirely white.

ISIA, in Geography, a town of Russia, in the government of Irkutsk, on the Lena. N. lat. 61. E. long. 123 50.

ISKA, a name given by the ancients to a light kind of agave, growing to the old stumps of the oak, hazel, and other trees. This being a very light kind of fuel, was used by the ancients in the manner of a cautery, as we have learned from the Indians to use moxa, or the down of mugwort leaves.

ISKARSKOIGOROD, in Geography, a town of Russia, in the government of Tobolsk. N. lat. 60 5. E. long. 59 14.

ISKASKAMAGTI, a lake of Canada; 84 miles N.W. of Quebec. N. lat. 47 50. W. long. 72 25.

ISKIM, a river of Persia, which runs into the Arabian sea, N. lat. 25 45. E. long. 57 9.

ISKOLDZ, a town of Lithuania, in the palatinate of Novogrodek; 30 miles S. E. of Novogrodek.

ISKOROSÉ, a town of Poland, in Volhynia; 48 miles N. of Zyptomiers.

ISLA, JOSEPH FRANCIS DE, in Biography, a Spanish Jesuit of Madrid, who, after the destruction of his order, retired to Italy, and died at Bologna in 1781. He was author of a satire on the ignorance and vices of the monks, entitled "Historia del Fra. Geruadio de Compazas alias Zotes," which the supreme council of Castile was obliged to suppress. It has been translated into English and German, and it is said that since the time of Cervantes, no Spanish writer has displayed so much wit and humour. Gen. Biog.

ISLA, in Geography, a river of Scotland, which rises in the shire of Angus, and runs into the Tay, 10 miles N. of Perth.

ISLA. See *ILA*.

ISLAM. See *MAHOMETANS*.

ISLAMABAD, a town of Bengal, and capital of the province of Chittigong, situated on the river Chittigong, or Currumpelly, about 12 miles from the bay of Bengal. N. lat. 22 20. E. long. 91 45.—Also, a small province of Bengal, between Goragot and Patladah.

ISLAMNAGUR, a town of Hindoostan, in the circar of Bopal; 10 miles N.N.E. of Bopalot.

ISLAMPUR, a town of Hindoostan, in the circar of Nagore; 36 miles N.E. of Didwana.—Also, a town of Hindoostan, in Bahar; 28 miles S. of Patna. N. lat. 25 8. E. long. 85 43.—Also, a town of Hindoostan, in Visiapour; 15 miles S.W. of Currer.—Also, a town of Hindoostan, in the circar of Jyenagur; 70 miles N.N.W. of Jyeepour.

ISLAMTI, a town of Asiatic Turkey, in Caramania; 30 miles S.S.E. of Kaiseriach.

ISLAND, or *ISLE*, a tract of dry land encompassed with water; either with the sea, a river, or lake. In which sense island lands contradistinguished from continent, or terra firma.

Some conclude that islands are as ancient as the world, and it is by no means probable, that the large islands far remote from the continent are new, or that they either arose

out of the sea, or were torn from the main land. Nor is it less certain, that there have been new islands formed by the casting up of vast heaps of clay, mud, sand, &c. as that, for instance, of T'fongning, in the province of Nansun, in China; or by the violence of the sea, which has torn off large promontories from the continent, as the ancients imagined Sicily, and even Great Britain, to have been formed. It is also certain, that some have emerged above the waves, as Santorini formerly, and three other isles near it in later times; the last in 1707, which rose from the bottom of the sea, after an earthquake, that was supposed to have loosened it from its hold.

Several naturalists are of opinion, that islands were formed at the deluge; others think they have been rent and separated from the continent by violent storms, inundations, and earthquakes. These last have observed that the East Indies, which abound in islands more than any other part of the world, are likewise more annoyed with earthquakes, tempests, lightnings, volcanos, &c. than any other part.

Varenus thinks most of these opinions true in some instances, and believes that there have been islands produced each of these ways. St. Helena, Ascension, and other steep rocky islands, he supposes to have become so, by the seas overflowing the neighbouring champaigns. By the heaping up huge quantities of sand, and other terrestrial matters, he thinks the islands of Zealand, Japan, &c. were formed; Sumatra and Ceylon, and most of the East Indian islands, he rather thinks, were rent off from the main land; and concludes, that the islands of the Archipelago were formed in the same way; imagining it probable, that Deucalion's flood might contribute towards it. Many islands in the South sea are formed by banks of coral, the production of insects. For an account of these by Alexander Dalrymple, see the Philosophical Transactions, vol. lvi. p. 394.

The ancients had a notion, that Delos and some few other islands rose from the bottom of the sea; which, how fabulous soever it might appear, agrees very well with some later observations. Seneca takes notice, that the island of Therasia rose out of the Ægean sea in his time, of which the mariners were eye-witnesses. Concerning the legal occupancy and property of new islands, see ALLUVION.

Islands may be considered under six different heads, with a view to their structure or subterranean geography: 1. Such as consist of an unstratified mass, as of granite, basalt, &c. of which some small rocky islands appear to consist. 2. Of mantle-shaped strata, as M. Werner has named those that surround a central hump or mass, from which they dip in all directions: the projection of such islands above the water being occasioned by an original hump in the strata. 3. They are occasioned by hummocks, or piles of strata, left when the surrounding strata were denuded, or excavated for the bed of the sea: England seems separated from France by this cause. 4. By lifted tracts of strata: it will only be practicable to distinguish this cause from the last in islands near to others, or to a continent, in which the same strata are found on the opposite coasts, by which to observe, whether the island tract has risen, or the intermediate part sunk which forms the channel of separation. 5. To volcanic eruptions in the bottom of the sea: such are generally of modern formation compared with the antiquity of the four preceding classes, and have, several of them, appeared within the periods of history; and, 6. To gravel sand and silt thrown up by the waves and tide, and accumulated in height by the blowing of the sands from the beach, until small islands are thus raised permanently above the level of the sea; some of them without assistance from man, but the greater part of the newly formed islands on the coasts of the

ocean have been gained, and are preserved by artificial banks, from the overflowings of the high tides. In large islands, like England, great varieties of these cases will doubtless be found to obtain in their structure: the eastern sides of the greater part of the islands are, perhaps, the flattest, and the western side the most abrupt, owing to the strata dipping towards the east, but it is by no means true, that the western sides of islands and continents are always the most abrupt, since often the strata dip to the west, as they do and pass under the sea, in the coal works at Whitehaven and Workington in Cumberland.

ISLANDS, *Floating*. Histories are full of accounts of floating-islands; but most of them are either false or founded on exaggerations. What we generally see of this kind is no more than the concretion of the lighter and more viscous matter floating on the surface of water in cakes, and with the roots of plants, forming congregations of different fishes, which not being fixed to the shore in any part, are blown about by the winds, and float on the surface. These are generally found in lakes, where they are confined from being carried too far; and from being broken by the agitation of the water. And in process of time some of them acquire a very considerable size. Seneca tells us of many of these floating islands in Italy; and some later writers have described not a few of them in other places. But however true the histories of these might have been at the time when they were written, there remain very few proofs of their truth at this time, these islands having either disappeared again, or having been fixed to the sides, in some part, in such a manner as to have made a part of the shore. Pliny tells us of a great island, which at one time swam about in the lake Cutilia, in the country of Reatinum, which was discovered to the old Romans by an oracle: and Pomponius tells us, that in Lydia there were several islands so loose in their foundations, that every little accident shook and removed them. Herodotus speaks also very largely of the lake Chemnis in Ægypt. See ABSORPTIONS of the Earth.

ISLANDS, *Fortunate*. See FORTUNATE.

ISLANDS, *Volcanic*. See VOLCANO.

Cryphiander has written a Latin treatise expressly on islands, "De Insula."

ISLAND Bay, a bay on the E. coast of the island of Paraguay. N. lat. 6 15'. E. long. 118 83'.

ISLANDS, *Bay of*. See BAY.

ISLANDS, *Bayona*. See BAYONA Islands.

ISLAND Magee, a peninsula on the east coast of the county of Antrim, Ireland, forming one side of the lough, or harbour of Larne.

ISLAND, or *Iceland Crystal*. See CRYSTAL.

ISLAND-Fish, in the Fish-trade, a name given to the common cod-fish, when it has been caught and preserved in Iceland.

ISLAS ESTOLAS, in Geography, a cluster of small islands in the Atlantic, near the coast of Spain. N. lat. 42° 12'. W. long. 8° 55'.

ISLAS Medas, three small islands in the Mediterranean, near the coast of Spain. N. lat. 42° 3'. E. long. 3° 4'.

ISLAS Osar, rocky islets in the Atlantic, near the coast of Spain. N. lat. 42° 17'. W. long. 8° 56'.

ISLAS de Sifarga, a cluster of small islands in the Atlantic, near the coast of Spain. N. lat. 43° 23'. W. long. 8° 50'.

ISLE, L', a town of France, in the department of the Tarn, and chief place of a canton, in the district of Gaillac; five miles S.W. of Gaillac. The place contains 542, and the canton 6715 inhabitants, on a territory of 82½ kilometres, in 3 communes.—Also, a town of France, in the department

partment of Vaucluse, and chief place of a canton, in the district of Avignon. The place contains 5155, and the canton 11,099 inhabitants, on a territory of 172½ kilometres, in 10 communes.

ISLE-Adam, L', a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Pontoise, 6 miles N.N.E. of Pontoise. The place contains 1381, and the canton 1,5965 inhabitants, on a territory of 147½ kilometres, in 23 communes.

ISLE-Bouchard, L', a town of France, in the department of the Indre and Loire, and chief place of a canton, in the district of Chinon, surrounded by the Vienne; 9 miles E.S.E. of Chinon. The place contains 1070, and the canton 10,437 inhabitants, on a territory of 240 kilometres, in 20 communes.

ISLE-Baudouin, L', or *Ile-Buen*, a town of France, in the department of the Vendee, situated on an island of the same name, about 5 miles long, on the coast; 9 miles N.W. of Challans.

ISLE de Cerf, a small island in the English channel, near the coast of France. N. lat. 48° 53'. W. long. 3° 25'.

ISLE-Dieu, L', a town of France, in the department of the Vendee, and chief place of a canton, in the district of Les Sables d'Olonne. The place contains 1049, and the canton 2053 inhabitants, on a territory of 65 kilometres, in 2 communes.

ISLE-d'Ouessant, L', a town of France, in the department of Finistère, and chief place of a canton, in the district of Brest. The place contains 1645 inhabitants, on a territory of 22 kilometres, in 1 commune.

ISLE-en-Dodon, L', a town of France, in the department of the Upper Garonne, and chief place of a canton, in the district of St. Gaudens; 18 miles N.N.E. of St. Gaudens. The place contains 1100, and the canton 10,832 inhabitants, on a territory of 232½ kilometres, in 24 communes.

ISLE-Jourdain, L', a town of France, in the department of the Gers, and chief place of a canton, in the district of Lombes, situated on the Save; 7 miles E. of Auch. The place contains 4686, and the canton 11,634 inhabitants, on a territory of 262½ kilometres, in 23 communes. N. lat. 43° 37'. E. long. 1° 10'.—Also, a town of France, in the department of the Vienne, and chief place of a canton, in the district of Montmorillon, 24 miles S.E. of Poitiers. The place contains 448, and the canton 7553 inhabitants, on a territory of 375 kilometres, in 11 communes. N. lat. 46° 15'. E. long. 0° 25'.

ISLE-sur-le-Doubs, L', a town of France, in the department of the Doubs, and chief place of a canton, in the district of Baume; 11 miles N.E. of Baume. The place contains 685, and the canton 7048 inhabitants, on a territory of 167½ kilometres, in 24 communes.

ISLE-sur-le-Serein, L', a town of France, in the department of the Yonne, and chief place of a canton, in the district of Avallon. The place contains 478, and the canton 8766 inhabitants, on a territory of 250 kilometres, in 23 communes.

ISLE des Moines, an island of France, in lake Morbihan, with a tower; 5 miles S.S.W. of Vannes.

ISLE Grande, or La Roche, an island in the South Pacific ocean, seen by Anthony de la Roche, in 1675. S. lat. 45°.

ISLE Royale, an island on the N.W. side of Lake Superior, within the territory of the United States, N.W. of the Ohio; about 100 miles long, and, in many places, about 40 broad. The natives suppose that this and the other islands on the lake are the residence of the Great Spirit.

ISLE Plate, a small island in the English channel, near the coast of France. N. lat. 48° 53'. W. long. 3° 24'.

ISLE of Dogs Canal, is the name of a very wide and deep canal for the passage of ships across the isthmus called the Isle of Dogs, in the river Thames, below London, of which an account has been given under the head of that river, in our article CANAL, and a plan of the same will be found in our plate of *Docks*.

ISLE of Wight, an insulated tract of land, situated in the English channel, near the coast of Hampshire, from which it is not more than three miles distant at the nearest point, and to which county it belongs in all political and civil matters. The form of the island is that of an irregular lozenge; measuring from the eastern to the western angle nearly twenty-three miles; and about thirteen from the northern to the southern point; its superficies is computed at 105,000 acres. Through the middle, in the longest direction, extends a range of hills, affording excellent pasture for sheep, and commanding views over every part of the isle, with the ocean on the south side, and the coasts of Hampshire on the north. The face of the country is much diversified; hill and dale, the swelling promontory and the lowly glen, appear in quick succession to animate, and give interest to the prospects. The land round the coast is, in some parts, very high, particularly on the south, or back of the island, as it is commonly termed; here the cliffs are very steep, and vast fragments of rock, undermined by the waves, lie scattered about the shore: on the northern side, the ground slopes to the water in easy declivities, excepting towards the Needles, or western point, where the rocks are bare, broken, and precipitous. The height of the cliffs, of which the Needles form the extreme point, is, in some places, six hundred feet above the level of the sea, and when viewed from the distance of about a quarter of a mile, have a grand and almost sublime and stupendous effect. These cliffs are frequented by immense numbers of marine birds; as puffins, razor-bills, wilcocks, gulls, cormorants, cornish-choughs, daws, starlings, and wild pigeons; some of which come, at stated times, to lay their eggs and breed; while others remain there all the year. The cliffs are in some places perpendicular; in others, they project and hang over, in a tremendous manner: the several strata form many shelves; which serve as lodgments for the birds, where they sit in thick rows, and discover themselves by their motions and flight, though not individually visible. Here are many caverns and deep chasms, which seem to enter far into the rocks; and in some places, the issuing of springs forms small cascades of rippling water down to the sea. The country people take the birds that harbour in these rocks, by the perilous experiment of descending by ropes, which are fixed to iron crows, driven into the ground: thus suspended, they with sticks beat down the birds as they fly out of their holes. A dozen birds generally yield one pound weight of soft feathers, for which the merchants give eight pence; the carcases are bought by the fishermen at sixpence per dozen, for the purpose of baiting their crab-pots. The rocks, called the Needles, derived their name from a lofty pointed one, resembling a needle in shape, which had been disjoined, with others, from the main land, by the force of the waves: this was 120 feet above the low water mark; but about forty years ago, its base having been excavated by the sea, it fell, and totally disappeared.

All the higher parts of the island are composed of an immense mass of calcareous matter, of a chalky nature, incumbent on schistus, which runs under the whole isle, and appears, at low water mark, on the coast near Mottistoun: this becomes so indurated by exposure to the air, as to make very good whetstones. The lime-stone is burnt for manure;

ISLE OF WIGHT.

and in the pits where it is dug for that purpose, are found numerous echini, sharks' teeth, and ammonis. These fossils are particularly abundant in the range of cliffs which forms the southern shore; together with bivalve and turbinated shells of various descriptions: the cornua ammonis are of all sizes, from one inch to eighteen inches in diameter. A stratum of coal discovers itself at the foot of Bimbridge cliff, and runs through the southern part of the isle, appearing again at Warden Ledge, in Freshwater parish. On the north side of this stratum lies a vein of white sand, and another of fuller's-earth; and on the fourth side is a vein of red ochre.

The soils of the island are of various kinds; but the most prevailing is a strong loamy earth, well adapted for agricultural purposes, and extremely fertile. The quantity of grain annually raised here, is computed to amount to seven or eight times as much as sufficient for all the inhabitants. The medium produce of wheat, throughout the island, is about twenty-one bushels per acre; of barley and oats about thirty bushels; and of beans and peas about twenty-eight bushels; potatoes are very productive, though not greatly in esteem, and turnips also yield a rich increase. The meadow lands are extremely fine, and produce from one to three tons of hay per acre. The elevated tracts are mostly appropriated to pasturing sheep; the number annually shorn is about 40,000; the wool is of the finest quality, and in much repute; the breed in general use is the Dorsetshire: about 5000 lambs are fold annually.

The climate is extremely salubrious, and highly favourable to vegetation: its genial qualities, and near approximation, in mildness, to more southern regions, may be instanced by the profusion of myrtles, and by the flourishing state of a vine-plantation at Appuldurcombe. The central parts of the isle are subject to frequent rains; the high range of hills proving a constant source of attraction to the vapours, and, in the winter months, involving all beneath them in gloom and humidity. The general fertility, however, is so little affected, and the vegetation is so abundant, that this island has often been styled the "Garden of England;" an appellation, perhaps, that is partly suggested to the mind by the innumerable plants and flowers which grow every where in wild luxuriance; among them are the *ophris apifera*, or bee-orchis; the digitalis, or fox-glove; and the *crithlum maritimum*, or rock-sampshire.

The contiguity of the Portsmouth, and other dock-yards for ship-building, has operated to deprive the Isle of Wight of much of its timber; and even Parkhurst, or Carisbrooke forest, which includes about 3000 acres of good land, is almost destitute of trees of any value. The woods of Swainston are of considerable extent; and those of Wooten and Quarr cover a superficies of nearly 1100 acres: the oak and elm are the most flourishing trees.

Great variety of fish is found on the coast, and in considerable abundance: those of the crustaceous kinds are particularly numerous on the southern shores. The lobster and crab are of uncommon size, and peculiar quality; some of the former are often taken upwards of six pounds weight; the latter so abundant on a particular part of the coast, that a neighbouring village has obtained the name of Crab-Niton from this circumstance. Cockles are in high estimation; and the sand-eel is also very plentiful.

The trade of the Isle of Wight is flourishing; the harbour of Cowes is particularly convenient for shipping and unshipping merchandise. The chief imports are coals, timber, deals, iron, wine, hemp, and fruits: the principal exports are wool, flour, barley, malt, and salt. The chief manufactures are those of starch, hair-powder, and salt; and latterly the making of woollens, sackings, &c. has been

carried to some extent in the House of Industry near Newport.

Several chalybeate springs have been discovered in different parts of the island; one of them, at Black Gang, under Chale cliff, is very strong; about half a mile from this, at Pitland, is a spring, impregnated with sulphur; and at Shankin is a spring, the waters of which are slightly tinged with alum. Springs of clear water are very numerous, and in general extremely pure and transparent, from the natural percolation which they undergo through the lime-stone strata.

The principal rivers are the Medina, the Yar, and the Wooten. The Medina, anciently called the Mede, rises near the bottom of St. Catherine's Down, and flowing directly northward, divides the island into two nearly equal parts; gradually widening in its course, it passes to the east of Newport, and in Cowes harbour unites its waters with the ocean. Numerous smaller streams also exist; and various creeks and bays run up from the sea. The two divisions of the island are called the hundreds, or liberties, of East and West Medina, from their relative situations to that river. They contain thirty parishes, in which are comprehended the following boroughs and towns; Brading, Newport, Newtown, and Yarmouth; the three latter of which return six members to parliament.

The ancient history of this island has been a subject of much controversy with topographical writers. Whitaker, in his History of Manchester, contends that it was formerly connected with the main land; and that it is the *Idis* of Diodorus Siculus. At this point, according to the latter writer, the Britons shipped their tin for Gaul; but the original tin staple of Britain was certainly the Caisterides, or Scilly islands. (See Borlase and Heath's Accounts of these Islands.) During the Anglo-Roman dynasty this island was called *Vidis*; but it does not appear that the Romans had any station or settlement here; though they had two or three considerable stations on the opposite coast; one at Clausentum, near Southampton, and another at Portchester. Suetonius, the first of the Roman authors, who notices the island under consideration, states, that it was subdued in A.D. 43 by Vespasian. Cerdic, a Saxon chieftain and founder of the kingdom of Wessex, made a second conquest of the isle, and appointed his nephews Sterf and Withgar to govern the inhabitants. In the year 661 it was again subdued by Wulphure, king of Mercia, but this monarch was dispossessed of this tract of land within the space of 15 years. The Danish marauders afterwards visited, and took possession of this island; and preserving a port here, they made frequent descents on the coasts of Hampshire, Dorsetshire, and Sussex. After the Norman conquest, the island was annexed to the crown, and was frequently granted, in trust, to the favourites of different monarchs.

A list of the different noblemen who were governors, or lords of the island, with the conditions on which it was held, are fully narrated in Sir Richard Worsley's History of the Isle of Wight. The situation of this island has rendered it liable to invasions in the time of warfare, and particularly when France has been at war with England, and many instances are recorded of descents on this coast. To protect the island, a large and strong fortress, called Carisbrooke castle, was constructed at an early period, and has been preferred as a place of refuge and strength even to the present time. Here a military governor occasionally resides. Other forts were constructed on different parts of the coast; but the great fortifications at Portsmouth, and at other places on the Hampshire coast, serve to guard the island. The southern shore is also naturally protected by rocks. The

ifland contains feveral feats and villas, the principal of which is Appuldrecombe park. Sir Richard Worley's History of the Ifle of Wight, 4to. Albin's History, &c. 8vo. Buller's Account of the Ifland, 12mo. Windham's Picture of the Ifle of Wight.

ISLE of Wight, a county of Virginia, on the S. fide of James's river, W. of Norfolk county, about 40 miles long and 15 broad, containing 5313 free inhabitants, and 4029 flaves. In this county is a mineral fpring, to which many perfons refort. It is fituated about 10 miles from Smithfield, and 12 from Suffolk.

ISLEBEANUS LAPIS, in *Natural History*, a name given by authors to a kind of blackifh flate, very heavy, not very hard, and eafily fplitting into thin flakes. It is dug near Ifleb, in Thuringia, whence it has its name, and is much of the nature of that fort of black flate which we have common in England, lying over the coal ftrata.

As our flate of this kind contains ufually leaves of fern and other plants, this foreign kind contains the impreffions of feveral kinds of fifh, fo exactly delineated in fhape, and with the fins, feales, and all other parts fo perfect, that the fpecies are eafily known. All the impreffions and delineations are, however, fo flat and thin, and have taken up fo little room in the flone, that they feem rather to have been the flins and exuvie of fifh than the whole bodies of them; but this is not wonderful when we confider how eafily the bodies, and even the bones of fifhes may be diffolved; and that thefe exuvie are lodged in a fubftance which contains a vitriolic falt, very capable of effecting fuch a folution. It is eafy to conceive, that this and other fuch falts, while in a flate of folution in water, before the concretion of the matter of this flone into a hard mafs, might make that water a menftruum capable of thus diffolving the bodies and bones of fifhes, while the outer flin and feales being much tougher, and of a very different nature, might efcape the effects of them. It is well known that the fins and feales, and other external parts of fifh, are much more capable of bearing maceration in water than the internal fubftances of them; and it is eafy to conceive that thefe, after having withftood that power in the water, would at length fubfide down among the muddy matter that was to form fome of the ftrata of this flate: the motion of the water would not fail to expand their flins, though ever fo thin, into the true and exact fhape of the whole fifh; and when thus laid along upon the furface of the new-formed flratum, the next quantity of the fame matter that fubfided would form another flratum, which falling evenly upon the former, would cover it, and on the following concretion of both, the figure of the fifh would be beautifully preferved between two plates or flakes of a fiffle flone.

It is very remarkable, that as in thefe flates of Ifleb preferring fifhes, the external parts only are preferved, the bones and flefh being wafhed: fo, on the other hand, in thofe foftle fifhes brought from Syria, the flins and feales are wanting, and the fkeletons are principally the part preferved. In fome of thefe the bones are not clean, fmall parcels of the flefh being found petrified among them; but this flefh is ftripped of the flin. The flone in which thefe Syrian fifhes are preferved is alfo very different from the Ifleb flate, being whitifh or greyifh, and very hard. The flones of this kind found on mount Libanus, where they are very common, have very fine delineations of the flat-fifh complete. Wo-dw. Cat. Foff. vol. ii. p. 23, &c.

ISLEBIANS, in *Ecclefiaftical History*, a name given to thofe who adopted the fentiments of a Lutheran divine of Saxony, called John Agricola, a difciple and companion of Luther, a native of Ifleb, whence the name; who, inter-

preting literally fome of the precepts of St. Paul with regard to the Jewifh law, declaimed againft the law, and the neceffity of good works. See ASTINOMIANS.

ISLEBOROUGH, in *Geography*, a townfhip of America, in Hancock county, Maine, formed by Long ifland, in the centre of Penobfeot-bay; 15 miles long, and from two to three broad: it was incorporated in 1789, contains 483 inhabitants, and is diftant 260 miles N.E. by N. from Bolton.

ISLES de Madane, iflands that lie at the S. end of Sydney, or Cape Breton ifland, on which they are dependent. The largeft of thefe, with Cape Canfo, the E. point of Nova Scotia, forms the entrance of the gut of Canfo from the Atlantic ocean.

ISLES of Don Jofeph Galevez, a large clufter of iflands in the South fea, populous, and affording plenty of potatoes, cocoa, bananas, and other fruits. S. lat 19 59'. E. long. 179 38 from Paris.

ISLES, in *Architecture*, the fides or wings of a building.

ISLEWORTH, in *Geography*, a parifh in the hundred of the fame name, and county of Middlefex, England, is delightfully feated on the banks of the Thames, and has long been the refidence of many perfons of rank and fortune. The parifh confifts of about 2370 acres, chiefly appropriated to arable and pafture; but nearly 500 acres are ufed as gardens and nurfery-ground. At Baberbridge, in this parifh, are fome large copper and brafs mills, rented by the fociety of the mines-royal. A confiderable china manufactory, fome extenfive calico-grounds, and two large flour-mills are alfo within this parifh. The chief buifnefs, or trade of the place, is derived from the gardens, which furnifh a vaft variety of fruit and vegetables for Covent-garden market. In the year 1794, fir Jofeph Banks obtained a correct ftatement of the population of this parifh: and it appeared that the number of houfes was 712; of which 43 belonged to gentlemen, 6 to farmers, 26 to publicans; the remainder confifted of fshops and cottages. The inhabitants at the fame time amounted to 4190. In the year 1800, the houfes amounted to 768, and inhabitants to 4346. The principal building in this parifh is Sion-houfe, a fpacious feat of the duke of Northumberland. The houfes occupy the feite of a convent of Bridgetines, founded by king Henry V. The prefent manfion was enlarged and fitted up by the late duke, who embellifhed it with feveral pieces of ancient fculpture, alfo with twelve Ionic columns, and fixteen plafters of fine marble. The improvements made in the houfe, and the elegant facade, adjoining the public road near Brentford, are from defigns by the late Mr. Adams. The gardens and pleafure-grounds, contiguous to the Thames, were laid out by the late Mr. Brown. The duke of Marlborough and the earl of Shrewfbury have feats in this parifh. Ifleworth Park was occupied by the barons' army, headed by Simon de Montford, in the year 1263. On the 4th of Auguft, 1647, general Fairfax appointed his head-quarters at Ifleworth, and received the parliamentary commiffioners here. Lyfons's Environs of London and Middlefex Parifher.

ISLINGTON, a village in Ofsuffon hundred, Middlefex, England, though formerly a fmall place, and feparated from London by feveral intervening fields, is now connected to the northern fuburbs of the metropolis, and indeed appears to form a part of this vaft city. "When it is confidered, that Iflington is fearely two miles from the centre of the original London; that it is feated upon the Ermin-ftreet of the Romans, and the fpot where they had a military poft; alfo, that it has, from the earlieft period of our hiftory, been celebrated for the richnefs of its paftures, and the excellent

which produce of its dairies, there can remain little doubt that these circumstances must have rendered it of considerable importance to the Londoners, as well as the garrison there." This village has been variously spelt in old records and publications; as Mendens, Mendon, Heldon, Veldon, and Eyfeldon; but it appears that the present name has prevailed from the close of the 16th century. The parish of Iffington is three miles two furlongs in length, from N.W. to S.E., and two miles one furlong in breadth. It consists of 3032 acres three rods, of which the chief part is appropriated to pasture. Besides the village of Iffington, the parish contains the following hamlets: Holloway, Ballspend, Battle-bridge, the City-gardens, Kingland-green, and great part of Newington-green. The population of this parish, in 1800, was returned at 10,212, occupying 1663 houses: in 1793, the latter was only 1200, and the former 10,000. Previous to the year 1714, the roads and highways were in so bad a state, that in an act of parliament then passed, they are described to be "very ruinous and almost impassable for the space of five months in the year." This furnishes a curious illustration of the amazing improvements made for public accommodation within 100 years: for now 6000 passengers are provided with good pavements, or gravel paths, and the public roads are firm, even, and generally clean. They are also furnished with lamps for winter, and watchmen and patrols are employed to protect houses and passengers. From an early period, even before the time of Henry II., Iffington has been noted as a place of recreation for the citizens of London; where wrestling-matches, shooting, archery, casting the stone, and other athletic pastimes were pursued. Now the mechanics and lower classes frequent public-houses, which are provided with grounds for skittles and Dutch-pins; places for playing at fives, cricket, and bowls. In this parish, to the north of White Conduit-house, are the traces of an encampment, which several writers have attributed to the Romans, but neither its present state, nor any discoveries that have been made, justify this opinion. Iffington contains several commodious, and some handsome houses belonging to London merchants and tradesmen.

For a full and circumstantial history and description of this parish, the reader is referred to "The History, Topography, and Antiquities of Iffington," by John Nelson, 4to. 1811.

ISLIP, a post-town of New York, in Suffolk county, Long Island, E. of Huntington, containing 958 inhabitants.

ISMADABS, a town of Japan, in the island of Niphon; 125 miles N.W. of Jedo.

ISMAELPOUR, a town of Hindoostan, in Bahar; 38 miles S.W. of Patna.—Also, a town of Bengal; six miles E. of Boglipour.

ISMAIL, or ISMAYLOW, a town of European Turkey, in the province of Bessarabia, situated on the N. side of the Danube, about 33 miles from the Black sea. The town measures about a mile toward the land, and half a mile by the side of the Danube, and was fortified by eight bastions. The ramparts are in general 18 feet high, and in some places 25. The moat is from 30 to 40 feet deep, and at an intermediate distance between the polygons named Bender and Brock was a false trench. Near the town was a cavalier of stone-work, capable of holding some thousand men. The side next the water was defended by ramparts and horizontal batteries. This place was taken by storm, December 22, 1790, by the Russians, under general Suwarow. It is said, that after the Turks had surrendered, the garrison was put to death, and 30,000 men massacred in cold blood; the town

was given up to the unrestrained brutality of the victorious army. The booty found in the place was immense: 144 miles S.W. of Otchakov. N. lat. 45° 23'. E. long. 29° 45'.

ISMANING, a town of Bavaria, which gives name to a county, situated on the Iser; eight miles N. N. E. of Munich.

ISMENIAS, in *Biography*, one of the most celebrated performers on the flute in antiquity, was a native of Thebes; and not less renowned for splendour, extravagance, and caprice, than for his skill in music. Having been taken prisoner by Atheas, king of the Scythians, he performed on the flute before this rude monarch; but though his attendants were charmed so much that they applauded him with rapture, the king laughed at their folly, and said that he preferred the neighing of his horse to the flute of this fine musician.

Ælian tells us, that he was sent ambassador into Persia. Lucian, that he gave three talents, or 58*l.* 5*s.* for a flute at Corinth. Antisthenes, not very partial to music, said he was sure that Ismenias was a worthless fellow, by his playing so well on the flute. Plutarch relates the following story of Ismenias: being sent for to accompany a sacrifice, and having played some time without the appearance of any good omen in the victim, his employer became impatient, and, snatching the flute out of his hand, began playing in a very ridiculous manner himself, for which he was reprimanded by the company; but the happy omen soon appearing, there! said he, to play acceptably to the gods, is their own gift! Ismenias answered with a smile, "While I played, the gods were so delighted, that they deferred the omen, in order to hear me the longer; but they were glad to get rid of your noise upon any terms." Thus we see that neither vanity nor impiety is peculiar to modern musicians.

The same author, in his life of Demetrius, informs us, that Ismenias used to instruct his pupils by examples of excellent and execrable performance; letting them hear, immediately after each other, a good and a bad player on the flute; saying of the first, "this is the way you *should* play;" and of the second, "this is the way you *should not* play." He is recorded by Pliny as a prodigal purchaser of jewels, which he displayed with great ostentation. Being at Cyprus, he found at a jeweller's an engraved emerald of the most exquisite kind, representing the princess Amyona, one of the daughters of Danaus, for which the jeweller asked him five talents, with which demand Ismenias immediately complied. But the jeweller, astonished at his facility, and expecting that an abatement would have been required, offered, contentedly, to return two of the five talents; but the magnificent musician refused to take them; saying, that it would for ever diminish the value of the gem. Upon this principle it seems as if the purchasers of scarce books were fearful of acquiring them cheap; as their value is often more heightened by their price and margin than contents. And we are convinced that the innumerable crowds who flocked to the Pantheon in 1775, when the Agujari first sung there, were not occasioned by her merit or celebrity as a singer, but by her having 10*l.* a night for her performance; and who knows but that Mrs. Billington's high salaries may have contributed to her attractions, as well as her extraordinary talents?

ISMID, or IS NICKMID, in *Geography*, a town of Asiatic Turkey, situated on a bay of the sea of Marmora; where the Greeks and Armenians have each a church and an archbishop. This is supposed to have been the ancient Nicomedia,

media, the capital of Bithynia; 45 miles E.S.E. of Constantinople. N. lat. 40 30'. E. long. 29 34'.

ISMID, a town of Asiatic Turkey, in Caramania; 24 miles E.S.E. of Cogia.

ISMIL, a town of Asiatic Turkey, in Caramania; 30 miles E. of Cogia.

ISTOKIL, a small island on the E. side of the gulf of Botnia. N. lat. 63 16'. E. long. 21 20'.

ISNAGAR, or ISNAJAR, a town of Spain, in the province of Cordova, 10 miles S. of Lucena.

ISNARDI, in *Biography*, according to M. Laborde, "after singing, in his youth, on the stage with success, quitted the theatre, and studied composition and poetry. After which he published sonnets, madrigals, and even short dramas, fit to rubie by himself. His works have been often reprinted." Now if Walther's dates are correct, and he gives authorities for them, Isnardi must have sung with success on the stage before the lyric stage or operas had existence; but we are unable to find a musician of this name.

ISNARDIA, in *Botany*, was so named by Linnaeus, in honour of M. Antoine Dauti d'Inard, member of the Academy of Sciences, in the Memoires of which academy may be found several of his tracts on botany, published between the years 1716 and 1726.—Linn. Gen. 61. Schreb. 84. Willd. Sp. Pl. v. 1. 680. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 1. 266. Juss. 333. Lamark. Illustr. t. 77.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Calycanthem*, Linn. *Salicaria*, Juss.

Gen. Ch. Cal. Perianth superior, bell-shaped, permanent, divided into four, slightly spreading segments. Cor. none. Stam. Filaments four, shorter than the calyx, one placed within each segment of it; anthers simple. Pist. Germen inferior; style cylindrical, longer than the stamens; stigma capitate. Peric. Capule square, of four cells, crowned by the calyx. Seeds numerous, oblong.

Ess. Ch. Corolla none. Calyx four-cleft. Capule of four cells, crowned by the calyx.

Obs. Linnaeus has observed, in a MS. note to his own copy of the *Genera Plantarum*, that the base of the calyx is furnished with two awl-shaped bractæes adhering closely together.

1. *I. palustris*. Linn. Sp. Pl. 175. (Glaux major palustris, flore herbaceo; Bocc. Mus. 105. t. 84. f. 2.) A native of rivers in France, Russia, Jamaica, North America, &c. It flowers in July, and was first introduced at Kew by Dr. Fothergill, in 1776.—"In general appearance this plant greatly resembles *Peplis Portulaca*. It is creeping and floating. Flowers axillary, opposite, sessile, green."—Leaves obovate, wedge-shaped at the base, veined and smooth. Seeds brown.—Swartz has described a plant in his *Fl. Ind. Occ. v. 1*. 273, under the name of *Ludwigia repens*, which he says differs only from *Ijnardia palustris* in being furnished with petals.

ISNARI, PAOLO, of Ferrara, in *Biography*, a disciple of the celebrated musician Manara, maestro di cappella of the Duomo in that city, and a voluminous composer of church music, flourished in the latter end of the sixteenth century. In 1565, he published his "Cantus Hebdomadae Sanctæ," or Music for Passion Week: in 1568, six-part masses: in 1578, the Vesper psalms in three parts, and three Magnificats in four parts. This last work was reprinted at Milan, 1590.

ISNELLO, in *Geography*, a town of Sicily, in the valley of Demona; 13 miles S. of Cefala.

ISNIK, a town of Asiatic Turkey, in Natolia, situated on a lake of the same name, called by the ancients Afcanius, that abounds with fish, and that communicates with the sea

of Maronora. The chief article of its trade is fish. It is the see of a Greek archbishop, though it contains scarcely 300 houses. It was anciently called "Nice," and famous for its council; 60 miles E. of Constantinople. N. lat. 40° 16'. E. long. 29° 50'.

ISNY, or YAKI, a town of Germany, lately imperial, situated in the Algau, betwixt the counties of Hohenneck and Truchburg, and the lordship of Eglof. The magistrates and great number of the citizens are Lutheran. It has often suffered by fire; 40 miles S. of Ulm. N. lat. 47° 45'. E. long. 9° 58'.

ISOCHRONAL, or ISOCHRONOUS, is applied to such vibrations of a pendulum, as are performed in equal times.

Of which kind are all the vibrations or swings of the same pendulum, whether the arcs it describes be longer or shorter; for when it describes a shorter arc, it moves to much the slower; and when a long one, proportionally faster. See PENDULUM.

ISOCHRONAL Lines, is that wherein a heavy body is supposed to descend without any acceleration.

Leibnitz, in the Act. Erud. Lips. for April 1689, has a discourse on the *linea isochrona*, in which he shews, that a heavy body, with a degree of velocity acquired by its descent from any height, may descend from the same point by an infinite number of isochronal curves, which are all of the same species, differing from one another only in the magnitude of their parameters; such as are all the quadrato-cubical paraboloids, and consequently similar to one another. He shews also how to find a line, in which a heavy body descending, shall recede uniformly from a given point, or approach uniformly to it. See CYCLOID.

ISOCHRONOUS PARCELS, in *Music*. Mr. John Holden labours in his "Essay towards a rational System of Music," to establish it as a principle, that "there is a certain propensity in our mind to be subdividing the large numbers (of equal and equidistant objects) into smaller equal parcels: or, as it may be justly called, compounding the large numbers of several small factors, and conceiving the whole by means of its parts," p. 288. "Seven, we conceive, as two threes disjoined, and one in the middle; five becomes two twos disjoined, and one in the middle," p. 289; and again, p. 305, "we readily conceive five by its affinity to four, and seven by its affinity to six," p. 292. "Among the isochronous single vibrations of musical sounds, the mind naturally seeks to constitute isochronous compound parcels."—"The size or magnitude of a musical interval is estimated by the inequality of the isochronous parcels of vibrations of its two terms; and in proportion as their isochronous parcels differ more from equality, the included interval becomes greater," p. 327. The above extracts shew the nature and uses to which this author attempts to apply his isochronous parcels of vibrations; in which we can scarcely admit him to have been more successful, than in the application of the GRAVE Harmonics (see that article), or Tartinian sounds; to accounting for the constitution of the musical scale; the incongruous system of intervals to which these fancies lead, will be seen in our article HOLDEN'S System of Musical Intervals.

ISOCRATES, in *Biography*, a celebrated Greek rhetorician, was born at Athens about the year 436 B. C. He received a good education, but his father, being ruined by the Peloponnesian war, left him no other inheritance. He had studied under Gorgias, Prodicus, and other great masters of eloquence, but the weakness of his voice, and his want of a proper degree of confidence, prevented him from exercising the talent of speaking in public. He employed himself, therefore, in composing discourses in his closet, and

in teaching the art of rhetoric. He was the instructor of Timotheus, son of Conon, whom he afterwards accompanied to several parts of Greece as his secretary. He had numerous scholars at Athens, and was amply remunerated for some of his writings, particularly for a discourse which he addressed to Nicocles, king of Cyprus, for which he received a sum equal to between four and five thousand pounds of our money. Though courted by the great, he had an ardent mind in defence of what was just and right. When Theramenes, proscribed by the thirty tyrants, took refuge at the altar, he pleaded in his defence, at the hazard of sharing his fate; and after the death of Socrates, when all his disciples took flight, he dared appear in mourning in the public streets of Athens. He passed a long life in peace and honour, and had reached his ninety-eighth year at the fatal battle of Cheronæa, when, unable to bear the calamity which had befallen his country, he abtained from all fullness for four days, and expired. It was mentioned, to his praise, that he never, by writing or accusation, injured a single individual. A statue of bronze was raised to his memory by Timotheus, and another by his adopted son Aphærus. The style of Isocrates is pure, sweet, and flowing; he was extremely attentive to the harmony of his periods, and he is reckoned by Cicero as the first who introduced into Greek prose that melody of which it is susceptible. He spent a deal of time in polishing his compositions; his panegyric on Athens is said to have cost him ten years labour. Twenty-one of his discourses remain, which have been distributed into the moral, the deliberative, the panegyric, and the agonistical. Moreri.

ISOETES, in Botany, an old name for one of the smaller kinds of *Sedum*, from *isos*, equal, and *etos*, the year, as being evergreen. It is for the same reason adopted by Linnæus for the present genus. Linn. *Ed. Scan.* 417. t. 419. Gen. 561. Schreb. 755. Mart. Mill. *Diët.* v. 2. Sm. Fl. Brit. 1144. Jul. 17. Lamarck *Diët.* v. 3. 314. Illustr. t. 862. (Calamaria; Dill. *Muse.* 540. t. 80. f. 1.) Clafs and order, *Cryptogamia Filices*. Nat. Ord. *Filices*.

Gen. Ch. Male, *Flowers* solitary, within the base of the inner leaves. *Cal.* a heart-shaped, acute, sessile scale. *Cor.* none. *Stam.* Filament none; anther roundish, of one cell, compressed, convex on one side, concave on the other, standing on the calyx.—Female, *Flowers* solitary, within the base of the outer leaves of the same plant. *Cal.* as in the male. *Cor.* none. *Pist.* Germen ovate, standing on the calyx, within the leaf; style none; stigma . . . *Peric.* Capsule membranous, nearly ovate, concealed within the base of the leaf. *Seeds* numerous, angular, rough.

Eff. Ch. Male within the base of the inner leaves. Anthers solitary, standing on the heart-shaped calyx. Female within the base of the outer leaves. Germen standing on the heart-shaped calyx. Capsule membranous. Seeds many, angular, rough.

1. *I. lacustris*. Common Quillwort.—Linn. Sp. Pl. 1563. Engl. Bot. t. 1084. Bot. Fil. 74. t. 41. (Subularia vulgaris erecta, folio rigidissimo; Raii Syn. 306.)—Fronde awl-shaped, semi-cylindrical, rather spreading. Capsules roundish, of two cells. Seeds granulated all over.—Found under water, about the margins of alpine lakes in various parts of Europe. In those of Wales, Scotland, and Westmoreland, it is abundant, making a sort of coarse evergreen turf, much below the surface. The root is perennial, tuberous, throwing out many long simple fibres. Leaves or fronds numerous, tufted, simple, awl-shaped, from three to twelve inches high, rather spreading upwards, and often recurved, semi-cylindrical, smooth, divided internally into four longitudinal cells or tubes, with numerous transverse partitions.

The base of each leaf is somewhat dilated, and bordered with a membrane, the *fructification* being situated on the inner side, under the cuticle, that of the inner leaves being male, the outer female. What supports the anther in one flower, the germen in another, may be termed either a calyx or receptacle. The ripe capsule is nearly as large as a split pea, brownish, thin, and membranous; we find it divided into two cells by a transverse fracture or partition, notwithstanding what Schreber has mentioned to the contrary, apparently from Oeder. The seeds are numerous, small, white, rough all over with minute granulations.

2. *I. fetacea*. Slender Quillwort. Lamarck *Diët.* v. 3. 314.—Fronde bristle-shaped, nearly round, erect.—Lamarck mentions this as very different from the former in the slenderness and straightness of its leaves, which are only about $2\frac{1}{2}$ inches high. The root also is entirely fibrous, not tuberous. It was found by the abbé Bonnatere, growing three or four feet under water, in the lake of St. Andréol, on the mountains of Aurbre, in Gévaudan. We have had no other tidings of this species, but should expect to find it in Britain.

3. *I. unilocularis*. Indian Quillwort—Roxb. MSS.—Fronde somewhat triangular, erect. Capsules elliptical, of one cell. Seeds granulated on one side, triangular on the other.—Sent from the coast of Coromandel by Dr. Roxburgh. Koenig sent what appears certainly to be the same, in a younger state, to Linnæus by the name of *I. indica*, as found in ponds on a sandy soil, in December. In these latter specimens the root of each is a globose tuber. Fronde about six, erect, straight, slender, obscurely triangular, with a broad membranous base. Fructification too young to be discernible. Dr. Roxburgh's specimens consist of separate fronds, larger than the former, as being more advanced, but otherwise exactly similar, the base of each winged with a broad membrane, and lodging an elliptical, slightly compressed, membranous, brownish capsule, from above half an inch to near an inch long, of one cell, whose inside is lined with innumerable compressed membranous stalks, each bearing a beautiful white seed, convex and granulated below, triangular and smooth above. A spongy body, above the capsule, but, in our specimens, disjointed from it, is lodged in the substance of the leaf, and the same is indicated by the figure of the first species in Engl. Bot. in both male and female flowers, as well as by Linnæus in his *Iter Scanicum*. Having never had an opportunity of tracing the progress of the fructification, we are not certain whether this be the part called sometimes calyx, sometimes receptacle, but if so, the capsule is reversed. S.

ISOLA, in Geography, a town of Naples, in Calabria Ultra, the see of a bishop, suffragan of St. Severina, from which it is distant S.E. 15 miles. N. lat. 39 4'. E. long. 17° 24'.—Alfo, a town of Iliria, seated on an isthmus which extends far into the sea, the environs of which are celebrated for wine; 7 miles S. of Capo d'Iliria. N. lat. 45° 37'. E. long. 15° 40'.

ISOLA Alta, a town of Italy, in the department of the Mincio; 11 miles N.N.E. of Mantua.

ISOLA de Dovargis, a town of Italy, in the department of the Upper Po, on the Oglio; 12 miles N.E. of Cremona.

ISOLA Pocarizza, a town of Italy, in the department of the Mincio; 18 miles N.E. of Mantua.

ISOLA Grassa. See **GROSSA**.

ISOLA delle Femine, a small island near the W. coast of Sicily, which was formerly a place of banishment for women.

ISOLA Sacra, a small island at the mouth of the Tiber, near Ostia.

ISOLA delle Scala, a town of the Veronese; 13 miles S. of Verona.

ISOLACCIO, a town of the island of Corfica; 33 miles N. of Porto Vecchio.

ISOLEPIS, in *Botany*, from $\iota\sigma\lambda\epsilon\iota\varsigma$, equal or uniform, and $\lambda\epsilon\iota\varsigma$, a scale, a genus separated from *Scirpus* by Mr. Brown, in his *Prodr. Nov. Holl. v. 1. 221*, on seed, by which alone it is distinguished; a mark, if constant, certainly sufficient in so difficult a tribe. Twelve New Holland species are defined by this author, amongst which are *Scirpus fluitans*, *spinus*, *setaceus*, and *capillaris* of Linnæus; *nodosus* and *prolijer* of Rottboll; with six never before described.

ISOLETTA, in *Geography*, a town of Italy, in the department of the Mela; 15 miles S. of Brescia.

ISOMERIA, formed of $\iota\sigma\omega\varsigma$, equal, and $\mu\epsilon\tau\epsilon\iota\varsigma$, part, in *Algebra*, a method of freeing an equation from fractions, by reducing all the fractions to one common denominator, and then multiplying each member of the equation by that common denominator.

This amounts to the same with what is otherwise called conversion of equations. See *CONVERSION of Equations*.

ISONA, in *Geography*, a town of Spain, in Catalonia; 24 miles N. of Balaguer.

ISONEMA, in *Botany*, from $\iota\sigma\omega\varsigma$, equal, and $\nu\epsilon\mu\alpha$, a thread or flamen. Brown. Mem. of the Wernerian Society, v. 1. 63.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Contorta*, Linn. *Apocinea*, Brown.

Est. Ch. Corolla salver-shaped; its mouth and tube without scales; limb in five deep segments. Stamens prominent; filaments inserted into the mouth, simple at the top; anthers arrow-shaped, adhering to the stigma by their middle part. Germens two; style one, thread-shaped; stigma thick, obtuse. No scales beneath the germen. Pouches . . .

The above characters are taken from a shrub gathered on the African coast, near Sierra Leone, by Smeathman, and preserved in the Banksian herbarium. It is hairy, apparently erect, with opposite leaves. Panicle terminal, oppositely divided, corymbose. Leaves of the calyx with a double scale at their base on the inside. Tube of the corolla half an inch long, cylindrical, bearded in the middle within.

ISOPERIMETRY, in *Mathematics*, is a branch of the higher geometry, which treats of the properties of isoperimetric figures, viz. of surfaces contained under equal perimeters; of solids under equal surfaces; curves of equal lengths, &c. Of the foregoing heads, the two first may be considered as containing the elements of the science, which relate principally to the maxima et minima of different surfaces and solids, when bounded by figures of equal perimeters, but of a greater or less number of sides, and posited in a different order. The other part, which relates to the maxima et minima of curves, treats of problems of another kind, and of the most difficult nature which have engaged the attention, and exercised the talents, of many of the greatest mathematicians of modern times; as Newton, Leibnitz, the Bernouillis, Euler, Lagrange, &c. and gave rise to many warm and even rancorous disputes, particularly between the brothers John and James Bernouilli, which we shall mention more particularly in the subsequent part of this article, after having given a slight historical sketch and view of the more elementary parts of this interesting branch of mathematical inquiry.

The problems in which it is required to find, among figures of the same or different kinds, those which, within equal perimeters, shall comprehend the greatest surfaces, and those solids which, under equal surfaces, shall contain the greatest volume, had long engaged the attention of

mathematicians before the invention of fluxions, and different methods had been devised for the solution of them by Des Cartes, Fermat, Sluze, Hudde, and others; but these were all supplanted by the simplicity and generality of the new analysis; after which time the elements of the science seem to have been lost sight of by mathematicians, who were all engaged in the solution of the higher order of isoperimetric problems.

Simon was the first who condescended to treat of the more elementary parts of this science, by giving, in his *Geometry*, a very interesting chapter on the maxima and minima of geometrical quantities, and some of the simplest problems concerning isoperimeters. The next who treated the subject in an elementary manner was Simon L'Huilier of Geneva, who, in 1782, published his treatise "De Relatione mutua Capacitatis et Terminorum Figurarum," &c. His principal object in the composition of that work was to supply the deficiency in this respect, which he found in most of the elementary courses, and to determine, with regard to both the most usual surfaces and solids, those which possess the minimum of contour with the same capacity; and reciprocally, the maximum of capacity with the same boundary. Legendre has also considered the same subject, in his "Elémens de Géométrie;" Dr. Hutton, in his "Course of Mathematics;" and Dr. Horley, in the *Philosophical Transactions*, vol. lxxv. for 1775.

Elements of Isoperimetry.

PROPOSITION I.—Of all triangles that can be contained under any two given right lines, and any other line joining their extremities, that will be the greatest that has the two given lines perpendicular to each other. Fig. 1. *Isoperimetry. Plate IX. Geometry.*

Let AB and BD be the given lines, then will the triangle ABD, in which they are perpendicular to each other, be the greatest: for let BC = BD, and the angle ABC either greater or less than the right angle ABD; and let also CF be drawn parallel to AB, and meeting BD in F; and join AF, A C, A C'.

Then the $\angle BFC$ being a right angle, it is evident that BC, or BD, is greater than BF, and therefore the triangle ABD, being greater than the triangle ABF, is also greater than its equal ABC. Q. E. D.

The same may be otherwise demonstrated, thus:—Assume either of the two given sides for the base of the triangle; then the area being directly as the perpendicular let fall upon that side from the opposite extremity of the other given side, the surface will be the greatest when that perpendicular is the greatest, that is, when the other side is not inclined to that perpendicular, but coincides with it; hence the area is a maximum when the two given sides are perpendicular to each other. Q. E. D.

PROP. II.

Of all triangles of the same base, and whose vertices fall in a right line given in position, the one whose perimeter is a minimum, is that whose sides make equal angles with the given line. Fig. 2.

Let AB be the common base of a series of triangles; ABC, A BC', whose vertices C, C', fall in the right line LM, given in position; then is the triangle of least perimeter, that whose sides AC, BC, make equal angles with the line LM.

For, let BL be drawn from B perpendicular to LM, and produce it to D, till DM = BM, and join DA; and from the point C, where this line intersects LM,

ISOPERIMETRY.

draw CB ; and AB from any other points C', C'' , assumed in LM , draw $C'A, C'B, C'D$; then it is obvious, that $C'D, CD, C'D$, are respectively equal to $C'B, CB, C'B$, and therefore $AC' + C'B = AC' + C'D$, and $AC + CB = AC + CD = AD$; and consequently, from two sides of a triangle are greater than the third side, we have $AC' + C'D > AD$, or $(AC' + C'B) > (AC + CB)$; and the same is true of any other point C' in the line LM ; therefore $AC + CB$ is less than any other two lines that can be drawn from A, B , to meet in the line LM , and consequently $AB + AC + CB$ is the triangle, having the minimum perimeter, and it has its sides meeting LM at equal angles, as is evident, *Q. E. D.*

Cor.—Of all lines drawn from two given points, to meet in a line given in position, the sum of those two shall be the least, that make equal angles with the given line.

PROP. III.

Of all triangles having the same base, and the sum of the other two sides the same, the isosceles is the greatest. *Fig. 3.*

Let ACB be an isosceles triangle on the base AB , and ADB a triangle on the same base, having its two sides $AD + DB = AC + CB$; then will ABC be the greatest triangle.

First draw CH perpendicular to AB , and DEF parallel to AB , intersecting CH (produced if necessary) in the point E ; likewise let AE and BE be drawn.

Now it is evident, that the angles AEF and BED are equal, and consequently by *Prop. II.* $AE + EB$ is less than $AD + DB$, or less than the equal sum $AC + CB$; therefore the point E , and consequently the whole triangle AEB , must fall within the triangle ACB , and therefore the triangle AEB , or its equal ADB , is less than ACB . *Q. E. D.*

PROP. IV.

Of all triangles standing on the same base, and having the same vertical angle, the isosceles one is the greatest. *Fig. 4.*

For since all triangles whose bases and vertical angles are equal have their vertices in the same circular segment, it is obvious, that the isosceles triangle ABC is that which has the greatest perpendicular; and since triangles whose bases are given, are as their perpendiculars, it follows that the isosceles triangle, which has the greatest perpendicular, will also have the greatest surface. *Q. E. D.*

PROP. V.

Of all right lines that can be drawn through a given point, between two right lines given in position, but not parallel, that which is bisected by the given point forms, with the other two lines, the least triangle. *Fig. 5.*

Let AB, BC be any two lines given in position, and D the given point; then I say that the line EDF , which is bisected in the point D , makes with the two given lines AB, BC the least triangle. For if EI be drawn parallel to BC , meeting GH in I , the equi-angular triangles DFH , and DEI , will be equal, because $ED = FD$; and DFH will therefore be greater, or less, than DEG , according as BG is less, or greater, than BE ; in the latter case, let the space $DEBH$ be added to both, so shall FEB be less than GHB ; and if in the former case, $DGBF$ be added, then will HGB be greater than FEB ; and consequently FEB , in this case also, less than HGB . *Q. E. D.*

Cor.—If DM and DN be drawn parallel to BC and BA , the two equal triangles DEM and DFN , taken together (since $EM = DN = MB$), will be equal to the parallelogram $DMBN$; and therefore this parallelogram is equal to half the triangle FEB , but less than half the triangle BGH ; whence it follows, that a parallelogram is always less than half the triangle in which it is inscribed, except when the base of the one is half the base of the other, in which case the parallelogram is exactly equal to half the triangle, which is the maximum parallelogram that can be inscribed in any triangle.

Scholium.—From the preceding corollary it might be demonstrated, that the least triangle that can possibly be described about, and the greatest parallelogram that can be inscribed within, any curve, concave to its axis, will be when the subtangent is equal to half the base of the triangle, or to the whole base of the parallelogram.

PROP. VI.

Of all right-lined figures, contained under the same number of sides, and inscribed in the same circle, that is the greatest whose sides are all equal. *Fig. 6.*

For, if possible, let some polygon $ABCDEFG$, whose sides CE, FE , are unequal, be the greatest; and let CDF be an isosceles triangle, described in the same segment with $CEFG$ which, being greater than CEF by *Prop. IV.* the whole polygon $ABCDGF$ is greater than the polygon $ABCEFG$, whereas we have supposed the latter to be the greatest, which is absurd; therefore the polygon which has all its sides equal is the greatest. *Q. E. D.*

Cor. 1.—It follows, with reference to the same figure, that of all right-lined figures, contained under the same perimeter, and of the same number of sides, the greatest is that which has all its sides equal.

For if $ABCEFG$ be supposed the greatest, in which the sides CE and EF are unequal, then the triangle CEF would be greater than the triangle CDF , the sum of the sides in both cases being equal; but, since CDF is an isosceles triangle, it is greater than any other on the same base, and of equal perimeter, *Prop. III.*; therefore DC and DF must be equal, and the same may be demonstrated of any other two unequal sides.

Cor. 2.—Hence again it follows, that of all right-lined figures, contained under the same number of sides, and of equal perimeters, the greatest is that which may be inscribed in a circle: the figure being a regular polygon by the foregoing corollary.

PROP. VII.

Of all rectilinear figures, in which all the sides except one are given, the greatest is that which may be inscribed in a semicircle, whose diameter is that unknown side. *Fig. 7.*

For conceive $ABCDEFG$ to be a rectilinear figure, that is not inscribable in a semicircle, and draw any two lines AD, FD , from the extremities of the side AF , to any angle of the figure; then it is obvious, that the whole figure will be the greatest when the triangle ADF is the greatest, but this will be *Prop. I.* when ADF is a right angle, and in the same manner we find that ACF is a right angle, and so on; and consequently when the figure is inscribed in a semicircle, of which the unknown side is the diameter, its surface will be the greatest. *Q. E. D.*

PROP. VIII.

Of all figures, made with sides given in number and magnitude,

ISOPERIMETRY.

nitude, that which may be inscribed in a circle is the greatest. *Figs. 8. and 9.*

Let $ABCDE$, &c., and $abcde$, &c. be two polygons, of which the sides of the one are respectively equal to the sides of the other; that is, $AB = ab$, $BC = bc$, $CD = cd$, &c., the first of which is inscribed in a circle, but the other not inscribable; then I say, that the polygon $ABCDE$, &c. that is inscribed in a circle, is greater than the polygon $abcde$, &c. which is not so.

For draw the diameter EP ; join AP , BP ; and upon $ab = AB$ make the triangle apb equal in all respects to the triangle APB , and join ep . Then of the two figures $edcbp$, and $pagfe$, one at least is not by (hyp.) inscribable in a semicircle, of which ep is the diameter, consequently one at least of these two figures is smaller than the corresponding part of the figure $ABCDE$, &c.; and therefore the whole of this last figure $ABCDEF GP$ is greater than the other whole figure $abcdefgp$; and if from each of these there be taken away the equal triangles APB , and apb , there will remain the polygon $ABCDE$, &c. greater than the polygon $abcde$, &c. *Q. E. D.*

Cor.—The magnitude of the greatest polygon which can be contained under any number of unequal sides, does not at all depend upon the order in which those lines are connected with each other. For since in all cases it must be inscribable in a circle, it may always be divided into the same number of isofceles triangles, which will be respectively equal in all cases.

PROP. IX.

Of all polygons circumscribed about the same or equal circles, that has the greatest surface which has the greatest perimeter. For conceive radii to be drawn from the centre of the circle to each of the points of contact, then it is obvious that the area of the polygon will be equal to the rectangle of the radius into half the perimeter of the figure; therefore the area being as the perimeter, it follows that the polygon, having the greatest perimeter, will have the greatest area. *Q. E. D.*

Cor. 1.—Hence the area of any polygon circumscribed about a circle, is to the area of the circle, as the perimeter of the former is to the circumference of the latter. Also, the area of different polygons circumscribed about the same, or equal circles, are to each other as their perimeters.

Cor. 2.—If a circle and a polygon, circumscribable about another circle, are isoperimeters, they will be to each other as the radii of the circles.

PROP. X.

The circle is greater than any rectilinear figure of the same perimeter; and it has a perimeter less than any rectilinear figure of equal surface. *Figs. 10. and 11.*

Let the circle PQ , and the polygon $ABCDEF$, be isoperimeters; then I say that the circle is greater than the polygon.

For first, whatever may be the number of sides of the polygon, it will be the greatest under the same perimeter when the polygon is regular, *Cor. 1. Prop. VI.*; and consequently there may be a circle inscribed within it, the area of which circle will be evidently less than the area of the polygon, and therefore by *Cor. 1.* of the preceding proposition, the circumference of this circle will be less than the perimeter of the polygon, or less than that of the circle PQ ; and consequently, also, the radius of the former will be less than the radius of the latter. But by *Cor. 2. Prop. IX.* the area of the circle PQ , is to the area of the polygon, as the radius of the circle PQ is to the radius of the circle ab ; and there-

fore the area of the former is greater than the area of the latter; that is, a circle is greater than any right-lined figure of equal perimeter.

Again, conversely, if the arcs are equal, the circumference of the circles is less than the perimeters of the polygon.

For conceive a circle to be made whose circumference is equal to the perimeter of the polygon, then will the circle be greater than the polygon by what is prov'd above, and consequently greater than that circle which is equal to the polygon; and therefore its circumference will also be greater, that is, the perimeter of the polygon will always be greater than the circumference of a circle of equal surface. *Q. E. D.*

PROP. XI.

The greatest rectangle, that can be contained under the two parts of a line, any how divided, will be when the line is bisected.

Let AB be a line that is bisected in C , then will $AC \times CB$ be greater than $AD \times DB$, D being any other point in the line AB .

For $AC \times CB = AC^2$, but $AD \times DB = (AC - DC) \times (AC + DC) = AC^2 - DC^2$; consequently the first rectangle is the greatest. *Q. E. D.*

PROP. XII.

The greatest solid that can be contained, under the three parts of a given line, any way taken, will be that in which the three parts are equal to each other.

For supposing the point C fixed, then the rectangle of the two parts $AD \times DC$, will be the greatest when $AD = DC$ (by *Prop. XI.*). In the same way, if any other point be supposed fixed, as D , then will the rectangle $DC \times CB$ be the greatest when $DC = CB$, and consequently the solid $AD \times DC \times CB$ will be the greatest when these parts are all equal. *Q. E. D.*

Cor.—Hence of all parallelepipeds having the sum of their dimensions the same, the cube is that which has the greatest capacity.

PROP. XIII.

A line being divided into two parts, the solid that is contained under one of those parts, and the square of the other, will be the greatest when the latter part is double the former.

Let AB be divided into two parts in the point C , making $AC = 2CB$, then will $AC^2 \times CB$ be greater than when C is taken in any other part of the line AB .

For in whatever part of the line AB the point C be taken, the point A may be bisected in D , and then we shall have $AC^2 \times CB =$ four times $AD \times DC \times CB$, but this last is the greatest when $AD = DC = CB$ (*Prop. XII.*) therefore the former is the greatest when $AC = 2CB$. *Q. E. D.*

PROP. XIV.

Of all prisms of equal altitudes, and whose bases are also equal, and like, the right prism has the smallest surface.

For the area of each face of the prism is proportional to its height; and therefore the area of each face is the smallest when its height is the smallest, that is, when it is equal to the altitude of the prism, which is evidently when the prism is a right one. *Q. E. D.*

Cor.—And hence, conversely, of all prisms whose bases are equal and like, and whose lateral surface is the same, the right prism has the greatest altitude and capacity.

ISOPERIMETRY.

PROP. XV.

A cylinder has a less surface than any prism of equal base and altitude.

For since the bases and altitudes are equal by hypothesis, the surfaces will be greater or less, as the lateral surfaces are greater or less; but these will be as the perimeters of the solid bases, of which that of the cylinder will be the least, being a circle (by Prop. X.), and consequently the cylinder is that which has the least surface.

Cor. 1.—And again conversely, of all solids on equal bases, and whose surfaces are also equal, the cylinder is that which has the greatest capacity.

Cor. 2.—In the same manner (by Prop. VI. Cor. 1.) it may be demonstrated, that of all right prisms of the same altitude, and whose bases are equal, and of the same number of sides; that has the least surface whose base is a regular figure, and therefore when the prism is a paralleloiped the base is a square.

Cor. 3.—And again, of all right prisms, whose altitudes and surfaces are equal, and whose bases have a given number of sides, that which has a regular figure for its base is the greatest; and therefore when the prism is a paralleloiped the base is a square.

PROP. XVI.

Of all right paralleloipeds, given in magnitude, that which has the smallest surface has all its faces equal, or is a cube; and reciprocally of all paralleloipeds of equal surface, the greatest is a cube.

For by the foregoing corollaries, the right paralleloiped, having the smallest surface, with the same capacity, or the greatest capacity with the same surface has a square for its base: but any face whatever may be taken for the base: therefore in the paralleloiped, whose surface is the smallest with the same capacity, or whose capacity is the greatest with the same surface, has necessarily every two of its opposite faces squares, and consequently it is a cube. Q. E. D.

PROP. XVII.

Of all cylinders of the same capacity, that has the least surface whose altitude is equal to the diameter of its base. *Fig. 12. and 13.*

Let $ABCD$, and $abcd$, be two cylinders of equal capacity, and of which the first, $ABCD$, has its altitude equal to the diameter of its base, and the other any cylinder whose dimensions are not the same with the first, then I say the cylinder $ABCD$ has the least surface.

For conceive each of these cylinders to be circumscribed by a square prism, then will the capacities of these prisms be also equal; and their surfaces will be to each other as the surfaces of the cylinders that they circumscribe, as is evident from (Cor. 1. Prop. IX.); and therefore reciprocally, the surfaces of the cylinders will be to each other as the surfaces of the prisms: but since these prisms have equal capacities, that which circumscribes the cylinder $ABCD$ has the least surface, because it is a cube (Prop. XVI.); and consequently, the surface of that cylinder is the least also. Q. E. D.

Cor.—In a similar manner it is demonstrated, that of all cylinders of the same surface, that has the greatest solidity whose altitude is equal to the diameter of its base.

Iso-perimetrical Problems—We have before observed, that the theorems relating to the surfaces and solidities of bodies, of equal perimeters, might be considered as forming the elements of isoperimetry, and which, as we have seen, are de-

monstrable from the simple elements of geometry; while those relating to the *maxima et minima* of curves are of the highest order of problems; which have called into action the talents, and excited the passions, of some of the ablest geometers of modern times, having led to a dispute, which, for want of impartial and competent judges, remained undecided for many years, and which has since been termed “the war of problems,” on account of the great interest it excited, and the determined and able manner in which each party supported its opinion, and contended that of its opponent; and as this dispute cannot but be considered as one of the most memorable events in the history of the modern analysis, we shall present the reader with an abstract of it, so far as it relates to isoperimetry, referring him for further information to the “*Histoire des Mathematiques*,” by Montucla, vol. iii. p. 322, and to Bossut’s “*History of Mathematics*,” p. 331; and also to an interesting little treatise on this subject, lately published by Mr. Woodhouse of Caius college, Cambridge.

The first problem which can be said to relate to this class, was proposed by Newton in his “*Principia*,” which was that of the solid of least resistance. But the subject and doctrine did not become a matter of discussion and controversy, till John Bernoulli required of mathematicians the determination of the curve of quickest descent, in a paper published in the *Leipfic acts* for June 1696, under the following form:

PROBLEMA NOVUM

ad cuius solutionem mathematici invitantur.

“Datis in plano verticali duobus punctis A et B, assignare mobili M, viam A M B, per quam gravitate sua descendens, et moveri incipiens a puncto A, brevissimo tempore perveniat ad alterum punctum B.” *Fig. 14.*

At the first view of this problem, it would be imagined, that a right line, as it is the shortest path from one point to another, must likewise be the line of swiftest descent: but the attentive geometer will not hastily assert this, when he considers that in a concave curve described from one point to another, the moving body descends at first in a direction more approaching to a perpendicular, and consequently acquires a greater velocity than down an inclined plane; which greater velocity is to be set against the length of the path, which may cause the body to arrive at the point B sooner through the curve than down the plane. Metaphysics alone, therefore, cannot solve the question; in fact it requires the utmost accuracy of mathematical investigation and calculation, the result of which shews that the path required is a cycloid reversed, as we shall see in what follows, being at that time a new and remarkable property of this curve, which the researches of Huygens and Pascal had previously rendered so celebrated. See *CYCLOID*.

According to Bossut, Leibnitz resolved this problem the same day on which he received it, but that he and John Bernoulli agreed to keep back their solutions; but the fact of Leibnitz having obtained a correct solution seems to be very doubtful; at all events, at the expiration of six months, the time allowed, no solution was published, and the time was accordingly enlarged to one year, during which period the solutions of James Bernoulli, Newton, and the marquis de l’Hôpital appeared; Bernoulli’s and Newton’s were both given in the *Acta. Erud. Lipf.* for May 1697, but the latter without a name, the real author of which, however, mathematicians had little trouble in divining, for as John Bernoulli observed on this occasion, “*ex ungue leonem*.”

James Bernoulli, in the course of his investigations, had ascended to problems on isoperimetrical figures requiring still more profound speculations, and, after having resolved them

ISOPERIMETRY.

them, he proposed to mathematicians in general, at the conclusion of his solution of his brother's problem.

The rivalry in glory that had long divided the Bernouillis, was fully displayed on this occasion. At first it was a little moderated by their habits of seeing each other, at least occasionally, and by the intervention of their common friends; but John having been appointed professor of mathematics at Groningen in 1695, all private intercourse between them soon ceased, and they no longer corresponded except through the medium of periodical publications, for the purpose of proposing to each other the most difficult problems; and here it was that James Bernouilli, desirous of avenging himself of the ingratitude of his brother, to whom he had been preceptor, challenged him by name to answer the following problem.

Of all isoperimetrical curves described on the same common base BN , to find BFN , such that another curve, BZN , shall contain the greatest space; the ordinate of which, PZ , is in any multiple or submultiple ratio of the ordinate PF , or of the arc BF . Or, as we should say now, the ordinate of which, PZ , is any function of PF , or of the arc BF . Fig. 15.

To this leading proposition, he added another more analogous to that of the line of swiftest descent, which was to find among all the cycloids, which a heavy body may describe from a point to a line given in position, that cycloid which is described in the least possible time, which propositions he concluded in nearly the following words. "A person for whom I pledge myself (*Prodit NOX NEMO, pro qui caveo*) engages to give my brother, independently of the praise he will deserve, a prize of 50 florins, on condition that within three months, he engages to resolve these problems, and within a year publishes legitimate solutions of them." Adding, "if at the expiration of this time, no one shall have resolved them, I will make public my solutions."

These propositions, as we have before observed, were sent with the solution of the *brachystochrone* (a term by which John Bernouilli's problem was designated); and as soon as he had noticed the solutions to this, in doing which he bestowed great praise on that of Newton and de l'Hôpital, and some slight censure on his brother's, he undertook the solution of James's problems above-mentioned, and imagining that his theory of the line of swiftest descent was alone sufficient to solve them, the following expressions of ingenious vanity escaped him. "Difficult," says he, "as these problems appear, I did not fail to apply to them the instant they came to my hands, and hear with what success: instead of three months allowed me to found their depth, and the remainder of the year to find their solutions, I have employed only three minutes to examine, enter upon, and dive to the bottom of this mystery." These high sounding phrases were accompanied with the construction he gave of the problems, and the consequent demand of the prize, which he said he should give to the poor, as it cost him so little trouble to gain it. But the business was by no means so far advanced as he supposed, as his solution only answered for particular cases, in consequence of his having made only two elements of the curve enter therein, while the general solution required three; and he therefore thus laid himself open to the keen reproaches of his brother, who soon perceived in what respect the solution was defective, and being at the same time perfectly sure of his own, he published an advertisement in 1698, in which he asserted that his brother's method was defective. He still allowed geometers time to find the solution, and if no one gave it, he pledged himself for three

things; 1st. To divine with precision the analysis of his brother: 2^{dly}. Whatever it might be, to point out fallacies in it: and, 3^{dly}. To give the true solution of the problem in all its parts. Adding, at the same time, that if any person was sufficiently interested in the progress of science to venture a wager upon these articles, that he would engage to forfeit an equal sum if he failed in the first; double the sum if he did not succeed in the second; and triple the sum if he did not accomplish the third.

The singularity of this advertisement, and the reputation of the writer as a geometer, a little staggered John Bernouilli's confidence in his method. He revised his solution, allowed that he had made a trifling mistake, which he ascribed to too great precipitancy, and sent a new result, but without assuming a more modest tone, and again demanded the prize.

To these pretensions, James Bernouilli laconically answered, "I beg my brother to revise his last solution anew, to examine it carefully in every point, and then to let us know whether it be all right; as he must be aware, that no attention can be paid to his excuses of precipitancy after I have published my solution." But John Bernouilli, who was not aware of the radical defect of the method that he employed, felt an entire confidence in his last result, and said in reply there was no necessity to revise what he had done, and that his time would be much better spent in making new discoveries. To this confident assertion James ironically answered, "I never believed that my brother was master of the true solution of the isoperimetrical problem, and I doubt it now more than ever, from the difficulty he makes of the revision of his solution; if it cost him but three minutes, as he asserts, 'to examine, enter upon, and dive to the bottom of the whole mystery,' surely the revival could not require more: but suppose he spent double that time, how many new discoveries would he be robbed of by the six minutes thus employed."

To this John again replied, and the matter still remained undecided; till, in 1700, James Bernouilli printed at Basil a letter addressed to his brother, in which he invited him with great moderation to publish his method, and concluded by giving the formulae of the problem, but without their demonstrations. John soon perceived how far he differed from his brother, but not discovering the principle of the true solution, nor the defect of his own method, he at length gave it in a paper which was sent under a seal to the Academy of Sciences at Paris, in the month of February 1701, on condition that it should not be opened without his consent, and after his brother had published his analysis.

As soon as James Bernouilli was informed of this, he had no longer any reason to keep his solution a secret: he accordingly made it public, and maintained it by way of a thesis at Basil, in March 1701, with a dedication to the four illustrious mathematicians, de l'Hôpital, Leibnitz, Newton, and Fatio de Duillier. He likewise printed it separately under the following title: "Analysis magni problematis isoperimetrici." This was considered as a prodigy of sagacity and invention; and indeed, if the time be considered, it will not be too much to assert that a more difficult problem was never resolved. The marquis de l'Hôpital wrote to Leibnitz, that he had read it with avidity, and that he had found it very direct and accurate, which testimony Leibnitz transmitted to John Bernouilli himself, though he was much prejudiced in his favour, having himself before examined and approved of John Bernouilli's solution; the latter having submitted it to him for his opinion.

After this publication John Bernouilli maintained a perfect silence.

multiply this by \dot{p} , and since $\frac{\dot{p}}{x} = q$, we thus obtain

$$P \dot{p} = q \dot{Q} + c \dot{p};$$

and now substituting this value of $P \dot{p}$, in the general expression for \dot{V} , it becomes

$$\dot{V} = q \dot{Q} + Q \dot{q} + c \dot{p}$$

and by taking the fluents on both sides

$$V = Qq + c\rho + c';$$

c and c' being the corrections.

If M be not equal to 0, we must add the fluent of $M \dot{x}$; in which case

$$V = fM \dot{x} + Qq + c\rho + c'$$

Case 3.—If $M = 0$, but N is not = 0; that is if the form be

$$\dot{V} = N \dot{y} + \dot{p} \rho + \dot{Q} q;$$

then since $N = \frac{\dot{p}}{x} + \frac{\dot{Q}}{x^2} = 0$,

we have by multiplying by $\dot{y} = \rho \dot{x}$, (because $\rho = \frac{\dot{y}}{x}$)

$$N \dot{y} - \rho \dot{p} + \rho \frac{\dot{Q}}{x^2} \dot{x} = 0.$$

But $\rho \frac{\dot{Q}}{x^2} \dot{x} = \left(\rho \frac{\dot{Q}}{x}\right) - \dot{p} \frac{\dot{Q}}{x} = \left(\rho \frac{\dot{Q}}{x}\right) -$

$q \frac{\dot{Q}}{x} \dot{x}$, which last expression being substituted for $\rho \frac{\dot{Q}}{x^2} \dot{x}$,

gives $N \dot{y} = \rho \dot{p} - \left(\rho \frac{\dot{Q}}{x}\right) + q \frac{\dot{Q}}{x} \dot{x}$, whence

$$\dot{V} = \rho \dot{p} + P \dot{p} - \left(\rho \frac{\dot{Q}}{x}\right) + q \dot{Q} + Q \dot{q};$$

and taking the fluents

$$V = P\rho + Qq + \rho \frac{\dot{Q}}{x} + c,$$

c being the correction, as before.

We might continue thus to deduce from the general formula other particular ones, but the foregoing are sufficient for the solution of such problems as the limit of our article will admit of in this place, which, for the sake of a more ready reference, we will again repeat.

1. If the general form $\dot{V} = M \dot{x} + N \dot{y} + P \dot{p} + Q \dot{q}$ &c.

becomes $\dot{V} = N \dot{y} + P \dot{p}$

then we have $V = P\rho + c$ [a]

or $V = fM \dot{x} + P\rho + c$ [b]

when M is not equal to 0.

2. If the formula be $\dot{V} = P \dot{p} + Q \dot{q}$

then will $V = Qq + c\rho + c'$ [c]

or $V = fM \dot{x} + Qq + c\rho + c'$ [d]

when M is not equal to 0.

3. If the formula be $\dot{V} = N \dot{y} + P \dot{p} + Q \dot{q}$

then will $V = P\rho + Qq - \rho \frac{\dot{Q}}{x} + c$ [e]

To which we may also add the following,

4. If the formula be $\dot{V} = P \dot{p} + R r$,

then will

$$V = c\rho + Rr - q \frac{\dot{R}}{x} + c' \quad [f]$$

By means of which formulæ the following problems are readily solved.

PROBLEM I.

Required the relation of x and y , such that the fluent of $(ax - y)y \dot{x}$, or $f(ax - y)y \dot{x}$, shall be a maximum, or a minimum.

Comparing this expression with $fV \dot{x}$, (the analytical expression for the maximum or minimum property,) we see that $V = axy - y^2$, consequently $V = ay \dot{x} + (ax - 3y) \dot{y}$; which compared with the general formula,

$$\dot{V} = M \dot{x} + N \dot{y} + \dot{c}.$$

gives $M = ay$, and $N = ax - 3y^2$, $P = 0$, $Q = 0$, &c.

But since $N = \frac{P}{x} + \dot{c} = 0$, this becomes

$$ax - 3y^2 = 0, \text{ or } y = \sqrt{\frac{ax}{3}};$$

which is the relation of x and y required.

PROB. II.

Required the shortest curve that can be drawn between two points, or between two curves.

Here, if we take x to represent the curve, x the absciss, and y the ordinate, it will be necessary to fulfill the following condition, namely, that fz be a minimum.

Now by the doctrine of fluxions, $\dot{z} = \sqrt{x^2 + y^2} = \dot{x} \sqrt{1 + \frac{y^2}{x^2}} = \dot{x} \sqrt{1 + p^2}$; which being compared

with $fV \dot{x}$, gives $V = \sqrt{1 + p^2}$, whence by taking the

fluxions on both sides, it becomes $\dot{V} = \frac{p \dot{p}}{\sqrt{1 + p^2}}$; and

M, N , &c. all equal to 0. Therefore comparing this with

the general value of V , we have $P = \frac{\dot{p}}{\sqrt{1 + p^2}}$, and consequently from the formula [B] we have, — flux.

$\left(\frac{p}{\sqrt{1 + p^2}}\right) = 0$; therefore $p = a \sqrt{1 + p^2}$; and by squaring $p^2 = a^2 + a^2 p^2$, or $(a^2 - 1) p^2 = -a^2$, whence

$$p = \frac{\dot{y}}{x} = \frac{a}{\sqrt{1 - a^2}}; \text{ or } \dot{y} \sqrt{1 - a^2} = a \dot{x},$$

taking the fluents $y \sqrt{1 - a^2} = ax + c$, which is an equation to a right line, as it ought to be.

PROB. III.

Required the curve of quickest descent between two given points. Fig. 16. Plate Isoperimetry.

Let A and B be the two given points, and AMB the required curve; draw PM perpendicular to AC ; and put $AP = x$, $PM = y$, $AM = z$: then since the time will be reciprocally as the square root of the height, it will be

required to find $\int \frac{\dot{z}}{\sqrt{y}}$, a minimum, but $\dot{z} = \sqrt{\dot{x}^2 +$

\dot{y}^2} , whence $\int \frac{\sqrt{\dot{x}^2 + \dot{y}^2}}{\sqrt{y}} = \int \frac{\sqrt{1 + \frac{\dot{y}^2}{\dot{x}^2}}}{\sqrt{y}} \dot{x} =$

ISOPERIMETRY.

$\int \frac{\sqrt{(1+p^2)}}{\sqrt{y}} \dot{x}$, a minimum, which compared with the minimum expression $\int V \dot{x}$, gives $V = \frac{\sqrt{(1+p^2)}}{\sqrt{y}}$; whence

$$V = -\frac{\sqrt{(1+p^2)}}{2y^{\frac{3}{2}}} y + \frac{p \dot{p}}{\sqrt{y} \sqrt{(1+p^2)}}, \text{ which compared with formula [A], gives } M = 0; N = -\frac{\sqrt{(1+p^2)}}{2y^{\frac{3}{2}}}; P = \frac{p}{\sqrt{y} \sqrt{(1+p^2)}}; Q = 0, \&c.$$

Therefore, since by formula [a] $V = P p + c$; therefore in this case $\frac{\sqrt{(1+p^2)}}{\sqrt{y}} = \frac{p^2}{\sqrt{y} \sqrt{(1+p^2)}} + c$,

whence $\frac{1}{\sqrt{y} \sqrt{(1+p^2)}} = c$; or multiplying both numerator and denominator of this fraction by \dot{x} , it becomes $\frac{x}{\sqrt{y} \sqrt{(x^2+y^2)}} = c$, which is reducible to $\dot{x} = \frac{c \sqrt{y}}{\sqrt{(1-c^2 y)}} \cdot y$, an equation to a cycloid; which, therefore, is the curve required.

PROB. IV.

Required the curve which, by its revolution round its axis, generates the solid of least resistance. *Fig. 17.*

Let ABC be the required curve, which by its rotation generates the solid, DAC, of least resistance; draw PM perpendicular to AB; put AP = x , PM = y , and the arc AM = z : then we know from the principles of mechanics, that the resistance = $\int \frac{y^3}{x^2+y^2}$, which must therefore be a minimum. Now this being put under the form,

$$\int \frac{y^3}{1+\frac{y^2}{x^2}} \dot{x} = \int \frac{y^3}{1+p^2} \dot{x}, \text{ (because } p = \frac{y}{x} \text{)}$$

which being compared with the expression $\int V \dot{x}$, gives

$$V = \frac{y p^3}{1+p^2};$$

the fluxion of which expression being taken, gives

$$\dot{V} = \frac{p^3 y}{1+p^2} + \frac{(3y p^2 + y p^4) \dot{p}}{(1+p^2)^2};$$

whence $M = 0$; $N = \frac{p^3}{1+p^2}$; $P = \frac{3y p^2 + y p^4}{(1+p^2)^2}$.

Hence by the foregoing form [a], and using $-c$ for a correction, we have

$$\frac{y p^3}{1+p^2} = \frac{3y p^2 + y p^4}{(1+p^2)^2} - c,$$

which by reduction gives,

$$c(1+p^2)^2 = 2y p^3, \text{ and } y = \frac{c}{2p^3} + \frac{c}{p} + \frac{c p}{2};$$

but since $p = \frac{y}{x}$, or $p \dot{x} = y$, we obtain

$$\dot{x} = -\frac{3c}{2p^3} \dot{p} - \frac{c}{p^2} \dot{p} + \frac{c}{2p} \dot{p};$$

whence, $x = \frac{3c}{8p^4} + \frac{c}{2p^2} + \frac{c}{2} \text{ hyp. log. } p + d$;

by means of which equation, and that above, viz. $c(1+p^2)^2 = 2y p^3$, the relative values of x and y are determined.

PROB. V.

Required the brachyochrone, or curve of quickest descent, when the length of the curve is given.

This is an isoperimetrical problem of the second order: those which we have been considering have only one condition enters, namely the minimum; but in the present problem, beside the minimum property, the isoperimetrical also enters; and we have, therefore, to find the variation of $(V - au)$, instead of V . See Woodhouse's *Treatise on Isoperimetry*, p. 122.

Here by means of the comparison of $\int (V - au) \dot{x}$, with the minimum condition of the problem, we obtain

$$V = \frac{\sqrt{(1+p^2)}}{\sqrt{y}}, \text{ and } u = \sqrt{(1+p^2)};$$

therefore $V - au$, or $V' = \frac{\sqrt{(1+p^2)}}{\sqrt{y}} - a \sqrt{(1+p^2)}$, and consequently,

$$\dot{V}' = -\frac{1}{2y^{\frac{3}{2}}} \sqrt{(1+p^2)} y^{\frac{3}{2}} + \left(\frac{1}{\sqrt{y}} - a \right) \times \frac{p \dot{p}}{\sqrt{(1+p^2)}}$$

Hence we deduce, by comparing this with the general formula [A],

$$\begin{cases} N = -\frac{1}{2y^{\frac{3}{2}}} \sqrt{(1+p^2)} \\ P = \left(\frac{1}{\sqrt{y}} - a \right) \times \frac{p}{\sqrt{(1+p^2)}} \end{cases}$$

Hence again by formula [a],

$$\sqrt{(1+p^2)} \left(\frac{1}{\sqrt{y}} - a \right) = \frac{p^2}{\sqrt{(1+p^2)}} \left(\frac{1}{\sqrt{y}} - a \right) + c p$$

or, $\left(\frac{1}{\sqrt{y}} - a \right) = c \sqrt{(1+p^2)}$;

whence again by reduction,

$$\dot{x} = \frac{c \sqrt{y} y}{\sqrt{[1 - 2a \sqrt{y} + (a-c)y]}}$$

where, by taking the fluents, we have the relation between x and y , the absciss and ordinate of the curve.

If, instead of the length of the curve, the area had been given, then $\int u \dot{x} = \int y \dot{x}$, and consequently we should have,

$$V' = V - au = \frac{\sqrt{(1+p^2)}}{\sqrt{y}} - ay;$$

in which case,

$$P = \frac{p}{\sqrt{y} \sqrt{(1+p^2)}}$$

and $\frac{\sqrt{(1+p^2)}}{\sqrt{y}} - ay = \frac{p^2}{\sqrt{y} \sqrt{(1+p^2)}} + c$;

whence again,

$$\frac{1}{\sqrt{y} \sqrt{(1+p^2)}} = c + ay;$$

which by reduction becomes,

$$\dot{x} = \frac{(c + ay) \sqrt{1 + p^2}}{\sqrt{[1 - y(c + ay)]^2}};$$

which expression, when $c = 0$, becomes

$$\dot{x} = \frac{ay \sqrt{1 + p^2}}{\sqrt{1 - ay}};$$

whence the relative values of x and y are determined in both cases.

PROB. VI.

Required the solid of least resistance, amongst all the solids of equal capacity.

Here, the same as in Prob. IV., we have $V = \frac{y \rho^2}{1 + \rho^2}$,

and $f u \dot{x} = f \pi y^2 \dot{x}$, (π being equal 3.14159, &c.) (see Woodhouse's Isoperimetry, p. 123); therefore $V - au$

$$= V' = \frac{y \rho^2}{1 + \rho^2} - ay' \text{ (including } \pi \text{ in the quantity } a).$$

Hence $P = \frac{3y \rho^2 + y \rho^4}{(1 + \rho^2)^2}$, and by formula [C]

$$\frac{y \rho^2}{1 + \rho^2} - ay' = \frac{3y \rho^2 + y \rho^4}{(1 + \rho^2)^2} - c,$$

whence, by reduction, we obtain

$$\left\{ \begin{aligned} c - ay^3 (1 + \rho^2)^2 &= 2y \rho^4, \text{ or } \\ c - ay^2 dx^2 &= 2y \rho^4 \dot{x} \end{aligned} \right\}$$

which expressions will furnish the relative values of x and y .

If, in stead of the condition of equal capacity, that of equal superficies be substituted, we have

$$V - au = V' = \frac{3 \rho^2}{1 + \rho^2} - ay \sqrt{1 + \rho^2}, \text{ and}$$

$$P = \frac{3y \rho^2 + y \rho^4}{(1 + \rho^2)^2} - \frac{ay \rho}{\sqrt{1 + \rho^2}};$$

whence we deduce from formula [A]

$$\frac{y \rho^2}{1 + \rho^2} - ay \sqrt{1 + \rho^2} =$$

$$\frac{3y \rho^2 + y \rho^4}{(1 + \rho^2)^2} - \frac{ay \rho^2}{(1 + \rho^2)} - c,$$

wh, by reduction, becomes

$$\frac{y \rho^2}{(1 + \rho^2)^2} = 2y \rho + ay (1 + \rho^2)^{\frac{3}{2}}.$$

$$\text{or, } c \rho^2 = 2y^2 \dot{x} + ay \dot{x}^2 \dot{x}.$$

PROB. VII.

Given the length of a curve, to determine its nature, when the solid generated by its rotation is a maximum.

Make, as before, $\pi = 3.14159$, &c. we shall have

$$f V \dot{x} = f \pi y \dot{x}, \text{ and } f u \dot{x} = f \sqrt{1 + \rho^2} \dot{x}.$$

Therefore V' or $V - au = \pi y - a \sqrt{1 + \rho^2}$;

and taking the variation on both sides,

$$V' = 2\pi y - \frac{a \rho \dot{\rho}}{\sqrt{1 + \rho^2}};$$

comparing this expression with the general one [A],

we have $P = -\frac{a \rho}{\sqrt{1 + \rho^2}}$; and, therefore, by

formula [C]

PROB. VIII.

$$\pi y' - a \sqrt{1 + \rho^2} = c - \frac{a \rho^2}{\sqrt{1 + \rho^2}};$$

and therefore

$$\sqrt{1 + \rho^2} = \frac{a}{\pi y' - c};$$

which, by reduction, becomes

$$\rho, \text{ or } \frac{\dot{y}}{\dot{x}} = \frac{y \sqrt{a^2 - (\pi y' - c)^2}}{\pi y^2 - c}; \text{ or,}$$

$$\dot{x} = \frac{(\pi y' - c)}{\sqrt{[a^2 - (\pi y' - c)^2]}} y;$$

which, if $c = 0$, reduces to

$$\dot{x} = \frac{\pi y^2}{\sqrt{a^2 - \pi^2 y^2}} \dot{y}.$$

This last result agrees with Simpson's, but it is restricted, because c is not necessarily equal to 0.

PROB. VIII.

The length of a curve being given, it is required to determine its nature, when the area is a maximum.

Here, by proceeding as in the foregoing examples, we shall have

$$V' = \sqrt{1 + \rho^2} - ay',$$

and therefore,

$$P = \frac{\rho}{\sqrt{1 + \rho^2}};$$

and hence, by means of the formula [A],

$$\sqrt{1 + \rho^2} - ay = \frac{\rho^2}{\sqrt{1 + \rho^2}} + c$$

Therefore,

$$\frac{1}{\sqrt{1 + \rho^2}} = c + ay,$$

which, being further reduced, becomes

$$\rho = \frac{\dot{y}}{\dot{x}} = \frac{\sqrt{[1 - (c + ay)^2]}}{(c + ay)},$$

$$\text{or, } \dot{x} = \frac{(c + ay) \dot{y}}{\sqrt{[1 - (c + ay)^2]}}$$

the fluents of which being taken, we have

$$x = c' - \sqrt{[1 - (c + ay)^2]},$$

which is an equation to a circle.

PROB. IX.

Required the curve that generates the solid of the least surface, the area being given.

Here $V = 2\pi y \sqrt{1 + \rho^2}$, and $u = y$;

therefore V' , or $V - au = 2\pi y \sqrt{1 + \rho^2} - ay$,

and $V' = [2\pi \sqrt{1 + \rho^2} - a]$;

$$\text{whence, by comparison with formula [A],}$$

$$P = \frac{2\pi y \rho}{\sqrt{1 + \rho^2}};$$

then, again, by formula [A], we have

$$2\pi y \sqrt{1 + \rho^2} - ay = \frac{2\pi y \rho^2}{\sqrt{1 + \rho^2}} + c,$$

which, by reduction, becomes

$$\rho = \frac{\dot{y}}{\dot{x}} = \frac{y \sqrt{[4\pi y' - (c + ay)^2]}}{c + ay}, \text{ or,}$$

$$\dot{x} = \frac{(c + ay) \dot{y}}{\sqrt{[4\pi y^2 - (c + ay)^2]}}$$

If, instead of the area, the length of the curve had been given, then we should have had

$$f u \dot{x} = f \dot{z} = f x \sqrt{(1 + \rho^2)}; \text{ and } u = \sqrt{(1 + \rho^2)}.$$

Therefore $V' = 2\pi y \sqrt{(1 + \rho^2)} - a \sqrt{(1 + \rho^2)}$, and consequently, by formula $[\Delta]$,

$$P = \frac{2\pi y \rho - a \rho}{\sqrt{(1 + \rho^2)}};$$

whence, again, by formula $[\alpha]$, we have

$$(2\pi y - a) \sqrt{(1 + \rho^2)} = \frac{(2\pi y - a) \rho^2}{\sqrt{(1 + \rho^2)}} + c;$$

whence, by reduction,

$$\dot{x} = \frac{c \rho}{\sqrt{[(2\pi y - a)^2 - c^2] - \rho^2}}$$

the fluents of which expression being taken, gives

$$x = \frac{c}{2\pi} \text{hyp. log.}$$

$$[(2\pi y - a) + \sqrt{(2\pi y - a)^2 - c^2}] + c',$$

and therefore the required curve is the catenary.

PROB. X.

Of all isoperimetric curves, drawn between B and N, (fig. 15.) to find BFN such, that BZN shall contain the greatest area, PZ being a function of P F. See the foregoing historical sketch.

Let P F = y , and P Z a function of $y = Y$; then $f V \dot{x}$ corresponds to $f Y \dot{x}$; and $f u \dot{x}$ to $f \sqrt{(1 + \rho^2)} \dot{x}$.

Hence $V + a u$, or $V' = Y + a \sqrt{(1 + \rho^2)}$,

and $\dot{V} = \frac{Y \dot{y}}{y} + \frac{a \rho \dot{\rho}}{\sqrt{(1 + \rho^2)}};$

whence we have, by comparison of formula $[\Delta]$,

$$P = \frac{a \rho}{\sqrt{(1 + \rho^2)}};$$

and hence, again, by form $[\alpha]$ is deduced

$$Y + a \sqrt{(1 + \rho^2)} = \frac{a \rho^2}{\sqrt{(1 + \rho^2)}} + c,$$

or, $\frac{a}{\sqrt{(1 + \rho^2)}} = c - Y$, and by reduction

$$\rho = \frac{\dot{y}}{\dot{x}} = \frac{\sqrt{[a^2 - (c - Y)^2]}}{c - Y};$$

and consequently,

$$\dot{x} = \frac{(c - Y) \dot{y}}{\sqrt{[a^2 - (c - Y)^2]}}$$

the equation of the curve.

In the equation, as it stands, there are two arbitrary undetermined quantities a and c . The integration of the equation would introduce a third; and to determine these three, we have given the two points B and N, and the length of the curve.

ISOPOGON, in Botany, from ισο , equal, and πωγων , a beard, because the seeds are every where equally bearded.

Brown Tr. of Linn. Soc. v. 10. 71. Prodr. Nov. Hoff. v. 1. 365. Class and order, *Tetrandria Monogynia*. Nat. Ord. *Proteeae*.

Eff. Ch. Perianth (rather corolla) four-cleft, with a slender permanent tube. No scales under the germ-tube. Style entirely deciduous. Stigma tapering or cylindrical. Not sessile, swelling, hairy all over. *Drosera*.

Mr. Brown, in the places above quoted, defines 12 species of this genus, all natives of New Holland, such of which as have come under the notice of other botanists have been confounded with the Linnæan *Prot. a*. They are rigid shrubs, with smooth leaves, which are either flat or thread-shaped, divided or entire. Heads terminal, rarely axillary. *Flowers* either very densely imbricated in the form of a globe *Strobilus*, or fastigiate on a flattish common receptacle, furnished with more or less of an involucre, and beset with crowded deciduous scales.—Examples of this genus are

I. anethifolia. (Protea anethifolia; Salisb. Prodr. 48. P. acufera; Cavan. Ic. v. 6. 33. t. 549.)—Leaves once or twice pinnatifid, thread shaped, furrowed above; their segments nearly erect. Branches smooth. Tube of the flower downy; segments smooth, bearded at the tip.—Native of heathy ground on the east coast of New Holland, near Port Jackson.

I. anemonifolia. (Protea anemonifolia; Salisb. Prodr. 48. Sims in Curt. Mag. t. 697. Andr. Repol. t. 332. P. tri-dactylides; Cavan. Ic. v. 6. 33. t. 548.)—Leaves once or twice three-cleft; segments linear, flat, rather spreading, smooth beneath. Scales of the cone spongy.—Found on flowery heaths near Port Jackson. The *flowers* are yellow.

We confess this genus seems too nearly related to Mr. Brown's *Petrophila*, with which it agrees altogether in habit, differing chiefly in the fruit of *Petrophila* being only partially hairy. To this latter belongs *Protea palebella*, figured by Dr. Sims in Curt. Mag. t. 796.

ISOSEPHUS, ισοσέφης , in Antiquity, an appellation given to judges, who had equal jurisdiction and authority; it was likewise applied to a case where the votes were equal on both sides. Another sense is given to it, viz. when the letters of different words make up the same sum, they were said to be ισοσέφης *παιάνη*; for the Greeks had no other cyphers to number with but the letters of their alphabet; so that α signified one, β two, γ three, &c. But beside words, the ancients had likewise whole verses of this kind; and it is pretended that there are several such verses in Homer. Hist. Acad. Inscrip. vol. iii. p. 311, seq.

ISOPYRUM, in Botany, from ισο , equal or like, and πυρον , wheat, a name adopted from Dioscorides, whose ισοπυρον , however, is very difficult to ascertain. He describes it as having the leaf terminated by a tendril. Various plants have been taken for it by different botanists, amongst others, surely with little probability, the *Aquilegia*, or Columbine, which we mention here because it appears to have induced Linnæus to choose the name for the present genus, very much akin to *Aquilegia*, and still more distinguished for delicacy and elegance.—Linn. Gen. 282. Schreb. 378. Willd. Sp. Pl. v. 2. 1334. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. v. 2. 271. Salisb. Tr. of Linn. Soc. v. 8. 306. Juss. 233. Gært. t. 65.—Class and order, *Polyandria Polygynia*. Nat. Ord. *Multifloræ*, Linn. *Ranunculaceæ*, Juss.

Gen. Ch. *Cal.* none. *Cor.* Petals five, ovate, equal, spreading, deciduous. Nectaries five, equal, tubular, very short, inserted into the receptacle within the petals, three-lobed at their orifice, the outer lobe largest. *Stam.* Filaments numerous, capillary, shorter than the corolla; anthers simple.

simple. *Pist.* Germens several, ovate or oblong, superior, sessile, styles simple, scarcely so long as the germens; stigmas obtuse. *Peric.* Capsules several, sessile, leguminous, oblong, of one cell and one valve, keeled at the outside, bursting at the inner edge. *Seeds* numerous, attached in two rows to the edge of the capsule.

Fl. Ch. Calyx n-ve. Petals five, deciduous. Nectaries tubular, three-cleft. Capsules sessile, of one cell and one valve. Seeds numerous, marginal.

1. *I. fumarioides*. Linn. Sp. Pl. 783. (Helleborus fumariae Gills; Ammann. Ruth. 74. t. 12.)—Stipules awl-shaped. Leaflets pinnatifid. Capsules nearly cylindrical.—Native of moist shady places, near rivers, in Siberia, flowering in spring and summer. It is sometimes cultivated in gardens, as being not only curious, but an elegant little annual plant, with the habit and glaucous hue of a *Fumaria*, to several of which genus its leaves bear a great resemblance, in their pinnatifid obovate leaflets. The flowers, however, are totally different, resembling a *Thalictrum*, small, whitish, short-lived, on long simple stalks. Capsules about ten or fifteen, spreading, pale green, near half an inch long, pointed with the permanent styles.

2. *I. thalictroides*. Linn. Sp. Pl. 783. Jacq. Astr. t. 105.—Stipules ovate. Leaflets three-cleft, dilated. Capsules ovate.—Native of shady rather moist places, in the mountains of Italy, Carniola, Austria, &c. Flowering in April and May, and soon ripening its seed. Root creeping, perennial. Stem a span high or more, naked below, smooth. Leaves ternate, leaflets more or less three-cleft, broadish, smooth, resembling those of an *Aquilegia*, or *Thalictrum*. Flowers white, with yellow flames, not unlike some small *Anemone*. Capsules only two or three, ovate, on a globular receptacle.

Such are the only certain species. *I. aquilegioides* of Linnaeus appears to be a nonentity, its synonymy, as far as it can be made out, belonging to *Aquilegia viscosa*, which is Hiller's *Ipopyrum*, n. 1190.

Mr. Salisbury, in Tr. of Linn. Soc. v. 8. 305, has established, by the name of *Capsia*, a very natural genus, though distinguished from *Ipopyrum* chiefly by having stalked germens and capsules. Of this one species is *Helleborus trifidus* of Linnaeus, Fl. Dan. t. 566; the other is *C. affinis* of Salisbury, of which we have specimens and a drawing from Mr. Menzies, who gathered the plant on the west coast of North America. This last, strange to tell! appears, by specimens from Thunberg, to be his *Thalictrum japonicum*, Tr. of Linn. Soc. v. 2. 337, called in Fl. Jap. 364. *Didyanthis Salviae similis*, though nothing can be less suitable than the latter description. He informs us he had never seen the flower, only the fruit.

ISORA, a Malabar name for some species of the *Helleborus* of Linnaeus, and adopted by Plumier to designate that genus. See HELICTERES.

ISOSCELES TRIANGLE, of $\sigma\sigma\sigma$, $\epsilon\epsilon\epsilon$, and $\alpha\alpha\alpha$; $\epsilon\epsilon\epsilon$, is a triangle which has two equal sides. In an isosceles triangle, FDE *Plat.* VIII. *Geometry*, fig. 105, the angles γ and ν , opposite to the equal sides, are equal: and a line drawn from the top or vertex F, cutting the base into two equal parts, is perpendicular to the base. The same line also bisects the vertical angle of the triangle. It appears likewise that if the equal sides be produced, the angles under the base will be equal, the sum of those above and below respectively being equal to two right angles. And if the vertical angles of two isosceles triangles be equal, the two triangles will be equiangular. Moreover, every equilateral triangle must be equiangular.

ISOTONIC Scale of *Muscle*, or the Equal Temperament Scale, is that in which the octave is divided into twelve equal parts; of course, each half note is equal $1 \div 2^{1/2} = 51 \Sigma + f + 4 \frac{1}{2} m$, which is sometimes called a mean semitone, and thus, a system of mean semitones. The following table shews some of the most useful particulars of this system, *viz.*

	1	2	3	4
C	.6989700	.50000	612 Σ +	12 f + 53 m
B	.7249538	.52973	561 Σ +	11 f + 48 $\frac{1}{2} m$
b	.7491417	.56123	510 Σ +	10 f + 44 $\frac{1}{2} m$
A	.7742275	.57460	459 Σ +	9 f + 39 $\frac{1}{2} m$
♯G	.7993133	.61966	408 Σ +	8 f + 35 $\frac{1}{2} m$
G	.8243992	.66742	357 Σ +	7 f + 30 $\frac{1}{2} m$
♯F	.8494850	.70710	306 Σ +	6 f + 26 $\frac{1}{2} m$
F	.8745708	.74915	255 Σ +	5 f + 22 $\frac{1}{2} m$
E	.8996566	.79379	204 Σ +	4 f + 17 $\frac{1}{2} m$

D	.9498283	.89090	102 Σ +	2 f + 8 $\frac{1}{2} m$
♯C	.9749142	.94387	51 Σ +	f + 4 $\frac{1}{2} m$
C	.0000000	1.00000		
Notes.	Common Logarithms.	Lengths of Strings.	Farey's Notation of the Intervals.	

The last column of this table was published in the Philosophical Magazine, vol. xxix. p. 347; in the xxxviii. vol. p. 47, schol. 7, the temperaments of the concertos in this system will be found, and in vol. xxxv. p. 472, he beats of all the concertos. Broadwood and some other tuners of pianofortes pretend, it is said, that they tune them to an equal temperament, but which a very much to be doubted. On the organ, it seems clear, as Mr. Smyth observes in the Phil. Mag. vol. xxxvi. p. 435, that an equal temperament never has been, and we may perhaps say, never will be practised; however many advocates this system may have had among speculative writers, among whom have been mentioned D'Alembert, Cavallo, Chladni, Couperin, Davis, Des Cartes, Emerson, Marjurg, Merriell, Merlennus, Rameau, Ricci, &c. Mr. Farey, in proposing what he calls his equal temperament, in the Phil. Mag. vol. xxviii. p. 65, expressly stated his object to be, to enable those to tune it who might wish to try it, and not as recommending its adoption. See EQUAL TEMPERAMENT.

ISPAHAN, in *Geography*, the capital city of modern Persia, situated in the province of Irak, on the small river Zenderud, which rises in the mountains of Galabat, three days' journey towards the north; but Abas the Great, at a prodigious expence, pierced some mountains about 30 leagues from Ispahan, and introduced another stream, so that the Zenderud was as large during the spring, as the Seine at Paris in the winter; for, in that season, the snows on the high range of mountains melted, and very much swelled the river. The city is surrounded by walls of earth, which are suffered to remain in bad repair, and which are concealed by the adjoining houses and gardens. It has eight gates, which, according to Chardin, could not be shut; and its streets are narrow, devious, and badly paved. This writer computes its circuit, the suburbs included, at about 24 miles, and its inhabitants, by the lowest estimate, at 600,000. But the royal square, or Meidan Shab, and its grand market, the palace of the Sefi, and those of the grandees, the mosques, the public bath, and other edifices, are magnificent and splendid. It contains the plantations of lofty plane trees on

both sides of the fleets, and the frequent waterings of them, contribute not only to its beauty, but its salubrity. The royal square is 440 paces long, and 160 broad, and is surrounded with a canal built with bricks, cemented with black mortar, which in time becomes harder than free-stone. The royal mosque is situated at the S. end of this square, and its portico is richly ornamented with a thousand figures of a rich profusion of gold and azure; the whole being also inlaid with enamelled squares, and a frieze encompassing it of the same materials. The royal palace, and the "haram," or women's apartment, are very splendid buildings. The former is nearly five miles in compass; its great portico stands in the royal square, and is built to a great height with porphyry. By the Persians it is regarded as sacred. The suburb of Julfa, or Yulfa, was very large, and possessed by the Armenians, whose cemetery was near the mountains of Ispahan, called Kou Sofah, or a mountain in the form of a terrace, and also Tag Rustan, the hill or throne of Rustan. This city is said to be encompassed by 1460 villages, the inhabitants of which subsist chiefly by their manufactures of silk and wool. Its environs are pleasant, and much diversified by the vicinity of mountains. Ispahan was taken by Timur Bec in the year 1387; when the inhabitants razed their lives by the payment of a large sum; but an insurrection happening in the night, Timur ordered all the inhabitants to be put to the sword; and in this massacre it is computed that 70,000 persons were killed by the soldiers, and their heads piled in heaps on the walls of the city. In 1722, it was taken by the Afghans, under Mahmoud, after a long siege, which occasioned the death of many of its inhabitants by famine. In 1727 it was recovered from the Afghans by Nadir Shah. By these repeated attacks, Ispahan was greatly reduced, so that a Persian merchant assured Mr. Hanway that not above 5000 houses were inhabited. N. lat. 32° 24' 34". E. long. 51° 50'.

ISPIDA, or **KING-FISHER**, in *Ornithology*. See **ALCEDO**.

ISPIRA, in *Geography*, a town of Turkish Armenia; 74 miles N.E. of Erzerum.

IQUINTIA, a town of Mexico, in the province of Guatimala; 30 miles W.N.W. of Guatimala. N. lat. 14° 32'. W. long. 93°.

ISQUITENANGO, a town of Mexico, in the province of Yucatan; 60 miles S. of Chiapa dos Espagnols.

ISQUITEPIC, a town of Mexico, in the province of Guaxaca; 40 miles W.N.W. of Guaxaca.

ISRAEL, in *Scripture History*, Heb. יִשְׂרָאֵל, who prevails with God, formed of יִשְׂרָאֵל, *Israhel*, to govern, and אֱלֹהִים, God, a name given to the patriarch Jacob by the angel who wrestled with him at Mahanaim, or Penuel, Gen. xxxiii. 1, 2, 28, 29, 30. This name was afterwards applied to the descendants of Jacob in general, hence called Israelites, as well as to Jacob himself, and also to the ten tribes who formed a kingdom distinct from that of Judah. These tribes revolted during the reign of Rehoboam, under the conduct of Jeroboam, who became head of this new monarchy, styled "the kingdom of Israel" in opposition to that of Judah. See **Jews**.

ISSA, in *Ancient Geography*, a town of the island of Lesbos; more anciently called Himeria.—Also, an island of Illyria, in the Adriatic gulf, upon the coast of Dalmatia, with a town of the same name. Strabo mentions it as a very celebrated island.

ISSACHAR, one of the twelve tribes of Israel, derived from the fifth son of Jacob, whose lot was assigned to him in one of the best parts of the land of Canaan. It was situated in Lower Galilee, and bounded by the Mediter-

ranean on the W., by Zebulon on the N., by the Jordan on the E., which parted it from that of Gad, and on the S. by the half-tribe of Manasseh. Its most remarkable places were mounts Carmel and Gilboah, the valley of Jezreel, and the great plain of Megiddo, called also the plain of Galilee, and now Saba, from a castle built upon it, and famed, like that of Jezreel, for the many battles fought upon it, and also for the abundance of corn, wine, oil, &c. which it produced.

ISSAGUNGE, in *Geography*, a town of Hindoostan, in Oude; 35 miles N.E. of Kairabad.

ISSAPOUR, a town of Hindoostan, in Oude; 25 miles N.E. of Lucknow.

ISSAWARRA, a town of Hindoostan, in Oude; 15 miles S.E. of Kairabad.

ISSE HEAD, a cape of Denmark, at the northern extremity of the island of Samsoe. N. lat. 56° 3'. E. long. 10° 29'.

ISSEDON, or **ESSEDON**, in *Ancient Geography*, a town of Scythia, on the other side of the Imaus.—Also, a town of Serica, situated E.N.E. of the former.

ISSEDONES, or **ESSEDONES**, a people of Serica according to Ptolemy; but Pomponius Mela places them in the vicinity of the Palus-Meotides; Pliny joins them to the Sauromatae, and assigns them an habitation near the Colchide. Herodotus speaks of Issidones as neighbours to the Massagetæ, as a numerous people, and living to the W. of the Caspian sea. Herodotus, who speaks of the customs and religion of the Issidones (l. iv.), says, that when any one of them has lost his father, all his relations bring him a number of cattle, whose carcases they cut in pieces, and in the same manner cutting the body of the deceased father, they mix all the pieces of flesh together, and serve them up at an entertainment, reserving only the head of the deceased parent, which they set in gold, and use as an idol, to which they every year offer solemn sacrifices.

ISSELBURG, in *Geography*, a town of the duchy of Cleves, on the Issel, containing a Lutheran and Calvinist church; 14 miles E.N.E. of Cleves. N. lat. 51° 58'. E. long. 6° 35'.

ISSELMOND, an island in the river Meuse, opposite to Rotterdam, with a town in it of the same name.

ISSELORT, a town of Holland, in Guelderland, situated at the separation of the Rhine and Issel near Arnhem.

ISSELSTEIN, a town of Holland, belonging to the state of Utrecht, and seated on the river Issel; it is the capital of a small territory formerly belonging to William III. king of England; five miles S. of Utrecht.

ISSENBRON, a town of Bavaria, in the principality of Aichflatt; six miles E.N.E. of Aichflatt.

ISSER, a river of Algiers, which joins the Tafna, near its mouth; anciently called "Alflanus."

ISSESUCAR, a town on the S. coast of the island of Java; 70 miles S.W. of Batavia.

ISSICUS SINUS, in *Ancient Geography*, a gulf of the Mediterranean sea, between Syria and Cilicia.

ISSIGEAC, in *Geography*, a town of France, in the department of the Dordogne, and chief place of a canton, in the district of Bergerac; nine miles S.S.E. of Bergerac. The place contains 879, and the canton 8316 inhabitants, on a territory of 210 kilometres, or 21 communes.

ISSIN, a town of Persia, in the province of Kernan, whither many of the inhabitants of Gomron retreat during the unhealthy season; six miles N. of Gomron.

ISSINI, a kingdom of Africa, on the Ivory Coast, consisting of 12 or 13 villages. From the Rio de Suero da

Coila to cape Apollonia, the coast is low and even, extending itself for a course of 12 miles eastward, bordered with large trees, and covered with villages, the chief of which are Boquin, Iffini Peguena, Great Iffini, Albiani, Tabo, and Akanimina. The first stands at a small distance from the shore, near the mouth of the river Da Coila, surrounded by woods and pleasantly situated. Iffini Peguena, and Great Iffini, are both situated on the sea-coast, at the distance of three or four miles, and between them is a number of villages. Three of them are considerable. Great Iffini is built at the entrance of a small river, which, during the dry season, is lost in the sands, but discharges itself into the sea during the rainy months. This town was pillaged and burnt by the inland Negroes in 1581; but has since recovered its importance by the addition of a great number of houses and inhabitants. Where the river empties itself into the sea, it forms a small island, very commodious for building a fort; but no such defence has been attempted by the Europeans. Great Iffini is celebrated for the purity of its gold, which probably comes from the kingdom of Assento, at the source of the Rio de Suero da Coila, a country rich in gold, but little known to the Europeans. East of Iffini are the little districts and towns of Albiani and Tabo, the former six miles and the latter ten from it, both surrounded by high groves of palms, seen at a great distance at sea, and much frequented by European shipping. A mile further east, and half a mile west of cape Apollonia, stands the village Akanimina, on a rising ground; commanding an extensive sea and land prospect. The interior country between Boquin and this village, is high, rugged, and mountainous, but affording some fine gold, ivory, and formerly a few slaves. The gold dust of these two places is commonly found at the depth of six fathoms, for two miles along the coast; and the Negroes mix it with pulverized copper so expertly, that it requires touching to discover the fraud.

ISSOIRE, a town of France, and principal place of a district, in the department of the Puy de Dôme, seated on the Couze, near the Allier; 15 miles S.W. of Clermont. The place contains 5097, and the canton 14,696 inhabitants, on a territory of 155 kilometres, in 15 communes. N. lat. 45° 32'. E. long. 3° 10'.

ISSONG, in *Botany*, a name given by the people of Guinea to a species of plant, which they infuse in water, and afterwards boil, and then wash the head with it, as a cure for all kinds of the head-ach. It is a plant described by the botanical writers under the name of *pisum vesicarium fructu nigro, alba macula notato*, the bladder pea, with a black fruit marked with a white spot; and called by the people of Malabar, where it also grows very plentifully, *ulinga*. It is also found in Barbadoes and Jamaica, and is there called *parley*. Phil. Trans. N. 232.

ISSOUDUN, in *Geography*, a town of France, and principal place of a district, in the department of the Indre, on the Theols; 18 miles N.E. of Chateauroux. The place contains 10,156, and the two cantons into which it is divided 23,207 inhabitants, on a territory of 662½ kilometres, in 27 communes. This place has considerable manufactures. N. lat. 46° 56' 9". E. long. 1° 59' 12".

ISSUABLE TERMS, in *Law*, a name applied to Hilary or Trinity terms, from the making up of the issues in those terms.

ISSUANT, ISSUING, in *Heraldry*, is understood of a lion, or other animal, in a coat of arms, that seems just coming out from under a chief, fesse, a house, a wood, or the like; and only shews half his body.

It is not very easy to distinguish the lion issuant from the

lion naissant: some say the issuant is that which comes out from the bottom of the chief, showing his head, neck, the tip of his fore-legs and his tail, against the chief of the coat; whereas the naissant has its rife about the middle of the field, and shews all his fore-part, with the tip of his tail, as if he were rising out of the earth.

ISSUE, in *Common Law*, has divers applications, being sometimes taken for the children begotten between a man and his wife—sometimes for profits growing from imbecilements or fines—sometimes for profits of lands and tenements—but more frequently for the point of matter depending in suit, whereupon the parties join, and put their cause to the trial of the jury.

On all these occasions, issue has but one signification, which is, an effect of a cause preceding: as the children are the effect of the marriage between the parents; the profits growing to the king or lord, from the punishment of any man's offence, are the effect of his transgression; the point referred to the trial of twelve men, is the effect of pleading or process.

Issues concerning causes are of two kinds; that upon matter of fact, and that upon matter of law. An issue in *fact* is when the plaintiff and defendant have agreed upon a point to be tried by a jury; and issue in *law* is when there is a demurrer to a declaration, plea, &c. and a joinder in demurrer, which is an issue at law to be determined by the judge. (See DEMURRER.) Issues in *fact* are either *general* or *special*. *General* seems to be that whereby it is referred to the jury to bring in their verdict, whether or no the defendant hath done any such thing as the plaintiff lays to his charge.

For example, if it be an offence against any statute, and the defendant plead not guilty; this being put to the jury, is called the *general issue*—So, if a man complains of a private wrong, which the defendant denies, and pleads not wrong, nor diffin; and this is referred to the jury; it is likewise the general issue. *Special*, is that, wherein special matters being alleged by the defendant in his defence, both parties join on this point, and so go to a demurrer, if it be *questio juris*; or else to a trial by the jury, if it be *questio facti*: as in assault and battery, where the defendant pleads that the plaintiff struck first.

ISSUE, *Collateral*. See REPRIEVE.

ISSUE, *Feigned*, in *Chancery*, is used when a matter of fact is strongly controverted, and the court directs the matter to be tried by a jury: but as no jury can be summoned to attend this court, the fact is usually directed to be tried at the bar of the court of king's bench, or at the assizes upon a feigned issue. For, in order to bring it there, and lay the point in dispute, and that only, put in issue, an action is brought, wherein the plaintiff, by a fiction, declares that he laid a wager of 5*l.* with the defendant, that A was born at law to B, and then avers that he is so, and therefore demands the 5*l.* The defendant allows the feigned wager, but avers that A is not the heir to B: and thereupon that issue is joined, which is directed out of chancery to be tried, and that the verdict of the jurors at law determines the fact in the court of equity. These feigned issues seem to be borrowed from the *spora judicialia* of the Romans; and are also frequently used in the courts of law, by consent of the parties, to determine some disputed right without the formality of pleading, and thereby to save much time and expence in the decision of a cause. Blackk. Com. book iii. p. 452.

ISSUES on *Shewings* are for neglects and defaults, by agreement and fine to the king, levied out of the issues and profits of their lands; and double or treble issues may be had on a shew

a sheriff for not returning writs, &c. But they must be taken off before they are eiltreated into the exchequer, by rule of court, on good reason shewn. Issues shall be levied on jurors, for non-appearance; though on reasonable excuse proved by two witnesses, the justices may discharge the issue. See DISTRESS, DISTINGUIS, and PROCESS.

ISSE denotes, in *Surgery*, an ulcer made designedly by the practitioner, and kept open a certain time, or even the patient's whole life, for the cure or prevention of a variety of diseases. The physician, in his practice, has frequent occasion to recommend the making of an issue, and the surgeon finds it a principal means of relief in several important cases; as, for instance, the white-swellings, the disease of the hip-joint, caries of the vertebrae, &c. Many persons are never in health, or at least fancy themselves always ill, unless they have an issue in some part of their body or another. Making an issue, indeed, is not unfrequently considered as an imitation of nature, who, of her own accord, often forms ulcers in various parts of the body (as is not uncommonly conjectured) for the purpose of discharging pernicious humours, whereby people are supposed to be freed from grievous disorders, and have their health preserved. The humoral pathologists were excessively partial to these notions, which, at the present time, will be found by every experienced practitioner to influence the mass of mankind, and render the formation of issues more common than perhaps is consistent with the better established principles of medical science. Few old subjects will allow a sore of long standing to be dried up, (as the expression is,) without requiring the surgeon immediately afterwards to make an issue for them. When an ulcer has existed a great length of time, the constitution may possibly become so habituated to it, that the health may really suffer from its being healed. We have often seen asthmatic complaints, and severe head-aches follow the cicatrization of an old ulcer; but whether they would have happened, if an issue had been made in time, we cannot undertake to determine positively, though the plan is commendable both as rational and exempt from danger. Whatever may be the felicity of the theories which have been offered by medical writers in regard to issues, the practitioner, who has his eyes open, cannot fail to see the benefit often derived from such means; and if there be any unquestionable facts in medicine and surgery, we may confidently set down amongst them the frequent possibility of relieving one disease by exciting another of a less grievous and more curable nature.

Surgeons of the present day have only two ways of making an issue; one is with a lancet, or scalpel; the other with caustic.

The place for the issue being fixed upon, the surgeon and his assistant are to pinch up a fold of the integuments, and with a lancet, or knife, make in them an incision of sufficient size to hold a pea, or as many peas as may be thought proper. The pea or peas are then to be placed in the cut, and covered with a piece of adhesive plaster, a compress and bandage. The peas first inserted need not be renewed for three or four days, when suppuration will have begun; but the issue is afterwards to be cleaned and dressed every day, and have fresh peas put into it. The preceding is the ordinary method of making such issues as are intended to contain only one or two peas.

When the issue is to be larger, which is generally proper in cases of diseased vertebrae, white-swellings, &c. the best plan is to destroy a portion of the integuments with caustic. The kali purum, blended with quicklime, is mostly preferred for this purpose. The situation and size of the issue

having been determined, the surgeon is to take care that the caustic does not extend its action to the surrounding parts. With this view he is to take a piece of adhesive plaster, and having cut a hole in it of the exact shape and size of the issue intended to be made, he is to apply it to the part. Thus the plaster will defend the adjacent skin from the effects of the caustic, while the uncovered portion of integuments, corresponding to the hole in the plaster, is that which is to be destroyed. The caustic is to be taken hold of with a bit of lint or tow, and its end, having been a little moistened with water, is to be steadily rubbed upon the part of the skin where the issue is to be formed. The frictions are to be continued, till the whole surface intended to be destroyed assumes a darkish corroded appearance. The caustic matter may now be carefully washed off with some wet tow. The plaster is to be removed, and a linseed poultice applied. As soon as the eschar is detached, or any part of it is loose enough to be cut away without pain or bleeding, the peas are to be inserted and confined in their proper place with a piece of adhesive plaster. Some use beans for the purpose; others beads, which answer very well, and have the advantage of serving for any length of time, when washed and cleaned every day. If the issue is at all of a longitudinal shape, the peas, beans, or beads may be more easily kept in their places when frang upon a thread.

Issues ought always to be made, if possible, in a situation where the peas will not be much disturbed in the ordinary motions of the body, nor interfere with the actions of the muscles. The interspaces between the margins and insertions of muscles are deemed the most eligible places. Thus, issues in the arm are usually made just at the inferior angle of the deltoid muscle, by the side of the external edge of the biceps. In the lower extremities issues are often made at the inner side of the thigh, immediately above the knee, in a cavity readily felt there with the fingers. Sometimes issues are made upon the inside of the leg, just below the knee. The nape of the neck is a common place for them. In caries of the vertebrae they are made on each side of the spinous processes. In diseased hips they are formed in a depression just behind and below the trochanter major. When the nature of the case does not fix the situation of an issue particularly, the arm should be preferred to the leg, as issues upon the upper extremity, especially the left arm, are much less annoying than upon either of the lower limbs.

The great art of keeping an issue open for a long while, is always to maintain an equal and effectual pressure upon the peas, by which means they will be confined in their places, and the granulations hindered from rising. Compresses of paste-board and sheet lead will often be found highly serviceable.

IS-SUR-TILLE, in *Geography*, a town of France, in the department of the Côte d'Or, and chief place of a canton, in the district of Dijon; 4 miles N. of Dijon. The place contains 1598, and the canton 10,170 inhabitants, on a territory of 355 kilometres, in 23 communes. N. lat. 47 3'. E. long 5 9'.

ISSUS, in *Ancient Geography*, a town of Asia, in Cilicia, situated on the sea coast. This town was large, rich, and populous. It is famous for the battle fought by Alexander in the year 333 B.C. in which, he defeated the Persians, and took as prisoners the wife, mother, and daughters of Darius.

ISSY L'ÉVÊQUE, in *Geography*, a town of France, in the department of the Saône and Loire, and chief place of a canton.

a canton, in the district of Antun. 19 miles S.S.W. of Antun. The place contains 1715, and the canton 5349 inhabitants, on a territory of 220 kilometres, in 7 communes.

ISTAD, *Str.* a small island in the Grecian Archipelago, near the S.E. coast of Argenticra.

ISTAKAR, a town of Persia, in the province of *Farsistan* (which see), at a small distance N. of Shiraz.

ISTAN, a town of Spain, in the province of Grenada; 6 miles S.E. of Mondá.

ISTANNA, a country of Africa, E. of Benin.

ISTAPPA, a town of Mexico, in the province of Culiacan; 40 miles E. of Culiacan.

ISTAPAN, a town of Mexico, in the province of Guadaluajara; 15 miles N.E. of St. Miguel.

ISTECHIA, a town of the Morea, in the gulf of Coron; 7 miles S. of Scardamula.

ISTEFAN, a town of Asiatic Turkey, in the province of Natolia; 20 miles N. of Sinob.

ISTENAZ, a town of Asiatic Turkey, in the province of Caramania; 18 miles W. of Satalia.

ISTEPEC, a town of Mexico, in the province of Guatimala; 12 miles N. of St. Salvador.

ISTER, in *Ancient Geography*, the name which the Greeks gave to the river which we call the *Danube*; which see.

ISTESSO, L'ISTESSO, *Ital.* in *Music*, the same sound, air, or interval. Domenico Scarlatti, in Roseingrave's edition of his first book of Lessons, has *l'istesso differente* for the same air, varied; and Padre Martini, for exactly the same thing, has *istesso, stessissimo*.

ISTHEVONES, or ISTEVONES, in *Ancient Geography*, a people of Germany, who, according to Pliny (l. iv. c. 14.), were situated near the Rhine, and of whom the Cimbric, in the interior of the country, formed a part.

ISTHMA, *Græc.* or ISTHMIAN GAMES, *Lat.* *Isthmii*, were solemn sports, being one of the four sacred games celebrated in ancient Greece.

They were called *Isthmian*, because they were celebrated in the Corinthian isthmus, a neck of land by which Peloponnesus is joined to the continent.

Plutarch, in the life of Theseus, tells us they were instituted by that hero to the honour of Neptune, in imitation of Hercules, who had before instituted the Olympic games to the honour of Jupiter; but Archias refers their institution to the honour of Melicertes, or Palæmon, son of Athamas, king of Thebes, whom the Latins call Portunus. Others say they were instituted by Niüs, son of Neptune; and others, by Sisyphus, brother of Athamas, king of Corinth, about 1326 years B.C. Others are of opinion that there were two distinct solemnities observed in the Isthmus, one in honour of Melicertes, and another in honour of Neptune.

The most probable account of the origin and subsequent renewal of these games, allowing, as it may perhaps be necessary, for some mixture of fable, is as follows: Athamas, king of the Orchomenians, a people of Bœotia, having divorced his former wife, named Nephele, by whom he had two sons, Phryxus and Hellê, and having married Ioo, by whom he had also two sons, Learchus and Melicertes, or Melicerta; the latter persecuted the children of the former marriage, so far as to make her husband believe that the oracle of Delphos demanded the blood of Phryxus, as the means of putting a stop to the famine of which the ver-

self was the cause; and the too credulous Athamas was upon the point of sacrificing his son to the safety of his subjects; but upon information of his wife's whole management, he flew her son Learchus, and pursued Ioo with such eagerness, that she was found to throw herself down with Melicerta, whom she held in her arms, from the top of the rock Moluria, into the sea. A dolphin, we are told, or rather the waves, carried Melicerta into the isthmus of Corinth; and the Corinthians, at the persuasion of Sisyphus, the brother of Athamas, after having given him a splendid funeral, instituted to his honour games, which obtained the name of Isthmian, from the place where they were celebrated for the first time. These games, in which were exhibited the same trials of skill as in the others, and chiefly those of music and poetry (see GAMES), having been interrupted, probably by some wars, were afterwards re-established by Theseus (1234 B.C.), who consecrated them to Neptune, whose son he pretended to be, as to the god who peculiarly presided over the isthmus of Corinth; and they were renewed so regularly every five years, about the middle of the month Hecatombion, that they were not even discontinued after the city of Corinth had been destroyed and reduced to ashes by Mummies (146 B.C.); the Sicyonians having received orders to celebrate them, notwithstanding the public grief and desolation. When the city was afterwards rebuilt, the new inhabitants resumed the care of these games, and continued to exhibit them with great regularity. Some time after, the Romans were admitted to them, and celebrated them with so much pomp and apparatus, that besides the ordinary exercises, a hunting match was there exhibited, in which were presented the most rare animals; the city of Corinth neglecting no means by which they might please their conquerors: and their fame was still increased, because they served as an era to the Corinthians, and inhabitants of the isthmus.

Archias and others say, the conqueror's prize at these games was a crown of parsley. Plutarch and Strabo say it was at first a crown of pine; and that this was afterwards changed for one of parsley; but that at length the pine was resumed; and to this was added a reward of 100 silver drachmæ, or about 3l. 4s. 7d. sterling.

These games were held, according to Pindar, every three years, or, according to Pliny, every five; and were to be celebrated, and the concourse at them was so great, that only the prime persons of the most remarkable cities could have places in them. The Athenians had only as much room allotted them as the sail of a ship, which they sent yearly to Delos, could cover.

ISTHMUS, *Græc.* in *Geography*, a narrow neck, or slip of ground, which joins two continents; or joins a peninsula to the terra firma, and separates two seas.

The most celebrated isthmuses are that of Panama or Darien, which joins North and South America; that of Suez, which connects Asia and Africa; that of Corinth, or Peloponnesus, in the Morea; that of Crim-Tartary, or otherwise called Taurica Cherfonesus; that of the peninsula Romania and Eriso, or the isthmus of the Thracian Cherfonesus, twelve furlongs broad, being that which Xerxes undertook to cut through. The ancients had several designs of cutting the isthmus of Corinth, which is a rocky hillock, about ten miles over; but they were all vain, the invention of sluices not being then known. There have been attempts, too, for cutting the isthmus of Suez, to make a communication between the Red sea and the Mediterranean.

ISTHMUS is also applied, by the anatomists, to several parts of the human body, particularly that narrow part of the throat situate betwixt the two tonsils.

Also to the ridge that separates the two nostrils; and to the passage in that part of the medulla oblongata of the brain which lies between the cerebrum and cerebellum, and which reaches from the place called *anus* to the fourth ventricle. The upper part or cover of this conduit, or passage, which is betwixt the testes and the foremost vermicular process of the cerebellum, and to which two it is tied at its two ends, and to the processes which come from the cerebellum to the testes at its sides, is called *valvula pectoris*; it is of a medullary substance, and its use is to keep the lymph from falling out above the nerves in the basis of the skull.

ISTIATZKA, in *Geography*, a town of Russia, in the government of Tobolsk, on the Vagai; 68 miles S. of Tobolsk.

ISTHÆ, in *Ancient Geography*, a town of the island of Eubœa; situated in the northern part of the island upon a mountain, nearly opposite to the Pelægic gulf, which belonged to Thebæly. It was anciently called Oros, from its situation, *oros* being a mountain. Its original inhabitants were driven from it by Pericles, and retired to the Egeiote, an interior country of Thebæly; and their place was occupied by a colony of Athenians, of the tribe Hæctia. It is now called Ori, or Oro.

ISTIB, in *Geography*, a town of European Turkey, in Macedonia; 72 miles N. of Saloniki. N. lat. 41 50'. E. long. 22 48'.

ISTILLAR, a town of European Turkey, in Macedonia; 56 miles S.E. of Saloniki.

ISTIZER, a town of Russia, in the government of Tobolsk; 24 miles E.S.E. of Tobolsk.

ISTLAN, a town of Mexico, in the province of Mexico; 60 miles N.W. of Mexico.

ISTRE, a town of France, in the department of the mouth of the Rhone, and chief place of a canton, in the district of Aix; 18 miles S.E. of Arles. The place contains 2111, and the canton 5922 inhabitants, on a territory of 34 1/2 kilometres, in 4 communes.

ISTRIA, a peninsula of Europe, bounded every where by the sea, except on the north, where it is joined to Carniola. This peninsula was anciently a part of Illyrium; but being conquered by the Romans, between the first and second Punic wars, it was annexed to Italy. In the middle ages it belonged to the patriarch of Aquileia, who was invested with it, as a marquisate, by the emperor Henry IV. In the year 1100 the maritime part was for the most part conquered by the republic of Venice, abating some interruptions on the part of the Austrians. Venetian Istria was divided into 4 bishoprics and 18 districts; it contained 6 large, and 12 small towns, or boroughs, 200 villages, and 100,000 inhabitants, who were chiefly employed in agriculture, the production of wine and oil, the rearing of bees, the manufacture of silk, leather, tallow, and salt, and fishing. The grain, wine, oil, and salt, have been reckoned excellent, and have afforded, together with the tunny fish and anchovy fishery, profitable articles of commerce. The marble and stone have likewise supplied important branches of trade. But the chief wealth of Istria has consisted in its forests, which overspread a great part of the country, and yield abundance, not only of fire-wood and timber for ship-building, but also of game. By the treaty of Campo Formio, in 1797, and that of Luneville, in 1801, the Venetian part of Istria was ceded to Austria. But by

the treaty of Presburg, in 1805, that part of the states of the republic of Venice, which had been ceded to the emperor of Germany and Austria by the treaties of Campo Formio and Luneville, were united in perpetuity to the king of Italy.

ISTRUP, or **ONSTRUP**, a town of the bishopric of Paderborn; 12 miles E. of Paderborn.

ISTUNALA, a town of South America, in the government of Tucuman; 130 miles E. of S. Miguel de Tucuman.

ISUNGO, a town near the centre of the island of Gilolo.

ISVORA, a town of Walachia; 12 miles E.S.E. of Brancoviana.

ISURIUM, in *Ancient Geography*, a town of the island of Albion, or Britain, in the country of the Brigantes. It is now Aldburtow, near Booughbridge, and probably derived its name from its situation on the river Ure. Although it is now a small village, it seems to have been once the capital of the Brigantes; being called, both in the Itinerary of Antonine and in Ravenna's, "Itarium Brigantum." The foundations of the ramparts may still be traced.

ISWARA, in *Hindu Mythology*, one of the many names of Siva; but it is sometimes applied, rather correctly, to other deities, being nearly equivalent to our lord, and susceptible of equivocal application. Generally, however, it is understood of Siva, and sometimes has the epithet *Mahes* prefixed, giving Maheswara, or the great Iswara. Under this form the name of his flocks, or consort, is Maheswari.

ISTWESTOSTA, in *Geography*, a town of Sweden, in the province of Skonen; 8 miles N.E. of Chriflianflatt.

ITABIER, a town of the island of Borneo; 30 miles N. of Negara.

ITABOCA, a town of Brazil, in the government of Para, on the Tocantin; 90 miles S. of Canuta.

ITACAMBIM, a town of Brazil; 60 miles N. of Villa Nova del Principe.

ITACORUSSA, a town of Brazil, situated on the Xingis; 60 miles S.W. of Curupa.

ITAIARA, in *Ichthyology*, a name by which some have called a Brazilian fish, of the turdus kind, of great beauty, and a very delicate taste, more usually known by the name *juruaçapba*.

ITÁKA, in *Geography*, a town of Japan, in the island of Nippon; 35 miles S. of Ixo.

ITALA, a town of Sicily, in the valley of Demona; 13 miles S.W. of Messina.

ITALAH, a town of Asiatic Turkey, in Naotia. N. lat. 38 43'. E. long. 28° 29'.

ITALIA, in *Ancient Geography*. See **ITALY**.

ITALIAN, the language spoken in Italy.

This tongue is derived principally from the Latin, and of all the languages formed from the Latin, there is none which carries with it more visible marks of its original than the Italian.

It is accounted one of the most perfect among the modern tongues. It is complained, indeed, that it has too many diminutives and superlatives, or rather augmentatives; but without any great reason: for if those words convey nothing farther to the mind than the just ideas of things, they are no more faulty than our pleonasmus and hyperboles.

The language corresponds to the genius of the people; they are slow and thoughtful; and, accordingly, their language runs heavily, though smoothly; and many of their

words are lengthened out to a great degree. They have a great taste for music; and to gratify their passion this way, have altered abundance of their primitive words; leaving out consonants, taking in vowels, softening and lengthening out their terminations for the sake of the cadence.

Hence the language is rendered extremely musical, and succeeds better than any other in operas, and some parts of poetry; but it fails in strength and nervousness: hence also a great part of its words, borrowed from the Latin, become so far disguised, that they are not easily known again.

The multitude of sovereign states into which Italy is divided, has given rise to a great number of different dialects in that language; which, however, are all good in the place where they are used. The Tuscan is usually preferred to the other dialects, and the Roman pronunciation to that of the other cities; whence the Italian proverb, "Lingua Toscana in bocca Romana."

The Italian is generally pretty well understood throughout Europe, and is frequently spoken in Germany, Poland, and Hungary. At Constantinople, in Greece, and in the ports of the Levant, the Italian is used as commonly as the language of the country; indeed in those places it is not spoken so pure as in Tuscany, but is corrupted with many of the proper words and idioms of the place; whence it takes a new name and is called *Frank Italian*. See *LANGUAGES*.

ITALIAN Coins, Measures, Marble, Silks. See the followings.

ITALIAN School of Engraving. Engraving, with the work of the former occasionally intermingled with that of the latter, had been practised in Italy, from time immemorial, in ornamenting those golden and silver vases, chalices, and other vessels of plate, which adorned the communion-tables of the Catholic church, and the side-boards of the noble and opulent, when, about the middle of the fifteenth century, Maso, or Thomaso, Finiguerra, a goldsmith of Florence, accidentally discovered the means of printing from the incisions thus sculptured on the metal: so that engraving on copper-plates, as it is now practised, with the view of rendering impressions on paper, is a scion from the decorative part of the art or trade of the goldsmith; but which has gradually far out-grown the parent tree.

Vafari, in his biography of Marc Antonio, has, with great propriety, connected his account of that distinguished engraver, with an history of the discovery which rendered his art so famous and so extensively beneficial. He says that Finiguerra, having performed an engraving on a piece of plate, and intending to fill up the hollows with enamel; in order to try the effect of it previously to putting on the enamel, cast some melted sulphur upon it, and, on taking it off, perceived that the dirt (or charcoal with which he first tried his work) collected at the bottom of the strokes, by adhering to the sulphur, gave an impression of what he had engraven. Struck with the discovery, he repeated the experiment, by applying moistened paper to his engraving instead of sulphur, rolling it gently with a roller, and this experiment being attended with success, he imparted his discovery to Baccio Baldini, who was also of Florence, by whom it was communicated to Sandro Botiicelli, and perhaps also Antonio Pollajuolo, and Andrea Mantegna.

The baron Heinnekin, however, believes that rolling-press printing had previous existence in Germany, and subsequent writers (among whom is our countryman Strutt), giving credit to the opinion of an author, who is so generally worthy of it as Heinnekin, have copied this belief, or re-

peated this assertion of the baron, perhaps with some reflection.

An accidental discovery of this kind, which might have taken place in any country where paper was known and used, reflects so little real honour upon its birth-place, as to be unworthy of half the importance which has been artificially endeavoured to be attached to it; yet for this reason or fancied honour, the coinseurs and Baratti of Italy and Germany have contended; and we must allow, that the mind of Heinnekin appears, in this instance, to have been influenced by an evident bias in favour of the pretensions of his country.

He opposes, however, only conjecture to the plain and simple fact of Vafari, which we have related above; and though he, as well as others, have sedulously sought for assistance in the dates of the earliest German engravings, no such evidence has been found. No German print impressed from an engraved plate, of which the date has not been subsequently altered to impose on the credulous, has been seen, or can be produced, as the present writer believes, bearing an earlier date than 1460, the year in which, according to Vafari, the accident happened in the workshop of Finiguerra, which gave to Europe the means of printing from the incision of the graver.

Finiguerra was born at Florence some time about the year 1424, and died in the same city at an advanced age. He is reported to have studied under Massaccio. Probably he learned drawing in the school of that master; and Baccio Bandinelli, in one of his letters says, that Maso worked with Pollajuolo and other contemporary artists, on the far famed metal doors of the church of St. John at Florence. About the year 1450, he engraved also for the church of St. John, the Passion of Christ on a sacred vase of gold, in a very art-like manner, though the figures were small. This fact is reported in a letter from M. Gabuori to Maricette; but of his other engravings we are compelled to speak with doubt.

Whether any *impressions* from the works of this artist remain to attest his discovery of printing, and corroborate the statement of Vafari, is at the best uncertain. Strutt has mentioned dubiously, "The Seven Planets;" which are really from the graver of Botiicelli, and with better show of reason, a small plate of an artist engaged in his profession, which is marked with the letter F on a stone, and is certainly in the very earliest style (for Baldini and Botiicelli can scarcely be said to have attained a style) of Italian engraving; to which the foreign writers on art have added the twenty-four following small engravings, which are, for the most part, of the circular form. According to Huber and Roit they were recognized as the work of Finiguerra by M. Otto, a well-known amateur of Leipzig, by M. P. Abbe Zani of Parma, and by the more celebrated baron de Stofch, the latter of whom resided a long time at Florence, whilst he was forming his immense collection of works of art. All of these coinseurs have admitted them into their collections as the work of Finiguerra; and Heinnekin, after attentive examination, has adjudged them to be his engraving and printing.

1. A couchant female, perhaps intended for a Venus. On a streamer surmounting the couch, is inscribed "Amor vuol sé, o dove sé nonne." 2. The male and female supporters (a young man and woman) of the arms of the Medici, with a vase of flowers, &c. The female is dressed in the Grecian taste, and holds two giriles. N. B. This seems to have been printed from the cover of a round box. 3. A half-length figure of a young man with a parrot on his shoulder, playing the guitar, enclosed by a border of fruit. 4. An adolescent cupid tied to a tree, his eyes

ITALIAN SCHOOL OF ENGRAVING.

Monday, and four females tormenting him. 5. The same subject, differently treated. 6. Eight small ovals enclosed in a circular border of foliage. In the middle are two profiles of character, and in each of the rest a little cupid playing on some puffed instrument. 7. A similar subject, except that a child in the middle, a cavalier and lady are represented dancing. 8. Another circle bordered with fruit. In the middle part, a bear in a landscape is attacked by five dogs, and at the top are two cartouches, on the scrolls of which the arms of the Medicis are traced with the initials M. 9. Another circle, bordered with foliage. The subject a small party, consisting of a cavalier and two ladies in a garden. 10. A monstrous visage, the mouth of which is closed by two hands, in a circular border. 11. Customary profile on a medallion bordered with laurel; above it are three hunting subjects, in one of which a dog is attacking a hare, whilst a hare is escaping. 12. A lady and her servant. A dog is at her feet, and her right hand is raised to her forehead. 13. Judith and Holofernes, in the antique taste. 14. The same subject, except that Judith is here more richly dressed than in the former, and crown'd. 15. A cavalier and lady walking in a landscape, whilst a youth plays the tambourine. 16. Judith and Medea, who appear as supporters to an armoiral bearing. 17. Two supporters to a sphere: the one on the left is a lion rampant, on which is written "Amor vincit omnia," the other is a female demigod, the attributes of which, and holding the motto "Amor vincit omnia." 18. Another heraldic subject, in the middle of which a female figure holds a book for an armoiral bearing. The figure supports on her right hand, and on the right hand is a griffin holding a wreath of laurel; a winged cupid is fluttering above, and beneath, a dog is asleep. 19. Another heraldic armoiral bearing, with a male and a female supporter. 20. A guardian angel, with expanded wings in a heraldic habit. 21. Cupids holding wreaths of flowers and fruit; one with his eyes bandaged. 22. Bacchanals; in the middle of which is a car drawn by cupids, surmounted by a group of goblins throwing out fire. Some of the cupids are playing instruments of music, others bearing flambeaus. The procession is led by one carrying a flag, on which is written "Purita," and clofed by another, whose motto is "Alles gedit." 23. Two women elegantly attired, sitting in a landscape, supporting a border of cornucopias. 24. Two warriors, with each a knee on the ground, supporting a triangular escutcheon, on which is a female with her hands raised towards heaven. N. B. The four latter are medals.

"An edition of the "Inferno of Dante," printed at Florence in the year 1481, has long been supposed to contain the earliest Italian engraving, excepting the maps to the edition of Ptolemy printed at Rome in 1478, of which the date is ascertained, and to have been the first book ever embellished with copper-plate prints, in which human figures, or other natural objects, were attempted to be represented. In 1711, however, a mistake. The extensive and well-chosen Biblio-polygraphical collection of earl Spencer contains a small part of a book, printed at Florence, by Nicolo Lorenzini (de La Magna), but in the year 1477, which is four years anterior to the "Dante." Its title is "Monte Santo d'Orto," and the author Antonio Botticelli, a pupil of Filippo; and if the book, as it is called, contains, one is much larger than the other, the subjects of Dante.

There is either accompanying both the book are the joint productions of Bernardo Baldini and Alessandro Botticelli, or Botticelli; and one of the two discover which shall either be the original execution. The same artists have also engraven a

set of the Prophets, single figures; and a much larger plate than had yet appeared in Italy, of which the subject is "The Last Judgment," and where the damned are represented in separate places of torment, which resemble ovens, each inscribed with a particular vice or mortal sin. But it must be add'd, that all the engravings which these artists performed in conjunction, are Gothic, vulgar, and inferior to those of their German contemporaries."

Baldini was a Florentine by birth, and was brought up to the business of a goldsmith. Judging from his engraving, and his obscurity in every other respect, he seems to have been one of those men of slender talent, who are pretty numerous in all times and places; whose mere want of employment affords them leisure to catch at, and avail themselves of the advantages of, the inventions and discoveries of others. From Finiguerra he obtained his method of printing; and Botticelli furnishing him with designs, he engraved, with the help of the latter, nineteen plates for the above-mentioned edition of the "Inferno of Dante." The whole of his other engravings, with which we are acquainted, have been already mentioned.

Sandro Botticelli, furnished Filippo, goldsmith, painter, designer, and engraver, was born at Florence in the year 1435, and died in the same city in 1515. Though apprenticed to a goldsmith, he studied the art under Filippo Lippi the painter, and acquired some reputation by his pictures, but more by his drawings. His biographers say, that he learned engraving (probably printing by means of the roller) of Finiguerra; and beside the designs for Dante's poem, and those which follow, Vasari mentions with distinction, as his very best performance, with the graver, a print, entitled "La Triompha de la Foi de Fra Girolamo Savanarola."

"St. Jerome on his Knees, extending his right Hand toward a Crucifix;" "St. Sebastian with the Virgin Mary," inscribed "O Mater Dei, memento mei—O beate Zebastianus;" a set of twelve of "The Sybils," with each a scroll, and eight Italian verses beneath; "The seven Planets." (N. B. It is one of them, namely, the planet Venus, which Strutt has copied, and ascribed to Finiguerra.) "The Triumph of Paulus Emilius," inscribed on a medallion, "Paulo Emilio Aug.;" a set of the "Vices" and "Passions," with "Innocence" and "Truth;" "The glorified Sacrament in Judgment, attended by the Prophets and Saints." The three latter are of small folio dimensions; and of the last of all we have already particularly spoken under the title of "The Last Judgment," the joint production of Botticelli and Baldini.

"Antonio Pollajuolo or Pollajuoli, who was also of Florence, and born some time about the year 1426, may with more propriety be call'd an artist. From the antique sculpture, which was now beginning to re-appear, he seems to have learned attention to the anatomy of his figures: to which most important requisite of historical art, Pollajuolo has the distinguished honour of having been the first to attract critical attention. He has shewn his predilection for this study, by representing the conspirators naked in the medal which he cut to commemorate the assassination of Juliano, and the attack on Lorenzo de' Medici; and also in a much larger engraving, that had hitherto been executed, of which the subject is a battle, and there wherein he has represented all the combatants naked. There is an impression of this very scarce print in the Cracherodean collection, print'd on reddish paper; each figure is nearly seven inches in height; the heads have some faint degrees of expression; and the shadows are produced without cross-hatching, by diagonal lines, apparently done to imitate the hatching of a pen, and in the same direction in which it is customary to write:

ITALIAN SCHOOL OF ENGRAVING.

wife: but the outlines and shadows are dry and hard, and the forms vulgar and heavy. It is only by comparing Pollajuoli with his contemporaries and predecessors, that we learn to respect his performances; and it has even been said of his most celebrated work, ("The Martyrdom of St. Sebastian,") that it "exhibits only a group of half naked and vulgar wretches discharging their arrows at a miserable fellow-creature, who, by changing places with one of his murderers, might with equal propriety become a murderer himself;" so little attention was paid even in Italy, at this early period, to character and expression." Landseer's Lecture.

Like most of the contemporary artists of his country, Pollajuoli practised occasionally the several branches of imitative art, which have since become distinct professions, and was at once goldsmith, medallist, sculptor in relief, painter, and engraver with the burin. Bartolucci was his principal, or at least his first instructor; but he worked with considerable credit, under Chiaberti, on the juttily celebrated metal doors of the church of St. John at Florence. He also executed the monument of pope Sixtus IV., which originally stood in the chapel of that name, and has since been removed by the order of Urban VIII. to the church of St. Peter; and that of Innocent VIII.; which are both in bronze, and are works of great merit. The plan of the Belvidere palace has been likewise attributed to him.

Of the prints now extant from the graver of Pollajuoli, we know only of the following:

The above-mentioned large folio, wherein six men are represented fighting with swords in a forest; an "Holy Family," also in folio; and two smaller prints of "The Labours of Hercules," in one of which he is engaged with Anteus, and in the other removing a column.

An obscure village near Mantua gave birth to the cavalier Andrea Mantegna, in the year 1451. Born in indigence, he was obliged in his early youth to tend sheep for a subsistence; but being gifted by nature with a happy genius for the imitative arts, he employed all his leisure in endeavouring to draw the objects around him. F. Squarione, that observant protector of the fine arts, who was thence furnished the Father of Painters, discovering the disposition of our young shepherd for painting, took charge of his education; and conceiving for him an ardent affection, which increased with the increasing merit of Mantegna, finally created him heir to his fortune.

Mantegna married the daughter of John Bellino of Venice. Correggio became his disciple, and the duke of Mantua his warm admirer and patron: from his hands our artist received the honour of knighthood; and for him he painted that celebrated picture, which he sent towards England, and which is now in the royal palace at Hampton-Court, of the "Triumph of Julius Cæsar."

He executed several great works for pope Innocent VIII., who invited him for that purpose to Rome. He painted an altar-piece for the church of St. Sophia of Padua; and several pictures for that of St. Justina, particularly one which has been much admired for its colouring, as well as design, in a chapel belonging to that church: namely, he depicted the same city (of Padua), highly honoured and adored, in the year 1517; and a tomb, surmounted by his bust, was raised to his memory in the church of St. Andrew.

Mantegna contributed much to the advancement of Italian engraving. "By his more intimate knowledge of the antique, and his superior use of that knowledge, he improved the drawing, without materially altering the style of engraving of Pollajuoli, by whom he is presumed to have been instructed in the new art. Indeed, as the local energies and

practical perfections of painting were at the time perfectly developed, it was not so natural, and not to the same degree more wily, for engraving to imitate pen and ink drawings than to imitate painting; and the school of Mantegna's prints derive a peculiar advantage and excellence from this circumstance. By imitating the appearance of the finer fir lines of the pen, and avoiding the use of shadows he effected a more easy and more happy imitation of the whole; he gave a more appropriate style of the ability he had in view; and the greater facility of his intended engraving to his own mode of drawing, (the pen and ink drawing, was the ordinary of his aim.

"A very curious pen and ink drawing from the hand of Mantegna, of which the subject seems to be a rather an allegorical picture which Apollo is seated on a rock in his own life, is now in the possession of his worthy grandson of the Royal Academy. He engraved, from his own designs, sometimes on copper, and sometimes, as it is said, upon tin. "In his engraving, as in his pictures, his contours are of a grand and decided character, sustained throughout by much of what has since been termed the noble simplicity of the Roman school. His prints are not few; but considering the early period at which they were performed, are much more extraordinary than most. The two "Labours of Hercules," in the Cræchavolles Collection, ought probably to be reckoned among the earliest of Mantegna's engravings. Like those of Pollajuoli, they are printed on reddish paper, and are designed in the same heavy style. His "Bacchanalian Procession" has still some considerable remains of Gothic grotesques; but he has here shown his talent in composition, and the fore-shortenings that occur are far better expressed than we have hitherto seen. The composition of his "Battle of Sea-Gods and Tritons" is wildly grand, with such a mixture of the grotesque, as may seem not improperly to belong to a subject which we should expect out of nature, or beyond the limits of the material world. The combatants in this battle are the offspring of his own fertile and vigorous fancy, generated by the sculpture of antiquity. Beside the tritons and sea-monsters, here are the general forms of horses and men; but, like the fawns and sylvan deities of the Greeks, these natures partake of the element in which they exist:—at least, the spectator is led to perceive that this intention existed in the mind of the artist, and that (in the words of Ariosto's song) they have undergone "a sea-change, into something in hand strange." Instead of hair, sea-ward decorates the human heads; and the fins and tails of marine animals help to constitute the horses and tritons. Their weapons, too, are congenial with themselves: they fight with fish and fish-bones, and the skull of some of them is the habitat of the deep ferns as a shell.

"The heads of the horses, as well as those of the tritons, are animated by no inconsiderable portion of the ideal energy of the antique; the anatomical workings, the various object of Mantegna's attention, are also successfully derived from the same estimable source of information; and in the early impressions, the chiselling has more breadth, as well as depth, than seems to belong to the Italian art of the early period, and is conducted through the whole with masterly address.

"A more slow and sedate magnificence moves his triumphal procession of Julius Cæsar. The wild imagination which reveals the recesses of the ocean, and his bacchanalian processions, is nearly excluded from hence; it but ferries, in the flaming of the candelabra, to glean through "the spoils of nations, and the pomp of wars;" or faintly

discovers itself in other subordinate accessories as the fringed ornament of stately grandeur.

"In his Dance of females, he has shewn so much of the graceful simplicity and general air of Greek sculpture, as to give rise to a belief that it has been copied from an antique basso-relievo: but till such a basso-relievo is shewn, it would be unfair in us to resign so much of the merit of Andrea Mantegna as this composition may claim. These three engravings abundantly demonstrate the wide range of his technical and inventive powers; and shew with what success he could combine, or separately exhibit, elegance, wildness, and grandeur, as occasion admitted or required.

"Some critics have thought that Mantegna's admiration of the antique was too predominant in his works; that it too frequently engrossed his powers; and hurried him too entirely away from that contemplation of nature, which must always be one of the parents of originality in art. Yet, if this enthusiasm be a fault, it is a fault proceeding so necessarily, and so immediately, from the localities of time and place, and the redundancy of his merits, that it is as secure of pardon from the candid, as those merits are of praise." Landseer's Lectures.

The monogram of this celebrated engraver, resembling that of Marc Antonio, will be found in our *Plat. I.* of those of the *Italian School*. The following list is believed to contain all his principal works, and it is not certain that he engraved any more than this list contains. They are of solo dimensions, and some of them very large:—"The Madonna and Infant Christ," (copied by Strutt in his *Biographical Dictionary of Engravers*); "The Choice of Hercules"; "Hercules overcoming Antæus," inscribed "Divo Herculi invicto." "The Marriage of Eneas with Lavinia"; "The Scourging of Christ"; "The Entombing of Christ," inscribed "Humani generis Redemptor"; "The Descent of the Saviour to Hell"; "The Resurrection of Jesus Christ"; "Judith with the Head of Holofernes"; and two grotesque monsters fighting in the presence of two warriors.

The following are the principal subjects of M. Landseer's comments which are quoted above:—"A Bacchanalian Procession," in which both fawns and satyrs are introduced; "A Battle between various marine Monsters"; "A Dance of Four Females"; "The Triumph of Julius Cæsar," engraven on nine plates, which, when joined, form a magnificent frieze; but it is uncommon to find a collection where the nine are complete.

Giovanni Maria da Brescia, or Brixienfis, was a native of Brescia, in the Venetian territory, and was born A.D. 1462. He was an ecclesiastic of the order of Carmelites, and about the beginning of the sixteenth century, painted "The History of Elisha and Elijah" for the monastery to which he belonged. He also practised goldsmithery; but it is his engravings, which are somewhat numerous, that are the proper subject of our present notice.

The style of his manual execution is not always alike. In some of his prints it is evidently formed on that of Andrea Mantegna, the lines which form the shadows being laid from one corner of the plate toward the other, without any cross-hatchings, somewhat neater than those of his great exemplar, but very inferior to him in every other respect. On other occasions he employed second courses of lines, but his drawing is heavy, and his extremities not well marked: yet his prints, of which the principal are entitled as follows, are much sought after by the curious:—"The Virgin Mary seated on a Bench with a Book in her right Hand, holding the Infant Christ"; "The Virgin seated upon Clouds with the Infant Christ"; "St. John Baptist, St. Jerome, and three Carmelite Friars below," dated 1502; "The Miracle of St. Gregory restoring a Boy to

Life." It is a large folio of thirteen inches by nine, and is inscribed "Opus frisii Marie Brixienfis, or Carmelitarum MCCCCCII." The manual part of the engraving of this plate is in a mixed style between those of Mantegna and Marc Antonio. "The History of the Emperor Trajan," wherein the artist has complimented the reigning pope, by introducing him at a balcony above.

Giovanni Antonio da Brescia, the brother of the preceding artist, was born at Brescia some time about the year 1461, and also became a Carmelite friar. He applied more closely to engraving than Giovanni Maria, and studied the works of Mantegna with somewhat better success. Yet his outline is poor, though his manual execution is sufficiently clear and neat. We have subjoined a list of his most esteemed works, of which the best appear to be copies from Andrea Mantegna:—"Hercules vanquishing the Nemean Lion," after Andrea Mantegna, inscribed "D. Here in victo"; two plates of "Hercules" and "Antæus," after the same master, one of them an upright 4to.; "A White Horse," resembling that by Albert Durer, except in the back ground, a small upright; "The Scourging of Christ," a large upright. Of these the earliest and best impressions are dated 1503, and a second edition was printed in 1509. "The Virgin and Child"; "The Holy Family, with St. Joseph asleep"; two plates of a "Satyr and Female," inscribed "Victoria Augusta," on a tablet; "A naked Female reclining with an Infant, while a Satyr is playing on a Pipe."

Hieronymus Mocetus, or Jerome Mocetto, engraved both on metal and on wood, and was born at Verona in the year 1454. Strutt's account of him is as follows:—"The prints by this ancient master are by no means common. He worked with the graver only; but did not excel in the management of that instrument. His style of engraving bears some resemblance to that of Robella. Though it is considerably neater and clearer, he did not draw the naked parts of the human figure correctly. The extremities especially are very defective. The study of the chiaro-scuro was at this time very little attended to. We must not wonder, therefore, at finding the works of this artist totally destitute of effect. However, they are not without merit; though, it must be confessed, that their scarcity stamps the greatest value on them. We have by him, "The Resurrection of Christ, with Four Soldiers at the Foot of the Tomb," apparently from his own design; "A Sacrifice," with many figures, from an antique bas-relief; a middling-sized plate, lengthways. Also several battles, with other subjects; which are variously marked, as may be seen in our *Plate I.* of the monograms, &c. of the *Italian School of Engravers*.

Nicoletta, or Nicolas da Modena, was a native of Modena, and seems to have studied architecture and perspective with more assiduity than success. He is ranked as one of the earliest engravers of the school of Lombardy; and, when we examine his works, it seems as if the name of engraving only had reached him; and that he had been obliged to work out his own system. It is astonishing, at a time when so many engravers of consequence were living, and had produced such a variety of excellent prints, especially Marc Antonio and his scholars, that this man, who was himself a painter, should have been so much at a loss, not only in the mechanical part of the execution of his plates, but with respect to the compositions and drawing of them also. If these rude productions have any merit to recommend them, it must consist in the buildings and architectural ornaments, which he introduced into his designs, and with which he has frequently crowded them in a very absurd manner: he worked with the graver only; and his

ITALIAN SCHOOL OF ENGRAVING.

largest plates seldom exceeded the common folio size. He usually signed his name at length; but, in some few instances, he used the two monograms which we have copied in our *Plate I.* of those of the *Italian School.* We have engraved by him, "The Adoration of the Shepherds," a middling-sized upright plate, marked with his name at length; "St. Sebastian," a middling-sized upright plate, marked with his baptismal name; "Nicoleto," on a tablet; another "St. Sebastian," inscribed with his monogram; "St. Jerome;" "St. George;" "St. Martin;" "A Triton embracing a Syren;" beside other works of less repute.

Benedetto Montagna, was born at Venice some time about the year 1458, and died at Verona in 1530. He engraved on copper, and the graver was the sole instrument of his art. His engravings are dated from a very early period of the art in Italy, and it is more than possible that the prints of Albert Durer, which were brought to Venice as an article both of taste and commerce, and those of Marc Antonio, who had now been following the profession of engraving for some time in that city, might induce him to take up the novel art either as a matter of profit or of curiosity. The efforts of Montagna, however, are but feeble; his outline is exceedingly defective, and his manual execution harsh and rude, though in some few instances he attempted to assist the blending of his lights and half-tints by means of stippling.

Benedetto engraved from his own compositions; and the resemblance which some of his prints bear to the earliest and rudest productions of Marc Antonio, of which we shall presently speak, may well be thought to strengthen our supposition, that from them he learned the rudiments of the art. His engravings, of which the following will probably be found the best, are very rare, and are generally, if not in every instance, marked with his name at length:—"An Holy Family," in which the Virgin Mary appears seated, holding the Infant Christ; St. John is standing beside her naked; and St. Joseph appears below. A view of a town, with a river and bridge over it, constitutes the background: at the top is the artist's name. "The Judgment of Midas," a small upright. A naked figure standing by a tree, somewhat larger. An elderly man and a youth; the former playing on the bag-pipes, the latter upon the *violin*. A landscape, with a hamlet in view, and an old man seated on a bank, both small uprights. Another landscape, with three women on the foreground. A young man sitting on a rock, passing a cord round a palm tree. "The Rape of Europa." "Venus chastising Cupid."

Strutt says, that Rubetta, or H. Robetta, flourished in 1610. This is evidently a mistake. The French writers on art, with much more probability, say that he was born at Florence in the year 1461; but the events of his life are very obscure, and his engravings of no value but from their antiquity and rarity, for they are wretchedly executed. The subjects of most of them are devotional, and he sometimes signed his name at length, and at others the initial letters R.B.T.A. on a little tablet.

His most esteemed engravings are, "Adam and Eve," a small upright folio; "The Adoration of the Magi," of a nearly square form; "The Resurrection of Jesus Christ," a small upright folio; and "The Golden Age," a large upright folio.

Titian also etched some plates about this time, probably in the way of recreation, and it is said, performed some engravings on wood. Among the former are several large landscapes from his own compositions, the subject of the most remarkable of which is a pastoral, where a shepherd is playing on a flute, before his flock, by the side of a stream. In another a traveller is sleeping by moonlight. He like-

wife etched an allegorical print of Death habited in the armour of a knight.

The most remarkable of his wood-cuts, if these are really by the hand of Titian, which appears very doubtful, are, "The Marriage of St. Catherine," a large upright, executed in a slight but masterly manner, and inscribed "Titianus Vecellius Inventor Lineavit." "The Triumph of Faith," represented by a procession of patriarchs, prophets, evangelists, apostles, saints, martyrs, preceding and following Jesus Christ: it is composed of from eight to ten prints, forming, when palled together, a very long frieze, and dated 1505. "The Destruction of Pharaoh and his Host," a very large print lengthways, composed of six parts. This is very rough and rudely cut, and by no means equal to the "Triumph of Faith," which is a very masterly performance. "Samson betrayed by Dalilah." "The Deluge," a larger engraving, printed on two sheets, of which Papillon says, that it is very correct and admirable; but Strutt, (who had seen the print) very properly observes, that this boasted precision seems to make against its being from the graver of Titian, who would scarcely have bestowed so much time and labour as must have been required to complete it in so neat and regular a manner.

The famous satirical engraving of an old ape and two young monkeys, in the attitudes of Laocoon and his sons, which was long ascribed to Titian, is now known to be the performance of Nicolo Vicentino. It was done to satirize Baccio Bandinelli, who boasted of having executed a Laocoon, which was superior to the antique.

But Strutt thinks, and with great appearance of probability, that most, if not all of the wood engravings ascribed to Titian, are really the work of his younger brother Cesare Vecelli, who also produced a set of *Svo.* prints, executed in a very spirited and masterly style, from the designs of Titian, of ancient and modern dresses, which was published at Venice in 1593; but perhaps there had been a former edition. The title of the edition of 1590 runs thus, "Degh Hubite Antichi et Moderni di diverse parte del mondo, Libri due fatti da Cesare Vecellio;" and in a subsequent edition, published in 1664, it is more fully expressed as follows: "Raccola di figure delineate dal gran Titiano, e da Cesare Vecellio suo Fratello diligentemente intagliate."

A single print in chiaro-scuro, serves to mark the talent, in that mode of engraving, of Baldassare Peruzzi, an extraordinary architect, painter, engraver, and antiquary of this period. He is generally supposed to have been a native of Sienna, but Vafari says, and probably with truth, that he was born at Volterra, in the year 1481. Beside building churches and palaces at Sienna, and other parts of Italy, he embellished them with his pictures; and wrote a treatise on the antiquities of Rome. He left behind him a commentary on Vitruvius, which Papillon informs us he intended, but that the hand of death prevented him, to have illustrated with engravings on wood. It is reported, but we cannot say on what foundation, that he was poisoned by some artist who envied his superior talents.

The print to which we have alluded is an upright folio, representing Apollo, Minerva, and the Muses, with Hercules expelling Avarice from their presence. It appears to be engraven on three blocks; one for the outlines, another for the half-tint, and a third for the deeper shadows. It is executed in a bold and spirited style, and inscribed "Bal. Sen." over which letters is a five-pointed star.

Domenico Campagnola was born at Padua A.D. 1482. He was the son of Jerome Campagnola, the sculptor, and the disciple of Titian. He chiefly excelled in landscape, and has produced a considerable number of prints, some of which

ITALIAN SCHOOL OF ENGRAVING.

are etchings and others engravings on wood, executed in a bold style, but very slight, and incorrect in his drawing of the naked. He died at Venice in the year 1550, but lies interred in the church of St. Anthony of Padua, near the tombs of his ancestors.

Of his etchings the following are the principal:—"The Adoration of the Magi and Kings," a grand composition, in folio; "Cæsar's Tribute Money;" "Our Saviour healing the Sick;" "The Parable of Dives and Lazarus," in large folio, etched on three plates, and marked "D.C. in Luca Bertelli;" &c.; "The Gift of Languages, or Defecit of the Holy Ghost," a large circle, inscribed

D O
C T P 1515;

"The Holy Family, with St. Jerome and St. John," after Titian, a large folio, dated 1517. Two circular prints, one of which is "The Decollation of a Female Martyr;" "A Group of Warriors, attended by Fortune, stopping the Progress of the Arts and Sciences." A landscape, with Jupiter and Calisto, after Titian. Another landscape, on the fore-ground of which is a chariot drawn by two bulls; marked D.C.; a bacchanalian subject; a Venus, inscribed "D.O. Camp. 1517."

The most esteemed of his letter press engravings are "The Holy Family," in a landscape, with St. John and other saints. The Virgin Mother is represented suckling the Infant Christ; a folio print. A grand landscape, in which is introduced St. Jerome. Another large landscape, with a soldier and his family. Three children near a pedestal, one of whom is contemplating a dog gnawing a bone. "The Malice of the Innocents;" and "The Destruction of Pharaoh and his Host," a large and grand work engraved on twelve blocks after Titian, and marked "Domenico del Vecchio 1549."

According to the testimony of the author of the *Abecedario*, Julio Campagnola, surnamed Antoneus, was the brother of Domenico; Florent le Comte says, that he flourished, as an engraver, from 1507 to 1517. He worked entirely with the graver, but in two very different styles, one of which was his own invention.

The only two prints by Julio, with which we are acquainted, exemplify this remarkable variation in his style. The first is a small upright of "The Rape of Ganymede;" the execution of which resembles, in the manual, that of Marc Antoine, though the drawing is very inferior. It is inscribed "Julio Campagnola Antoneus fecit;" the other is somewhat larger, and represents St. John standing, holding a cup and looking upwards. In this plate he has entirely departed from his former manner. The back ground is executed with round dots, made apparently with a dry point. The figure is outlined with a stroke deeply engraved, and finished with dots, in a manner somewhat resembling those prints which Demarteau engraved at Paris, in imitation of red chalk. The hair and beard are expressed by dots. It is a very extraordinary print, and proves the possibility of that mode of engraving, which has been erroneously considered a modern invention; but its merit consists chiefly in its singularity; for the drawing of the figure is not so good, and there is nothing in the general effect to recommend it.

About the time now under our consideration, there also arose in Europe another mode of engraving, which successfully imitated drawing worked with bitile, or those ancient Greek pictures which were called monochroms by the ancients. Mr. Landier says that "the title of engraving in *chiaroscuro*, was at that time exclusively, and therefore improperly applied to this new mode of art," since

chiaroscuro, or effect of light and shade, is a necessary and elementary part of every mode of engraving that goes beyond a mere outline.

The invent on of prints in *chiaroscuro* is claimed both by the Germans and Italians. The latter assert that soon after the commencement of the sixteenth century, Ugo da Carpi, a man of great ingenuity, discovered a mode of imitating slight drawing by the means of different blocks of wood. The Germans on the other hand, produce several engravings by Mair, which are dated 1499, and one by Lucas Cranach, dated 1500, which are prior to the time ascribed by the Italians for the invention by Da Carpi. This circumstance, even if we should suppose that the prints by Mair are the first attempts in this style of engraving, is sufficient to prove the priority of the exercise of it in Germany. Baron Hinnekin is of opinion that the *chiaroscuros* of John Ulric are still more ancient than those by Mair.

There is, however, a material difference between the *chiaroscuros* of the old German masters, and those of the Italians. Mair and Cranach engraved the outlines and deep shadows upon the copper. The impression taken in this state was tinted over by the means of a single block of wood, with those parts hollowed out which were designed to be left quite white upon the print. On the contrary, the mode of engraving adopted by Ugo da Carpi, was to cut the outlines on one block of wood; the dark shadows upon a second; and the light shades, or half tint, upon a third. The first being impressed upon the paper, the outlines only appeared; this block being taken away, the second was put in its place, their coincidence being secured by a mechanical contrivance, and being also impressed upon the paper, the dark shadows were added to the outlines, and the third block being put in the same place, upon the removal of the second, and also impressed upon the same paper, made the demi-tints, and the print was completed. In some few instances, the number of blocks were increased, but the operation was still the same, the print received an impression from every block.

Da Carpi, who first practised this mode of art in Italy, was born at Rome in the year 1486. He studied painting with his great contemporary Raphael, but appears to have possessed one of those minds which, in all ages, bear hard upon rectitude, by preferring novelty to established principle. He painted an altar piece for the church of St. Regard, in the execution of which he used no pencil, but laid on the colours immediately with his fingers; Michael Angelo being importuned for his opinion of this work, simply replied that "it would have been better had he used his pencils."

It is probable that his passion for novelty led him to practise that new mode of engraving on wood, which is now under our notice, which also calling into action his acquired talents as an artist, enabled him to produce those masterly and spirited imitations of the sketches of the great painters, from whose works they are taken, which he sometimes printed in green, sometimes in brown, and sometimes in other colours, as his love of novelty and experiment directed.

Of these works, those which are most sought after by the curious, are as follow:—"A Sybil with Tablets and a Stylus, with an Infant Genius holding a Torch," after Raphael, printed in green, and, according to Vafari, the first work of the kind produced by Da Carpi. "Eneas escaping from Troy with his Father Anchises," a large upright, from the same master. "The Defecit from the Cross," an upright folio; "David beholding Goliath;" "The Slaughter of the Innocents;" "Jesus preaching in the Temple;" "Elymas Stricken with Blindness;" "The Death of Ananias;" "St. John in the Desert;" "A Dead Christ on the Knees of his Mother;" and "Raphael conversing

ITALIAN SCHOOL OF ENGRAVING.

verfing with his Miftrefs;" are all after the works of this great painter.

After Parmegiano, he has engraven a philofopher feated, with a book open before him, and in the back ground, to the right, a bird, with its feathers plucked off; probably intended for Diogenes, and the cock which he plucked in ridicule of Plato's definition of man. This is a large and curious folio print, fome of the impreffions of which are printed in four different colours. "The Holy Virgin, with St. Sebaftian, and St. Nicholas." "A Satyr fathoming Water with his Flute." All of thefe prints are of fofo dimenfions.

Dominico Micarino of Siena, furnamed Beccafudi, was born at Siena, or in fome neighbouring place, in the year 1484, and died in 1549 in the fame city, which, by his various works in fculpture, architecture, painting, and engraving, he greatly contributed to adorn. He was not poor parents, and like Andrea Mantegna, paffed the early years of his life in keeping fhops. His family name was Micarino; but fignor Beccafudi, a celebrated citizen of Siena, observing him buied in tracing forms upon the wall with his crook, conceived a favour and opinion of his natural abilities, and raifed him from obfcurity.

From this kind patron, he fuccefsfully pleafed our young artift under Antonio Veracchi, and Pietro Perugino, he took the name of Beccafudi. He travelled to Rome to complete his ftudies from the works of Raphael and Michel Angelo; after which he returned to Siena, where he was employed in feveral works both in frefco and oil, which acquired him great applaufe, but nothing contributed more to the eftablifhment of his reputation than the Mofaic pavement with which he ornamented the cathedral of Siena.

Micarino appears to have worked occasionally in all the modes of engraving which had then been invented. He was a very good engraver on wood, and particularly excelled in chiarofcuro, fometimes working from his own defigns, and at others from thofe of Titian and other mafters. He alfo etched feveral plates in a very fpirited ftyle, and we have fome few prints executed by him with the graver only. In thefe the hand of the mafter is very evident; the figures are drawn in a fpirited ftyle, and the extremities are finely marked, but, from want of skill in the management of the point and the graver, the mechanical part of the work has a hard and unpleafing appearance to an eye accuftomed to neatnefs and precifion.

His engravings, of which the following illuftrates the principal, are fometimes marked with his name at length, and at others with the cypher which will be found in our Plate I. of thofe of the *Italian School*.—A large folio print of "The Nativity," after Titian, cut in wood in a very fpirited manner. "The Holy Virgin embracing the Infant Chrift," printed in chiarofcuro, in three colours, and probably from his own compofition. Four prints executed in the fame manner of "St. Peter," "St. Philip," "St. Andrew," and "St. Jerome." "A Philofopher fitting wrapt in his Mantle." Portrait of pope Paul III. Three engravings on copper, of which the fubjects are groups of academy figures; and ten engravings on wood of alchymical fubjects.

The next engraver of decided talent that Italy produced was Marc Antonio Raiboldi, whose name marks a memorable era in the hiftory of engraving. He was born at Bologna in the year 1487 or 88, and died in the fame city about the year 1539. Like many of his cotemporary artists and predecessors, he was brought up to the bufinefs of a goldsmith, but studied drawing, in which he fo much excelled under Francesco Raiboldi, furnamed Francis, from his attachment to whom, Raimondi himfelf obtained the cognomen of

Francis. His earlieft prints, as far as is known, were "The four Heroes," and "Pyramus and Thisbe," the latter of which is dated in the year 1522, when he could have been only 14 or 15 years of age; thefe early works are both engraved after the defigns of this mafter, and the letter F, which forms part of the monogram, affixed to them, may be fuppofed to ftand for either Francis or febit.

Our artift, however, is now generally known by his baptifmal names, Marc Antonio. Being eager for improvement in his art, he travelled to Venice, where he firft met with the works of the German engravers, particularly a fet of wood cuts by Albert Durer, representing "The Life and Paffion of our Saviour." Thefe pleafed him fo much, that he purchafed them, though they coft him nearly all the money he had brought with him; and he copied them with great exactnefs on copper. The deception, it feems, anfwered well to Marc Antonio; for, we are told by Vafari, that they were frequently fold for the originals. This circumftance, according to the fame author, coming at laft to the ears of Albert Durer, he complained to the fenate of Venice of the injury which he had fufained, but all the redrefs he could obtain was, that Marc Antonio fhould not, for the future, add the cypher or monogram of Albert Durer to any of the copies he might make from his engravings. This ftory, if true, is not without its difficulties, and one of the moft ftriking is, that the copies which Marc Antonio made from the Life and Paffion of Chrift by Albert Durer, have not the mark of that artift at all upon them, but the cypher of Marc Antonio only. Vafari indeed might have miftaken the life of Chrift for the life of the Virgin, by Albert Durer, becaufe Marc Antonio copied them both with equal precifion. The latter was much larger than the former, and have the monogram of Albert Durer represented in the fame manner as upon the originals; and to thefe Marc Antonio has not put his own cypher, except upon the left plate; but even that has the monogram of Albert Durer alfo. Of courfe, thefe prints will much better agree with the ftory above related, than thofe mentioned by Vafari.

When Marc Antonio quitted Venice, he went to Rome, where his merit was recommended to the notice of Raphael, who not only employed him to engrave a confiderable number of his defigns, but formed an intimate friendfhip with him, and it has been faid, though without fufficient authority, that he affifted him in tracing and correcting the outlines upon the plates.

The firft plate he engraven from a drawing of Raphael's was, "Lucy-tia daffing herfelf," in which he feems to have exerted all his abilities to make it neat and delicate. Soon afterwards he executed the ftate of "The Judgment of Paris," which, though not fo neat as the former, has more freedom and fpirit. Raphael himfelf was fo particularly well pleafed with the works of this admirable engraver, that he lent many fpecimens of thefe to a contemporary prelent, to Albert Durer, which he thought well worthy of his acceptance.

The great reputation which Marc Antonio acquired under the patronage of Raphael brought him many young Italian artists to Rome, moft of whom were his difciples; and among them were the following: Giovanni Maffi, Marc de Ravenna, Giulio Bonanni, Nicolo Caracci, and Luca Vico, who all of them became his copies, and who were equal to be known abroad, Barthelemy Peruzzi, Giorgio Fetti, and James Binck, with others; and of Germany, came into Italy, and frequented his ftudio. For engraving fome plates after the defigns of Michel Angelo, of which the fubjects are taken from the head and neck of Chrift, he was permitted to difpen by pope Clement VII. but recovered his freedom through the intereft of Duke of Bandinelli.

ITALIAN SCHOOL OF ENGRAVING.

After his release, Marc Antonio, to manifest his gratitude to Bandinelli, engraved, from a picture of his, that admirable print representing the Martyrdom of St. Lawrence; and succeeded so happily, correcting carefully several faults which were in the picture, that the pope, who was a great lover of the arts, upon seeing an impression from the plate, pardoned his offence entirely, and took him under his protection. We now see our artist in the zenith of his good fortune; but his decline was still more sudden than his advancement: for the city of Rome being taken by the Spaniards, A.D. 1527, Marc Antonio lost in the pillage all the wealth he had accumulated. He retired afterwards to Bologna, where perhaps he died; but of this there is no certain account. The last dated print we have by him is, "The Battle of the Lapythæ," engraved in 1539; after which time, we hear no more of him, or of his works. Malvasia indeed affirms, that he was assassinated by a nobleman of Rome; because he had, contrary to his engagement, engraved a second plate of the Murder of the Innocents, after a design of Raphael. This design was certainly twice engraved by Marc Antonio, with very small variations, as will be mentioned below. Baldinucci, following Malvasia, mentions this story; and adds, that Marc Antonio was married, and that his wife was also an engraver. But the total silence of Vasari as to this circumstance, renders it exceedingly doubtful.

The style and the principal works of so distinguished an artist, the founder of the Roman school of engraving, call for particular comment. In his fifth lecture, delivered at the Royal Institution, Mr. Landseer says, "The style of Marc Antonio possesses not the exterior of oratory; but he pronounces every sentence so distinctly, with a confidence so modest, and an emphasis so true to Raphael and to nature, that those who attend are convinced, without being persuaded. To speak without a metaphor, there is something in his manner of employing his graver, something dry, unambitious, severe, unattractive to the sense; which, by all sound critics, has been thought to deserve praise, without desiring it; and peculiarly appropriate to the works of a painter, who not merely does not require, but will not admit, the aid of foreign ornament.

"The Dead Christ of Raphael, where the excess of his mother's sorrow is softened, but not subdued, by her divine resignation, he repeated with variations; of which the principal are, that, in the second plate, the Virgin Mary appears much younger than in the first, and her right arm divested of drapery; from which circumstance, it is known among collectors by the appellation of "The Virgin with the naked Arm." The second plate is more delicately engraved, but is feeble, when compared with the masterly vigour he has shewn in the first. The nudités are here drawn with Marc Antonio's, inspired by Raphael's, usual superiority; but the drapery and ground are softened and enriched beyond the ordinary powers of Marc Antonio's graver, and are so much in the improved style of his pupil, George Peuz, as may incline us to suspect that these parts have been engraved by his hand. Whether Raphael authorized or allowed Marc Antonio to substitute the younger Virgin, who seems more like the sister, for the elder, who is the mother of Christ, does not appear.

"In "The Virgin of the Palm," Marc Antonio discovers, if possible, a still more exquisite feeling, and of course produces a more perfect transfiguration, of Raphael. Christ is bestowing his benediction with the sublimity of inspiration; and St. John receiving it with dignified and divine, though infantile, submission. The subordination of parts is just: the whole is perfectly graceful; and the head of the Virgin Mary, the most graceful part of that whole.

"Marc Antonio's powers as an engraver appear not to have declined from their acme, in his martyrdom of St. Lawrence, after Bandinelli. He not merely copied, but his long acquaintance with the works of Raphael enabled him, and his gratitude to Bandinelli, who had obtained his release from prison, disposed him, to improve the drawing of his original. The print is defective, yet not more so than many other of his works, in chiaroscuro: but, expression of the textures of substances, and the existence of reflex light, are here feebly acknowledged; the folds of the draperies are ample; the drawing of the naked excellent; and the characters of the heads far better than would seem to belong to the reputation of Bandinelli."

The several monograms with which Marc Antonio marked his engravings, from time to time, will be found in Plate I. of those of the *Italian School of Engravers*; though a great number of them were published without any other mark than an intelligent eye will perceive, in the peculiar style and purity of outline of this accomplished artist.

Coincisors are extremely, and very justly, observant of the goodness of the impressions, in collecting the works of Marc Antonio; and early and well preserved impressions sell for very considerable sums. Since they were first published, the plates have been successively the property of Thomas Barlacchi, Antonio Salamanca, Antonio Laureri, and Nicholas Van Aelt; lastly, they became the property of the print-dealer Rossi, at which time, after being frequently re-touched, and of course very much impaired, they were, as works of art, utterly worn out. Those impressions are the earliest, and by far the most valuable, which were taken before the name of any publisher was inscribed on them.

Baron Heinekin, in his "Dictionnaire des Artistes," printed at Leipzig, A.D. 1778, has given a complete catalogue of the works of Marc Antonio, to which the curious reader is referred, and from which we have extracted the following list of those which are held in most esteem, beginning with his portraits.

Portraits.—An artist wrapped in a mantle, seated, and in an attitude of meditation; a little table, palette, and colours, in the back ground; supported by Malvasia to be the portrait of Raphael, drawn and engraved by Marc Antonio: Aretin the Poet, with a long Latin inscription; one of the very finest works of the artist: the Emperor Charles V. in his youth; Pope Clement VII.; both on medallion: Pope Julius II. holding a bonnet: Prince Octavius Farnese.

Subjects from Holy Writ.—"Adam and Eve," after Raphael, a very fine and rare print, the same which Strutt has copied and placed as the frontispiece to his second volume of the Lives of the Engravers; "Adam and Eve expelled from the terrestrial Paradise," after Michael Angelo; "Noah sacrificing after leaving the Ark;" "The Blessing of Abraham;" "God appearing to Isaac;" "The Escape of Joseph from Potiphar's Wife;" "David discomfiting the Philistines, and beheading Goliath;" "David," an erect figure, with the head of Goliath, a very rare print; all after Raphael.

"The Adoration of the Shepherds," either from a design by Marc Antonio himself, or after his first master Francia; two plates of "The Murder of the Innocents," after Raphael, in the second of which Marc Antonio has introduced the upper part of a small yew tree, called by the Italians la Felchetta, and which does not appear in the first. Good impressions of both these plates are extremely rare and valuable; "An Holy Family;" from the thigh of the Virgin Mary being immoderately long, this print is distinguished among coincisors by the name of "The Virgin of the long Thigh." Another "Holy Family," wherein the Infant Saviour reposes on the knees of his mother,

ther, who is bestowing her benediction on the little St. John. This is commonly known by the name of "The Virgin of the Palm." Another, called "The Virgin of the Cradle," from the circumstance of the Infant Christ being represented in his cradle; and two plates of the "Virgin and Child;" all after Raphael.

An "Holy Family," after Michael Angelo; a very rare print of an "Holy Family," after Raphael, wherein St. John is holding a reed, and St. Elizabeth is spinning; another "Holy Family," in which the Infant Jesus is receiving a fish from Tobit, distinguished by the name of "The Virgin of the Fish," and after a very celebrated picture which Raphael painted for the church of the Dominicans at Naples, and which has since been in the gallery of the Escurial; "The Holy Virgin sitting on the Clouds, with the Infant Christ," a plate which afterwards fell into the possession of Agostino Carrache, who re-touched it, and added two fine heads of Cherubs; a set (mentioned above) of seventeen plates, coarsely copied from the wood-cuts by Albert Durer, of the "Life of the Virgin Mary," and marked with Durer's cypher, except the last, which has that of Marc Antonio. These are in small folio, and very rare. A set of thirty-six small uprights, from Albert Durer's "Life of Christ," marked with the ordinary tablet of Marc Antonio.

A set of thirty-six small uprights, called "The Life and Passion of Christ," copied from Durer, but marked with the tablet of Marc Antonio. A duplicate set of these are by some critics supposed to be the production of Wirix, or some other of the disciples of Marc Antonio, and this set bears the cypher of Albert Durer. "Christ at the Entrance of the Temple, surrounded by his Disciples;" "The St. Mary Magdalen at the Feet of our Saviour;" "Christ celebrating the Passover;" "The Descent from the Cross," in which, with the holy women, is introduced Joseph of Arimathea. Three prints, which are known among collectors by the title of "The Virgin of Grief." In one the Holy Virgin with extended arms is lamenting over the dead body of Jesus Christ. In the second, of which we have spoken more particularly above, and which is also called "The Virgin with the naked Arm," the holy mother appears much younger than in the first, and a dead tree is omitted; in other respects the two compositions are alike. And in the third, which is also a dead Christ, his head reclines on the lap of the Virgin; mount Calvary is in the back ground, and three disciples with Nicodemus are present. A glorified Christ with the Holy Virgin, St. John the Baptist, St. Paul, and St. Catherine, called "The Five Saints;" three of the cartoons, viz. "The Death of Ananias," (engraved in conjunction with Agostino Veneziano;) "Elymas struck Blind," and "St. Paul preaching at Athens." Proofs of the latter, before the two figures were placed within the balustrade of the temple of Mars, are extremely rare and valuable. St. Cecilia, with the Magdalen and other saints, known by the name of "The Saint Cecilia with the Necklace;" "The Martyrdom of St. Felicité." A duplicate plate of this subject, in which the right ear of the saint is omitted, is more scarce and valuable than the former. "St. Catherine reclining on her Wheel of Martyrdom." A set of thirteen, of Jesus Christ and the twelve apostles. All these are of folio dimensions, and after Raphael.

"The Martyrdom of St. Laurence," a large folio, after Baccio Bandinelli, is a very fine engraving, which obtained Marc Antonio's release from prison, and recommended him to the favour of pope Clement VII. "St. George and the Dragon," either from a composition by Marc Antonio him-

self, or after his first master Raibolini. "St. Gregory celebrating Mass," from Albert Durer's wood cut, entitled "The Mystery of the Mass."

Subjects from Profane History and Greek Mythology — "The Rape of Helen," a grand composition: "Æneas retreating from the Conflagration of Troy, bearing off Achi-ces, and preceded by the young Æcanus;" "Venus appearing to Æneas in the Disguise of a Huntress;" (an early work of the master); "The Death of Dido;" "The Death of Lucretia;" "Infernal in the Greek language, "Better to die than live dishonoured," and the first plate engraved after Raphael by Marc Antonio; a subject, by some termed "Alexander the Great depositing the Poems of Homer in the Coffin of Darius," and by others "The Books of the Sybils placed in the Tomb of Numa Pompilius." A battle-piece, known among connoisseurs by the title of "The Battle of the Cutlasses," all after Raphael, and in folio.

From the same master he has engraven "The Three Angles of the Lodge of Chigi," of which the subjects are, 1st. "Jupiter caressing Cupid;" 2d. "Mercury descending from Olympus;" and 3d. "Cupid and the Graces." A very grand composition of "The Judgment of Paris;" and from Andrea Mantegna, "Mars, Venus and Cupid;" of which the collector should be careful to obtain those impressions that were taken before the name of Rossi was added as the publisher. "Apollo leaning against the Shepherd Hyacinthus, and accompanied by Cupid," is either after his first master Raibolini, or from a design by Marc Antonio himself. A tablet is here suspended, from a tree, on which is inscribed the date 1506, and A.E. 19 is added, which gives the year 1487 as that of his nativity.

"The Triumph of Galatea" is a capital print, of which the best and rarest impressions are before any letters, and those with the names of Van Aelst and Rossi are comparatively worthless.

"Mount Parnassus" is a large and grand composition from the celebrated picture in the Vatican, except that Marc Antonio has very properly substituted a lyre for a violin; the instrument upon which Apollo is playing in the original picture. It is not improbable that Raphael himself, having discovered the anachronism, directed this emendation.

The above two are after Raphael. A very fine engraving of a Bacchanalian subject, with children bearing baskets of grapes, and Bacchus seated on a tub, is also after Raphael, but was drawn by him from an antique bas-relief; "Bacchus and Silenus" is by some critics said to be after Julio Romano, and "Hercules smothering Antæus," after Michael Angelo; but others ascribe both these compositions to Raphael.

"The Battle of the Lapithæ;" the last work of Marc Antonio, is of the frieze form, dated 1539, and after Julio Romano. Of "Orpheus" the designer is not certainly known. "Pyramus and Thisbe" is after Raibolini. "Le quos ego," or Neptune appeasing the Tempest which had dispersed the Fleet of Æneas, is surrounded by a border, in which are nine small compartments, containing subjects from the Æneid, and is after Raphael. Impressions of this plate, before it was re-touched, are rare and very valuable. The disagreeable hardness which the abdominal muscles in the figure of Neptune have acquired in the retouching, renders them easily distinguishable.

The above are all of folio dimensions. In quarto, Marc Antonio has engraven a set of twenty amorous and indecent subjects after Julio Romano, to accompany the sonnets of Aretin, of "The Loves of the Gods and Goddesses," which are, as they certainly ought to be, exceedingly scarce, and a

set of thirty-two, of "The Loves of Cupid and Psyche," after Raphael, each accompanied by eight Italian verses.

Partic. Inventionis, &c.—"Le Stregozzo," the design of which is by some attributed to Raphael, and by others to Michael Angelo. Sometimes it is called, "Raphael's Dream," and probably with great truth, for though it differs from the rest of his works, yet it differs not so much, but that it may be the production of his mind, and it possesses all the romantic wildness of a nocturnal chimaera. A monstrous carcass is converted into a sort of triumphal car, in which is seated a forceful; it is drawn by naked men, and a youth mounted on a goat is blowing a horn. It is in very large folio, and in the later impressions the initials of Agollino Veneziano are added to the mark of Marc Antonio. "Il Morbetto," or The Plague, another large folio after Raphael, good impressions of which are extremely rare. Three figures from Michael Angelo's Cartoon of Piffa, dated 1510, and known among collectors by the title of "The Climbers," "Il Pito," or The Triumph of Love, an allegory, by some supposed to be after Andrea Mantegna. "The Emperor Trajan crowned by Victory," from a bas-relief on the arch of Constantine; "The Chace of a Lion," from another antique bas-relief; "The Caffolette," a grand Bacchanalian procession, of the frieze form, nineteen inches in length; "An Offering to Priapus;" the statues of Apollo and Cleopatra; a bas-relief of "The Three Graces," and a dance of nine children, all after Raphael.

Agollino de Musis, surnamed Veneziano, from the place of his nativity, and called in England Angulfin the Venetian, was born at Venice some time about the year 1490. He travelled to Rome for improvement, and became one of the most celebrated of the numerous disciples of Marc Antonio, with whom he sometimes worked in conjunction. From the circumstance of his earliest known engraving being dated in the year 1509. Strutt supposes that he began to study under Marc Antonio, whilst that distinguished master yet resided at Venice. Marc of Ravenna was his fellow pupil; and Vasari classes them among the very best of the Italian students who followed the art of engraving.

When the city of Rome was taken and sacked by the Spaniards in the year 1527, Agollino retired to Florence, and applied for employ to Andrea del Sarto, who was then in high repute, but del Sarto, dissatisfied with the dead Christ which he had already engraved after his design, refused to permit him to engrave any more of his pictures. Agollino afterwards returned to Rome, where he followed his professional pursuits with great success, and where he died some time about the year 1540.

He generally marked his prints with the initials A. V., which were sometimes inscribed on a tablet. He imitated the style of his master with great attention, and, as far as regards manual execution, with considerable success: sometimes, indeed, he in this respect excelled Marc Antonio; but in point of taste, and in the purity and correctness of his outline, he fell far short of that distinguished artist.

Good impressions of the works of Venetian are now become extremely scarce, and a complete set is hardly to be obtained; among them will be found a few, wherein he has expressed the flesh entirely by means of stippling, in a manner which, being imitated by Boulanger, grew by degrees into what is now termed the *chalk* manner of engraving. The following list is believed to contain the description or titles of his best performances.

Portraits of Charles V. after Titian, superferibed with sixteen Italian verses; another of the same emperor, inscribed "Progenies divum quintus sic, &c. &c. &c."

XXVI.," a profile of pope Paul III. in a leathern cap & the same, wearing the papal crown, dated MDXXXVI. 2. all in folio. Ferdinand king of the Romans, in 4to.—Francis I., of France, dated 1536; a profile of the emperor Soliman, dated 1535; Barbarossa holding a turban; all in folio.

Subjects from Sacred History.—"The Creation," a folio plate, engraved partly by Agollino and partly by Marc of Ravenna, and inscribed "Exc. Deus enim Omnia," &c. "Abraham offering up Isaac;" "The Benediction of Isaac," dated 1522; the same subject, with some trifling variations, dated 1524; "The Passage of the Red Sea," engraved in conjunction with Marc of Ravenna; "The Fall of Manna," a plate which presumptively was begun by Marc Antonio, and finished by Venetiano, all after Raphael and of folio dimensions. "Samson bound by the Philistines," a circular print, nine inches in diameter, is supposed to be from a composition by Venetiano himself.

"The Queen of Sheba visiting Solomon," after Raphael, has been attributed to the graver of Marc Antonio, but is by Agollino and Marc in conjunction, and one of their early performances. It is of the folio size.

A set of the four evangelists, in 4to. is after Julio Romano. "The Annunciation" is after Raphael, and engraved by the friends and fellow students Agollino and Marc; "The Nativity" is after Julio Romano; and both are of folio dimensions.

"St. John the Baptist in the Desert," of an anonymous invention, dated 1532; perhaps designed by the engraver himself. "The Massacre of the Innocents," a rare engraving, is copied from the celebrated print of Marc Antonio; "The Last Supper," in folio, after Albert Durer; the same subject in smaller folio, attributed to Raphael; "Christ bearing the Cross," in folio, after Raphael, dated 1519; "The dead Christ," after Andrea del Sarto, a folio print, with which, as mentioned in our biography, the painter was so dissatisfied, as to refuse Venetiano the liberty of engraving from his works during his own lifetime. Another dead Christ, in small quarto, after Albert Durer, a very rare print; "The Archangel Michael," in folio, after Raphael; "The Holy Family," in small folio, marked only with the initials of our artist, and probably from his own composition; another "Holy Family," after Francia, dated 1516; "The Holy Virgin and Child, sitting on a Pedestal," six friars and a nun are present, and above are two angels, holding a tablet with an Ecce Homo, in folio; "The Crucifixion," with six figures of saints and angels receiving the blood of the Saviour, dated 1528, and also in folio; "St. Jerome," after Raphael, in quarto; "St. Margaret kneeling, and putting a Demon of the Serpent Form to Flight, by means of the Mirror of Truth," an early performance of Agollino, engraved before he frequented the school of Marc Antonio.

Subjects from Greek Mythology and History.—"Iphigenia en Tauride," an anonymous plate, in quarto; "Diogenes lying on his Cloak near the Margin of a River," a small engraving after Baccio Bandinelli; "The Loves of Alexander and Roxana," an anonymous plate, in folio, the design of which Vasari attributes to Raphael; "Tarquin offering Violence to Lucretia," in 4to. after the same master; a very fine copy of Marc Antonio's print of Lucretia, in quarto, with Latin verses beneath. "Camillus redeeming the Tribute imposed on Rome by the Gauls," and a naked figure of Cleopatra, both in small folio, and after Bandinelli; a small figure of Mars, after Raphael; "Vulcan presenting Venus with Arrows," dated 1530, and "Venus seated on a Dolphin," both

both in folio, and after Raphael; "The Assembly of the Gods," engraved by Agollino and Marc of Ravenna; attached to which, by the same artist, is "The Marriage of Cupid and Psyche," both after Raphael. From the same painter, are "Leda cared by the Swan," in 4to.; "The Fall of Phaeton," in folio; and "Apollo and Daphne" in quarto; the latter of which is by some falsely attributed to the graver of Marc Antonio.

"The Dispute between the Muses and Pierides," an anonymous plate, in large folio, attributed by Vafari to the pencil of Rosso, and by the French to that of Perin del Vaga: this plate was afterwards re-touched and re-published in 1553, by Eneas Vico; "The Metamorphose of Neptune into a Horie," in 8vo., after Julio Romano, dated 1516; "A Bacchanalian Triumph," in 4to., after Raphael, or, according to Mariette, after Raphael del Colle; "The Entrance of Orpheus into Inferno," a small engraving, after Julio Romano, dated 1525; "The Infant Hercules destroying the Serpents," in small folio, after the same master; "The Death of Anteus," in small folio, after Michael Angelo, wherein Earth is personified as an old woman, dated 1533; "Hercules killing the Nemean Lion," a small print after Raphael, dated 1528, and a frieze of considerable length, of which Mariette attributes the invention to Bandinelli, and of which the subject is a female figure on Olympus, blowing a trumpet, in preference of the assembled deities.

Allegoric Inventions, &c.—An old Man seated on a Bank, with a Cottage in the back Ground," one of the few plates wherein Agollino has stippled the flesh with the graver. Providence: on a tablet held by two angels is inscribed "Causar. Cognitio;" this is a small folio, and after Marc Antonio; "The Cumæn Sybil," after Raphael, in 4to., and dated 1516; "The Cemetery," in large folio, after Bandinelli. This is the print sometimes called "The Skeletons of Baccio," wherein Death is represented tearing a book in preference of various other skeletons; "The Battle of Charles the Rash," a small folio, dated 1518; "The Climbers," being part of Michael Angelo's Cartoon of Pifa, in large folio; "The Academy of Baccio Bandinelli," also in large folio; "A Combat between Five Warriors," also said to be from the celebrated Cartoon of Pifa, in 4to.; "The Three Marys (veiled figures), on their Way to the Sepulchre," in folio, an anonymous design, but attributed by Huber to Michael Angelo; another from Michael Angelo's Cartoon of Pifa, in 4to., a very rare print; "A Shepherd caressing a Shepherdess," in folio, after Raphael; "An aged Philosopher measuring a Diuk," after Dominic Campagnola. A very rare print in 4to., after Raphael, of "A Female resting her Right Hand on a Vase;" "A Dance of Fawns and Bacchantes," of the frieze form, dated 1518, after an antique bas relief, but by some ascribed to Primaticcio. A set of sixteen plates of bronze and marble vases, from the antique, in small folio, inscribed "Sic Romæ Antiqui Sculptores," &c. Another set of thirty-six, in 4to., of grotesque subjects, after Raphael, some of which only are marked with the cypher of Agollino; the rest are by other pupils of Marc Antonio. A set of forty-eight bustos, in 4to. "The Arch of Constantine," in a circle, dated 1517.

Marcio Ravignano, commonly known by the name of Marc of Ravenna, was born at Ravenna in the year 1496. He studied at Rome, and became the pupil of Marc Antonio, and co-disciple and friend of Agollino of Venice.

As long as Raphael lived, i. e. till the year 1520, our two engravers worked together, after which each began to

engrave on his own account, and to mark his prints with his own peculiar cypher.

Mark died at Rome about the middle of the 16th century. Strutt says of him that he "imitated the bolder style of engraving which was adopted by his master, with great accuracy; but when he attempted to follow him in his nicest manner, he was not equally successful. He handled the graver with more freedom than his fellow scholar de Muis, who, however, surpassed him in neatness and precision.

Ravenna drew well, as his best prints sufficiently testify; though not with that purity or outline which distinguishes the works of his master; neither are the extremities of his figures marked with equal correctness or judgment. His works, however, are justly held in estimation by the connoisseurs.

The usual mark adopted by this artist is a cypher, composed of an R and an S joined together, which has been the occasion of several mistakes, not only with respect to his works, but with respect to himself; and has led several authors to suppose that there were two Ravennas, the one named Marco, and the other Silvestro; and they have been confirmed in this opinion by the declaration of Vafari, who tells us, that Marco da Ravignano, for so he writes the name, marked his plates with an M and an R, which, in some few instances, he certainly did. Those, who do not suppose there were two Ravennas, have imagined that these two letters were designed for Raphael Sanzio, and placed upon the plate to denote that it was taken from a design by that master. This opinion, however, is easily confuted; for the same mark is found on "The Slaughter of the Innocents," after Baccio Bandinelli, and of course cannot, by any means, refer to Raphael. It certainly should be read *Ravenna* or *Ravignano, sculptor*. He sometimes marked his engravings with a single R without the S, and at others, as will be found in our Plate I. of the Monograms, &c. of the Italian School.

Of the engravings of Ravignano, the following are those which are held in most request, beginning with the

Sacred Subjects.—A set of twelve, of the frieze proportions, from Bible history, after Raphael; "The Slaughter of the Innocents," a large folio plate, after Bandinelli. A duplicate plate of the same subject, differently cyphered, and without the name of the painter; "The Transfiguration," marked with an R on the bole of a tree, under which a disciple is seated; "The Last Supper," marked R, and from the same original as that by Marc Antonio; and "The Virgin of the long Thigh," varied from that by Marc Antonio, by the introduction of a small key, all in folio, and after Raphael; "The Holy Family," after Polidoro, in folio. A set of thirteen, of the Saviour and Apostles, in 4to., after Raphael, and distinguishable from those of Marc Antonio, by the cypher of Ravenna; "The Victory of St. Michael," in small folio, after Raphael; "The Cemetery, or Memorial of Death," in folio, after Bandinelli, but differing so widely from that by Agollino de Muis, both in particulars and the general composition, as to warrant an opinion that it is engraved from another design.

Profane Subjects.—"The Rape of Helen," and "Alexander depositing the Works of Homer in the Coffin of Demetrius," both in folio, and after Raphael. A pair in folio, of "The Interview between Scipio and Hannibal," and "Scipio's Victory over the latter," after Julio Romano. A small anonymous print of an armed Jupiter, the design of which is attributed to Salviati; "Venus quitting Juno and Ceres," a small folio, from the fable of Psyche; "The Triumph of Galatea," in large folio, marked with an R,

and "Jupiter and Antiope," in small 4to., all after Raphael; "Euridice in L. ferno," engraved in the table of Marc Antonio, apparently after Julio Romano; "A Nymph and Triton," in 4to., anonymous but after Raphael; "Polyphemus, attended by Cupid, pursuing Galatea;" "The Triumph of Galaten," and "Aspasia as a Shepherd guarding the Flocks of Admetus," all in 4to., and after the designs of Raphael. A set of three prints, called "The Nymphs of Marc Antonio:" the first, accompanied by Cupid, is drawn by two marine monsters, the second is watched by a satyr, and the third is drawing a thorn from her foot, all after Raphael; "The Birth of Venus," in folio; "Cupid mounted on a Dolphin," in 4to.; "Vulcan forging Arrows for Cupid," in 4to., all after the same painter; "A drunken Silenus, supported by two Bacchantes," an anonymous print, in 4to.; "A Satyr holding a Nymph in his Arms," anonymous also, but supposed to be after Julio Romano; and "A Combat between a Satyr and a Goat," of anonymous design, both in 4to.; "The Combat between Entellus and Daret," in folio, after Raphael; "Orpheus," in 4to.; "Poey," a duplicate plate, or copy from that by Marc Antonio, of the same subject, in 4to., dated 1542; "Infant Bacchanals," from Julio Romano, in folio. An emblematical subject, in which are represented a lion, a fox, and a dragon, with the word "Ergo," an oval print.

Antique Bas Reliefs, Statues, &c.—A sacrifice from the antique, in 4to. The same subject reversed. A bas-relief, from the arch of Constantine, in folio. An antique frieze with architectural decorations: the subject is three cupids, or genii, two of whom hold shells, and the other a trident. The original is preserved in Ravenna, the native city of our artist, in the church of St. Vital, with the inscription "Opus hoc antiquum reperit Ravennae in aed. divi vitalis MDXVIII." A battle piece, in folio. A female conducting a lion towards a funeral pile. Notwithstanding that this print is inscribed with the cypher of Marc of Ravenna, it is so much in the style of Marc Antonio, that some connoisseurs attribute it to his graver. A set of four bas-reliefs from the Trajan column, in small folio, and in a slight unfinished manner. The antique group of the Laocoon, a large upright folio, and exhibiting the only instance which has come to our knowledge, where the artist has inscribed his name nearly at length, omitting only the letter A in Marcus. Another engraving of this group, in folio, marked with the ordinary cypher of our artist, and inscribed on the base "Prout in H. denicos P. V. Maronis." It is supposed by many that Raphael made the drawing for the latter print: both of them are rare and remarkable, as shewing the exact state of this wonderful monument of art at the time when it was discovered.

The remainder of Ravignano's engravings from the antique are, the equestrian statue of Marcus Aurelius, in folio, inscribed "Sic Romæ acq. sculp. ante Portum Eccl. &c." The three Graces. A naked female drawing a thorn from her foot, called "The Venus of the Rabbit." Two females with a callosette or censer, after Raphael. Statue of a man sitting, inscribed "Roma in Capitoli," all in 4to. Mutilated statue of an emperor, marked with the large R, a small folio plate.

Julio Bonafoni, or Bonafone, was a native of Bologna, and for that reason is sometimes called Bolognese: he was born in the year 1468, and died at Rome in 1564. He studied the rudiments of art under Laurent Sabatini, a Bolognese painter, but afterwards became the disciple of Marc Antonio. He worked from the pictures of Raphael,

Julio Romano, and other great masters, and occasionally from his own designs. Excepting one or two subjects, in which he called in the assistance of the point (which, however, he never well understood the use of), his plates are executed entirely with the graver, in a manner though much varied from that of his tutor, yet evidently founded upon it. It is neither so firm, nor so clear and matterly. His drawing is often heavy, and the extremities of his figures frequently neglected. The folds of his draperies are seldom well expressed, and the back-grounds to his prints, especially his landscapes, are extremely flat and stiff. However, with all these faults, which are not always equally conspicuous, his best prints are not without their merit; and though not equal to those of his master, are held in no small degree of estimation by the generality of collectors. One thing in particular is remarkable in them, namely, the attempt which he has made of preserving the masses, and a breadth of light and shadow, as well upon the groups of figures, as upon the figures separately.

Mariette has written a catalogue raisonné of 160 selected engravings by this master; and Mr. Cumberland a small book, wherein he bestows on Bonafoni much more praise than he deserves.

Bonafoni sometimes affixed to his prints his name at length, sometimes he contracted it, but not always in the same manner; and sometimes he employed the monogram, which will be found in our Plate I. of those of the *Italian Engraver*. The most esteemed of his engravings are those which follow.

The *Portraits* of Pope Marcelle II. in 4to., anonymous, and very rare; Philippus Hispaniarum Princeps, Caroli V. filius," in large 4to.; Cardinal Bembo, aged 77, after Titian; Raphael d'Urbino; Michael Angelo Buonarroti, aged 72, in a circle; Franciscus Flori of Antwerp, a Belgic painter; Johannes Bernardinus Bonifacius; and Niccolò Ardinghella, Cardinalis, annus ægens XLIII.

Sacred Subjects.—"The Creation of Eve," after Michael Angelo; "Adam and Eve in Paradise:" they are sitting in an arbour embracing each other; and "Adam and Eve after the Fall:" Adam is here digging the earth; Eve is spinning; and two children are present. These are in small folio, and from composition—by Bonafoni himself; "Adam and Eve driven out of Paradise," a small folio, after Amico Aspertini; "Joseph sold to the Ishmaelites;" and "The Cup found in Benjamin's Sack," both after Raphael; "The Fall of Manna and Moses striking the Rock;" on the same plate, after Parmegiano; all in small folio; "Judith leaving the Tent of Holofernes," a large folio print, after M. Angelo; "The Nativity," designed by the engraver, in 4to. Another of the same subject, in folio, from a grand composition by Julio Romano; "The Adoration of the Shepherds," in folio, of anonymous invention, but attributed by Malvasia to Parmegiano; "The Holy Family," a folio print, after Julio Romano; another "Holy Family," where St. Joseph is seated on an ass, designed by Bonafoni; "A dead Christ," after Raphael; "The Entombing of Christ," after Titian; "The Resurrection," designed by Bonafoni himself; "St. Peter placed at the Head of the Church," after Raphael; "St. John and St. Peter healing the Sick," after Perino del Vaga; "St. Paul preaching to the People," an oval, after Perino del Vaga, all in small folio. A large folio upright plate, arched at the top, of "The Last Judgment," after Michael Angelo, inscribed "Julius Bonafonius Bononi, propria Michaelis Angeli pictura quæ est in Vaticano, nigro lapillo exceptis in ætate incidit;" "Jesse, David, and Solomon," in folio, from the celebrated picture

ITALIAN SCHOOL OF ENGRAVING.

in the Sistine chapel, by the same master; "St. Joachim and St. Ann presenting Mary their Daughter to the High Priest," after Parmegiano; "Christ meeting St Peter at the Gates of Rome," after Raphael; "The Virgin and Child," after Parmegiano; "St. Cecilia," after Raphael; "St. George," after Julio Romano; "The Emperor Augustus, and the Sybil," after Parmegiano, all in small folio. In 4to. a set of twenty-nine prints, from "The Life and Passion of Jesus Christ;" and in Svo. a set of thirteen, from "The Life of the Holy Virgin."

Profane Subjects.—"Achilles dragging the Corse of Hector at his Chariot Wheels;" after Primaticcio; "The taking of Troy," after the same painter, a large folio, engraved on two plates; "The Dispersion of the Fleet of Eneas," after an anonymous, but very indifferent design; "Alexander and Bucephalus," in folio, from a composition by Bonafoni; "Cimon nourished by his Daughter," of the frieze form, after Poldore; "A Combat of Cavalry," being the first idea of Raphael for his battle of Attila; "Scipio wounded and retiring from the Combat," from a design by Bonafoni; "The myserious Saturn with his Three Sons," after Julio Romano. A set of twenty-two fine engravings, designed by Bonafoni, of the loves, disdain, and jealousies of Juno; "The Rape of Europa," after Raphael, in large folio; "Mars and Venus," in folio, after Primaticcio; "Vulcan discovering the Amours of Mars and Venus," in 4to., of anonymous invention; "Venus attired by the Graces," in 4to., after Raphael; "The Birth of Adonis;" "The Triumph of Cupid and Psyche;" and "Phæbus in his Car, attended by the Hours, with Time walking on Crutches before them, and a Man and Woman waking from Sleep," are all in small folio, and from compositions by the engraver himself; "The Destruction of the Children of Niobe," after Perino del Vaga, dated 1541; "The Fall of Phaeton," in large 4to., after M. Angelo, and a group of three females, after the same master, in folio.

From Antique Sculpture and Architecture, &c.—Small busts of Jupiter, Juno, Latona, Bellona, and Minerva, five plates; "Hercules and Dejanira;" "A Satyr and Nymph;" "The youthful Olympus holding a Flute;" "The Flight of Medea," a bas-relief; a ditto representing "A Female and Two Children feated;" "The Loves of the Centaurs," with grotesque foliage, all in 4to.; "The Temple of Jupiter and that of Neptune," both in folio; and a considerable number of book-plates, the subjects of many of which are from the amours of the heathen deities.

Jean Baptista Franco, was born at Venice in 1498, and died in the same city, A.D. 1561. He learnt the principles of design in his native country; but travelled to Rome to perfect himself by studying the works of Michael Angelo. According to Vafari, he made a drawing after the famous Last Judgment of that master, which passed in his time for a chef-d'œuvre. Franco had an excellent taste in design, and perfect knowledge of anatomy. He excelled greatly in the correctness of his contours, and the learned manner in which he indicated the play of the muscles. But as a painter he was deficient; he knew very little of composition; or colouring, his pictures were therefore without harmony, and hard. He felt their imperfections, and quitting painting, applied himself to drawing and engraving. Of whom he learnt the art of engraving we are ignorant; it has been said he was of the school of Marc Antonio; but the mechanical part of his engraving bears more resemblance to that of Julius Bonafoni. He used the graver, and probably that instrument alone, notwithstanding that many of his prints appear as if done with the point. His taste was free, and he worked in a grand style; his figures were generally

well proportioned, and his attitudes various and well contrived; his heads were often small, but always well designed and characteristic; and the other extremities were rendered with the hand of a master.

Franco generally marked his prints B. F. V. F. that is to say, Baptista Franco Venetus Fecit; and his best engravings are as follow:—"Abraham receiving Melchisedec;" "The Sacrifice of Abraham;" and "Moses striking the Rock;" all in small folio. "The Israelites receiving Manna in the Desert;" in large folio. "The captive Kings brought before Solomon;" ditto. "The Adoration of the Shepherds;" "The Virgin sitting at the Foot of a Rock, caressing the Infant Jesus, and in the back ground the little St. John;" "St. John the Baptist lying on the Earth;" all in small folio. "St. Jerome holding a Death's Head;" a large folio print. "Jesus Disputing in the Temple with the Doctors of the Law;" "The Disciples laying the Body of Christ in the Tomb;" large folio. "Simon the Magician, practising his Impostures before the Apostles;" "A Cyclop in his Forge, with Cupid at his Side;" "Hercules bending his Bow against the Centaur Nessus;" "Two Leopards, two Lions, a Wild Goat, and a Griffin," from the antique; "The Donation to the Roman Church, by the Emperor Constantine," after Raphael; "A Bacchanal," a grand composition, from Julio Romano; "Triumph of Bacchus," a grand composition, all in large folio; "The Deluge," in small folio.

Jacques Franco was born at Venice some time about the year 1560; and probably of the same family as Baptista. His taste in engraving bore much resemblance to that of Augustin Carrache, of whom he was the contemporary. He was a good designer, and marked his heads and other extremities very well: among the number of his productions, the following are the most esteemed:—Part of the 4to. engravings for the edition of Tasso's Jerusalem, which was published at Genoa in 1590, after the designs of Bernardo Celli; the rest are done by Augustino Carrache; a collection of portraits of great men, published in 1626, dated 1596; "The Crucifixion," a small piece, marked Giacomo Frasco fec.; "St. Jerome," ditto; "Hercules between Vice and Virtue," from an antique bas-relief; besides many other plates after Baptista Franco.

Nicholas Beatrice, Beatrici, or Beatrizet, was a native of Thionville in Lorraine, but studied engraving in Italy, and chiefly at Rome. He was born some time about the commencement of the sixteenth century, and continued practising his art at Rome till the year 1562, about which time he probably died. Whether he became the disciple of Marc Antonio, or of Agostino of Venice, is not certainly known; Strutt thinks he studied under the former. A fabled contemplation and imitation of Marc Antonio's excellent print of "Neptune calming the Tempell," after Raphael, certainly contributed to the formation of what little he possessed that might be called style in his art. Yet it is much more the merits of Michael Angelo, Raphael, and the other great masters after whom he engraved, than his own, which makes his prints desirable, for he neither drew accurately, nor had attained any considerable powers in handling his graver; and his knowledge of chiaro-scuro was but very superficial.

The opinion which was held by many collectors, that Beatrice was the author of the engravings which are marked with a small die, inscribed with the letter B, seems at length to be justly abandoned. They are the performances of a superior artist, and perhaps of Bartholomew Beham. The marks which do belong to him will be found in our Plate I. of the monograms of the Italian School of Engravers.

ITALIAN SCHOOL OF ENGRAVING.

The prints by this artist which are most sought after, are those which follow, beginning with his

Portrait.—Plus III. with a Latin inscription; Paul II.; Paul IV. dated in 1558; Plus V.; Henry II. of France, dated 1558; another of the same monarch, with accessories, dated 1558; Hippelito Gonzague; Don Juan of Austria, in an oval, with the battle of Lepante in a cartouche; and other accessories; a set of medallions of the kings of Poland. All the above are of folio dimensions.

Subjects from Sacred History.—"The Death of Abel," in 4to.; "Joseph interpreting the Dreams of his Brethren," in folio, after Raphael, one of the best of Beatrice's engravings; "Abigail meeting David," a small folio, of which critics have disputed, without settling whether the design is by M. Angelo, Bandinelli, or Julio Romano; "The Nativity of the Virgin Mary," after Bandinelli; "The Annunciation," after M. Angelo; "The Adoration of the Magi," after Parmegiano; "The Holy Family," after Jerome Moutien; "The Good Samaritan," after M. Angelo; "Jesus Christ on the Mount of Olives," after Titian; "The Crucifixion," after Mucianus Braxianus; "The Virgin in Grief," after M. Angelo; "The Descent from the Cross," after N. Circignani; "The Ascension," after Raphael; "The Conversion of St. Paul," after M. Angelo; "St. Michael's Victory over the Devil," after Raphael, all in folio; "The Holy Virgin distributing Rosaries," a large oval print; "The Adoration of the Holy Cross," (an altar piece in large folio); "The Prophet Jeremiah," from M. Angelo's picture in the Sidine Chapel; "St. Jerome," after Titian; "St. Elizabeth, of Hungary, healing the Sick," after Muciano, all in large folio; and "The Last Judgment," a very large print engraved on several plates; from the far famed picture of M. Angelo.

Subjects from Profane History, &c.—"The Sacrifice of Iphigenia," after del Vaga, or Salviani; "The Rape of Ganymede," after Michael Angelo; "The Fall of Phaeton," after the same master; Strutt speaks highly of this engraving, but says it was not originally the work of Beatrice; "A Bacchanalian Piece," after Michael Angelo; "The Dream of Human Life," after the same master; a very singular allegorical print, exhibiting the influence of the passions, and said, by some, to be composed and painted by Michael Angelo, from a vision which he really experienced; "The Archers," from the same master; "Vertumnus and Pomona," from Jacobo Fiorentino; "The Combat of Reason and Love," after Bac. Pandinelli, called here Bradin; "Combat of five Men against five ferocious Beasts; two Lions, a Bear, a Bull, and a Wild Boar," anonymous, marked 1532, attributed to Julio Romano; "Battle of the Amazons," after a grand bas-relief on a sepulchral urn in the Capitol, a large piece, on two plates; "The Battle of the Dacians," from the Arch of Constantine, inscribed "Tabula marmorea Pugne Dacie, &c.;" "The Emperor Trajan in a triumphal Car;" "The Pantheon of Agrippa;" "The Temple of Fortune," from a drawing by Raphael; all in folio; "The Grand Circus," a large print engraved on two plates; "Front of the Farnese Palace," after Michael Angelo; "The Statue of Moses," from Michael Angelo; "Equestrian Statue of Marcus Aurelius," engraved in 1558; a standing figure of Christ, after Michael Angelo; "Statue of the Philosopher Anaximenes reading," since retouched, and re-named "St. Paul;" "The Castle of St. Angelo;" "Siege and taking of Thronville," a bird's-eye view, dated 1558. Most of the above are of large folio dimensions.

The foregoing artists worked with the graver only, but the art of etching had now travelled from Germany to Italy,

and Leo Daris, otherwise called Leon Daven, or Louis d'Avexne, who was the countryman and contemporary of Beatrice, is believed to have been among the very first who practised it in Italy. He was born some time about the year 1500: studied at Florence and at Rome, and returned to France, perhaps to Lorraine, or still more probably, to Fontainebleau, with Primaticcio, after whose compositions his principal works are for the most part engraved.

His style is singular, and though not imitable, has not often been imitated. His plates are chiefly etched in rather a coarse but spirited manner, in short hatchings; his lights are kept broad and clear, but his shadows wear degradation, his outlines are stiff and hard, and his heads, hands, and feet, are not correctly drawn. The following list will probably be found to contain his best engravings:—"Venus blinding Cupid," designed by the engraver, in 4to. A pair of "Jesus Christ," and "The Holy Virgin," each surrounded by a glory and heavenly host, after Primaticcio; from whose pictures Daris also engraved, an "Holy Family;" "The victorious Saviour;" "Alexander and Bucephalus," an oval; "The Marriage of Alexander and Roxana;" "Cleopatra standing under a Tent, holding the Asp in her hand, and resting the other on a Vase;" "The Contenance of Scipio;" "The Rape of Europa;" "Danae in the Shower of Gold," an oval; "Jupiter pressing the Clouds to cause Rain on the Earth;" "Venus bathing," a grand composition, where there is in the back ground an old woman bringing refreshments, in a sculptured border; "Venus entering with Mars into a Tub;" on the foreground are cupids playing with the arms of Mars, and two women with vases; "The Forges of Vulcan;" "The Rape of Proserpine;" "The Chace of a Stag;" "The Rapose of Diana after the Chace;" (she is lying by the side of her game with a dog under her arm); marked Fontainebleau; "Hercules undressing to enter the Bath with Omphale;" ditto; "Hercules in the Arms of Omphale, surprised by Fawns, with Flambeaus;" "Cadmus preparing to combat the Dragon;" "The Masquerade;" "The Elephant and the Caravan," all in folio, and after the pictures of Primaticcio.

After Rosso, our artist has engraven "Francis I. of France surrounded by his Court;" the same monarch entering the Temple of Glory; "Venus and Adonis;" and "The Dispute between Neptune and Minerva."—After Lucas Penni, "The Trojan Horse;" "Jupiter seated on his Throne;" "Psyche approaching the Dragon-guarded Fountain;" and "Parnassus with Apollo and the Muses."—After Julio Romano, "The Combat for the Body of Patroclus," after Parmegiano, "Crece and Ulysses," and a battle, after an antique bas-relief, all in folio.

Lucas Penni was born at Florence some time about the beginning of the sixteenth century, and was the brother of Giovanni Francesco Penni, surnamed il Fattore. He frequented the school of Raphael, and studied a considerable time under Perino del Vaga. He possessed considerable merit as an historical painter, and George Ghisi of Mantua has engraven from several of his pictures. After visiting Genoa and Lucca, he travelled to England, where he was employed by Henry VIII.; he afterwards went to France, and practised the fine arts for a while at Fontainebleau. On his return to Italy he applied himself to etching and engraving, and we have several meritorious prints from his hand; he sometimes worked from his own design, but oftener from Rosso and Primaticcio. His mark was usually composed of an L and an R joined together, or separate; for he chose to add the word Romanus, or the Roman, to his name, or the initials of it; but it is necessary to caution the young collector, with re-
spect

ITALIAN SCHOOL OF ENGRAVING.

spect to these marks, all of which will be found in our *Plate II.* of monograms of the *Italian Engravers*, because they were used by other masters greatly inferior in point of abilities to Penni, and to state that his engravings are not only executed in a very spirited style, but also accurately drawn. He chiefly etched, but at times worked with the graver only.

The following is a list of his principal works:—"Two Satyrs giving Wine to Bacchus;" "Leda drawing Arrows from Cupid's Quiver;" "Sufannah at the Bath furrowed by the Elders," all of which are from Rosso: but the four following are from Primaticcio; "Abraham sacrificing Isaac;" "The Marriage of St. Catherine;" "Jupiter metamorphosing Calisto into a Bear;" and "Penelope at work with her Women," all of which plates are of folio dimensions.

At the same period with Penni lived Francesco Marcolini, of Forlì, an ingenious engraver on wood, who engraved, printed, and published a volume, entitled "Giardino de Penfieri," ornamented with wood cuts after Jos. Salviati. The subjects are emblematical and satirical, and are executed with considerable delicacy for that mode of engraving. Marcolini was also an architect of no mean talent.

Another engraver on wood, Giovanni Niccolò Rossiliani, or Vicentino, also lived at this period, he was of Venice; of mediocre talent; engraved a few subjects after Raphael, and "The Entry of Henry III. into Venice."

Battista Vicentino, so called like Rossiliani, from his birth-place, has been sometimes mistaken for him. According to Vafari, he was born at Venice in the year 1500, and engraved, in conjunction with Baptist del Moro, fifty subjects of landscapes and ancient edifices, in a firm and agreeable style; these are chiefly of folio dimensions, and among them are Monte Quirinalis, the Coliseum, &c. &c.

The Ghisi of Mantua, each of whom was successively termed the Mantuano, were a numerous family of artists. Jean Baptiste, the patriarch of this Mantuan race, was born at the commencement of the sixteenth century, and, according to Vafari, was the disciple of Julio Romano, and he was occasionally painter, itatuary, architect, and engraver. In the latter art he worked with the graver only, and his style bears resemblance to that of Marc Antonio, when mingled with the work of his pupil Pezz, as in the celebrated print of "Neptune rebuking the Winds," where the lines of the shadows are gradually blended into stippled light. Baptista understood the human figure, but his drawing is mannered, and his effects deficient in harmony.

His usual mark will be found in our *Plate I.* of monograms of the *Italian School*, and his principal engravings are: a large folio, of which the subject is a "Naval Combat," from a composition by himself, dated 1538; some heads of warriors, helmeted, in 4to.; "The Holy Virgin suckling the Infant Christ," in 4to. dated 1530; "David beheading Goliath," in folio, dated 1540; "A Warrior eloping with a Female," probably the Rape of Helen, 1539; "A River God," after Lucas Penni, in 4to.; "Mars, Venus, and Cupid," in folio; "The Conflagration of Troy," a capital print from his own design, of large folio dimensions.

Georgio Ghisi was born at Mantua A. D. 1524. He was the nephew, or, as others say, the son of Jean Baptiste, whom we have mentioned above, and appears to have learned from him the rudiments of engraving, though in the progress of his studies he much improved the style of his predecessor.

Georgio was eminently successful in the technical and academical parts of the art: in particular he studied the extremities of the human figure with much attention; and ex-

pressed the knitting of the joints and turns of the limbs with considerable accuracy. The knees of his figures especially, he frequently drew in a manner which has been justly admired. There is, indeed, a sameness of style in the drawing and marking of his figures, which has made it suspected that he always drew from the same individual model, and thus obtruded a manner of his own, instead of rendering the forms of the great painters after whom he worked in all their variety. This may be the reason why he has succeeded so indifferently in working from Michael Angelo; whose forms he to a certain degree caricatured: the swelling of the muscles being too powerfully expressed, the lights became divided, the masses confused, and the necessary degrees of roundness impaired in the effect. These faults may be but too obviously seen in "The Last Judgment," engraved after that celebrated master, where the dorsal and abdominal muscles, as well as those of the limbs, are marked in a heavy, affected, and unpleasing manner.

Such defects as these, however, which do not always predominate in the works of Georgio, are often more than counterbalanced by the degrees of truth and beauty which are found in them.

Indifferent impressions of his prints are by no means rare, but such as are finely printed and well preserved appear but seldom, yet without seeing them, it is impossible to form an adequate idea of the merits of this engraver. His monograms will be found in our *Plate I.* of those of the *Italian School*; and the following are among his most justly valued performances.

"The Mystery of the Trinity," from his own composition; "The Prophets and Sybils" of Michael Angelo; a set of six upright folios from the pictures in the Sistine chapel; "The Last Judgment" of Michael Angelo, a very large upright, arched at the top, engraved on ten or eleven plates. The portrait of pope Julius II. after Raphael; and from the same master, "A Holy Family;" "The School of Athens," very large, and "The Dispute of the Sacrament."

His print of "The Dream of Raphael" is of doubtful original, for while some call it by this name, others term it "Michael Angelo's Melancholy." It is of large folio dimensions, dated in 1561, and represents an aged philosopher contemplating a shipwrecked vessel, while a nymph advances towards him: in the back-ground are strange and fantastic appearances. Bafan says that Raphael had no hand in it, yet the words "Raphaelis urbinatus inventum," are affixed to it, and the style of composition and design appear to justify the inscription.

Of a long 4to. size are, a female sitting in a boat, to whom an old man is bringing a new-born infant, of anonymous invention; and a winged female holding a globe. The remainder are in folio, viz. an allegorical print, in compliment to the birth of the prince of the house of Gonzague, after Julio Romano; "Cupid and Psyche crowned by Hymen;" and "The Birth of Memnon," both from the same master; the latter one of the finest engravings from the hand of Mantuano; "Cephalus and Procris," from the same; "The Interview between Scipio and Hannibal, previous to the Battle of Zama;" "Regulus reviv'd by the Carthaginians," and "Regulus enclosed in the Calk," all after the same master; "Venus at the Forge of Vulcan," is after Perin del Vaga; "Mars and Velus," after Raphael del Reggio; "Diana and Endymion," after Lucas Penni; "The Adoration of the Shepherds," is very large, and engraved on two plates, after Angelo Bronzini; "The Last Supper," after L. Lombart; "Hercules vanquishing the Hydra of Lerna," after Bernard Ma-

tuano; and after the same master, "The Judgment of Paris," "The Grecian Heroes before Troy," "The Destruction of Troy," and "The Cemetery," sometimes called "The Resurrection of dry Bones," a fine specimen of the artist's ability, wherein skeletons, tombs, and emaciated figures form a grand composition.

Adam Ghisi, also known by the cognomen of Mantuano, was a younger brother of George, and engraved much in the same style, though he was certainly somewhat inferior to his elder brother, both in correctness of outline, and the ability with which he handled the graver. The cypher with which he sometimes marked his engravings, will be found in our *Plate I.* of those of the *Italian School*, and among his best works are the following:—"Nativita de Nostra Signore," after Julio Romano, which is thus treated: In the heavens is the Deity surrounded by the heavenly host; lower in the composition is the Holy Ghost, surrounded by a radiance, and on the earth is the Holy Virgin and Child, and St. Joseph; "The Presentation in the Temple," after Nicolas Martinelli; a group from the marble of Michael Angelo, called "The Virgin of Pity," of which the subject is a dead Christ laying across the knees of his afflicted mother. Collectors should be careful to note, that in the early impressions, as the plate came from the hands of Adam Ghisi, the back ground is blank, but it has since been re-touched, and a landscape background added by Ant. Leferri, who, however, has affixed his own name to the print. The above are all of large folio dimensions.

In 4to. our artist has produced, "Mars preparing for Battle," and "Diana preparing for the Chase," either after Julio Romano, or from designs by himself; "Angelica and Medora;" "Diana and Endymion;" "Hercules and Joli;" "The Choice of Hercules;" "Two Cupids conducting a Car with a river God;" and "Two Cupids riding on Dolphins," both of the oval form; and "The God Pan playing on the Syrinx, with Venus and Cupid listening."

Diana Ghisi, of Mantua, was sister to the two preceding. The year of her birth has not been recorded. She was a woman of considerable ingenuity, and probably learned drawing and engraving from her brother George, whose style she successfully imitated. She employed no monogram or cypher, but marked her engravings, of which the following are the principal, with the name of Diana, sometimes without any addition:—"A Conversation Party of three Figures," and "The Holy Family," both of anonymous invention, and perhaps done from compositions by herself; another "Holy Family," in a landscape ornamented with ruined edifices, after Correggio, in large folio, dated 1577; another "Holy Family," after Raphael, where the little St. John is presenting a scroll to the Infant Saviour, while St. Joseph, in the back ground, repose on the base of a column, in folio; "The Virgin Mary caring the Infant Christ," after F. Salviati, in small folio; "The Holy Virgin and Child sitting on Clouds, and attended by the Archangels Gabriel, Michael, and Raphael:" this plate is probably engraved from her own composition, and the earlier impressions are without the inscription "Regina Angelorum:" it is in large folio; "The Institution of the Papacy, or St. Peter appointed Head of the Church," after Raphael; "The Woman taken in Adultery," after Julio Romano; "The Heroism of Horatio Coles," after the same master, all in large folio; "The Continence of Scipio," in small folio; and "The Birth of Castor and Pollux," which latter is perhaps the very best of Diana's engravings, are also after Julio Romano.

We shall add to this list but one more, namely, "The grand Festival of the Gods," after the same great painter, done from the celebrated picture in the palace del T. at Mantua. It is a very large production, which Diana, from a motive of convenience, has engraved on three plates.

Of Domenico del Barbieri, better known by the name of Fiorentino, we shall say but little; for, as an engraver, he merits not much, though he painted in *lucco*, under the superintendance of Rosso, with considerable ability. He was born at Florence in the year 1506, or thereabouts; and travelling to Fontainebleau in the year 1544, worked with credit from the designs of Primaticcio and Rosso. His engravings, which are executed in a stiff and incorrect manner, are sometimes marked with his name at length, with the occasional addition of Fiorentino, and at others with the cypher which will be found in our *Plate II.* of the monogram, &c. of the *Italian Engravers*.

Besides several plates of groups, and sometimes single figures, from the Last Judgment of Michael Angelo, he engraved a "Reposo," in which the holy family are attended by angels, in large folio; "A dead Christ," from Salviati; and an antique Banquet, from Primaticcio, both in small folio; "Mars and Venus," from Rosso, in 4to.; and "An Angel, or Figure of Fame, standing on a Globe holding two Trumpets," in folio.

We have now to speak of that extraordinary artist, Francesco Mazzuoli of Parma, more commonly known by his cognomen Parmegiano. He was born A.D. 1505, and died, at Castel Maggiore, at the early age of 35; yet in that short life very high degrees of excellence were attained in the art of painting and etching, notwithstanding that no inconsiderable portion of it was fruitlessly spent in alchemical pursuits.

For an account of his merit as a painter, see MAZZUOLI. He acquired the first rudiments of art under the tuition of his two uncles at Parma, and at the age of 16 surpassed the partiality of relationship, and even antonished the existing taste of that part of Italy, by the production of a picture of "St. John baptizing the Saviour in the River Jordan;" but the fame of Raphael and Michael Angelo soon attracted him from his native city to Rome, where he remained till Rome itself was sacked, studying with ardour from the works of those great artists, yet at times retarded, in no trifling degree, by his unfortunate predilection for alchemy.

It has been stated by some writers, and is generally believed, that Parmegiano (if not the inventor of etching) was the first Italian who successfully practised that art. Strutt says of him, with great justice, that "in the etchings of this great master we discover the hand of the artist, working out a system, as it were, from his own imagination, and striving to produce the forms he wanted to express. We see the difficulty he laboured under; and cannot doubt, from the examination of the mechanical part of the execution of his works, that he had no instruction. It appears to be something entirely new to him without the knowledge of any thing better. We know that he certainly was not the first inventor of etching, because it was practised in Germany before he was of age to attempt it; yet it appears as if he had been unacquainted with the prior discovery, or only knew of it imperfectly by report; and in the latter case he might have been nearly as much at a loss as in the former. The spirit and genius which appear through the clouds are such as justly render his etchings exceedingly valuable; and on this account they have been often copied, and sometimes indifferently. The mechanical part of them is scratched in with the point, often badly corroded with the aquafortis, and re-touched with the graver, without
the

the least appearance of knowledge as an engraver. But looking beyond these defects to the sweet characters of the heads, to the elegant turns of the figures, and to the beauty and simplicity of the composition of these rude sketches, what is wanting in the excellency of the mechanical part of the art, is abundantly supplied to the judicious eye, in the fire and animation of the matter. The copies are always better than the originals, with respect to the regularity of the workmanship; but even the best of them are exceedingly defective in style and spirit, so that they are easily distinguished upon comparison. Good impressions of the originals are very rare; such, I mean, as are not re-touched. From the fouls of the copper upon which he engraved, and the little skill he had in managing the aquafortis, his etchings are seldom clear or perfect in their appearance, though some indeed are greatly superior to others in this respect; and those perhaps he executed in the latter part of his life.

“It is also said that he engraved many prints on wooden blocks in *chiaroscuro*; but it is much more likely, as Bafan justly observes, that he was only the designer and director of these works, and that they were executed by Ugo da Carpi, Andrea Andreani, and other masters.”

The alarms of war, much more the distrest and horrors of a siege, are destructive to the pursuits of an artist. When Rome was taken by the Spaniards, Parmegiano retired to Bologna, whither misfortune pursued him. Many of his designs, etchings, and *chiaroscuro* blocks, were here stolen from him by an engraver, whom he retained in his service, and whom Huber calls by the name of Antonio de Trente, and De Piles, Antonio Frontana. They were afterwards recovered, or recovered in part; but whether by legal process, or the remorse of Antonio, has not been explained. Poor Parmegiano was for a time almost distracted by the event, which, with a debt due to the church, and other misfortunes, drove him from Bologna to Castel Maggiore, where he soon after died of a fever.

The most important of the prints from the hand of this great master, are, “Moses and the Burning Bush,” a small plate, and apparently one of his first attempts in etching; “Joseph solicited by the Wife of Potiphar,” and “Judith with the Head of Holofernes,” both in small 4to.; an antique sacrifice; a set of thirteen small uprights, of Christ and the twelve apostles; “The Virgin Mary receiving Inspiration from the Holy Spirit;” “The Adoration of the Shepherds,” a small upright; “The Marriage of St. Catherine,” in small 4to.; “A Holy Family,” where the Virgin is seated, and the Saviour is lying in a cradle; another “Holy Family,” where St. John is presenting a basket of flowers to the Infant Christ, in folio; another “Holy Family,” in larger folio, where a bishop and a saint are introduced; a very rare print, done with the graver, marked “Franc. Parm. fecit,” and of folio dimensions, of which the subject is also an “Holy Family;” “The Entombing of Christ,” a small upright folio, which Guido has copied of the same size; “The Resurrection of Christ,” in 4to.; “A Shepherd leaning on his Crook;” “A Mother instructing her four Daughters;” a back figure of a man with a woman seated by his side; all from his own compositions.

After Raphael, he has etched the celebrated cartoon of “St. Peter and St. John healing the lame Man,” in small folio; of which Strutt says, that it is one of Parmegiano's finest and most determined etchings, adding, “we see he has mixed his own sweet manner with that of Raphael, in the treatment of the heads, and it seems to me to lose nothing by the alteration.”

We conclude our list of his etchings with those of “Pene-

lope engaged with her Women at Embroidery;” “Diogenes busied with mathematical Diagrams at the entrance of his Tub;” and a small folio of the “Adoration of the Magi;” in *chiaroscuro*.

Antonio de Trente was born at Trentin A.D. 1508. He studied under Parmegiano, though but three years older than himself, and became a painter of some merit, and an excellent engraver in *chiaroscuro*, which latter art he is supposed to have learned from Ugo da Carpi. His style of engraving is by no means elaborate, and his extremities are often neglected, yet his prints are valued by connoisseurs. Respecting the robbery of his master, of which Huber has accused him, though we have thought it right to mention the report, we shall not very strenuously insist on the fact. Authors agree that the plates and blocks were restored after a time, and differ in the name of the robber; under such circumstances it would surely be unfair to brand with cyclopedian notoriety the memory of Antonio de Trente.

His most remarkable prints are, “The Virgin Mary embracing the Infant Christ,” from Beccafumi; another “Virgin and Child,” from Andrea del Sarto; “The Tiburtinian Sybil, pointing out the Saviour to the Emperor Augustus;” (which latter was printed in green ink,) after Parmegiano; a man holding a lyre; a back view of a man leaning against a bank, with a female head at some little distance; “Circe receiving the Companions of Ulysses,” of the octagon form; “Psyche saluted with divine Honours,” of the same octagonal shape; all of folio dimensions, and after Parmegiano; “The Martyrdom of St. Peter and St. Paul,” a still larger print after the same master, is particularly mentioned by Vasari, in his life of Marc Antonio.

Nicolas Vicentino, known under the name of Boldrini, an engraver on wood, was born at Vienna some time about the year 1510. Of this ancient engraver there is very little known, but it is supposed he was a pupil of Titian, from whose designs he commonly worked. There is a large upright print by him, representing Venus naked, sitting on a bank with Cupid, and a squirrel appears behind on the branch of a tree; the figures, back-ground, &c. are executed in a bold, free style, chiefly with a single stroke; but there is some cross hatching in the deep shadows. It is marked Titianus inv. Nicolas Baldrinus Vicentinus incipiat, 1566. The following are among his best engravings, which are very rare:—A portrait of Jean Baren de Schwarzenberg, surrounded with a border of warlike implements, after Albert Durer, in folio; “The Adoration of the Kings,” after Titian, marked with the cypher of Boldrini; another large print of “St. Jerome at Devotion at the Foot of a Rock,” in a landscape; “Saint Sebastian and St. Catherine,” with four other saints, of a large size; both this and the last are from Titian; a large print representing a mountainous landscape, with animals, a female leading a cow, and a young man carrying a large tub; another large print of an old ape between two young ones, entwined with a serpent, intended as a satire on the boat of Baccio Bandinelli, that his Laocoon surpassed the antique. This wood cut has been attributed to Titian by some authors, and to Boldrini by others.

To Antonio Salamanca, who was born at Rome in the year 1500, has been attributed a whole length portrait of Bandinelli; “God creating the Animal World,” after Raphael, both in large folio, with some other works, which are marked with one or other of the three monograms, which will be found in our second plate of those of the *Italian School*; yet Strutt doubts whether he was the author or only the publisher of these engravings.

Giovanni Giacomo del Caraglio, or Caralus, surnamed

Jacobus Veronensis, was born at Verona in the year 1512, and died at an advanced age at Parma. Caraglio went to Rome to study under Marc Antonio Raimondi, whose style he imitated with great success, and he occupies a distinguished rank among the engravers of Italy. He was a very clever designer, and possessed great knowledge in drawing the human figure, especially the heads, which are in general very characteristic and expressive, but his draperies are not so well drawn; the folds are not broad enough, and not sufficiently varied; and most of his prints are defective in the management of the chisello. Caraglio was also very skilful in engraving gems, and executed some medals which added to his reputation.

Sigismond I. king of Poland, being informed of the merit he possessed, invited him to his court, where he lived to a happy old age, rich in royal favour, and surrounded by his friends and pupils. He commonly marked his prints with his name, and occasionally with a cypher, which will be found in our second plate of monograms of the *Italian Engravers*. The following are among his best works: "The Virgin sitting with the Infant Jesus under an Orange Tree," marked Jacobus Veronensis; in 4to.; another quarto plate of "St. Anne, and other Saints, with the Virgin kneeling, holding the Infant Christ," marked as the former. A large folio print of "A Holy family," from the famous picture by Raphael, done for Francis I. since well known by the fine engraving of Edlinck. This one is without a name, but there are proofs with the name of Caralius; another "Holy Family," after Raphael, representing the Virgin holding the Infant Jesus on a cradle, and caressing St. John, who is presented by St. Elizabeth, in folio.

F. de Poilly has engraven this subject with the inscription "Deliciae mea esse." "The Marriage of the Virgin," from Parmegiano, in large folio. "The Annunciation of the Virgin," marked "Titiani figuram ad Cosareni exemplar. Jac. Caraglio," in large folio. "The Supplication of Tantalus," after the same master, in large folio; "The Rape of Ganymede," after Michael Angelo; this plate is attributed to Caraglio, but it is without his name, in 4to.; a print in 4to. of an anatomical figure holding a skull in its hand, sitting on a serpent, from P. Rolli del.; "Hercules receiving the Arrows of the Centaur Nessus," likewise from Rolli, in large quarto; "Hercules killing the Robber Cacus," after the same, in large quarto; a large square folio print, representing a number of young men and women cultivating a garden, in the middle of which is a statue of Priapus, after the same painter; a set of twenty prints in 4to. representing the statues of the heathen deities, with their attributes, in niches, from Rolli. Professor Christ says of these, that "the figures or statues of the heathen deities, which appeared under his name, are not by him; I find these ancient plates come originally from James Binck." But here he is certainly mistaken; those by Carabus are dated 1526; and the copies by Binck 1530; which is four years posterior to the first publication of them.

"The Loves of the Gods," in twenty small upright plates from Perin del Vaga; a large folio plate of "The Contest between the Mules and the Pterides;" "The Death of Melaeger," and "The Creation of the Universe," both after Perin del Vaga, in large folio.

Iean Baptiste d'Angelo del Moro, surnamed Torbido, was born at Verona in the year 1512. In his youth he frequented the school of Titian, but afterwards became the disciple of Francesco Torbido, called Il Moro; whom he imitated both in his name and fortune. Del Moro was both painter and engraver, and in the former art was esteemed a good colourist; his etchings are slight but spirited, and he

drew the extremities of the figure in a very tastefully style. Among his works, we find fifty very fine landscapes which he engraved in conjunction with Baptista Vicentino, of whom we have before spoken, and also the following: "The Nativity," after Parmegiano, in folio; "The Virgin bathing the Infant Jesus, with the little St. John," in folio; "A Holy Family," wherein angels are ministering to the Holy Virgin and Child, an anonymous composition, but certainly after Raphael, in folio; another "Holy Family," from Raphael, in large folio; a battle piece, in large folio; "The Martyrdom of St. Catherine," from Bernardino Campi of Cremona; another large folio print, representing a shepherd, with his crook, accompanied by his dog, and visited by an angel; without names. There is a very grand composition by Julius del Moro, brother to the preceding artist, preserved in the album, of the grand council at Venice, entitled "Papa Alessandro terzo che dona al Doge li standardi e trombe nella Chiesa di S. Giovanni."

Marc d'Angelo del Moro was the son of Jean Baptista, and was born at the same place, in the year 1531. He studied under, and was not inferior to, his father, either in painting or engraving. We are acquainted with thirty of his engravings, which are executed with considerable ability, among which are the following:—"The Nativity, or the Adoration of the Shepherds;" "A Holy Family;" "The Adoration of the Kings;" and "The Baptism of our Saviour;" all of large folio dimensions. This artist died at Rome at an early period of life.

Aeneas Vico, or Vicus, or Vighi, was born at Parma A.D. 1512. It has been supposed that he learned the principles of design of Julio Romano; and that, hearing of the great reputation which Marc Antonio had acquired at Rome by his engravings, he went to that city, and became his disciple. He was a man of talent, though inferior to his master; neither his chisello nor his manual execution are commendable; and in the latter a certain impatience of temper is but too obvious; yet he understood the human figure very well, and, when he pleased, could draw correctly. But in many of his productions the extremities are hard and heavy, and the proportions neglected. His engravings are neither so neat nor so clear as those by Marc Antonio. Indeed he succeeded best when he attempted a more open style; a good specimen of which is, a female figure, with her right arm extended, over which appears an owl flying in the air, from Parmegiano; it is a half sheet print, dated 1548.

Vico sometimes engraved on wood, and it appears that his small works done in this style are ranged among his first productions. Of this number is a portrait of Charles V. surrounded with emblematical figures, in an oval, composed with taste, very correctly drawn, and cut with great care. Upon a piece of a ruin, which serves as a tablet at the bottom, is this inscription: "Inventum sepulchrum ab aenea vico parmense." But Vico was also an antiquary, and published a tract on medals, embellished with engravings by himself, and a collection of thirty-six plates of engraved gems after the antique. This artist ended his days at the court of Alphonso II. duke of Ferrara, but in what year his biographers have not recorded. Of his numerous engravings, the following will probably be found to possess the most merit.—Four medallions. Portrait of John of Medicis, in large folio, dated 1550. Portrait of Cosimo of Medicis, in his youth, in large folio. Portrait of Alphonso, duke of Ferrara. A sacrifice, in the antique taste, dated 1542, in 4to. of his own composition. A plate in small folio of the Three Graces. A Rosicrucian subject from the life of Virgil, inscribed "Virgilium cludens meritas dat fermina pænas, Roma, 1542." "The Army of Charles V. passing

ITALIAN SCHOOL OF ENGRAVING.

passing the Elbe," from a composition of his own, a large upright plate, in an oval; "The Battle of the Amazons," the same, inscribed "Bellum Amazonum," dated 1543; "Vulcan working at his Forge, with Venus on a Bed behind him." In the first impressions of this plate, Mars was represented with Venus, from Parmegiano. "The Combat of the Centaurs and Lapithæ," after Rosso, in large folio, dated 1542; "The Dispute of Cupid and Apollo in the Presence of the Gods," from Baccio Bandinelli; "The Sons of Luccio Bandinelli," with his portrait, after Parmegiano; "The Conversion of St. Paul," after F. Salviati, all in 1636; "St. George and the Dragon," from Giulio Carracci, a very rare print, in folio; "Judith with the Head of Holofernes," after Michael Angelo's celebrated picture in the Sistine chapel, in folio; "Jupiter and Leda" and a large folio print of a bacchanalian subject, both from the same master, marked Enca Vico, 1546. (This subject has been also engraved by Beatrixet.) "Christ taken from the Sepulchre," after Raphael, in folio. Another dead Christ, supported by Joseph of Arimathea, with the Virgin and other females bewailing him, a middling-sized upright plate, from Raphael; "Lucretia stabbing herself," with a Greek inscription; "Venus and Cupid," this has also been engraved by Marc Antonio; "The Annunciation of the Virgin," a small plate from Titian. A set of vases from the designs of Polidoro da Caravaggio. A set of fifty plates, of dresses of different nations. And one of the Trajan column.

Martin Rota was a native of Sebenigo in Dalmatia, he studied at Rome, where he passed his youth, but afterwards removed to Venice, and remained there till towards the close of the sixteenth century. Huber says he was born in 1561, but this must be a mistake, since his print of "Jesus Christ meeting St. Peter," after Raphael, is dated in 1568. It is very certain by what a master he was instructed in the art of engraving; but his works prove him to have been a man of great abilities. He drew the human figure very correctly, and marked the extremities in a very masterly style.

Rota worked entirely with the graver, which he managed with great delicacy, and without dryness, though his plates are not very highly finished. Among his works is a set of portraits of the Roman emperors from Julius Cæsar to the emperor Alexander Severus, which he published at Venice in 1570. He commonly marked his prints with his name, and sometimes with the small wheel which will be found in our Plate II. of monograms, &c. of the *Italian Engravers*, and which constituted a sort of pun upon his family name. His principal works are, as follows.—"The Last Judgment," a middling-sized upright plate, dated 1569, from Michael Angelo Buonarroti. This excellent engraving, which is justly considered as the chief d'œuvre of Martin Rota, has been copied very exactly by Leonard Gaultier; the difference, however, is easily discovered by comparison, the copy being much inferior to the original; that is, supposing the original to be a good impression. But a more striking distinction is to be seen in the face of the portrait of Michael Angelo, which is introduced in a small oval at the top; it is turned towards his right shoulder in the original, and towards his left shoulder in the copy. "The Resurrection," from his own design, dated 1577, executed in a very delicate style. Another "Resurrection" executed in a very coarse style; "The Slaughter of the Innocents," from his own design, in small folio; "Paying Tribute to Cæsar," three figures, seen as low as the knees, in folio; "The Martyrdom of St. Peter the Dominican," a middling-sized upright plate from Titian. A "Mary Magdalen," after the same master, in 4to; "Prometheus chained to a Rock," after

the same; "The Satyr Mærias slayed by Apollo;" "Our Saviour appearing to St. Peter at the Gates of Rome" after Raphael, in folio; "A Last Judgment," from his own design, a very fine plate, dedicated to the emperor Rudolphus II. dated 1575, in folio. Another "Last Judgment," also from his own design, which remained unfinished at his death, but was completed under the care of Anselmo Boodt. It is distinguished from the former one, by two female figures in the middle of the picture, instead of an angel; this latter is the most rare, but the former is the finest engraving. "The Battle of Lepanto, and Defeat of the Turkish Fleet," from his own design, dated 1572, in large folio, a very rare print, as are also the good impressions of all the plates of this matter.

Jerome Porro was born at Padua in the year 1520. He is not mentioned by Strutt, and very little is known of the events of his life, except that he resided for some years in the Venetian territory. He appears to have been a man of a mechanical turn of mind, and more remarkable for patient industry, than for such talent as properly constitutes an artist. Huber says, he invented and constructed a sort of sailing car, large enough to contain thirty persons, and there is yet preserved at Parma an engraved curiosity from his hand, of which it is difficult to say, whether it exhibits more patience or want of taste. The subject of this print is "The Passion of Christ," and the hatchings, which constitute the shading, are found, on near inspection with a magnifying glass, to consist of very delicate writing. Hence the chiroscuro is not effective, and the writing is not legible.

Among his other works, are a set of plates for an edition of the Orlando Furioso, which was printed at Venice in the year 1548, and is now become very rare. A set of an hundred vignettes for "Les Imprefsi degli Uomini Illustri di Camillo Camilli;" and a set of letter-press engravings, neatly executed for a book of the funeral ceremonies of the ancients, by Thomas Portacci, printed at Venice in 1591; this was the last, and perhaps the best, work of Jerome Porro.

About the same time lived Antonio Fantuzzi, or Fantuzzi, an obscure Italian engraver, who etched a considerable number of plates in a coarse style, resembling that of Tempella. He studied under Primaticcio, and marked his prints either with his initials, or the cypher which will be found in our Plate II. of the monograms, &c. of the *Italian Engravers*. Though his prints possess not much merit, rarity has conferred on them an imaginary value, and they are sought after by the curious, particularly a bacchanalian subject, where Silenus is followed by a number of Satyrs, after Rossi, dated 1545; "The Contest between the Muses and Pierides," in large folio, after Primaticcio; and, after the same master, "Alexander and Roxana," and "Alexander and Thalestris," dated 1543. A large print from the history of Psyche, of Jupiter, Minerva, &c. in an oval; and "Titan resting on the Surface of the Sea," in folio, after Bologna.

Now also lived Andrea Schiavone, surnamed Meldolla, a celebrated historical painter, who performed some etchings somewhat in the taste of Parmegiano, and a few prints in chiroscuro, among which are, "The Finding of Moses," in small folio, after Parmegiano; "The Flight into Egypt," in 4to; and "A Holy Family," in folio, after Parmegiano, in all of which the hatchings appear as if of white chalk on a blue ground; in the "Resurrection of Lazarus," the hatchings are of gold colour on a blue ground, and the same in "Christ laid in the Sepulchre," both of which are after Parmegiano; "St. Peter and St. John," after the cartoon of Raphael, is executed in the same manner, as is

also the "Rape of Helen," in folio, from a composition by Schiavone himself; for an account of whose merits as a painter, see SCHIAVONE.

Paolo Farinato was born at Verona in the year 1522, and died in 1604. He learned the first rudiments of art of Antonio Badaia, but afterwards became the disciple of Nicolo Goltino. His genius, which began to unfold itself at a very early age, inclined him to historical painting, and he continued, occasionally, to practise that art until a late period of life. A picture from his pencil, of "The Miracle of the Loaves and Fishes," adorns the church of St. George at Verona, and he painted several for the Escurial, where he passed some years.

Farinato's style of engraving was bold, free, and decided, and confits almost entirely of etching; he sometimes marked his plates, which are somewhat numerous, with his name at length, and at others with the initials P. F. or P. V. F., the V standing for his native city of Verona.

His best productions in this art are, a figure of "St. John," a small upright, a ditto of "St. Jerome kneeling;" "St. Mary Magdalen, seated with a Book and Crucifix, &c.;" "The Holy Virgin with the Infant Christ and St. John," in folio; "Angels bearing the Cross," a small upright; "Venus and Cupid;" and "Venus at the Forge of Vulcan;" both in folio. They are all after his own compositions.

The three following engravings are by Horatius Farinato, who was the son and pupil of Paolo: he was of very promising talents, but died at an early period of life. Strutt says "he would have equalled the greatest masters;" but this may be saying a little too much. They are after his father's compositions, which may be one reason why they have generally been confounded with his works.

"The Invention of the Cross, with St. Francis and the Holy Women," a large folio print, marked P. F. inv. Ho. F. V. fecit. 1583. Another large folio, of "The Destruction of Pharaoh's Host," marked Ho. P. F. inv. 1585, and "An Holy Family with St. John."

Giacomo Batista Fontana was born at Verona A. D. 1524. He worked at Venice great part of his life, and died in the service of the emperor. He designed as well as engraved, and we have several slight etchings by his hand, executed with the boldness and freedom of a master, though the drawing is by no means correct. Of these it may suffice to mention the following:—Several subjects from Virgil's *Æneid*, in folio, from his own compositions; "The Vision of Ezekiel," in large folio; "The Martyrdom of St. Peter, the Dominican, in a Forest," from the famous picture by Titian; (Martin Rota, and Le Fevre have also engraved from this picture.) "The Battle of Cadova, between the imperial Troops and the Venetians," a middling-sized plate, lengthways, from Titian; "Our Saviour on the Cross," in large folio; and twenty-eight small plates from the history of Romulus, including a dedication to Ferdinand, Archduke of Austria, dated 1573.

Dominico Maria Fontana was born at Parma in the year 1543. Strutt has mistakenly dated his birth in 1673. He learnt drawing in the school of Bologna, and engraved chiefly after his designs. Le Comte and others have confounded this artist with Dominico Fontana, the famous architect. The following are some of his works:—"A Flight into Egypt;" the scene lies in a mountainous landscape; "St. John preaching in the Desert," in large folio; "Our Saviour speaking to the Women of Jerusalem, on his way to Mount Calvary," in folio, dated 1584; "Mount Calvary," with a Latin and German inscription; "The erection of the great Obelisk, before the Church of St. Peter at Rome," with all the apparatus necessary for the elevation of

such an immense mass, marked Dom. Fontana inv. Seb. Bonifacio fc. 1586, a very rare piece, engraved on three large plates.

Veronica Fontana, who engraved small portraits in wood with considerable neatness for that mode of art, was daughter to the above, and studied the art of design under her father and Elizabeth Serani.

Christofano, or Christopher Bertelli, was a native of Rimini, in the duchy of Modena, and appears to have lived about the end of the sixteenth century, though his engravings are not dated. He worked entirely with the graver, but in a stiff mannered style.

From whom he learnt the art of engraving is by no means certain, and by no means important, as he neither invented a style of engraving, nor improved on those already known. He engraved after Correggio and other Italian masters; and the following are among his works: a Portrait of Octavius Farnese, duke of Parma, in folio; "The Conversion of St. Paul," a very grand composition, from Pordenone, marked "Per me Christofano Bertelli," in large folio; "The Virgin with the Infant Jesus, and four Saints," after Correggio, in folio; another of "The Virgin and Child, with St. George," from the same painter; a folio print, representing the different ages of man, marked Christofano Bertelli, &c.

Ferrando, or Ferdinand Bertelli, was of Venice, and contemporary with the preceding artist, to whose family he probably belonged; he worked after many of the Venetian masters, but did not much distinguish himself, and we therefore only mention the following of his works: "Our Saviour healing the Sick," marked Farinati pinx. F. Bertelli, exc. 1566, of large folio size; "Our Saviour on the Cross," after Julio Romano; "Venus reclining," after Titian, marked Nic. Bertelli, 1566. *Specchio della Vita humana*. In Venezia per F. Bertelli, 1566. Another, intitled "Omnium fere gentium nostræ ætatis habitus, a F. Bertellio æneis typis excus. Venet. 1569," in folio.

Lucas Bertelli, likewise a native of Venice, was a print-feller, but engraved some plates in the style of Cornelius Cort; among which are the following:—A portrait of Hippolyta Gonzaga, a daughter of Ferdinand, signed Lucas Bertelli, exc. in 4to.; "The People of Israel tormented by Serpents," after Michael Angelo; a folio print of "The Baptism of our Saviour," signed as before, with four verses at the bottom, beginning "Non isti Christiani latites," &c.; another folio print of "The Magdalen washing our Saviour's Feet;" "The Flagellation," after P. Farinati, in large folio, inscribed as before; "A Crucifixion," in large folio; "The Descent from the Cross," where Nicodemus is holding the nails, a meritorious print, signed as before; "The Four Evangelists sitting at a Table in the Temple, with their Attributes," from Michael Coxe, in large folio; "The Last Judgment," after J. B. Fontana; "An old Woman and Children, warming themselves at a large Fire," with eight verses, after Titian, in folio. N. B. This engraver flourished towards the close of the sixteenth century.

Frederico Barocci, was born at Urbino in the year 1528, and died at Rome A. D. 1612. He learnt the principles of design under Battista Franco at Venice, whom the superiority of his genius very soon enabled him to surpass. He went very young to Rome; studied with the pupils of Raphael; and, according to De Piles, was employed by pope Paul III. to paint several subjects in fresco. Barocci painted both portrait and history with the greatest success, and particularly excelled in sacred subjects; it is said that

ITALIAN SCHOOL OF ENGRAVING.

he generally painted his Virgin Maries from his sister, and Infant Christs from his little nephew.

He engraved several pictures from his own compositions, which, though slight, and not well managed with respect to the mechanical part, are nevertheless most admirable, on account of the expression and excellent drawing discovered in them. His heads are very beautiful and characteristic; and the other extremities of his figures finely marked. Amidst all the difficulties he appears to have met with, in corroding his plates with the aquafortis after he had etched them, and his unskillfulness in handling the graver to harmonize and finish them, the powers of a master appear like the orb of the sun, when seen through the thin clouds of morning. The following are among his best engravings, all of which are from his own compositions. A small print of "The Virgin and Child," which was never completely finished at the bottom; "The Virgin and Infant Jesus in the Clouds," signed F. B. V. F. in 4to.; "The Annunciation," a large upright plate, of which the good impressions are very rare; "St. Francis receiving the Stigmata," a small upright plate; "The extatic Vision of St. Francis," in which our Saviour and the Virgin appear to him, a large upright plate arched at the top, esteemed the most capital of the engravings of Barocci.

Battista da Parma, or Parmensis, was a native of Parma, born A. D. 1530. Huber, without adverting to dates, says "he was probably a disciple of Parmegiano;" now Parmegiano, as we have already stated, died in the year 1540.

The truths, Battista studied at Rome, but under what master it is not known; and here he practised the art of engraving in a style somewhat resembling that of Cornelius Cort.

Among the most esteemed of his productions are the following:—"The Virgin and Child appearing to St. John the Divine," from Federico Barocci, signed Battista Parmensis fecit. Romæ 1588, in folio; "Philippus II. Hispaniarum Rex, 1589," in large folio; "Christ baptized in the River Jordan," Bapt. Parmensis dedicavit, in large folio; "The Chastity of Joseph," in large folio, dated 1592; and "Mount Calvary," a very grand composition, marked as formerly.

Jacques, or Jacobus Parmensis, was another artist, probably of the same family, from whose hand we have a print executed in the style of Caraglio, of "The Martyrdom of St. Peter and St. Paul," and a middling-sized print lengthways, from Parmegiano; it is executed with the graver, in a slight style, and has often been attributed to Caraglio, but the heads and other extremities are not so well drawn as we find them in the works of that artist.

Gaspar ab Avibus, likewise called Gaspar Patavinus, or Padovano, was born at Padua in the year 1530. He appears to have been the pupil of George Ghis Mantuanus, whose style he imitated, but never equalled. His prints are dated from the year 1560 to 1580, and signed in different manners, sometimes with the monogram of Gaspar, which will be found in *Plate II.* of those of the *Italian Engravers*.

We shall notice the following of his productions: a print, in large folio, of "The Marriage of the Virgin Mary," from Paul Veronese, inscribed Gaspar ab Avibus Citadelenfis fecit, 1577; "The Woman taken in Adultery," marked with his cypher; "The Scourging of our blessed Saviour," a large upright plate, signed Gaspar ab Avibus Citadelenfis fecit, Lucæ Bertelli Formis; "Our Saviour crowned with Thorns," marked as before, in large folio; "The Last Supper," from Lamb. Lombard, in large

folio; "Apollo on Mount Parnassus, with Pegasus and the Muses, Homer, and Virgil," from L. Pemi; a large volume in folio, in five parts, containing the portraits of the Emperors, Archdukes, Princes, &c. of the Austrian family. Each portrait is a whole length figure, ornamented with an appropriate border. Here Gaspar has changed his usual manner of engraving, and something more of the style of the Saddlers appears in it: the figures, though stiff, are neatly engraved, and well proportioned.

Giovanni Battista Cavalieri was born at Lagherino some time about the year 1530. He worked at Rome from 1550 to 1590. His style of engraving bears considerable resemblance to that of Encaes Vico, the disciple of Marc Antonio; though he has not, in every instance, attained the same degree of excellence.

Cavalieri understood the mechanical part of his art very well; but his prints are defective both in chiaro-scuro and drawing, particularly in the extremities of his figures. He was a very industrious engraver, and, according to the abbé Marolles, his works amount to upwards of three hundred and twenty-seven; a great part of which, however, were but copies from the engravings of other masters. He sometimes signed his prints with his name, and at others with his cypher, which will be found in *Plate II.* of those of the *Engravers of Italy*.

Among the most esteemed of his works are the Frontispiece and Heads to the "Lives of the Popes," dated 1588; the plates to a work on the "Life and Miracles of Apollinaris, first Bishop of Ravenna," in folio, which are coarsely etched, and slightly finished with the graver; "Ecclesie Anglicane Tropæa," in folio, from Nicolaum Circignano; "The Ruins of Rome," from Jean Antonio Dollus, in 30 plates; "Jesus Christ teaching among the Doctors," from his own design; "The Last Supper," from his own design; "The Statue of the Virgin of Loretto;" "The House or Chapel of Loretto, and the Miracles which were supposed to be done there," 1569; "The Celebration of the Jubilee of 1585," in the back-ground of which is a view of the cathedral church of St. Peter. (Here the engraver is called, for what reason has not been explained, Tridentinus.) And "A Naval Combat against the Turks," for the book of Cicioni, of folio dimensions.

"The Virgin of Silence," where the Virgin is reading, and the infant St. John making a sign not to disturb the sleeping Christ, accompanied by St. Joseph, from Michael Angelo, is in large folio; "The Conversion of St. Paul," after a picture of Michael Angelo, in folio; "The Martyrdom of St. Peter," in large folio, all signed with the engraver's name; "The Apostle St. Paul," after Michael Angelo, in large folio; "The Animals returning from the Ark," after Raphael, of the same size; "Moses showing the Tables of the Law to the People," from the same master; "The Miracle of feeding the five thousand," in two large plates; "Jesus Christ appearing to St. Peter at the Gates of Rome," with the cypher of the engraver, dated 1569; "The Battle of Constantine against Maxentius," a large upright, all from Raphael; "The Slayer of the Innocents," after Bacio Bonduelli, a grand composition, which was likewise engraved by Michel Angelo; "Susannah and the Elders," from Titian, in folio, dated 1586; "St. John preaching in the Wilderness," from Andrea del Sarto; a large 16mo print of "The Descent from the Cross," from Daniele de Volterra. The same subject was engraved by Dorigny. "The Virgin seated on the Clouds, with the Infant Jesus and Angels shimmering to her," from Livio Agresti, in large folio; "The Elevation of the Cross,"

Cross," from the same master, signed "Opus Livio Agrelli Iordensis, Romæ incidit, Joan. Bapt. de Cavalieriis," in large folio.

For an account of Paul Veronese, who etched some plates about this time and is a distinguished ornament of the Italian school, see the article CAGLIARI.

Cesare Vecello was born at Venice some time about the year 1550, and died in the same city. He was the younger brother of the celebrated Titian, and probably the engraver of those wood-cuts which are generally attributed to that great artist. We have by this master a set of prints in octavo, etched in a free spirited style, from the designs of Titian, of the costume, or various dresses, ancient and modern, of different parts of the world: they were published at Venice in the year 1595, entitled "De gli Habiti antichi et moderni di diverse Parte del Mondo, Libri due fatti da Cesare Vecello." In the year 1664, another edition was published, more complete than the preceding, where the title is more fully explained, thus, "Raccolta di Figure delineate dal gran Tiziano, e da Cesare Vecello suo Fratello, diligentemente e intagliate."

Joseph Porta, otherwise called Salviani, della Grafagnano, was a native of Castelluccio Grafagnano, born in the year 1555. He was the disciple of Francis Salviani, whose name he assumed. He settled at Venice, where he painted, both in oil and fresco, with great success, and performed several meritorious engravings on wood. M. Papillon says, that he has seen twelve prints by this master, executed on wood, of which the subjects were "The Prophets," and "The Sybils," "Psyche finding Cupid asleep," and "A Chemist in his Laboratory," a print ten inches by sixteen. He continues: "But I also possess a print by this master, much superior to the preceding, of 'Jesus Christ on the Cross, accompanied by the Virgin, Mary Magdalen, and St. John,' at whose feet is a little tablet, with the name of Joseph Salviani. The characters are very admirably expressed, and the excellence of the design equals that of the execution." Porta's engraving of the Academy of Arts and Sciences, a very fine composition, in small folio, proves that in this instance Papillon is no exaggerator. Andrea Zucchi, and many other Venetian artists, have engraved from the pictures of this master, who died at Rome in the year 1585.

Julius Sanuto, or Sanutus, was born at Venice A. D. 1536, but is very little known. Among the small number of plates executed by this artist are the following: "The Birth of a monstrous Child," signed Jul. Sanutus Venet. fec. This print is executed with the graver in a coarse heavy style, with single strokes, without any cross hatching, and bears great resemblance to a wood-cut. "Venus and Adonis," after Titian, from the gallery of the King of Spain, marked Giul. Sanuto exc. 1550; "The Fable of Apollo and Marsias," a very singular composition, from Correggio, engraved on three large plates; on the middle plate of which is introduced the Parianus of Raphael.

Of Dominico Vitus it is only known that he was a native of Italy, born some time about the year 1536, and that he continued to engrave at least till the year 1580.

He was an ecclesiastic, of the order of Val-Ombreuse, a monastery situated in the Apennines, and was probably instructed in engraving by Agostino de Musis, whose style he imitated, and not unsuccessfully. He engraved several plates after contemporary painters, and likewise from the antique.

We have, by him, "St. Joachim holding a censer," from a design by Andrea del Sarto, dated 1580; "St. Bartho-

lomew," inscribed "Dom. Vitus Ordinis Vallumbrosi Monachus excidit, Romæ, 1578;" a set of small plates of "The Passion of Jesus Christ," surrounded with borders of birds, beasts, and fishes; several antique statues, marked "Dom. Vitus fec.;" "Jupiter and Calisto," in 4to.; and "A River God," from the antique, of the same size.

Raphael Guidi was born at Florence in the year 1549, and, judging from his works, appears to have been instructed in the school of Cornelius Cort, or Agostino Carracci. He worked entirely with the graver, which instrument he handled with much facility. He drew correctly, and the extremities of his figures are very well expressed. Though Guidi cannot be said to have equalled Carracci, yet his prints manifest that he was a man of very superior talents. The following prints are by him, and will probably be found among his best performances: "King David playing on the Harp," from Josephine, in folio (the same picture has been engraved by Eg. Van Panderen); "The Crucifixion," after Christopher Schwartz, in folio; "Jesus Christ laid in the Sepulchre," from F. Barocci, dated 1598; "Æneas carrying his Father from the Burning of Troy," from the same; "Jupiter grasping his Thunderbolts," from Polidoro; and "Vulcan" from the same master, both in folio. In larger folio, and engraved with much freedom after Josephine, is "The Fall of Icarus."

Bartolomio Passarotti was born at Bologna in the year 1540, and died in the same city A. D. 1592. It is very likely that he learned drawing in the school of Thadæus Zuccherò. Bartolomio was the most eminent of the numerous family of artists of his name, and excelled both in historical subjects and portraits. Huber claims for him the honour of having been the founder of the celebrated Academy at Bologna, where the Carracci so much distinguished themselves. He was a painter of great merit, and Ph. Thomassin, C. Cort, Aug. Carracci, and many other artists, have engraved after his pictures. He likewise produced many etchings from his own designs, and from those of F. Salviani, and P. Perugino, of which the following are best known, and probably possess most merit.

"The Virgin and Child, accompanied by St. John," from his own design, in large folio; "The Visitation of the Virgin," a rich composition, after F. Salviani; signed Bart. Passarotti fec. a very rare print, in large folio, and another large folio print of "The Marriage of Jacob and Rachael," from P. Perugino.

Marius Kartarus, or Mario Kartaro, was born in Italy some time about the year 1540, but the time and place of his death are unknown, and the events of his life are somewhat obscure. Bafan says that "Marius Kartarus was an engraver, who flourished in Italy about the middle of the sixteenth century; Rodolphus Fuesli calls this engraver Marius Cartari, who, in the year 1578, engraved at Rome the portraits of the twenty-four first Roman emperors, from Julius Cæsar to Heliogabalus. And Strutt thinks "that he was probably a German, though he resided at Rome, and learnt the art of engraving in his own country; he copied several of the engravings of Albert Durer with some degree of precision: they are executed entirely with the graver; but his principal works are etchings in a coarse, incorrect style, finished with the graver. Some of them are very large, and in general from his own designs." Kartarus commonly marked his prints with a monogram, which will be found in our second plate of those of the *Italian Engravers*, and never with his name at length. The following are among his most distinguished productions: "The Adoration of the Shepherds," in a very neat style, executed with the graver only;

ITALIAN SCHOOL OF ENGRAVING.

only; "Our Saviour crowned with Thorns," a large upright plate, also executed with the graver; "Diana and Endymion," a large plate lengthways; "Christ praying in the Garden of Olives," from Albert Durer, marked on a tablet 1567, Rome, in folio; "St. Jerome seated in a Chamber," from the celebrated print of the same subject by Durer. "The Descent of Christ into Hell," from Andrea Mantegna, etched in his rough style, in folio; "The Last Judgment," in large folio, from the famous picture by Michael Angelo, in which print the oval at the top, that in the original picture contains the painter's portrait, is left blank.

Andrea Andreani, called Mantuano, was born at Mantua in the year 1546, and died at Rome in 1623. He learnt the elements of his art in the place of his nativity, but went afterwards to study at Rome. Andreani engraved on wood only, in the style distinguished by the appellation of *chiaroscuro*; which he performed by the help of two, and sometimes three blocks, but never more. Among his own countrymen, he had Ugo da Carpi, and Antonio da Trento for models, whom he seems to have followed very closely in the early part of his time; but at length he carried the mechanical part of the art to a far greater degree of perfection. His great merit, as an artist, is acknowledged by all who are conversant in prints; his drawing is executed in a very masterly style, and with great spirit; the heads of his figures, though slight, are characteristic and expressive; and he has displayed great judgment in the management of the various tints.

The number of prints by this master is very considerable, for besides those which he performed himself, he procured a great many engravings by other artists, retouched them when occasion required, and, adding his cypher, sold them as his own productions. This distinguished artifice, altogether unworthy of him, renders it very difficult to distinguish his works precisely; for, after all, it is most likely that many prints are attributed to him, in the engraving of which he had no concern. He commonly marked his prints with one of the cyphers which will be found in our second plate of *Italian Monograms*. The Abbé de Marolle mistakenly calls this artist Andreotti; others have mistaken him for Andrea Mantegna, who lived nearly a hundred years before him, and others again for Albert Aldorfer, on account of the similarity of their monograms. We have endeavoured to exclude his adopted engravings from the following list of his works, and to select the best of his own. A portrait of Albert Durer; "The Pavement of Siena," after a drawing by Francesco Vanni, from Domenico Beccafumi Sanefe, consisting of eight subjects, said to be the moll rare of all Andreani's engravings; "The Deluge," from Titian, a very large piece, on three plates; "The Army of Pharaoh passing the Red Sea," from the same; "The Adoration of the Magi," from Parmegiano, in small folio; "The Purification of the Virgin," from Salvati, in folio, dated 1608; "The Virgin and Child, worshipped by a Bishop," half figures, from Al. Casolani, with the artist's cypher, and the words Andrea Mantuano, Pittore Sanefe, 1591, in large folio; "The Virgin, St. John, and Infant Jesus, accompanied by a Saint," from Giac. Ligozzio, in folio. Another folio print of "Our Saviour healing the Lepers," from Parmegiano; "Jesus Christ healing the Paralytic," from Francesco de Nanto da Salandria, in folio; "Christ descending from the Cross, with his hands," one of his most finished productions, on two blocks engraved from a bas-relief of Govan. Bologna, in large folio; "Christ bearing the Cross," after Al. Casolani, with the name of d. Andreani in Siena, 1591, in folio; "The Entombing of Christ," a large folio print, dated 1591, from Giuf. Scolari Vicentino, pittore eccellente (Papillon mentions a Joseph Scolari, an engraver on wood,

to whom he attributes many prints in the *Italian School*); another "Entombing of Christ," from Casolani in Bologna, a small upright plate, half figures; "St. Peter, seated," marked with the name of Polidoro, and the year of Andreani, 1668; "St. Sebastian, with a Bishop, and the Virgin and Child, in Rays of Glory," marked 1618, from Barotinus Urbias, in large folio; a emblematical print representing the Christian after his spiritual warfare in the previous life, received as victorious into heaven, and crowned by Christ; it is signed B. Pitta Franco de Venetis, and bears the cypher of Andreani, in large folio; a perpetuation of human life, represented by a female figure assailed by the passions, signed Jac. Ligotus, inv. et Andreani 1585, Firenze, in large folio; there are different impressions of this plate, both with and without the characters. "The Rape of the Sabines," from a group by the sculptor Govan. Bologna; three several views, dated 1584; another print of the same subject, from a bas-relief of the same name, on three blocks, dated 1585; "The Triumph of Julius Cæsar," from Andrea Mantegna, the original of which is at Hampton Court, it is cut on ten blocks of wood, including the title, and dated 1598; a large print of a scene in a play, intitled "Ortenio," represented by the academicians, called Intronati, in the presence of the grand duke Cosimo I. at Florence, from the design either of Marco Ricci, or Bart. Neroni.

Jacques, or Giacopo Palma, usually called the younger, in contradistinction to his uncle Giacomo, who was a very eminent historical painter, was a native of Venice, born A.D. 1544, and died in the same city in the year 1628. Giacopo became the disciple of Tintoretto, whose style he followed during the earlier part of his life, but he afterwards studied with great care and attention the works of Titian and other great masters, to complete his taste. Palma has etched a number of free spirited plates in a slight style, to which he frequently signed his name at length, and sometimes used the monogram of a palm-branch, crossing diagonally the letter P, which will be found in our *Plate II*; of *Italian Monograms*.

The following are by him, and are his most esteemed prints:—"Samson and Dalilah," after Jac. Franco; and "Judith and Holofernes," both middling-sized plates lengthways, marked with his name; "The Nativity," in small 4to.; "A Holy Family, worshipped by St. Jerome and St. Francis," half length; "St. John in the Desert," in 4to.; "The beheading of St. John," the same size; "St. Jerome in Conference with a Pope," in 4to. very rare; "Pallas sitting on a Trophy, holding a little figure of Victory in her Hand," in large 4to.; "Paying Tribute to Cæsar," the same; "The Woman taken in Adultery," the same; "Christ answering to the Pharisees, when they disputed his Authority," the same; "Christ appearing to St. Thomas," half length figures; "Two Men in Tartarus," the same size; "An Ecclesiastic, and a naked Figure, with two Boys underneath," with the monogram of the artist; in 4to.

Dominico Pellegrino Tibaldi, who excelled in the three arts of painting, engraving, and architecture, was born at Bologna A.D. 1546. He was the son and pupil of Pellegrino, known by the name of Tibaldi da Bologna, after whose compositions he etched several spirited plates. The following short list will probably be found to contain the best of Dominico's works on copper: "The Virgin of the Rose," after a picture by Parmegiano, in the gallery of Dresden, in folio; "A View of a Fountain at Bologna," from John de Bologna, signed Domin. Tibaldi, 1570, in large folio; "The Trinity," a grand composition, after Horace Samacchini, in large folio; and a print representing "Peace,

"Peace, laying the Instruments of War at the Feet of Jove."

Camillo Procaccini was born at Bologna in the year 1546, and died at Milan in 1626. He very probably learned the principles of painting from his father Ercole Procaccini. Huber pronounces him the precursor of the Caracci, and calls our attention to the fulminancy of his conceptions, and the grandeur of his taste. He resided chiefly at Milan, where he painted a great number of pictures, and died in that city at the advanced age of eighty. He amused himself much with etching, which he performed in a bold, masterly style. The heads of his figures are often admirable, and the other extremities very finely marked. Among others, the following etchings are the production of his needle:—"A Repose of the Holy Family," in which Joseph is represented in the front, a fore-shortened figure lying upon the ground, and leaning upon the fiddle of the ass, a middling-sized plate, lengthways; another "Holy Family," in which Joseph is represented giving an orange to the Infant Christ, a small upright; another "Repose," where the Virgin is represented suckling the Infant Jesus, in folio; "St. Francis receiving the Stigmatics," dated 1592, in folio; (Justin Sadler has engraved the same subject.) "The Transfiguration of our Saviour," a large upright plate, of which it is very difficult to find a good impression.

Julius Cæsar Procaccini, the brother of Camillo, mentioned in the preceding article, was born at Bologna in the year 1548, and died at Milan in the year 1626. He learned the principles of painting of his father, but completed his studies under the Caracci. He excelled in historical composition, and his works are very much esteemed. He etched for his occasional amusement, but we have never seen more than a single small plate by him, of which the subject is "The Virgin and Child."

Bernardino Passeri, or Passeri, was born at Rome some time about the year 1542, and resided there most part of his life. In painting he possessed some talent, and appears to have imitated the Zuccheri, but the attitudes of his figures are, to a certain degree, forced and uneasy. In the *Alphabetario* he is called an universal engraver, but for what reason is not known, unless it means, that he occasionally practised all the branches of that art which were then in vogue. It is certain that he has engraved a considerable number of prints, which, in general, he first etched, and afterwards finished with the graver, in a bold, easy, and loose style. His works prove him to have been a man of ability, but his drawing is not always correct, nor are the characters of his heads always beautiful, or well chosen. He often signed his name at length; and sometimes used a monogram, which will be found among those in *Plate II.* of the *Italian School*. The following are the names of a few of his works, which are by no means uncommon:—"A Holy Family," where the Virgin is represented with a Bohemian bonnet, dated 1583, in 4to.; "The Life of St. Bruno," represented on several middling-sized upright plates, in 4to.; and a considerable number of Holy Families, Madonnas, and other pious subjects.

Ventura Salimbene, called Bevilacqua, was born at Sienna in the year 1555, and died in the same city in 1613. He learned the rudiments of his art of his father, Angelus Salimbene, who was the disciple of F. Zuccheri. He was half brother to Francesco Vanni, whose style of painting he imitated; at Rome he chiefly worked in the library of the Vatican, and the church of St. John de Lateran. We have several slight etchings by this artist, in a bold, masterly style, and among them the following, all from his own

compositions:—"The Marriage of the Virgin," a small upright plate, dated 1590; "The Salutation of the Virgin," in folio, 1591; a large folio plate of "God appearing to the Virgin seated in the Clouds, surrounded by Angels;" "St. Agnes," a half-length figure in 4to.; "The Baptism of our Saviour," and "Jesus Christ appearing to St. Catherine of Sienna," both in small folio.

For an account of the merits of Antonio Tempesta, as a painter, see the article TEMPESTA, ANTONIO. Fertile and vigorous in his invention, and various and versatile in his artificial powers, he took up the pencil or the etching point with equal facility, and almost with equal success. Though he delighted in cavalades, battles, processions, and such other subjects as called forth his copious powers of composition, his prints are exceedingly numerous, amounting, according to Le Comte, to eighteen hundred, and according to Mariette, to no fewer than two thousand!

Tempesta's style of etching, in perfect unison with the general character of his art, was bold and free; the lights are kept broad on his single figures; his figures are often grouped with grandeur, and he possesses a certain ardent liveliness of expression, both in his human figures and animals.

From this aggregate of his merits, some deductions must, however, be made. The muscles of his horses, which frequently occur in his battles and hunting pieces, are generally overcharged; his draperies are not elegantly drawn; his lights and shades are not collected into broad masses, so as to give unity of effect to his chiaro-scuro, and his etchings are often coarsely corroded, so as to destroy the clearness and value of the middle tints.

Tempesta did not always mark his prints with the same cypher. We have collected his various marks, and they will be found in our *Plate II.* of the monograms, &c. of the *Italian Engravers*. The following list is selected from the best catalogues of his works:—"Our Saviour crucified between the two Thieves," in large folio, very rare; a set of middling-sized plates, lengthways, the subjects of which are taken from the Old Testament, and commonly known under the name of "Tempesta's Bible;" a set of a hundred and fifty prints, from "Ovid's Metamorphosis," in 4to.; a folio print of "Diana and Actæon;" "The Entry of Alexander into Babylon," of the same size; a set of twenty-four pieces, entitled, "Vita S. Antonii Abbatis, &c." in 4to.; "The Labours of Hercules," in thirteen plates of octavo dimensions, comprising a frontispiece and dedication; "The Four Ages of the World," represented by the manner of living at those different periods; four hunting pieces, namely, a stag hunt, a hare hunt, a wolf hunt, and a wild-bird hunt, in octavo; another set of chaces; another set of four of field sports; two subjects of battles between the armies of the ancients, in folio; two more, of modern battles; another battle, dedicated to the duke of Gravina, dated 1600; another set of six battles, with a frontispiece, inscribed "Facunda quam sit—aliens ex. Tempesta f. de Wit ex.;" all of folio dimensions.

Of the illustrious family of the Caracci, we have already written as painters, see the articles CARACCI LODOVICO, AGOSTINO, and ANNIBAL. It remains to add some account of their merits as engravers, and to point out their best productions in this art to the notice of connoisseurs and collectors.

Lodovico has left us a few small prints from his own compositions. His practice was to etch his designs, and employ the graver in giving them a few finishing touches; hence his plates are slight, free, and masterly; with the extremities of his figures tolerably well defined, and still better understood;

understood; as is sufficiently obvious to an intelligent eye. He generally marked his prints, of which we select the following as the most worthy of notice, with the initials of his name, but not combined in a cypher. "A Madonna and Child, surrounded by Angels," in 4to.; "A Holy Family, wherein St. Joseph is leaning his Head upon his Hand;" "The Holy Virgin suckling the Infant Christ;" "A Holy Family, in which the Virgin Mary is reading a Book," all in small folio; "Samson killing the Lion," in 4to.; Frontispiece to the poems of Cesar Rinaldi, and a folio print of the armorial bearings of the family of Bonfigliuoli, in which the figures of Hercules and Mercury are allegorically introduced.

Agostino Caracci was the son of a tailor of Bologna, who, desirous of educating his family in a superior manner, intended Agostino for a scholar, but a strong inclination for the pursuits of the fine arts becoming very manifest, the father was induced to alter his design, and placed his son under a goldsmith: here he learned the rudiments of engraving, for the Bolognese goldsmiths of that time were accustomed to ornament their productions with engraving, which was often executed with a degree of taste and beauty corresponding with the general existing state of art.

From this pursuit, however, the great success of his younger brother Annibal, as a painter, appears to have attracted him for a time, and he placed himself for instruction in that art under Fontana, then under Passerotti, and finally under his cousin Ludovico.

Under these masters he attained a degree of excellence in the art of painting, of which we have already spoken, but was afterwards induced, from local circumstances, with which we are unacquainted, to resume the graver, and for further improvement went to study in the school of Cornelius Cort.

The professor Fuseli says, it was "a singular modesty which prompted him rather to propagate the fame of others by his graver, than by steady exertion to rely on his own powers for perpetuity of name;" but he who has produced the engravings which we shall enumerate, even if he had done no more, must certainly have possessed some steadiness of exertion, could scarcely, indeed, have been "less assiduous than his brother," and might surely rely on the art which he did practise so successfully, for perpetuity of name.

The truth has been, that his great merit as an engraver remains unimpaired by time, and unimpached by posterity, while his picture of "The Three Nymphs in the Garden Scene of St. Michael in Bosco," was nearly "in a state of evanescence," when M. Fuseli was in Italy.

Strutt says that Agostino imitated the style of Cort "so exactly, with respect to the mechanical part of it, that were it not for the great superiority which appears in the drawing of the prints of Caracci, it would be difficult to distinguish them from each other: a striking instance of which may be seen in "The Holy Family with St. Jerome," from Correggio, which was engraved by both artists."

Agostino Caracci worked entirely with the graver, in a bold free style; and his drawing of the naked parts of the figure are admirable. The heads are remarkably fine; and the extremities are marked in the most accurate and masterly manner. His draperies are frequently stiff, and crossed with a square second stroke, which gives them an unpleasing effect. But, perhaps, his greatest defect is the prevalent fault of the age in which he lived, namely, the little attention paid to the chiaro-scuro. The lights are too much scattered, and left unmounted, as well upon the distances, as upon the fore-ground

and principal objects; which not only destroys the harmony of the effect, but gives a slight unfinished appearance even to the neatest engraving. Balan speaks of him in these words: "This excellent artist, equally versed in the sciences and fine arts, treated his engravings in so perfect a style, that one knows not which to admire most, the correctness of his drawing, or the beauty of the performances. All young artists ought carefully to observe, with what facility and perfection he expressed the extremities of his figures, and with what art he executed even landscape with the graver."

The engravings of Agostino are numerous, though these dimensions, generally speaking, are large. The following list will be found to contain those of most merit and importance. His prints are marked either with the initial letters, or some contraction of his names, but not combined in a cypher.

Portraits and Historical Prints from his own Compositions.—Anthony Caracci, the father of Agostino and Annibal, a small print, but very rare; his own portrait; Henry IV. of France, at the age of thirty-six; the emperor Augustus, on medallion, with a reverse; bust of Cosmo I., with ornamental figures; a fine female head, cited by Malvasia; portrait of a duchess with a pearl necklace; portraits of Jean Tomaso Coltozano, the prince's Christiana of Lorraine, Ulysses Aldrovandus, Marc Antonio Raimondi, Titiano Vecelli, Anthony Caracci, as St. Joseph; "Adam receiving the fatal Apple;" "The Virgin and Child;" "The Virgin suckling the Infant Jesus;" "A Repose;" "The Virgin in the Clouds, with the Infant Jesus;" was engraved by Marc Antonio, after Raphael; but Agostino, having got the plate into his possession, added two fine heads of Cherubs; "The Virgin in Heaven, giving the Scapulary to a Saint," a very fine engraving; "The Virgin sitting on a Step near St. Joseph and an Angel, accompanied by the Infant Christ and St. John," a large folio print, very rare; "The good Samaritan," in folio. (The impressions of this plate, without letters, are very rare; and those with the name of Bertelli are re-touched.) "The mysterious Crucifix," where a female figure represents Christianity and another Judaism, in folio; "The Resurrection of Jesus Christ," in folio; "Le Nome di Dio," representing the pope and senate of Venice supplicating the Virgin and saints to intercede for them, in an oval, surrounded with accessories, and subscribed "Luc. Bertelli formi," but without the name of Agostino, who certainly engraved it, in large folio; "The Pea-hen, with Diana on Medallion," beneath is a landscape, with the fable of Salmacis and Hermaphrodite; and lower down in the plate are three ovals, with the dispute between Neptune and Minerva, the Three Graces, and a bust of Minerva; these are all on one plate, in large folio; the frontispiece to the book of Alde Manuce, entitled "Vita di Cosimo de Medici," in folio. Another frontispiece, after Antonio Campi, for the book, entitled "Cremona Fidelissima," in fol. (This is a very rare book, consisting of thirty-three portraits, engraved by Agostino.) Nine plates, from Tasso's "Jesusalem Delivered," published A.D. 1590. The rest of the plates for this work were engraved by Giacomo Franco; "St. Francis receiving the Stigmatics," a large folio print; "The Girdle of St. Francis," a grand composition, representing a saint distributing the girdle of his order to different Christian sects; a large folio print of "St. Jerome kneeling at the Entrance of his Cave." There are impressions of this plate upon it was about three parts finished, which are extremely rare; the remaining part is a mere sketch, marked with a very free touch. An inspection of this print shows

with what ease and vigour Augustino managed his tool. There are imitations of the same plate, quite finished, by F. Villanena, his pupil. Two landscapes, in folio, with figures; "Cupid conquering Pan," inscribed "Omnia vincit amor, 1599;" "Eternity in the Clouds, surrounded by female figures," in folio; "Perseus in the Clouds fighting with the Sea-monster;" both this and the former, one are theatrical scenes.

The following are from the Pictures of various other Masters.—"A Child blowing Bubbles," from Goltzuss, very rare, in folio; "Jac b keeping the Flock of Rachel," 1531, after Denys Calvart; "Judith," a half figure, after Laur. Sabbatini, both of the folio size; "The young Tobias conducted by an Angel," from Raphael da Riggio. (It is mistakenly marked "Raphael d'Urban") in large folio; "The Presentation in the Temple," signed Horace Samacchini, pinx. in large folio; "The Virgin and Child giving the Keys to St. Peter, accompanied by other Saints;" Id. pinx. in folio; "The Adoration of the Kings," signed Balthazar, Peruzzi pinx. very large, engraved on seven plates, the same subject repeated, where one of the kings is kissing the feet of the Infant Christ. There are impressions of this, both with and without the name of the painter, Marco del Moro; "The Virgin and Child, with Mary Magdalene, St. Jerome, and an Angel holding a Book," from Coreggio, in large folio. This picture, known under the name of the Day of Coreggio, which was in the academy at Parma, is at present in the museum at Paris. "An Ecce Homo," accompanied by the Virgin and other half figures, in large folio, from the same master; "Our Saviour shewn to the People," half figures, after Vesp. Strada; "The Body of our Saviour, supported by an Angel," half figures, the same size; "The Crucifixion, or Mount Calvary," in three very large plates, from Tintoret; "The Body of our Saviour on the Knees of his Mother," from a marble group by Michael Angelo, in large folio; "The Nativity," from Andrea del Sarto; "The Virgin crowned in Heaven by the Trinity," from Aug. Mofaert, in folio; "A Holy Family," from Fred. Barroccio. Another "Holy Family, with St. John presenting a Scroll," with the words "Ecce agnus Dei," from Raphael, in folio. Another "Holy Family, with St. Michael," from Laur. Sabbatini, in folio; "The Virgin sitting in a Crescent with the Holy Infant," from the same master, in folio. Another "Holy Family," placed high in the print, with St. Anthony and St. Catherine lower down, from Paul Veronese, in large folio; "The Holy Virgin opening her Cloak to protect Two Monks," in folio. Another large folio print of "The Marriage of St. Catherine," a grand composition. A very large upright print of "The Martyrdom of St. Justitian," on two plates, all from Paul Veronese; "The Holy Trinity, in a radiance of Glory, between Two Columns," from Titian, in large folio; "St. Paul restoring a Saint to Life," from Antonio Campi, inscribed "D. Pauli Miraculum in Noronis palatio factum;" "The Virgin and Child surrounded by Angels," from Julius Campi; "The Virgin resting, with the Infant Jesus and St. Joseph," from Bern. Paturus, in folio; "The Virgin," a half figure, from Giacomo Francia; "St. Sebastian," in folio, from Franço Franja; "The Virgin suckling the Infant Jesus," from Jac. Ligotius, in folio; "St. Jerome," half length, from Vann. in folio; "St. Jerome contemplating the Virgin in Heaven," in large folio, from Tintoret; "The Temptation of St. Antony," in large folio, a print which, being without the name of Augustino, has been mistakenly attributed to C. Cort.; "Mercury, and the Three Graces,"

in small folio; "Wisdom, accompanied by Peace, pursuing the God of War," the same size, both from Tintoret; and "Eneas saving his Father from the Destruction of Troy," a very large upright plate, from Barroccio.

The etchings of Annibal Caracci, the younger brother of Agollino, and author of the Farnese Gallery, are performed with all the firm confidence and fire of a master. They are held in high and deserved estimation among artists and connoisseurs, and no collection of the productions of the Italian School should be without good impressions of the following:—"Christ crowned with Thorns," from a simple and admirable composition of his own, wherein the elevated dignity, yet meek submission of the Son of God, is contrasted to the brutality of the scoffers, in a most affecting and wonderful manner. In the opinion of Strutt, and of the present writer, this is one of the very finest etchings of Annibal Caracci. It has been often copied, and in some instances tolerably well; the original is inscribed "A C. inv. et fec. 1626." "A dead Christ on the Lap of the Holy Virgin," commonly known among collectors by the name of the "Christ du Caprarole;" "The Adoration of the Shepherds," called by the priest dealers "The little Crib," from the circumstance of one of the shepherds introduced, being leaning against a manger, nearly in the middle of the composition: this also has been copied several times. The above are both of 4to. dimensions.

Of the same size are "The Adoration of the Magi;" "Christ and the Woman of Samaria;" "A Holy Family," where Joseph is seated, leaning against a column, holding a book, is a small plate lengthways; "The Virgin holding the Infant Christ and giving Drink to St. John," is distinguished by the name of "The Virgin of the Porringer," another small plate lengthways; "The Descent of the Holy Ghost," a small upright plate, nearly square; "Suffanna and the Elders," a middling-sized plate, nearly square; "Jupiter and Antiope," a small plate lengthways, dated 1592; "Silenus and two Satyrs," a small circular plate, of about eight inches and a half diameter, the border of which is ornamented with vine branches and grapes; this is commonly called the "Dish" of Annibal Caracci, having been engraved for the bottom of a salver, belonging to cardinal Farnese; "The Virgin supporting the Infant Jesus, who is asleep," in 4to.; "The Virgin of the Nightingale," where the Infant Christ is taking a bird from the hands of St. John, of the same size; "St. Jerome of the Spectacles," a half figure; a small plate of "St. Francis sitting, holding a Skull on his Knees and a Crucifix in his Hand;" another, in quarto, of "St. Francis kneeling at the Foot of a Rock, with a Disciple before him;" "Apollo playing the Lyre, with Pan, or Marsyas beside him, biting his Fingers," a very rare print, in octavo; "An old Man speaking to two other Figures," of the same size; "Venus asleep, with Cupid observed by a Satyr," in quarto; another "Venus asleep, with Cupid and a Satyr," of the same size; "The Triumph of Bacchus," in quarto; of this subject Annibal engraved a duplicate plate, as is said, with the view of instructing Lanfranc in the art of etching. "Acis and Galatea watched by a Satyr," in folio.

Francesco Caracci, commonly termed Francefcchini, was the nephew of Agollino and Annibal, and was instructed in the arts of design by Lodovico. With such opportunities and strong natural talents, he in a short time attained an extraordinary knowledge of the human figure, which he drew so correctly, as to astonish his learned relatives, and Strutt thinks he might have attained a reputation equal, if not superior, to any of the Caracci: but his unfortunate propen-

fities to debauchery ripped all these fair promises in the bud. He died in an hospital at Rome, A.D. 1662, aged only 28 years.

Fra-ceschini etched with ability some few prints from the compositions of his uncle Annibal, among which are the following. He usually marked his work with the monogram, which will be found in our *Plate II.* of the *Italian Masters*:—"The Madonna and Child seated on a Cloud;" "St. Charles Boromius kneeling before a Table, contemplating a heavenly Light;" two plates of "Angels teaching the Lesson of Mortality," of which our artist did himself was too heedless; a set of four plates of illustrious women of antiquity: namely, "Semiramis," "Lacretia," "Artemisia," and "Portia." These latter are after Lodovico Caracci, and are very rare, and all his prints are of small dimensions.

Of that distinguished engraver Cherubino Alberti, who was living at the period now under our review, we have already detailed the biography, and delineated on the leading traits of his excellence, under the article ALBERTI CHERUBINO. His monogram will be found in our *Plate II.* of those of the *Italian School*; and we are now enabled to render our select list of his performances somewhat more copious, by the addition of the following:—The Portraits of Pope Gregory XIII. in an oval, with accessory ornaments; Pope Urban VIII. companion to the above; Henry IV. of France, also in an oval, with accompaniments; and Pietro Angelo Bargeo; all of folio dimensions, and from pictures by Cherubino himself.

Historical Subjects from his own Compositions:—"Judith, with the Head of Holofernes, and a Sword," in folio; "The Nativity," a grand composition, dedicated to Pope Clement XII. inscribed "En Deus Omnipotens," &c. both in folio, and marked with his cypher;" "The Flight into Egypt," where the ass is led by an angel, accompanied by St. Joseph and Elizabeth, in large folio; another folio print of "The Virgin and Child with St. Joseph," signed with Cherubino's cypher;" "The Body of our Saviour, carried through the Clouds by two Angels," inscribed "Magnum pietatis opus," &c. in folio;" "The Virgin and Child in the Clouds, surrounded by Cherubim's Heads, and two Angels strewn Flowers," entitled "Regina Cœli," in folio; another folio plate, of "St. Catherine of Sienna stigmatized, and supported by two Angels," 1574, marked with the artist's cypher;" "St. Chiriliana and St. Francis stigmatized, accompanied by two Angels," 1599;" "St. Charles in the Clouds surrounded by Angels, prostrating himself before the Virgin and Child," 1612, all of folio dimensions; six subjects for ceilings, of children, after the pictures by Alberti, painted at Ti voli; six genii in the air, dedicated to Cardinal Visconti; the first is inscribed "Ex picturis, quas Cherubinus Albertus in ejus Villa Tusculana pinxit, las ipemet incidit, 1607," in large quarto.

Historical Subjects from various other Masters:—Standing figure of "Sufanna leaning against a Pedestal," on which is written, S. Sufanna Vir. & Mart.; lower down, Alexander Albertus inv. dedicated to Cardinal Rustici, in large folio; "Our Saviour on the Cross," to the left is the Virgin, to the right St. John with extended arms, from Michael Angelo, in folio; a large folio print of "St. Jerome sitting meditating on a Cross," from the same master, engraved at Rome, A.D. 1575; another in folio, of "St. Andrew bearing a Cross," engraved in 1580, and taken from the Last Judgment of Michael Angelo; two other figures, in folio, from the Last Judgment, one inscribed "Nuda Veritas," the other, "Petit ad Æthera;" these are very fine engravings, and dated 1591; the figure of Charon, accompanied by

two others, and some heads, from the same Last Judgment, engraved A.D. 1575, in folio; "Prometheus torn by the Vulture," painted for an angle of the Sibine Chapel, in folio, engraved A.D. 1580; a group of four figures, namely, "The Body of Our Saviour;" "The Virgin;" "Nicodemus;" and "Mary Magdalen;" in folio. The original sculpture by Michael Angelo, from which this engraving was made, was taken to Florence, and placed behind the altar of the cathedral, with the following inscription: "Poliretum Michaelis Bonarotæ opus, quamvis ab artifice ob vitium marmoris neglectum, exitum tamen aris canon. Cosmus III. Magnus Dux Etrurie Romæ jam erectum hic, P. I. anno MDCCXXII." Three prints representing "The Creation of Adam and Eve;" "Adam and Eve chased out of Paradise;" and "Adam and Eve subjected to Labour," Rome, Polidorus de Caravag. invent.; a large frieze, of "The Death of the Children of Noë," in five plates; another frieze, of "The Rape of the Sabinæ," with a Latin inscription; "The Triumph of Camillus," in the antique taste; "Pluto," a figure holding a flambeau; "Fortune;" with her left foot on a wheel; "The Presentation in the Temple," from Raphael; this was published after the death of Alberti, in folio; "The Resurrection of Christ," a grand composition, with an angel sitting before the door of the sepulchre, dated 1628, in folio; "Jesus on the Mount of Olives," where an angel presents him with a chalice, dated 1574, and published in 1628, in folio, from Rosso; this, as well as the last, was published after the death of our engraver. "A Holy Family," in large folio, after Raphael, engraved in 1582; a folio print of "Jupiter caressing Ganymede," from the Vatican, by Raphael; two more from the Vatican, on the same plate, of "The three Graces;" and "Venus quitting Juno and Ceres," 1582; "The Adoration of the Magi," a grand composition, after Rosso, dated 1574; "The Transfiguration," marked with Alberti's monogram, from the same master, 1574; "St. Stephen stoned," an architectural design for a grand tabernacle, on two plates, Rome 1575, in folio, all from Rosso; "The Baptism of our Saviour," after Andrea del Sarto; "The Miracle of St. Philip Benizvio," where those who had despised his exhortations were struck dead with lightning, from a picture by Andrea del Sarto, 1582; a folio print of "The Guardian Angel conducting the youthful Tobias," from Pellegrino Tibaldi, 1575; "Our Saviour in the Garden of Olives, with his three Disciples," engraved by Perin del Vaga, and Ch. Alberti, in folio; "The Nativity, or the Adoration of the Shepherds;" over head is a glory of angels, inscribed "Gloria in Ecceis," in large folio, on two plates, from Thadæus Zuechero; another "Holy Family," where the Virgin holds the Infant on a cradle, from the same master; "The Flagellation," from a picture by T. Zuechero, in the church of the Consolation at Rome, in folio, dated 1575; "The Conversion of St. Paul," a grand folio print, from the same master, dated 1573; "The Body of our Saviour in the Arms of God the Father, surrounded by Angels, with the Instruments of the Passion," from the same; "The Assumption of the Virgin," engraved in 1577, from T. Zuechero, and dedicated to pope Theani, in large folio; another Assumption, a large print from T. Zuechero, engraved in 1571; "The Virgin crowned in Heaven," from the same master, engraved A.D. 1572.

We have already treated of the biography and merits of Lodovico Cardi, surnamed Civoli, both as an engraver and painter. (See the article CARDI LOBOWIC.) His monogram will be found in our *Plate II.* of those of the *Italian School*.

Christopher Lederer was born at Nuremberg in the year 1560. He travelled to Italy in his youth, for the sake of studying the arts to advantage; and here, for some reason which has not transpired, he changed his surname for that of Coriolano, or Coriolanus. He resided at Venice for some years, where, according to Vafari, he engraved on wood a set of portraits of celebrated artists, a work which other writers have still more mistakenly ascribed to his son.

Now as these portraits first appeared in the year 1568, if Christopher was born in 1560, as Huber reports, and Bartholomew not until 1590, they could not have been engraved by either of the Coriolani. Again, he is said to have engraved for the anatomical work of Vesalius, of which the drawings were supplied by Titian, but as this celebrated book first appeared in 1542, Lederer's blocks must have been for some subsequent edition, if he cut them at all.

It appears more certain that he engraved the figures for Ulysses Aldrovandini's work on natural history, and for another book, entitled "*Ars Gymnastica*," &c.

Bartholomeo Coriolano was the son of Christopher, and was born at Bologna in the year 1590. He learned the rudiments of art in his father's house, but finished his studies in the Bolognese academy.

In return for the dedication to pope Urban VIII. of a capital work which he engraved on wood, after the Caracci, Guido, and other great masters, that pontiff bestowed on him a pension, and the order of knighthood. According to Papillon, our artist pretended to be a descendant of Caius Martius Coriolanus, the great Roman general, but this is most likely a mere joke, fabricated on the occasion of his military, or equestrian title.

He likewise engraved in clair-obscur, and his productions in that style are very much esteemed by connoisseurs. He had a good taste in design, his heads are finely characterized; and the other extremities of his figures are very well marked. In general he used no more than two blocks of wood; on the first he cut not only the outlines, but the darker shadows in imitation of hatching with a pen; the second served for the half tints; and with these two blocks, judiciously managed, he produced a pleasing effect. He signed many of his prints with his name at length, and the addition of the word *Eques*, which is known to be synonymous with knight. The following are among his most esteemed productions: "St. Jerome meditating before a Crucifix," a small upright print from Guido; this is engraved on three blocks of wood, and inscribed "Barthol. Coriolanus, *Eques*, sculptit, Bonon. 1637;" "Herodias with the Head of St. John," also in clair-obscur, and from Guido; "The Virgin and Infant Jesus, asleep under Drapery," on wood, from Guido; the same subject, in clair-obscur, very finely executed, both in 4to. and marked Barthol. fec. 1630; another "Virgin and sleeping Christ," from Vanni, in clair-obscur, not marked, in large 4to.; "Peace and Plenty;" from Guido; "A Sybil sitting, holding Tablets," both in 4to.; "The Fall of the Giants," a large upright print, on four separate sheets which paste together, in clair-obscur, "The Seven Wife Men transported to Bologna," in large folio.

Tierrefia Maria Coriolano, was the daughter of this artist, and learned engraving of her father, and painting of Elizabeth Sirani. We only know of a single etching by her, of "A Virgin and Child," half figures.

Giovanni, or Jean Batista Coriolano, was brother to Bartholomew, and was born in the year 1596, in Bologna; where he became the scholar of Valico, a painter of some eminence.

As a painter, Batista never acquired any great degree of

reputation, but he engraved both on copper and wood, his works on the latter material being however greatly superior to his engravings on copper. The following may be reckoned among his best productions: a portrait of Vincent Gualdi; another of Fortunatus Licetus; another of Joannes Cottinius, Patricius Vericenis, Coriolano, for all of quarto dimensions; the statue of the Virgin in a palm-tree, commonly styled "Our Lady of the Palm," before which is a small altar: "The Miraculous Image of the Virgin," from Guido; "Christ crowned with Thorns," from Lodovico Caracci; "A sleeping Cupid," in chiaro-scuro, very rare, after Guido; a triumphal arch in honour of Louis XIII. in folio; "Paul Masi Emblemata," being a set of eighty-three prints, of which twenty-seven are by Coriolano, and the rest by O. Gatti, and A. Parini.

Giovanni Luigi Valico, was born at Bologna in 1561. There were two other engravers of this name, who lived some time about the same period, and probably belonged to the same family; but as their productions have nothing remarkable to recommend them, we will pass them over in silence. Giovanni frequented the Bolognese academy, and has engraved several things in a good taste. Most of his prints consist of allegorical and emblematical designs, frontispieces for books, and other ornamental plates; some of which he marked with a monogram, which will be found in our *Plate II.* of those of the *Italian Engravers*. The following are among his most esteemed productions: "The Virgin with the Infant Christ seated on her Lap," a small upright plate; "Venus threatening Cupid," and "Venus chastising Cupid," its companion, two small upright plates; "Hymen with two Lions at his Feet," and "A Group of Genii," from Lodovico Caracci, in folio.

Jean Frederic, the son of Matthew Greuter, of Strasbourg, was born at Rome some time about this period. Our countryman, Strutt, has entered into rather a lengthened argument with the foreign writers respecting the date of Jean Frederic's birth, of which his merits as an artist do not appear to render him worthy. What does it signify when or where men are born, who are possessed of no greater talent or taste than this engraver? or whether or not there was a Frederic and a Jean Frederic also?

The son of Matthew Greuter, of whom we have given some account in our *GERMAN School of Engraving*, resided at Rome, being educated to the profession of engraving by his father. Here he engraved a considerable number of plates with commendable industry, working with the graver only; but he neither drew well, nor possessed feeling for art that might in any degree supply the place of drawing; yet his prints, of which we shall only mention a few, are sometimes sought after by the curious. "Hercules in the Garden of the Hesperides," from Pietro da Cortona; "The Forge of Vulcan," after Lanfranc; and "A Battle," from Tempesta, both in large folio. "The Death of St. Cecilia," after Dominichino, a large plate, nearly square. An emblematical subject relative to the progress of Christianity, a large folio print, from Romanelli; and "A Madonna and Child, with St. Francis kneeling," from a composition by himself, arched at the top, of folio dimensions, and dated 1623.

He also engraved several portraits, and other subjects from Guido, Vouet, Stella, And. de Ancone, and other masters.

Francesco Vanni, a very celebrated historical painter, was born at Sienna A.D. 1563, and died in the same city in 1610. He was first the disciple of Salimbini, afterwards of Passarotti, and at last of Giovanni de Vecchia; though in preference

ITALIAN SCHOOL OF ENGRAVING.

preference to all these, he adopted the style of Fred. Barroccio. We have four small etchings by him: the Spirit, beauty, and correctness of drawing that appear in those prints, makes it to be regretted that he etched so little. The subjects of these etchings are as follow: "The Virgin contemplating the sleeping Christ;" "St. Catherine of Siena receiving the stigmata, or Brand;" "St. Francis receiving the Stigmata;" and "The Extatic Vision of St. Francis;" the faint is a half figure, and an angel appears above playing on the violin. Huber says that the beauty which is discoverable in this print cannot be too much admired. Agollino Caracci engraved from the same design, with some variations.

Giovanni Maggi, or Magius, was born at Rome in the year 1566, and is better known as an engraver than as a painter; we have by him many slight etchings, which are not worthy of any very great commendation. In 1612, he published a collection of all the principal fountains in Rome, which he engraved in conjunction with Domenico Parafachi. He undertook to engrave, on a very large scale, the plan of Rome, with all the streets and principal buildings, &c. but wanting money, the enterprise was never performed by him. We have by him, the portrait of a cardinal, as large as life; a landscape, with figures, ruins, &c. inscribed "J. Maius, v. et fec. 1595;" and "Figura della Vita Humana, Joh. Maius fec. 1600," in large folio.

Francesco Villamena was born at Alessia, a city of Italy, in 1566, and died at Rome in 1626. He went to Rome under the pontificate of pope Sixtus V. and studied the best pictures and statues there. He studied engraving under Cornelius Cort and his scholar Agollino Caracci, with whom he was contemporary. Villamena drew with considerable ability; he engraved in a bold open style, and produced a clear but not powerful effect; his lights, though broad, are too much spread over the whole engraving, which makes his prints appear unfinished. But this defect was common to the artists of that age, and these faults in the prints of Villamena, are amply compensated by the beauties with which they abound, particularly with regard to the expression of the heads, and the excellency of the drawing. The extremities of his figures are also very finely marked. Some of the engravings of this artist are performed almost entirely with single strokes, without any cross hatchings laid over them; and it was perhaps from them that Mellan originally took the hint, which afterwards became the marked peculiarity of his style. The number of Villamena's prints is very considerable: M. Mariette mentions three hundred and sixty; and he marked them either with his name, initials, or monograms, which will be found in our *Plate II.* of those of the *Italian School*, we shall mention the following, from his own designs; a portrait of cardinal César Barroccio Soranus, in folio; and four other portraits of men of rank; "St. Theresa in her Cell writing, under the Inspiration of the Holy Ghost," in folio; "Mary Magdalen penitent in the Desert, crowned by an Angel," in 4to.; "St. Francis praying before a Crucifix," in folio; a set of six grotesque little figures, one of which is a beggar, accompanied by two children; a set of five faints, three of which are from his own design, and the two others from Ferrau Franzoni; "St. James, appearing in the Air, to the Army of Ferdinand," a very grand composition; "A Man, angered by a Crowd of People, fighting in his own Defence;" a large print lengthways, commonly called *The Boxes*; a middle-sized plate, in which is represented John Alto, the antiquary, standing in one of the streets of Rome. The following prints are

from various other Masters. — Moses exalting the Brazen

Serpent," from Ferrau Franzoni; "A Holy Family, with St. John, Elizabeth, and St. Ann," a middle-sized upright plate from Raphael, dated 1602. Villamena repeated this subject, and dated the second print 1611. "The Salvation of the Virgin," a large upright plate, from M. Arconio; "The Virgin and Infant Jesus worshipped by St. Francis;" "St. Bruno, with his Companions, doing Penance in the Desert;" a large plate lengthways from Lanfranco; "Christ taken from the Cross;" a large folio plate, arched at the top, from Barroccio; another "Annunciation of the Virgin," a grand composition from Resp. Andreassius, in large folio; "The Presentation in the Temple;" a middle-sized print lengthways, from Paolo Veronese; "St. Bernard, and the Virgin in the Clouds," after F. Vanni; "Alexander at the Battle of Arbella," from Ant. Tempesta; a large plate, lengthways, representing "Heracles holding the Globe, with the armorial bearings of Cardinal Arconio;" from Allori; another subject of the same kind with the arms of Cardinal Barberini; the same subject with the arms of Spain, all which are of large folio dimensions; the bible of Rhabad in twenty plates, fifteen from the Old Testament, and five from the New, intitled "Luca Geni figurata da Raffaele, intagliata da Francesco Villamena, dedicata al Cardinal Aldobrandino, Rom. 1626.

Leonardo Norfini, who assumed the name of Parafole, from its being the family name of his wife, was born at Rome in the year 1570, and died in the same city, at the age of sixty. He was an engraver on wood of some merit, and was much employed by A. Tempesta. At the command of pope Sixtus V. he engraved the plants, &c. for the herbal of Carlo Durante, the physician of that pontiff.

The figures in Norfini's engravings, after Tempesta, are correctly drawn, and executed in a finished style, for that mode of art.

His son, Bernardino Norfini, likewise engraved on wood; he frequented the school of Jofephine, and began to make progress in painting, when he died at an early age.

Isabella Parafole, the wife of Leonardo, was a woman of great ingenuity, and composed a book of patterns for lace and embroidery, of the prints in which she engraved on wood. She likewise did a great number of plants for a herbal of prince Cesi of Acquafarta.

Jermicina Parafole, a lady of the same family, equally distinguished herself by engraving on wood; and there is by her hand a large print of "The Battle of the Centaurs," from A. Tempesta; it is coarsely executed, though with much spirit; but the drawing is not correct.

Odoard, or Edward Fialetti, was born at Bologna A.D. 1573, and died at Venice in 1638. He learned the rudiments of design of J. B. Crenonini, but afterwards travelled to Venice, and finished his studies in the school of Tietto-retto. He was an historical painter as well as engraver, and his works in both arts are spoken of with the warmest commendation; Biscioni mentions thirty-eight pictures by Fialetti, which he painted for churches and other public buildings in Venice. He etched a great number of prints as well from his own designs, as from those of other artists.

His etchings are executed in a slight, but not merely style. He drew correctly, frequently selected or invented very graceful attitudes, and composed his figures with much life. If he had not no other testimony of his merit than his prints, they would have been sufficient to prove that he was a man of very great ability. He is generally marked by letters with a cypher, which will be found in our *Plate III.* of those of the *Italian School*. We shall mention the following productions of his graver, as well worthy of the notice of the connoisseur. A long piece from his own composition of tritons, sirens,

ITALIAN SCHOOL OF ENGRAVING.

fiens, dolphins, and other marine chimera; "The Marriage of Cana in Galilee," a middling-sized plate lengthways, from Tintoretto; four subjects from Le Pordonone, "Venus and Cupid;" "Diana at the Chase;" "The God Pan;" and "A Man holding a Vase;" "The Pastimes of Love," a set of twenty small upright plates, from his own designs; entitled "Scherzi d'Amor espressi da Odoardo Fialetti, pittore in Venezia;" a book with studies for drawing, in folio, published at Venice A.D. 1608; a book of the costumes of different nations; and another of antique friezes, after Polifilo Ziancalei.

Guido Reni, the celebrated historical painter, was born at Bologna in the year 1575, and died in the same city in 1642. He learned the elements of drawing of Denis Calveart, whom he quitted, to study in the Bolognese academy. But of his great talents as a painter we shall treat under the article *RENI*, and have only to notice him here as an engraver.

There are a great number of prints by his hand, which are etched in a bold, free style. His heads are beautiful and expressive, and the other extremities are drawn with all that taste and judgment which might be expected from so great a master; though they are very slightly executed, their intrinsic beauty, and the vigorous but discriminating intention of the artist, which is every where apparent to the eye of taste, have stamped a high value on them, which they justly deserve. Simon Cantarini, called *Il Pefarole*, copied the style of etching of Guido with so much precision, as sometimes to deceive the eye of the unwary connoisseur; but in general, the extremities of the figures in the plates of Cantarini, are not marked with that admirable taste so discernible in the works of Guido.

He sometimes marked his plates with his name, or monogram, which is among those of the Italian engravers in our *Plate II*. The following are among the productions of his hand, the whole number of which, according to Mariette, amount to two hundred and eighty-nine.

From his own Compositions.—A bust of pope Paul V. in oval, very rare; the profile of a man; another, with a long beard; "The Virgin with the Infant Jesus, with St. Joseph in the back ground," in 4to. one of the finest engravings of Guido; "The Virgin with the Infant Jesus asleep at her Breast;" a subject which Guido has treated in three different ways; another "Virgin and Child, with a Book;" the only plate which Guido has executed entirely with the graver; three other holy families, represented in different ways; "St. Christopher, with the Infant Jesus on his Shoulders, going over the Sea;" "St. Jerome praying before a Crucifix, in his Cave," in 4to.; "Cupid contemplating a female Figure, who holds a Compass and Tablet;" "Two Children carrying a third on their Shoulders," in 4to.

The following are after other masters: "A Glory of Angels," after Lucas Cambi, in folio. This print is reckoned Guido's master-piece. "The Entombing of Christ," a middling-sized upright plate, from Parmegiano, a very fine print; "The Infant Christ sitting on his Mother's Lap, laying his Hand on the Tabernacle, with St. Joseph," from Aug. Caracci, falsely attributed to Annibal, in 4to.; "The Virgin Mary suckling the Infant Jesus," from Caracci, in 4to., executed on a blank ground; "The Clarity of St. Roch," dated 1610, in large folio. These are the principal engravings of Guido, of the whole of which Adam Bartsch of the library at Vienna has given a very good catalogue.

For an account of Francifeo Brizzio, the pupil and assistant of Agostino Caracci, see the article *BRIZZIO*; and

for the biography of Horace Borgiani, who lived also at this period, see *BORGIANI*. The monogram usually affixed by the latter to his engravings will be found in *Plate III*. of those of the *Italian School*.

Raphael Scaminofi, or Schiaminoffi, was born at Borg S. Sepolcro in the year 1580. He was the disciple of Raphael dall Colle. He performed some few engravings on wood; and there are a considerable number of etchings by him,—Florent le Compe says a hundred and thirty,—which are executed in a bold dark style. There is a coarseness in them, which gives them a disagreeable appearance at first sight; but on examination, they will be found to possess great merit. His knowledge of drawing seems to have been very extensive; and the characters of his heads are striking and appropriate. His monogram is copied in *Plate III*. of those of the *Italian School*.

The following are some of the best productions of his needle: "The Virgin and Child," a middling-sized upright, inscribed "Raphael Schiaminoffius, Pictor ex Civitate Burgi Sancti incidit, A.D. 1633;" "St. Francis preaching in the Desert," from his own composition; a set of the twelve Apollies; a set of fourteen small plates, lengthways, entitled "Mytheria Rosarii beate Mariæ Virginis;" published at Rome, 1609, and from his own designs; the fifteen Mysteries of the Rosary, in folio; "The Martyrdom of St. Stephen," a middling-sized plate, lengthways, from Lucas Cangiagi; "Mary Magdalen carried away by Angels," after the same, in folio; "The Visitation of the Virgin," from Barroccio, in folio; a middling-sized plate, lengthways, from the same master, of "A Resposso;" "The Holy Virgin in the Clouds, with St. Cecilia, and another Saint," from P. Veronese, in folio; "The Virgin Mary on a Globe, surrounded by Angels," from B. Castelli, in folio; a set of twelve wood-cuts of the twelve Apollies; another set of portraits of the first twelve Cæsars, from T'empella, also engraved on wood.

Jean Lanfranc. This distinguished artist was born at Parma A.D. 1581, and died at Rome in 1647. He first studied under Augustino Caracci; but on the death of this master, went to Rome to complete his studies under his brother Annibal, where he was knighted by pope Urban VIII.

His merit as a painter will be treated under the article *LANFRANC*. We shall speak of him here only as an engraver.

The mode of art which he practised was etching, and his etchings, though hasty productions, possess merit. He commonly marked his plates with his name, or initials, but not combined in a cypher; and his most esteemed prints are mentioned in the following short list: "The Triumph of a Roman Emperor," in large folio; "An Emperor haranguing his Soldiers," the same; the Bible of Raphael, from pictures in the Vatican, engraved in conjunction with Sisto Badolocchio, (of whom we shall next proceed to speak), and dedicated to Annib. Caracci, 1627, in 4to.

Sisto Badolocchio was of the family of Rosa, born at Parma in the year 1581, and died at Rome in 1647. He was the contemporary and fellow-student of Lanfranc. There are some picturesque little etchings by him, in which we discover correctness of design, and facility of handling his tool. He marked his prints, of which those that follow are held in most esteem, Sisto B. "The Statue of the Laocoon," from the antique, in large folio; "The Apollies and the Angels, with the Chandlers of the Cupola of Parma," from Correggio, six plates in folio; "A Holy Family, with St. John," a small upright plate of half figures only; Raphael's Bible, from the pictures of Raphael

Raphael in the Vatican, small plates, lengthways, engraved conjointly with Lafrance.

Ottavio Leoni was born at Rome in 1582, and, under the instruction of his father, he acquired some degree of excellence as a painter. As an engraver, he is believed to have been self-taught; for, excepting the hints which he might have borrowed from Boulanger and Agollino of Venice, he imitated none of his predecessors. There are a set of twenty portraits, chiefly of distinguished artists, from his hand, engraved in a singular and striking manner. The hair and draperies are executed with strokes; the flesh is done in round dots; and the dark parts of the eyes and sharp shadows being assisted with strokes, which are managed in a skillful manner, produce a pleasing effect. These heads are finely drawn, and some of them finished in a much higher style than is usual with painters, when they take up the point or the graver. The following are among the portraits: Eques Ottavi Leonus, Ludovico Leonus, Johannes Fraciscus Barberi, Marcellus Provenzalini, Eques Christophier Ronchalis de Pomeraniis, Eques Joseph Cesar Arpinas, Antonius Tempeita, Thomas Salinus, Don Antonius Barberinus, Pierre Jacopo Martello, a poet, whose portrait is adorned with pastoral allusions.

Remigio Cantagallina was born at Florence in 1582, and died in the same city A.D. 1624. He for some time frequented the school of the Caracchi, but afterwards learned (with his two brothers Antonio and Giovanna Francisco) engraving of Julio Parigi. Remigio drew extremely well with a pen and ink, and sometimes, with great good sense, imitated this mode of art in his etchings.

His etchings are chiefly after his own designs, though he sometimes engraved after other masters; and it is no small addition to the fame of this artist, that Callot and Della Bella were his pupils. The cypher which he commonly used is copied in Plate III. of the monograms of the *Italian School*. We shall specify the following of his works: "The Assumption of the Virgin, wherein she is crowned by two Angels," in 4to., after Callot; four small landscapes, dated 1609, from Rossi; a set of six landscapes; another set of twelve, in octagons, with the cypher of the artist; another set of six; another set of nine and twenty prints, the scenes of an opera; and the representation of the fête given on the Arno, at the marriage of the prince of Tuscany, from the designs of Julio Parigi, in folio, 1595.

We now approach two artists, both of them disciples of Cantagallina, of a very different kind from any of their predecessors, of more enterprising spirit and more original powers, if not of more vigorous intellect, than the schools of Italy have yet presented to our notice; but having already treated of the biography and professional merits of Callot and Della Bella, (see the articles *BELLA* and *CALLOT*.) before our classification of the engravers into the several schools of Europe was determined on, we can do little more in this place than add more copious lists of their very estimable engravings.

The number of Callot's engravings, considering the short period of his life, is not less wonderful than the various multitudes of figures by which some of them are peopled. The best catalogue with which we are acquainted is contained in the third volume of the *Paris Heineckim's Dictionary*, from which we have extracted the principal, in conformity with our plan.

Subjects from Holy Writ, and the Monkish Legends.—"The Passage of the Red Sea," in 4to. of which coin-officers are desirous of possessing each of the two different states in which the plate was printed. "Elias and the widow of Sarepta;" "Ecce Ancilla Domini;" or "The Annunciation;" after

Matteo Roselli, in 4to. This is a rare *plata*, and is distinguished from another of the same subject, called "The little Annunciation," as well by its being without the engraver's name, as by its Latin inscription: "St. John preaching in the Desert." 4to. "The Parable of the Husbandman sowing Seed," with a Latin inscription, 4to. This *plata* is solely the work of the graver. "Ecce Homo;" after Stradan, folio, engraved at the age of eighteen: "Christ bearing the Cross;" a small oval, engraved on a silver plate. "The Crucifixion, with the Virgin Mary, St. John, and Mary Magdalen, embracing the Cross," a small and rare print. "The Entombing of Christ," after Ventura Salimbeni, the work of the graver alone. "Our Saviour with the Disciples at Emmaus." "The Virgin Mary with the infant Christ," an oval. Another, wherein the Virgin is embracing our Saviour, 4to. Another of the Virgin, after Andrea del Sarto, wherein is introduced St. John and Elizabeth, 4to. Another, after P. Farnini, with the infant Christ and St. John, folio. "Our Lady, with three Ears of Corn," 4to. "A Holy Family," inscribed "Minor servi et majoris, &c." 4to. Another Holy Family, after Sadoler, in 4to. entirely performed with the graver. "The Assumption with the Cherubim," 8vo. There is another of this subject, called "The little Assumption," in an oval. "Benedicite," another Holy Family, 4to. "The Triumph of the Virgin," folio, dedicated to Charles IV. duke of Lorraine, and Bar. folio; "St. John the Evangelist in the Isle of Patmos," in 4to. nearly square; "St. Francis;" of this subject there are two engravings, one known by the name of "The little St. Francis of the Tulip;" and the other termed "The Tree of St. Francis," at the foot of which are several monks at prayers, 4to. nearly square; "The Temptation of St. Anthony," the first plate of this subject, (which is a large folio,) is dedicated to Monsr. Philippeaux de la Ville, beneath it are Latin verses with his coat of arms, and it is dated in 1635.

As Fuseli has painted three pictures from the same fairy scene in Shakespeare's *Midsummer Night's Dream*, so Callot, to show that his imagination was far from being exhausted on the subject of the temptation of St. Anthony, has engraved a still larger plate from this celebrated legend, which is very considerably varied from that of which we have spoken; and, though not the best, the second is by much the scarcest print of the two; for the plate, having been materially damaged by accidental contact with some acid, a good impression, before the accident, is now rarely to be met with. "The Martyrdom of St. Lawrence," a small oval; "The Martyrdom of St. Sebastian;" this is a large and grand composition, in form of a frieze. "St. Nicholas preaching in a Wood;" "The Miracle of St. Manfuette;" this is reported to be the earliest of Callot's etchings, it is in folio, and the shadows are expressed by broad and coarse hatchings, and almost, if not quite, every line in it is re-entered with the graver. St. Manfuette was a bishop of Tours, who is here represented as resorting to life the son of king Leuegaris, who had fallen into a river in reaching for his tennis ball. "The twenty-three Marvrs of Japan," in 8vo.; "The Infant Christ, or carrying the Host," a small plate, for which Callot himself is said to have entertained so great partiality, that he occasionally wore it, as some of the foreign orders of nobility are worn, suspended from a button hole of his waistcoat. The proofs which were taken before the plate was perforated to admit the ribbon or string are rare, and are esteemed valuable among connoisseurs. "A Nun kneeling before a Crucifix," in 4to.: this piece is known by the name of "Santa Teresa," but it appears from the inscription that it is the portrait of Marie Victoire, the foundress of the convent

convent of the nuns of the Annunciation, at Genes, who died Dec. 15, 1617. "The Possessed," or the Exorcism, after And. Boscoli, in folio, entirely the work of the graver. "The Course of Human Life," after Bernardino Poutti. This is a set consisting of four plates, which are vulgarly called Hell, or Purgatory. "Vita beate Marie Virginis Matris Dei, Emblemata delineata;" a set of 27 plates in 12mo. "Gloriosissima Virgi de Deipare Elogia," consisting of nine plates of devotional subjects. 8vo. "The New Testament," consisting of twelve plates, including the title. N.B. The most valued impressions of this set, are those which were printed before the inscription that Fagnani inserted underneath the engravings. "The Passion of Jesus Christ," consisting of seven finely executed plates in 4to. "The Paintings in the Church of St. Peter at Rome," consisting of twenty-nine or thirty plates, in 8vo of which the subjects are the Acts of the Apostles. These are the plates of which we have spoken in our biography of Callot, as engraved at Rome, with the graver alone, under the direction of Philip Thomassin. "Vita Historia Beate Marie Virginis, Parisiis," fourteen plates, including the title and tail piece. These may be distinguished from Callot's other plates, in honour of the blessed Virgin; by the inscription "Attributa beate Marie." "Male and Female Penitents," six plates, of which the subjects are 1. The Title by Ab. Boffe; 2. St. Jerome; 3. St. John; 4. St. Francis; 5. St. Mary Magdalen; 6. The Death of the Magdalen. "Salvatoris beate Marie Virginis sanctorum Apostolorum icones," a set of sixteen plates in 8vo. published at Paris in 1631. "Martyrium Apostolorum," a set of sixteen finely engraved plates, in 12mo. "The four little Banquets," a set of four small plates, of which the subjects are 1. The Marriage of Cana; 2. The Repast at the House of the Pharisee; 3. The Lord's Supper; 4. Our Saviour with the two Disciples. "The Life of the Prodigal Son," in 12mo, published by Israel in 1635. "Sulta d'alcuni miracoli, etc." after various masters, forty-one plates in 12mo. "Lux Claustri," representing, under various emblems, the sweet ferocity of a religious life, and consisting of twenty-seven plates with an historical title. "The seven Mortal Sins," on seven plates, 12mo.

Battles, Sieges, &c.—"A General on Horseback," an army in flight, surmounted by a hat and feathers, and the truncheon of command, small. "A Pistol shot," a grand review of cavalry. "Descent of the Troops into the Isle of Ré;" this engraving is of an oblong form, and is enclosed in an ornamented border. "The Siege of Ré," a set consisting of six large engravings in ornamented borders; the border is engraved on separate plates, and four plates of writing accompany the set. These were engraved at Paris, under the patronage of the king of France. "The Siege of Rochell," embellished in the same manner, and also done under the patronage of the French king. The portraits of the king, and of Gallon of France occur in the borders. "The Siege of Breda," a set consisting of six large engravings, and two double leaves of engraved writing, recording the events of the siege; these plates were engraved for the Infanta of Spain. "Battaglia de ri Tefsi et del re Tintin," a large engraving, which is usually called "L'Evantail," or "The Fan," on account of its form. It is enclosed in a border, and represents a curious firework which was played off on the Arno. The words Tefsi and Tinta allude to the weavers and dyers (tisserand and teinturier) who at that time enjoyed great privileges at Florence. "The House Actions of the Medici," after Ant. Tempesta, engraved on sixteen folio plates, and without any etching. The impressions from these plates, which are found in the

"Galeria Medicea," are not esteemed the best. "The Great Miseries, or Horrors of War;" these admirable compositions are a set of eighteen 4to. plates, and were published by Israel in 1633. They were followed by "The Lesser Evils of War," on seven 8vo. plates, including the title, (which is by Ab. Boffe,) published in 1636. "Military Exercises," on fourteen small plates, published also by Israel. "Combat at the Barrier," a set consisting of eleven plates, including the title. These prints are of different forms and sizes. They were originally published by Callot himself, at Nancy, in the year 1627; but have since undergone some alterations; the work is in 4to. "Naval Engagements;" these consist of the victories gained by the grand duke of Tuscany over the Turks, and are also in 4to. dated 1617. "Seven Tilting Pieces," in 4to. engraved at Florence, four only of these bear the name of Callot. "Jousts and Tournaments," a set of five spirited prints in Callot's best manner, in 4to. of which the subjects are, 1. A plan of the Jousts and Tournaments. 2. A Battle enclosed within oval lists, inscribed "Uno Degli abbatimenti;" 3. Several squadrons in battle array, enclosed in a similar manner, and inscribed "Mostra della Guerra, d'Amore;" 4. Parties of cavaliers racing in a circle; 5. Four triumphal cars characteristic of the quarters of the globe, drawn by appropriate animals, and inscribed "Carra del Asia," &c.; they were published at Florence, and are after the designs of Callot's first Roman master, Giulio Parigi. "La Guerra d'Amore," consisting of four 4to. plates, from the designs of the same master. They represent the ballets, &c. celebrated at Florence on the occasion of the arrival of the prince of Urbino, by the grand duke and Tuscan nobility on the plain of St. Croix.

Profane and Miscellaneous Subjects.—"The Giants," a large folio plate, in which Callot has introduced an assembly of the heathen deities, Temple of the Muses, &c. "The Giants struck by Jupiter's Thunderbolts," in folio, of the oval form, and now very scarce. "Pandora," a folio plate. The gods are here represented as assembled on Olympus, with Jove armed with thunder on its summit. "Catafalque de l'Empereur Mathias," a folio plate, dated 1619, and inscribed "Esseque celebrati in Fiorenza," &c. "A Gambling House," a folio plate, the subject a night-piece, with gamblers; Callot afterwards repeated this engraving, reversing the right hand to the left. "The Punishments," in 4to.; this is regarded as one of the chief d'œuvres of the master, not only on account of its intrinsic merits, but of the great number of figures contained in it, of the composition and grouping of which we have already spoken. Its subject is the execution of various criminals. In the most perfect impressions of this plate, a small square tower appears above the houses, a little to the left of the middle of the print, and a very small image of the blessed Virgin, is placed at the angle of a wall which forms the corner of a street, and is also near the middle of the engraving.

The following are generally known among collectors by the name of the three ovals; "The Adoration of the He-goat or the Sabbath;" "An Altar, with two small Figures at Prayers;" "A vessel Fenale, standing before the Throne of an Emperor;" "Esseque della Regina d'Espagna," consisting of twenty-six plates in 8vo., after Ant. Tempesta. Of these Callot himself engraved only eight, the remainder are by Tempesta himself, or by anonymous artists; "The Whims or Fancies" of the noble Jacques Callot, fourteen small plates of whimsical subjects, published by Israel in 1635; "Capriccie de varii Figure di Jacobo Callot in aquaforti," on sixteen small plates engraved at Florence; "The Caprices," which are copies of the above, engraved at Nancy.

ITALIAN SCHOOL OF ENGRAVING.

Nancy. Beneath the title of the latter is inscribed "excud. Nancy;" but the Florentine set is executed with superior taste and feeling; "Varie figure di Jacobo Callot," on seventeen small plates, including an historical title; "Balli di Stefania," on twenty-four small plates, including an historical title: each plate contains three figures; "Varie figure Gobbi di Jacobo Callot, fatte in Fiorenza," a set of sixteen small plates, generally called, in England, the Hunchbacks, or Pigmies. This is a droll set, and as the author may be said to have here presented us with a back view of nature, the title page is a figure who shows his posteriors. Callot repeated this set with some variations: "Les Guerra di Callot," twenty-five plates in 8vo., which are much sought after by connoisseurs. On a piece of drapery in the title page, is inscribed "Capitano di Baroni;" "March of the Bohemians," on four 4to. plates in form of friezes. These are probably done from his lively recollections of the gang with whom he first travelled from Lorraine to Florence; "Nobility, or the Fashions of the Times," twelve plates in 8vo., on which are portrayed six of either sex with very amusing backgrounds.

There are four other similar prints, but of a larger size, by Callot, which are very finely executed, and which consist of the costume of the inferior orders: 1. A Woman in a Corset trimmed with Fur. 2. A Villager spinning. 3. A Countrywoman walking with a Basket on her Arm. 4. A Woman with her Face seen and Petticoat turned up. "Tragedia del Co. Bonarelli," on sixteen quarto plates, with a portrait; "The three Interludes of Florence," in 4to. after Giulio Parigi. These represent a festival given at Florence during the carnival, and are rare, particularly the two latter; the plates for "A Voyage to the Holy Land," consisting of forty-eight in 8vo., which Callot engraved for a Grey friar, with whom he had formed a friendship, and who published this voyage; "The Twelve Months of the Year;" these twelve prints are rare; they are after Jodocus de Momper, in 4to., and solely the work of the engraver; "The Four Seasons," in 4to., extremely scarce. These prints are copied from four engravings that the Sadclers engraved after Baffan; "The current Coin of Germany, Italy, &c." ten sheets, engraved at Nancy for Galton of France, and published at Paris by Israel Silvestre in 1662; "A Woman sitting in a Field," a child in her arms, and another eating fruit, is seated under a tree, a small engraving, and very rare; two small prints, called by the French collectors "Deux Filenies affiles," and "Deux Dames qui se promient," are also rare; "Two Females habited al Allemande;" "A female Gardener with an Afs;" and "An old Man, accompanied by a little Boy," are small plates, with landscape backgrounds.

The following farcical subjects are executed on small plates, in the same style as the celebrated "Beggars" by this artist, and with equal spirit, viz. "A comic Figure," (a sort of Falstaff, with a large belly and wearing a sword); "Two Harlequins," who are dancing in grotesque attitudes; "A Buffoon," "A Scaramouch," and "A Pierrot," three plates with theatrical backgrounds; "A Comb Merchant," another comic figure, bearing a pedlar's pack on his back, and holding a comb in his hand.

Topographical and other Landscapes.—"View of the Louvre, with the ancient Tower of Neile," a folio plate; "View of the Pont-Neuf at Paris," ditto. These are of the belt of Callot's landscapes. Another view of the Pont-Neuf was engraved by our artist in 1629, in which the ground was etched by Silvestre. This is a 4to. plate, and the impressions which are (on account of their rarity) much in esteem, are those which were taken before Silvestre touched the plate; "The

Parterre of Nancy," where many persons are walking, a piece in the long and narrow form of a frieze; "The Garden of Nancy," an extremely rare print, inscribed *Jul. Callot, inv. et fec.*; "La Carriere," the new flicet of Nancy, in which is introduced a carousal and tilting match. This is also in the form of a frieze, and the earlier impressions are without the name of Silvestre; "La petite Place de Sienne," in 4to.; "The Great Fair of Madama del Impronetta," called in England "The Great Fair of Florence," on account of its having been engraved in that city. It represents a fair which is annually held in honour of the miraculous conception; and is esteemed one of the most capital, and is one of the largest of the engravings of Callot, being in length twenty-six inches and sixteen in height. It consists of a bird's-eye view over a vast area, which is terminated by the church of the holy Virgin, and more remotely by distant mountains. Within the area thousands of figures, grouped with appropriate taste and skill, are engaged in all the varieties of business and entertainment which is presented by an Italian fair held under a general sky. It perfectly suggests Milton's idea of

"The busy hum of men,"

and is in truth a surprising production, such as modern art, and modern attention almost would seem from in despair; yet so superior was the patient attention of the public of two centuries ago, and the patient skill of our artist, that Callot copied this print, on account of the great demand for it, and even, as some authors have asserted, engraved a third plate of the same subject, with some slight variations.

The first plate, which was published in the year 1620, is distinguished from the second, by the words "in Fiorenza," which appear below at the right hand corner of the margin of the plate, whereas in the second plate, the words in the same part of the margin are "se Fiorentie—et excudit Nan j," which latter word has occasioned it to be contradistinguished among connoisseurs and dealers, by the title of "The great Fair of Nancy." The first plate may also be known to persons of taste and discernment, from the second, by its superior style of execution: there is a certain spontaneousness, the result of original feeling, in the first, which could not be copied even by the author himself, without some symptoms of restraint. The scarcity of good impressions also makes it bear a much higher value than the copy; for as it was far less successfully corroded with the aquafortis, the number of good impressions which the plate produced was much more limited.

A third plate of this subject is mentioned by Roß and Huber, but the present writer has not seen it, nor does it appear to have been seen,—at least it is not mentioned—by Strutt. Perhaps the copy by Savery may have led these authors into error on this point. The copy may easily be known from those by the hand of Callot, by its inferior merits, and by its being reversed. "La petite Foire," (the little fair) otherwise called "The Players at Bowls," is not properly the representation of a fair, but of a village fête. Peasants are dancing in a ring, and the musicians are seated in a very large old tree, which has all the appearance of being a portrait. The players at bowls, are a group at the right hand corner of the print. Strutt says, that "this is one of the finest of Callot's works, and it is very difficult to meet with a fine impression of it, for the distance and other parts of the plate filled in the bit." It is an oblong folio, and the proof impressions, which, of course, are most sought after, are before the name of Callot was engraved. A landscape, in the front of which are two pilgrims. It is in 4to. and without the name of Callot. "A group of four."

in the ordinary impressions of this plate, the small and distant wild boar hunt is scarcely seen. It is a folio, and of the frieze proportions. "A double Rock in the Middle of the Sea;" on the top of this double rock are two eagles with a banner, and an inscription in honour of Columbus, in 4to.; "The two jolly Mariners," a well executed plate, in 4to.; four landscapes, lengthways, in small 4to.; "The Grand Theft," two emblematic plates in folio, dedicated to the duke of Lorraine; "A Vine Arbour," a small 4to. plate, the subject of which is a fête before the door of a country public house, with an inscription on the margin, signifying that this is the *last* plate engraved by the late Jacques Callot, to which the aquafortis was not applied till after his decease; from which it may be presumed that the death of our artist was somewhat sudden.

The following *Portraits* are also from the graver or etching needle of this distinguished engraver. Cosmo III. grand duke of Tuscany, in an ornamented oval. François, grand duke of Tuscany, ditto, in 4to., very rare. Charles III. duke of Lorraine, in 4to. rare. Louis de Lorraine, prince of Phalbourg, on horseback, 4to. Le Marquis de Marignan, a general in the service of the emperor Charles V. 4to. Denatus Antellensis, senator, commonly known by the name of "The Senator," in an oval, 4to. rare. Charles de Lorme, first physician to Louis XIII., in an ornamented oval, 4to. Giovanni Domenic Peri d'Archidoffa, in an ornamented border, commonly known by the name of "The Gardener," in 4to.

The reader may perhaps be pleased to be informed that a small portrait of Callot himself has been drawn and engraved by Michael Lafine. It has the following inscription, "Jacobus Callottus Nobilis Lotharingus Calcographus."

The engravings of Della Bella are little less numerous than those of Callot; though the largest of Callot's exceed the dimensions of any of those of his successor. Their merits were in many respects very similar. If with the elegant lightness of form and exquisite taste of Della Bella, we seem more in the fairy land of engraving, Callot possessed more perpendicularity, more firmness of outline, and greater powers of composition; yet they are twin brothers in point of excellence, and, to the present hour, unrivalled in their department of art, though it must be allowed that Mons. Berthaud, the Parisian, has of late years made some very near approximations toward the merits of Callot and Della Bella. We are enabled to add the following list of select prints by the latter, to the scanty list of Strutt, which the reader will find affixed to our biography of Della Bella:—A portrait of Della Bella, dressed in the Persian habit, drawn and engraved by himself. Other portraits of Sigismund Boldrini, a noble Milanese. Mount-Joy St. Denis, king at arms, with a grand funeral procession in the back ground; a very rare print, in 8vo. Horace Gonzales, in an oval; likewise very rare. Ferdinand II. emperor of the Romans, in folio. Bernardo Ricci on horseback, surnamed Il Tedescofino; Ferdinand II.'s jester, in folio. St. Antonin, archbishop of Florence, kneeling on the clouds, Della Bella's earliest engraving.

Historical Subjects, &c.—"St. Anthony, mounted on a Mouflon with two Heads, a Man's and a Woman's," inscribed "Super aspidem et basiliscum ambulans;" a small upright plate of "The Departure of Jacob with Rachel and her 1000," "Jacob's Journey to Egypt in quest of Joseph," in 4to.; "The Battle of the Arabick's," of the same size; a small upright plate of "St. John, leaning his right Hand on a Lamb;" a small upright print of "The Virgin sitting with the Infant Jesus;" another "Virgin and Child;" another of "The Virgin suckling

the Infant," on a white ground; "A Repose," in a circle; another "Repose," where, in the background, St. Joseph is leaning against a tree, reading, in 4to.; "A Flight into Egypt," surmounted by cherubs heads; another small upright print of the same subject, representing "The Holy Virgin, with the Infant in her Arms, sitting on an Ass, led by St. Joseph;" another "Holy Virgin suckling the Infant Christ," inscribed Caracci inv. in a circle; "The youthful Saviour explaining the Sacred Writings to his Mother and St. Joseph;" in the clouds is God and the Holy Spirit, a very rare little print, first etched, and afterwards finished with the graver; a very rare print, entitled "Effigie del glorioso Martire Sto. Benedetto;" the discovery of the miraculous image of "Notre-Dame del Imbrunetta," near Florence; "The Church Triumphant," an allegorical figure, clothed in a priest's garment of white linen, and crowned with a tiara, with one foot on the earth and the other on the sea; a small folio print of "St. Prosper descending from Heaven;" a nearly square print of the tyrant Phalaris, enclosing Perillus in the brazen bull, from Polidoro; an antique bas-relief of a female with her face covered, from the same master; a small standing figure of Lucretia, from Parmegiano; a small plate, nearly square, of three children holding above their heads a wooden dish, on which are three veses, from Guido; an antique bas-relief of a female, standing, trying to stop a ball; a folio print in a square ornamented border, of a soldier on horseback, galloping away with a female, called "Clovis and Clotilda," very rare; a sailor, of whom a beggar is asking charity; a young sailor, sitting on a hillock half covered with his cloak, laying his hand on a dog's head, with other figures; a small print of four Turks, half length; another of three, with a negro and a boy; the hunters holding a dog, a singular engraving, marked twice with S. D. Bella; an eagle, with extended wings, devouring a man; above, in a circle, are two horses escaping, and a multitude of spectators, in small folio; "The Philosopher's Stone," in large 4to. a very fine and large print; "The Fan," or a fête on the Arno, an oval print, which was long attributed to Callot; a perspective view of the catafalque of the emperor Ferdinand, and of the interior decoration of the church, with the arms of the family of Medicis, in folio; a grand Theft supported at the canonization of Francis Solanus Condieler, at Rome, a rare print, in large folio; a plan of the siege of Rochelle, signed Stefano Della Bella del. et fecit; a large upright print of the plan of the siege of Arras, done for cardinal Richelieu, signed as before; the Repose, or feast of God, a large print, lengthways, of which it is very difficult to find a good impression; a view of the Pont-Neuf at Paris, a large print lengthways; the first impressions of this plate were taken before the weathercock was added to the flestep of St. Germain l'Auxerrois; a folio print of the Castle of St. Angelo; on the foreground are groups of figures.

The following are in Sets.—Two landscapes; two other landscapes in the taste of St. Pierre; six different views of the Pont of Livourne, in large folio; the four seasons, represented in ovals; the four elements; eight marine subjects, in the style of Callot, entitled "Divers Enbarquements, faits par S. D. Bella," dedicated to Lorenzo de Medicis; six prints of vases, in 4to. in a rich and exquisite taste, and very finely executed; six landscapes, in circles; four very fine landscapes, with figures, in folio; four views in Rome, namely, the temple of Antoninus Pius, the arch of Constantine, the temple of Concord, and the celebrated vase in the gardens of the Medicean palace, in which Della Bella has introduced his own portrait; three

grand subjects of battles, 1. A naval combat before the life of Ré; 2. The descent of the English in the life of Ré; 3. The defeat and capture of general Lombay, with a plan of the battle: these three plates were drawn and engraved by Della Bella, for the book of Valdor, entitled "Triumphes de Louis le Juste;" twelve prints of Moor, Hungarians, Asiatics, and Africans, on horseback, in circles, with very fine backgrounds, in 4to; a set of sixteen small square subjects, representing warriors, hunters, shepherds, and peasants, &c. very rare, and attributed by some to Callot; another set of eighteen, entitled "Raccolta di rari capitoli, nuove invenzioni di Cartelli et Ornamenti, posti in luce dal Sign. Stefano Della Bella," of different sizes; another set of twenty-eight, entitled "Vues d'edifices et d'endroits particuliers, mis au jour par Israel Silvestre," in folio; more than half of these views in France and Italy are engraved by Della Bella; a set of twenty-two, entitled "Divers griffonnemens et épreuves à Peau forte, faites par St. F. Della Bella," of different sizes: this set has often been reprinted and enlarged, and the good impressions are now become very scarce; a set of five of Death preying upon the human species of all ages, with fine backgrounds; and one entitled "La sixieme mort," a melancholy subject, begun by Della Bella, under his unfortunate malady, and finished by his pupil Galiffucci.

Antonio Francisco Lucini was also of Florence, and born in the same year with his countryman Della Bella, from the study of whose works, and those of Callot, he appears to have formed his style. His plates are marked with one or other of the monograms which will be found in our *Plate III.*

His principal works are a set of sixteen very rare prints of the battles and assaults of the Turks during the siege of Malta, from the pictures by Mattia Perez de Alecio, and a set on the Arno, of folio dimensions, after Della Bella, dated 1634.

Francisco Cozza has been already noticed as an historical painter in fresco. (See *Cozza*.) His prints consist of spirited etchings, in which the manual part is executed with more neatness than has often been attained by painters. In "St. Peter's Contrition," he has shewn much good drawing, though the print is flight. The other works we shall mention from his hand are, "A penitent Magdalen," and "A Roman Charity;" they are all from his own compositions, and of folio dimensions.

César Bassano, or Bassanus, was born at Milan in the year 1584. Under whom he studied has not been ascertained. He worked entirely with the graver, and his style bears considerable resemblance to that of Cornelius Cort.

The most considerable work in which he was engaged, and which he executed in conjunction with Falsoni and Ciambellanus, is a set of sixteen plates, entitled "Il Santo Senso de Gesu," a very rare work, which both Heinenkin and Strutt have omitted to mention. It consists of heads of the Virgin Mary, Jesus Christ, and the Apostles, selected and engraved from pictures of the very first celebrity.

The other known engravings of Bassanus are, a portrait of Gaspar Adellius; an architectural Frontispiece for a work by Francis Piccolini, in folio; and "The Nativity," of the same dimensions.

His coadjutor Ciambelano, or Ciambellanus, was originally a doctor of laws, but quitted the study of jurisprudence for that of engraving. The cypher which he affixed to his prints will be found in *Plate III.* of the monograms of the *Italian School of Engravers*; and we have already men-

tioned the leading events of his life under the article *CIAMBELLANO*.

The principal engravings by this artist are "A dead St. Jerome, lying on a Stone," after Raphael; a set of ten plates, after different masters, in 8vo, consisting of devotional subjects; "Angels holding the Instruments of the Crucifixion, Passion, &c.;" another set of fourteen, in small 4to, after Raphael, of "Jesus Christ and the Apostles;" "Jesus Christ of the Mount of Olives, comforted by an Angel," from Al. Cafolini, in folio; "Jesus Christ appearing to Mary Magdalen in the Garden," from Barroccio, in large folio; "Christ appearing to St. Theresa with his Cross," 1615, in folio; two subjects of "The Resurrection," dated 1618, in large folio.

Giuseppe Francesco Barbieri.—Guercino da Cento is the name by which this justly celebrated painter is most commonly known; for an account of whose great merits as a painter, see the article *BARBIBI GIOVANNI FRANCESCO*. A more engraver, he has left but few memorials behind him; but those are executed with great freedom and spirit, in a manner much resembling those admirable drawings of his with a pen, which are held in such high estimation: "St. Anthony of Padua;" "St. Peter in Grief," both half lengths, inscribed "Joan F. Barbieri f. Id.," in folio; "St. John," the same; "St. Jerome before the Crucifix;" a portrait of a man with a hat on, and a curled beard; portrait of a female with curled hair; and a bust of a man in an eastern costume, all of folio dimensions; are probably all the prints that Guercino ever produced.

Luciano Borzoni was born at Genoa in the year 1590, and died in the same city in 1645. He learned the elements of art of his uncle Philippe Bertolotto, and Caesar Corte. His pictures possess much merit, are well coloured, and carefully executed. He painted with the same success in oil as in fresco; and whilst painting the ceiling of the church della Nunziata, he unfortunately lost his life by a fall from the scaffold.

He left three sons, all artists, among whom Francien Marie distinguished himself most, by painting landscapes and marine subjects.

Borzoni etched many of his own compositions with a considerable portion of taste, among which the following will probably be found to possess most merit: a portrait of Guistiniani; "St. Peter delivered from Prison;" "The Vulture preying on Prometheus;" all of which are in 4to. Some Holy Families, Madonnas, and other devotional subjects, constitute the remainder of his works on copper.

Vespaiano Strada was the son of a Spanish painter of some eminence, but was born at Rome in the year 1591, during the residence of his parents in that city, where he died at the age of thirty-six.

His works consist of etchings from his own compositions, executed in a painter-like style; slight and rapid, but masterly and free. Those held in most estimation are "Pontius Pilate producing Christ to the People," half figures, in small folio; the same subject, of the upright form; "St. Catherine adoring the Infant Christ," in 4to.; "Christ crowned with Thorns," in small 4to.; "The Holy Family, with St. John," ditto; "The Holy Virgin supported by Angels." His plates are generally marked with the initial letter of his names.

Of Alessandro Algardi, a Bolognese artist, who lived at this period, we have already treated. (See *ALGARDI*.) To the engravings we have mentioned by him, the collector should add "The Cries of Bologna," consisting of eighty 4to. prints after Caracci, engraved by Algardi, in conjunction with Simon Guain.

The etchings of Spagnoletto (for an account of whose extraordinary talents as a painter, see the article *RIBERA*) are executed in a bold, firm, and free style; his chiaroscuro is broad, powerful, and pleasing; and he drew with admirable skill. His heads, hands, and feet, are marked in a masterly manner; and among the former, those of his old men, which he was fond of introducing into his compositions, are deservedly admired.

In *Plate III.* of the monograms of the *Italian Engravers*, will be found the various cyphers with which he occasionally marked his performances, of which the following are justly held in esteem: "A dead Christ;" "The Martyrdom of St. Bartholomew," both of folio dimensions; in small folio, "A penitent St. Jerome, with an Angel blowing a Trumpet." (Note.—There are two plates of this subject, in one of which the angel is omitted.) Another St. Jerome, a small upright, where a skull lies on the ground, and the faint is reading; a folio plate of "Bacchus made drunk by Satyrs," dated 1628; two small heads of old men, one of them with the face covered; "Dante crowned with Laurel, sitting in a Desert;" "Don Juan of Austria on Horfbeck," a folio plate.

The above are all from his own compositions; and we know of but one work of Spagnoletto that is after another painter, namely, "A Repose, during the Flight into Egypt," from Charles Saracenus, wherein angels are foisting the holy travellers with divine music.

Oliviero Gatti was of the Bolognese school, and apparently studied engraving under Agostino Caracci. He was born at Parma in the year 1598; but the time or manner of his death have not been recorded.

Gatti worked chiefly, if not entirely, with the graver; and his prints have a considerable share of merit. He attended but little to the textures of various substances, and hence his execution is somewhat dry; but he possessed that first requisite of a good engraver,—found drawing.

His best prints are "St. Francis Xavier kneeling on the Sea-shore to take up a floating Crucifix," from his own composition, and of folio dimensions; a half figure of "The Holy Virgin caressing the Infant Christ," in 4to., after Garbieri; "St. Jerome embracing a Crucifix," a folio plate, after Augustino Caracci, dated 1662; an emblematic or heraldic subject from Lodovico Caracci, representing an armed knight, surrounded by Jupiter, Hercules, Neptune, Apollo, and Pallas, and an armorial bearing supported by two river gods, of a folio size; and a set of four ovals, in 4to., after Pordenone, of which the subjects are "The Deity forming the World," "The Creation of Adam," "Abraham's Sacrifice," and "Judith with the Head of Holofernes."

Giovanni Battista Vanni was celebrated to a certain degree in the three arts of architecture, painting, and engraving. He was born at Pisa in the year 1599, and died at Florence in 1660. He frequented different schools, and is believed to have learned etching of Julio Parigi.

His etchings are performed in a painter-like manner, with freedom and spirit, but are deficient in correctness; and are marked either with the initial letters, or some contraction of his names. Of these the most distinguished are "The Dome of the Cathedral at Parma," after Correggio, engraved on fifteen plates, and dated 1642; "The Martyrdom of two Saints," also from a picture by Correggio; and "The Marriage of Cana in Galilee," a large folio print, engraved on two plates, after Paul Veronese, dated 1637, and justly reckoned the master-piece of Vanni.

Giovanni Battista Mercati also produced some spirited etchings about this period. He was a native of Sienna,

born about the beginning of the seventeenth century, but resided for the greater part of his life at Rome. His prints are flight, yet manifest some taste; and he etched both history and landscape.

The following will probably afford the collector the most satisfactory specimens of his powers: a set of fifty small plates of the ruined edifices of Italy, in a style which might be suspected to be borrowed from that of Silvestre, if Silvestre had then appeared; a set of four of the bas-reliefs which adorn the arch of Constantine, of the folio size, and circular form; "St. Bibian refusing to sacrifice to Jupiter," after Pietro da Cortona, in folio, dated 1626; and "A Holy Family, with St. Catherine," a small folio, after Correggio, dated 1620.

Giuseppe, or Joseph Cremonese, was born at Cremona in the year 1600, and resided at Ferrara. There is a picture of his, of St. Mark, preserved at the church of St. Benet, at Ferrara, which is mentioned with great praise in the Italian tour of Cochin. The following prints of mediocre pretensions are engraved by this artist from his own designs:—"Samson and Dalilah;" "David, with the Head of Goliath;" a kneeling figure of "St. Roch," all of folio dimensions; "David contemplating the Head of Goliath;" a bishop of the order of St. Bernard; and, a study of a naked female; all of quarto size.

Pietro, and Jacques-Antonio Steffanoni, father and son, were born at Venice, the father in the year 1600, and the son in 1620. They went to Rome, where they engraved in conjunction with each other. There is a book, etched by Pietro, of instructions in drawing, consisting of forty plates; and some prints for a work of antique gems, by Fortunius Licetus. This book was first printed at Rome A.D. 1627, and reprinted by J. A. Steffanoni at Padua in 1664. We have, among others, the following etchings by the son, which possess some merit:—"The Virgin and Child, with St. John and several Angels," known by the name of "The Virgin of the Swallow," from L. Caracci; another "Virgin and Child, with St. John," half figures, from Aug. Caracci, both in quarto; a middling-sized upright print, of "A Merchant and his Family reduced to Beggary;" two more subjects of Holy Families, from Aug. Caracci; "The Slaughter of the Innocents," from Guido; "The Miracle of St. Antony of Padua," from Lorenzo Paffinelli, in large folio; and "The Martyrdom of St. Ursula, and her Companions," of the same size.

Jean Baptista Pafcalini, or Pasqualino, was born at Cento, a village near Bologna, A.D. 1600, and frequented the school of Cyrus Ferri; though he does not appear to have made any meritorious progress in painting. He engraved a great number of prints from various Bolognese painters, but particularly from his countryman Guercino; whose bold spirited style in drawing with a pen he attempted to imitate with the graver, but he did not possess sufficient command of that instrument to succeed, neither is it at all adapted to such a purpose. The etchings of Pafcalini, according to Huber, always convey the idea of original compositions, but in this praise we cannot conscientiously join. Those among them which are entitled to most commendation, are "St. Felix, a Capuchin, kneeling before the Virgin and Infant Christ," in folio; "St. Diego," from L. Caracci, marked J. B. Centensis; a large folio print of "The Death of St. Cecilia," from Dominicchio; "The Aurora," a large print lengthways, on two plates, from the celebrated picture of Guido, which has since been finely engraven by Giacomo Frey, and also by Audenaerde.

The following subjects are from Guercino:—A small print of "Jesus Christ dictating to St. John;" a large upright print

print of "The Resurrection of Lazarus;" "Christ giving the Keys to Peter;" a middling-sized upright; "Christ taken into Custody in the Garden of Olives," in folio; "The Apparition of the Angels, who flew to Mary Magdalen the Instruments of the Passion," in large folio; "The Pilgrims on their way to Emmaus," in quarto; "The Incredulity of St. Thomas," in folio; a small folio print of "Orpheus playing on the Violin;" two Holy Families, both in quarto; "St. Charles Borromeus;" a middling-sized upright, entitled "St. Felice Cappuccino miracolosamente refuscitata infanciuolo morto;" and "Tancred and Erminia," dated 1620.

Of ANDREA CAMASSI, the two CURTI, FRANCESCO BERDINI, CAMILLE COSGIO, and GIULIO CARPIONE, who all lived at this period, we have already treated: as, see these articles respectively.

Giulio, or Julius Ciesar Veneti, was born at Bologna in the year 1609. He learned drawing under Philip Brizio, who was of the school of Guido, and one of the best of his disciples. Veneti was a gentleman of fortune, and not professionally an artist, yet the meritorious plates which he etched *con amore*, have been thought worthy of a place in the Italian school. His etchings are performed in a slight style, are marked with one of the two monograms which we have copied in *Plate III.*, and their subjects are—"The Guardian Angel," in quart; "Mithridates presented with a Cup of Poison;" "Tancred and Clorinda," all after D. M. Canuti; "The Virgin of the Rose," after Parmegiano, all in small folio; and "The Holy Family reposing," after Annibal Caracci, in larger folio.

For the biography of Francesco Grimaldi, furnished BOLOGNESE, see that article. His etchings are performed with painter-like freedom and spirit, and in those of landscape in particular, he discovers a fonder knowledge of perspective, than perhaps had yet appeared in Europe, and his trees are ably characterized.

Of his numerous plates, which are almost entirely from his own compositions, we shall mention as worthy of preference—a rich landscape, with buildings, and fishermen on the fore-ground; another, in which the baptism of our Saviour is introduced, both in folio; two ditto, in larger folio, of mountainous scenes, with figures and ruined buildings; two ditto, of the upright form, after Annibal Caracci, in one of which is a river winding through forest scenery; four ditto, from the same master. His view of Castel Gandolfo is a well-known and justly admired production, which will long continue to be a favourite study with landscape painters, and of which there has been a finely engraved copy produced in our own country by Vivares and Chatelain.

Agottino Metelli (the elder), was a native of Bologna, born A.D. 1609. He studied successively under Gabriel Ferrantini and Dentone, and, besides his merit as an engraver, excelled in painting architectural ornaments both in fresco and in oil. He was invited to Spain by Philip IV., and died at Madrid in the year 1666.

His etchings are performed with no inconsiderable portion of taste, and we believe are entirely of an ornamental character. His set of forty-eight friezes are after his own designs. Twenty-four plates of ornaments, are partly taken from the designs of F. Curti, and are partly engraved by the younger Metelli, of whom we are about to treat.

Gioseffo Marie Metelli was the son and scholar of Agottino, and was born at Bologna in the year 1634. After acquiring the rudiments of art from the instructions of his father, he successively frequented, for his improvement, the schools of Albano, Guercino, Del Torre, and Can rivali.

The plates of Gioseffo consist chiefly of etching, which

he executed in a slight manner. His *chiaroscuro* is feeble, his drawing incorrect, from haste or neglect, and he gave no attention whatever to the art of expressing the textures of various substances; yet what he did, could only have been done by the practised hand of an artist, and this circumstance combined with the intrinsic merits of many of the pictures after which he engraved, have made his prints (which are somewhat numerous) sought after by the collectors.

The various monograms with which he occasionally marked them, will be found in *Plate III.* of those used by the *Italian Masters*, and among his best works may be ranked the following:—A set of twelve large upright folio prints, from the most esteemed pictures in the churches of Bologna; a set of twenty, from the history of Enca, painted by the three Caracci, in the Favian palace at Bologna, in large folio; a set of forty, in small folio, and of the upright form, of "The Cries of Bologna," from Annibal Caracci; "The Adoration of the Shepherds," a large upright folio, from Correggio; "The Martyrdom of St. Erasmus," from Pouffin; "David and Goliath," from Titian; "The Invention of the Cross," from Tintoret, all in large folio; "Lazarus at the Gate of Dives," after Paul Veronefe.

He also produced several plates from his own composition, particularly "The four-and-twenty Hours of human Felicity," which were published at Bologna in 1675, and to which he afterwards added two plates, so that the complete set consists of twenty-six; and a set of which we know not the precise number, called "Metelli's Collection of Proverbs," published in the year 1678, both of which series are now become exceedingly rare.

Pietro del Po was born at Palermo A.D. 1610, and died at Naples in 1692. He travelled to Rome, and was much employed there in the adornment of churches, both as painter and architect, and also by the Spanish ambassador.

Del Po engraved a considerable number of plates which consist of etching mingled with the work of the graver. The general style of his art appears to be studied from that of Dominichino; and the most distinguished of his prints are "St. John Baptist in the Wilderness;" "The Woman of Canaan;" and "A dead Christ on the Lap of the Holy Virgin," all in folio, and after Annibal Caracci; "The Madonna and Child attending to the divine Harmony of Angels;" "St. Jerome on his Knees, consoled by an Angel;" and a set of the cardinal virtues, "Prudence," "Justice," "Temperance," and "Fortitude," all in large folio, after Dominichino; "The Annunciation;" "The Nativity;" and "The Flight into Egypt;" in folio, after Pouffin; "Achilles and Ulysses," after the same master; "Venus and Cupid visiting the Forge of Vulcan," after Silvio Badochio; and "Neptune in his Chariot," after Julio Romano, of the octagon form; all of tolle dimentions.

Giacomo del Po, and his sister Theresa, the son and daughter of Pietro, also etched several plates, in a style resembling that of their father, among which is "Susanna tormented by the Elders," after Caracci, a folio plate, engraved by Theresa.

Simon Cantarini, surnamed Il Pefarefe, was born at Pefaro, a city of Urbino, in the year 1610. He learned the rudiments of art under Ridolfi, but afterwards became one of the most distinguished of the pupils of Guido, whose style, both of painting and etching, he imitated with so much success, that the works of the disciple are not unrequently mistakenaken for those of the master.

Cantarini died at Verona, at the early age of thirty-eight. He produced a great number of prints, which are for the most part of religious subjects, and of which Adam Bartsch has formed a catalogue which we believe is complete.

Among

Among these are seven of what the Italians term *Reposos*, during the flight into Egypt, three, of which the Holy Family is the subject, and four, of the Madonna and Child; they are after his own compositions, and of 4to. dimensions.

The remainder that are worthy of selection from the works of Cantarini are, "The Beatification of the Holy Virgin;" two plates of "St. John Baptist in the Wilderness;" "The Martyrdom of St. Sebastian;" "St. Anthony of Padua on his Knees adoring the Infant Saviour surrounded with a Glory of Angels," in folio; a small print of "St. Anthony of Padua kneeling before an Altar, holding the Infant Christ in his Arms;" "St. Benoit curing the Demoniac," from Louis Caracci, in folio; "A Guardian Angel conducting an Infant to Heaven;" "Jupiter, Neptune, and Pluto, doing Homage to Cardinal Borghese," who is represented in heaven surrounded by geni, who display the attributes of the four cardinal virtues, in large folio; this print has been mistakenly called the *Quos ego*, and it is one of the finest engravings by Pefaresc, though long attributed to Guido; "The Rape of Europa," in folio, a very fine print, and very rare; "Mercury and Argus;" "Mars, Venus, and Cupid, at the Foot of a Tree," from P. Veronese, both in folio; "Venus and Adonis, with Cupid," in 4to.; "Love and Fortune," in 4to. (connoisseurs attribute this print to Pefaresc, though it is marked "G. Reus in. & fec.") and a frontispiece to a book, representing a coat of arms, supported by two angels, blowing trumpets; at the bottom is a river god leaning on an urn; a very spirited etching.

Giovanni Andrea Sirani was born at Bologna in 1610, and died in the same city A. D. 1660. He was successively the disciple of Cavdone and Guido, and imitated the style of the latter, both in painting and engraving, with success. We have some masterly etchings from his hand, which may be regarded as original works, since they are from compositions by himself; these he commonly marked with his initials, G. A. S. or I. A. S. The following are generally, and we think justly, esteemed among his best productions:—"Judith, with the Head of Holofernes," half length, in the background is an old woman, in folio; "The Virgin and Infant Christ sitting on a Cushion, with St. John at her side," in an oval (this is from Guido); a small print of "St. Michael overpowering Satan," a middling-sized upright print of "A Sybil sitting on a Bank, listening attentively to an Angel, who is placed behind a Pedestal," from Guido. "The Rape of Europa," (this print is attributed to Sirani, but it is not in his style); "Apollo slaying the Satyr Marfyas," a small upright plate in an oval; "Saturn sitting on the Clouds," in 4to.; "Cupid standing on a Dolphin, shooting an Arrow into the Sea;" a bacchanalian subject of four children, one of whom holds a flask and goblet.

Elizabeth, was the most distinguished of the three daughters of G. A. Sirani, who were all artists; and was born at Bologna in the year 1638; she learned the rudiments of design and painting of her father, and her historical pictures are mentioned with the greatest commendation. She died at the early age of twenty-six, as it is said, by poison, administered by some that were envious of her great reputation. There are many etchings by her hand, executed in a slight, spirited style, but the extremities are finely marked; among which the following are the most esteemed: a middling-sized upright plate of "The Virgin of Grief," surrounded with the Instruments of the Passion, and accompanied by Angels; "The Virgin with the Infant Jesus, whom she holds on a Cushion, with St. John,"

in a circle: this very rare and excellent print was engraved by Elizabeth, at the age of nineteen, from a picture of her own, and is reckoned her best production; a small half length of "The Virgin, with her Hands crossed on her Breast;" "St. Eustace," magnificently habited, in the act of prostrating himself, striking his breast with his hand, in folio; "The Decollation of St. John," on the foreground is a profile of Herodias, accompanied by two of her women: this print has been retouched in many parts with the graver, and is not executed in the style of Sirani; yet her name is affixed to it, and its authenticity may therefore be regarded as doubtful; "Lucretia stabbing herself," dedicated to the prelate Paleotti.

Lorenzo Loli was born at Bologna in the year 1612. He was a favourite disciple of Guido, who was accustomed pleasantly to call him his gentleman of the bed-chamber; yet the improvement of a student is not always in proportion to the favour of his master, and Loli never attained any great degree of excellence as a painter; but there are many etchings by him executed in a free spirited style, from Guido, Sirani, and his own designs, of which the following are held in most esteem:—"A Flight into Egypt," in folio; "A Holy Family, with St. John and Elizabeth;" another "Holy Family, with St. Joseph leaning on a Pedestal in the Background," a small upright; two plates of "The Madonna and Child," one a small upright oval; "The Assumption," where the holy Virgin is represented as standing on a crescent, and angels worshipping (this is a rare print, and one of the very best productions of Loli); "St. Jerome in his Cavern;" "Mary Magdalen meditating on a Crucifix and Skull," both in 4to.; the latter is perhaps the only plate upon which this artist has worked with the graver; "The Holy Virgin in a Radiance of Glory," in folio; "The Recompence of Study," a small plate, wherein Genius and the Sciences are represented as leaning on the horn of Plenty; "Hercules combating the Nemean Lion," and "Periclus and Andromeda," both of the folio size; "The Infant Hercules straggling the Serpents;" "A sleeping Cupid;" "Cupid breaking his Bow;" three small plates of infant bacchanalians.

Contemporary with this artist was Gaspar Dughet (surnamed Pouffin from his very distinguished brother-in-law Nicholas). For the biography and general merits of these great artists, see the articles *DUGHET* and *POUSSIN*. Gaspar etched a few plates with spirit, (though not equal to that of his pencil,) among which are a set of four landscapes in circles, of a small folio size; and another set of four, somewhat larger.

Jean Dughet, the brother of Gaspar, received instructions both from him and Nicholas Pouffin, yet never attained to eminence either in painting or engraving.

The following prints from his hand are admitted into the portfolios of the curious, much more on account of the original pictures by Pouffin, whence they are taken, than from their intrinsic merits as etchings; namely, "The seven Sacraments," from the set of pictures painted for the Commandeur del Pozzo, which differ in many respects from those which were in the royal collection of France, and are now in the marquis of Stafford's gallery; these are in folio, so large that each subject is engraved on two plates. "The Judgment of Solomon;" "The Birth of Bacchus;" and "Mount Parnassus," are also in large folio.

Pietro Testa, sometimes called among the Italians *Lucchini*, from the place of his birth, was born, of indigent parents, in the year 1611, and poverty appears to have attended him through life, notwithstanding his merits. From his youth he manifested a violent inclination to pursue the
fine

ITALIAN SCHOOL OF ENGRAVING.

fine arts, and it is said, travelled from Lucca to Rome in the habit of a pilgrim. Here, regardless of external appearances, and even of the ordinary means of subsistence, he employed his time in drawing with the utmost assiduity from the antique statues, reliefs, and urns, and in studying from the celebrated pictures with which that great metropolis abounded.

Under such circumstances, and entirely unknown to the great, Tella was forced to distress; according to one of his biographers, his situation was most miserable, having scarcely wherewithal to cover his nakedness, or satisfy the cravings of hunger; and in this situation he was found by Sandrart, sitting among ruins, abstracted from all around him, and copying an antique bas-relief.

Struck with such meritorious raggedness, and naturally benevolent, Sandrart took our young enthusiast home with him; provided him with food and raiment, employed him to make copies of the great works in the Julian gallery, recommended him to other employ, introduced him to the schools of Dominichino and Pietro da Cortona, and world in other respects have rendered him a social being, as well as a great artist, but for Tella's natural aversion to company and conversation, which was so great, that even his patron could seldom obtain a word from him.

His propensities to art, solitude, and silence, which, with Sandrart's friendship, conducted him to the high degree of excellence which he attained, occasioned also his death. In reaching for his hat, which the wind had blown into the Tiber, as he sat drawing alone, upon the banks of that river, he unfortunately fell in, and was drowned in the thirty-ninth year of his age.

The following summary is partly copied from the just estimate which Strutt has formed of the merits of this artist. He drew with great taste, and marked the extremities of his figures in a very masterly manner. The character of his heads are finely expressed, and the female faces are often very beautiful. When the extravagance of his fancy did not hurry him beyond the bounds of nature, his outlines are correct and elegant. The draperies of his female figures especially, are ample, flowing, and easy, and the forms of the naked parts beneath are accurately and sufficiently indicated, without academical ostentation. Yet, though his composition is frequently grand, and many of his figures highly graceful, it must be owned that awkward and contraired attitudes are sometimes introduced.

His style of etching is simple and free, bearing superior resemblance to that of Antonio Tempesta, and every where animated by the wild energy of his nature; but his light and shades are not collected into broad masses, and of course his chiaroscuro, like that of most of Italian engravers of the age of Tella, is deficient in force.

The manogram with which our artist usually marked his engravings, is copied in our third plate of those of the *Italian Masters*. His prints, in general, of which Mariette possessed twenty-two, are held in high request by artists and connoisseurs, and among them the following are distinguished. They are all of folio dimensions, and some of them very large.

"The Sacrifice of Abraham;" "Angels ministering to the Holy Family," an emblematical subject, in which the Infant Saviour is embracing a cross held by angels, very large; a large upright print of "Our Saviour crucified between the Two Thieves;" "The Martyrdom of St. Erasmus," inscribed "S. Erasmus pro nobis;" "St. Jerome at Devotion;" "St. Roch and Two Bishops praying for a Cessation of the Plague;" "The Sacrifice of Camma," who having drunk of a poisoned cup at the celebration of her marriage with Simeon, the assassin

of her first husband, presents him with the cup, a large print; "Thetis plunging Achilles into the Styx;" "Achilles dragging the Body of Hector round the Walls of Troy;" "The Death of Cato;" "The Sacrifice of Iphigenia," an allegorical print in honour of pope Innocent X. with his medallion on a monument; "Socrates, at a Table with his Friends;" "The Study of Painting," dedicated to cardinal Francotti; "The Lyceum of Painting," inscribed "Il Liceo della Pittura," (with a dedication; "The Passions explained;" "Merit recompensed, and Parnassus triumphant;" "The Triumph of Love;" and "The Triumph of Bacchus."

Jean César Tella was born at Rome in the year 1636, and palled for the nephew of Pietro, whose style of engraving he imitated. The following five are all we know of his works. A small quarto portrait of his uncle, entitled "Petrus Tella Luceas, Pictor ac Incisor celeberrimus, Cesar Tella fecit." "The Death of Dido, with Iris plucking off the Fatal Lock;" "The Centaur Chiron teaching Achilles to play on the Lyre, and throw the Javelin;" "The Emperor Titus consulting the Prophet Balduis on his Expedition against Jerusalem," from a picture by P. Ciotta, in the church of St. Martin du Mont, at Rome; all of large folio dimensions: and a very large and very rare print of "The Last Communion of St. Jerome," from a picture by Dominichino, which has since been engraved by Farjat and Giacomo Frey.

Hyacinth, or Jacinto Gemignano, or Jemiiani, was born at Pistoia in the year 1611, from whence he travelled to Rome, and became the disciple of Pietro da Cortona. Here he resided for many years with great reputation. He afterwards returned to Pistoia, and died there at the age of seventy.

His plates are not numerous, and consist almost entirely of etchings, performed in a slight manner, and from his own compositions, of which the following are the chief.

A set of twelve, in quarto, of groups of children variously occupied; "Cleopatra dissolving the Pearl," in folio, and another folio plate from the reign of Semiramis, entitled "Semiramis jurat non nisi deviato hosti religaturum capillorum."

Giovanni Batista Bolognini was born at Bologna A.D. 1611, and died in the same city in the year 1688. He was instructed in the principles of painting by Guido, and soon became one of his best pupils. He painted in the style of his master, and his works are held in very great esteem.

We have many spirited etchings by Bolognini, from the compositions of Guido, which are executed in a slight style, resembling that of his master, but inferior in merit; among these, the following will probably be found most worthy of the collector's notice. "A Crucifixion," with St. John and the two Maries, standing at the foot of the cross, in folio; "Bacchus and Ariadne," a large print, lengthways, engraved on three plates; "St. Peter receiving the Keys;" and "The Murder of the Innocents," all of folio dimensions.

Salvator Rosa, (for an account of whom as a painter see ROSA, SALVATOR,) was born at Rinella, in the environs of Naples, A.D. 1615, and died at Rome in 1673. His etchings, though bold, present not the discriminating and characteristic ruggedness of his pencil. His drawing is incorrect; the heads of his figures are occasionally characteristic, but generally mean, but his chiaroscuro is broader and better than is to be found in the generality of the etchings of the Italian painters. Yet it is to be observed that, in point of executive power and feeling, his prints are far from being always alike. In his "Alexander visiting Diogenes," his
line

line is dry and inexpressive, while in his "Meditation of Democritus," and his allegorical print commonly known by the title of the "Genius of Salvator," he has entered much more into the detail of forms, and expressed the substances of the bones, reptiles, &c. which lie strewn about, with taste and with truth.

The cypher with which this great master marked his etchings, which amount to between eighty and ninety in number, all from his own compositions, will be found in our *Plate III* of those of the *Italian School*.

The following list of his prints will be found nearly, if not quite, complete:—An octavo book, containing 60 plates of *quinditti*, in various military and other dresses, some single figures, and others in groups; a set of six, consisting of tritons, nereids, and other marine monsters, in the lengthened proportion of friezes; a set of four, in small folio, of "Apollo and Daphne," "Glaucus and Scylla," "Ceres instructing Phidias in the Art of Agriculture," and "Jason and the Dragon," of the same size are two plates of "St. William doing Penance," and "A Soldier sleeping on his Shield," "Plato with his Disciples in the Garden of Academus," "Diogenes throwing away his Cup," "Democritus meditating," "Alexander visiting the School of Apelles," and "Alexander visiting Diogenes," are of the same large folio dimensions; in the last, Salvator Rosa has committed a great and palpable blunder, for Diogenes is desiring Alexander not to intercept the ravs of the sun, yet is himself placed between the sun and Alexander; an academy of philosophers, which is inscribed "Ingenius liber Pictor," and "The Genius of Salvator Rosa," are also in large folio; and in still larger folio are "The Execution of the Tyrant Polyocrates," a very grand composition; "The Discovery of Oedipus on Mount Cytheron," "The Death of Regulus;" and (of the upright form) "The Fall of the Giants."

Carlo Sacchi of Pavia, whom Strutt, by mistake, has called a native of Batavia, etched a few plates of small importance about this period. He was born in the year 1616, studied under Rosso and died in his native city in 1706. "The Adoration of the Shepherds," from Tintoret, and "The wife Men's offering," from Paul Veronese, two large uprights, are among his best productions.

Now also lived Luigi, or Aloysius Searamuccia, who obtained the addition of Perugia, from the place of his birth. He studied under Guido, and, as an historical painter, attained some eminence, but never reached beyond mediocrity as an engraver. Among his best prints are, "Caird crowned with Thorns," a folio plate after Titian; "Venus and Adonis," after Annibal Caracci; and a large folio print after Lodovico Caracci, from the legendary history of St. Benedict: The devil, it seems, had caused a large stone, which was to be used in building a certain church, to be immoveable, and the saint broke the spell by the fervency of his prayers.

Or Benedetto Castiglione, an artist of very superior powers, who engraved several large plates at the period now under our review, we have already treated. (See CASTIGLIONE, GIOVANNO BENEDETTO.) His monogram may be seen in *Plate III* of those of the *Italian Engravers*, and the following tasteful productions from his hand, may with advantage be added to those contained in our former list:—"The Genius of Castiglione," a folio print, which is generally placed as a frontispiece to collections of his works; a set of six heads, of which one is the portrait of the artist; "Tobit going forth to bury the Dead, with an Effect of Night," in folio; another from the history of Tobit, which appeared without a name, and is in clear-

obscure, is also ascribed to Castiglione; "The Adoration of the Shepherds; a night-scene with 'The Interment of St. Peter and St. Paul';" another night-piece, with the effect of torch-light, of which the subject is "Philosophers visiting a Cemetery," all of folio dimensions; two of the proportions of a frieze, of which one is "Pan instructing Apollo on the Flute," and the other "Silenus with his Flute, and a Shepherdess playing the Tympanum;" "A Combat between two marine Horfes;" "A drunken Silenus, with three Satyrs; a bacchanalian subject, with a satyr on the statue of Priapus; a menagerie of hens, turkey cocks, and drakes; a landscape, inscribed "Gio. Benedetto Castiglione. Gen. fec. 1658;" another landscape in form of a frieze; "A shepherd Boy watering his Flock;" "Shepherds riding and on foot, conducting their Flocks;" "A Capuchin Friar, marked with the letter T, discovering the Body of St. Jerome," in folio; and eleven small vignettes of various sizes, finished with the dry point.

Bernardino Capitelli was born at Sienna in the year 1617, and received instructions both from Cafolani and Rutilius Manetti, but never attained to any considerable eminence. In his style of engraving, he singled etching with the work of the graver, but his execution is careless and heavy, and his outline incorrect. Among other plates of less importance, he engraved the life of the patron saint (Bernard) of his native city, on 12 small plates; "The Miracles of St. Anthony of Padua," a folio plate divided into compartments; "A Rope-dancer," from his master Rutilius Manetti; "The Marriage of St. Catherine," after Correggio; and "Ceres drinking at the Cottage Door," after Elsheimer, from the same painter which count Goudt has engraven in a very superior manner.

Giacomo Piccini, or Piccina, was born at Venice A.D. 1657. Under what master he studied is not known, but he worked chiefly with the graver, in a stiff laboured style, without much effect; and the outlines of his figures are exceedingly incorrect. His brother William was likewise a Venetian engraver, and engraved the portraits for the "Conchilia Aelste," of J. B. Fabri. Giacomo, on some of his plates, styles himself engraver to the king of France. The most considerable works he executed were a set of 30 portraits of the principal Venetian painters, affixed to an account of their lives by Carlo Ridolfi, published at Venice in 1648; most of the plates for a book, entitled "Le Glorie degli Incognita;" a portrait of Alexander Farnese; "Diogenes, with his Lanthorn, sitting at the Entrance of his Tub," from P. Liberi; "A Holy Family," from the same painter; "Judith with the Head of Holofernes at her Feet," from Titian; and "A Holy Family," in a landscape, from the same, all of folio dimensions.

Giovanni Battista Galefrucci was born at Florence A.D. 1618. He learned the rudiments of painting of Francesco Furini, and was elected a member of the Academy of St. Luke at Rome, A.D. 1652. He is mentioned as a painter, but is much better known as an engraver. He engraved in a neat, correct, and masterly style, and was for some time the pupil of Della Bella, after whose death he finished some plates which had been begun by that master. His style bears some resemblance to that of Podetta. There are a great number of prints by his hand, which in general are marked with the cypher, which will be found in our *Plate III*, of the monograms of the *Italian Masters*, and of which Jean Jacques Rossi has given a catalogue.

Of these the most considerable are, a set of antique gems, in four volumes quarto, with explanations by Leonard Agostino, published at Rome in the years 1657 and 1659; several sets of antique bas-reliefs and friezes, from Polidoro Caravaggio,

ITALIAN SCHOOL OF ENGRAVING.

Caravaggio, which appeared under the title of "Opere di Polidoro de Caravaggio," "John Baptist in Prison," from Battista Ricci; "Paris receiving the Apple," and "The Caduceus of Mercury," from Annibal Caracci, both in quarto; and the Mausolea of the family of cardinal Mazarin; a set of six prints in folio, from the Abbe Elpidius Benedictus.

Giovanni Francesco Venturina was born at Rome in the year 1619, where he studied and resided for many years, but afterwards removed to Florence. To judge from the style of his works, or at least appear that he was the disciple of Gallestrucci, or at least worked under his direction, after his removal to Florence. From the designs of this master, he has executed a good number of prints in a neat pleasing style, from which we select the following, as affording the most satisfactory specimens of his talents: "Diana and her Nymphs sporting," from Dominichino; "The Pulpit of St. Peter," from Bernini, in folio; a set of bird-eye views of palaces and gardens in and about Rome; and a set of fountains, from Rosa of Tivoli, being a continuation of the fountains in Rome, engraved by Falda. He also engraved after Polydoro Caravaggio, and other painters.

Giovanni Batista Bonacini, or Bonacina, was born at Milan about the year 1620, and worked in his native country, and at Rome. His prints are executed in a stiff laboured style, entirely with the graver; and he appears to have studied in the school of Cornelius Bloemart; but he never arrived at any superior degree of excellence. Of his works we shall only mention the following: four portraits, in folio, of pope Clement IX., Guido Visconti, Ernes Visconti, and Giovania Battilla, Count Truchi; "The Alliance of Jacob and Laban," from Pietro de Cortona, in folio; "The Virgin with the Infant Jesus, and St. Martin kneeling before him," from the same master, which is esteemed a capital print, in large folio; another "Holy Family, with St. John and St. Catherine;" a middling-sized upright plate, from Andrea d.1 Sarto; and a medallion of pope Alexander VII., with an inscription, from Bernini, in folio.

Flaminio Torre was born at Bologna A.D. 1621, and died at Modena in 1664. He learned the principles of painting from Cavedone, and completed his studies in the school of Guido. His chief excellence was in copying the pictures of the most celebrated masters, which he did to very exactly, as to render it nearly impossible to distinguish the copy from the original. He etched several plates in a good style; and he had copied the pictures of the Caracci, in the palace of count Farn. at Bologna, for the purpose of engraving them, when, at the age of forty, he died at Modena, whither he had been invited by the duke; and they were afterwards engraved by Metelli from Torre's copies. From among the prints of Torre we select the following, as most worthy of attention: "The Virgin and Child, accompanied by St. Francis and St. Jerome," a middling-sized upright, from Lodovico Caracci; "The Patron Saints of the City of Bologna," a large upright plate, from Guido; and "Pan conquered by Love," a small upright, from Annibale Caracci.

Pietro Francesco Mola merits a distinguished place both among the painters and engravers of the Italian school. He was born, according to some authors, at Cosola, a village on the frontiers of the Milanese, in the year 1609; whilst others affirm that the place of his birth was Lugano, and the time 1621. From his childhood his talents were promising, and his father, who was a painter and architect, according to these early dispositions toward the fine arts, placed

him first in the school of Jofephian, and afterwards in that of Albano, at Rome.

When he quitted the latter, he travelled to Venice, and studied the works of Titian, Tintoretto, Bassan, and Paolo Veronese, with great assiduity, and with to much advantage, that it is said Guercino became jealous of his progress, and that this jealousy occasioned his return to Rome, where queen Christina allowed him a pension, and where he was patronized by the popes Innocent X. and Alexander VII.

His friends seemed to multiply as his merits increased. He accepted an invitation to France from Louis XIV.; but during an altercation which he had with prince Pamili, respecting the value of a ceiling which he had painted, he was seized with a violent paroxysm of headache, and expired in about six hours.

For an account of his peculiar merit as a painter, see the article MOLA. His etchings, though slight, are performed "with a milder's hand and poet's fire." To a vigorous style of handling, he added correctness of drawing. He occasionally etched, as he painted, both landscape and history; his heads in the latter are beautifully characteristic, and carefully drawn; and in the former, his trees and his various grounds, &c. are touched with considerable taste.

"The Madonna suckling the Infant Saviour," a small upright, from his own composition; "A Holy Family, with Angels presenting Flowers to Jesus Christ," in folio, from Albano; "Joseph discovering himself to his Brethren," in small folio; and another "Holy Family with Angels," a folio print of the upright form, from his own composition; will be found among the best etchings of Francesco Mola.

Of the latter print, collectors should, if possible, obtain the impressions as the plate came from the hand of Mola; for it was afterwards worked upon with the graver by some unskillful person, who has much impaired the freedom and beauty of the etching.

Giovanni Battista Mola, born in the year 1622, was brother to Francesco, and was also the disciple of Albano. He etched a few plates, the style of which bears a distant and inferior resemblance to that of his brother, as may be seen in a 4to. print, after Albano, of "Cupid drawn in his Chariot."

Carl Cesso, or Cessini, was born at Antrodeco, a village in the late territory of the Roman pontiff, in 1654, and died at Ricci A.D. 1686. He studied as a painter under Pietro da Cortona, but is much better known by his engravings, than by his pictures. His plates are chiefly etched and harmonized with the graver in a free and masterly manner. He drew correctly; and the extremities of his figures are in general finely marked, though slight, and in the broad, bold style of a painter.

Among the number of Cessi's engravings, which is considerable, the following will probably be found most worthy of selection: the frontispiece, in 4to., to "Dionisi della Musica;" and "The Holy Family," in an oval, both from his own composition; two folio prints of "St. Andrew prostrating himself before the Cross," after a celebrated picture painted by Guido in conjunction with Dominichino; and "The Woman of Canaan," after Annibal Caracci; the Farnesian Gallery, consisting of forty-one plates, after the same master; the Pamphilian Gallery, consisting of fifteen plates, after Pietro da Cortona, of which the subject is "The History of Moses;" "The Life of St. Augustin," after Lanfranc, consisting of four very large and four smaller folio prints, engraved from pictures which adorn the church of St. Augustin at Rome.

Andrea Podetta was born at Genoa in the year 1628, and became

became the disciple of Andrea Ferrari. Strutt says, that "as a painter it does not appear that he greatly distinguished himself; but several spirited and masterly etchings, which he produced, prove him to have been a very skilful artist. The heads of his figures are finely characterized, and the other extremities are well expressed."

Among the best of Podetta's prints, which in general are marked either *AND. P.*, or *And. P. in et fec.*, are the following: four Bacchanalian subjects, in large folio, after Titian, one of which is from the celebrated picture of "Bacchus leaping from his Car to greet Ariadne," which was lately in the collection of the earl of Kinnaird, and from which Mr. Bone has executed a most exquisite copy in enamel; "Love cultivating the Arts," an allegorical print in folio, dedicated to Guido; and a pair from "The Life of St. Diego," after Caracci, also in folio.

For an account of Carlo Maratti as a painter, see the article *MARATTI*. He was born at Camerino, in the marquise of Ancona, A. D. 1628, and died at Rome in 1713. Strutt says, with great justice of his etchings, that "they are executed in a free and spirited style; much neater, and better finished, than those of painters usually are." The characters of the heads of his figures are finely expressed; and their graceful airs have been the subject of frequent commendation.

His engravings are somewhat numerous, and are held in great estimation. No collection of the works of the Italian masters should be without good impressions of the following:—A set of ten, from the Life of the Holy Virgin, after his own compositions, in quarto; "Heliodorus driven from the Temple," after Raphael, a large folio print, arched at the top, and engraven on two plates; "The Flagellation of St. Andrew," after Dominichino; "Joseph discovering himself to his Brethren," after Francesco Mola, of folio dimensions; "St. Charles Borromeus interceding for those afflicted with the Plague at Milan," a large upright, from Pietro Perugino; and (of the same form) "Christ discouering with the Woman of Samaria," after Annibal Caracci; besides several plates of the Madonna and Bambino, of various sizes.

Giovanni Batista Cavazza was born at Bologna in the year 1620. He was successively the disciple of Cavedone and Guido, and painted several pictures for the churches of his native country. He likewise engraved some subjects for his amusement, among which are the following:—"Christ on the Cross;" "The Resurrection of Jesus Christ;" "The Death of St. Joseph;" and "The Assumption of the Virgin;" all of folio size.

Dominico Maria Canuti was born at Bologna A. D. 1623, and died in the same city in 1684. This extraordinary artist, by the force of his own natural genius, acquired so much knowledge of design and colouring, that Guido beheld his works with astonishment, and received him among his pupils with pleasure.

Besides his pictures, we have a good number of etchings by his hand, in the style of Guido, whom he surpassed in neatness, finishing, and boldness, if not truth, of fore-shortening, which has ever been held one of the difficulties of art; though, in the general excellency of his drawing, and the spirit of his outline, he has not equalled that great artist. He commonly marked his prints with his name, or initials, among them the following will probably be found most worthy of selection:—Three portraits of Ludovico, Augustus, and Annibal Caracci, in 4to.; "The Virgin seated in the Cloud," with Christ standing by her," a small upright print, from his own composition; "St. Roch;" and "St.

Francis praying," a small upright plate, from Guido, marked "Doms. Ma. Canuti fec."

Laurentio Passignelli was born at Bologna in the year 1629, and died at Parma in 1700. His instructors in the rudiments of art were Andrea Barone and Simon Cantarini, but he also frequented the school of Flaminius Torre. From Bologna he went to Turin, and from thence to Mantua and to Venice. At Mantua he was employed by the duke in the adornment of his castle at Monmirola, but at Venice, struck with the superiority which he perceived in Paul Veronese, his style of painting, and his notions of art in general, underwent a complete revolution. He afterwards returned to Bologna and established a school.

In Cochin's Italian Tour, he speaks highly of Passignelli's picture of "The Resurrection" in the church of St. Francis, and his few prints are sought after with justifiable avidity by the connoisseurs. They are chiefly from his own composition, and to the best of our knowledge "St. John preaching in the Wilderness," (a very fine etching,) and "The Martyrdom of various Saints," in one composition, afford the best specimens of his talents in this art; both are of large folio dimensions.

Of Luca Giordano, who was now living, we have already treated pretty much at large (see the article *GIORDANO*). His *fa presto* attended him in his voluntary offerings to engraving, as well as in his devotions to the finer art. Yet his taste allowed him to delineate the heads, hands, and feet in his etchings in a good style, and hence his works on copper are of a masterly character, though they possess not the severity of the highest class of historical or epic compositions. His "Destruction of the Priesthood of Baal in the Presence of Elijah and Ahab," and "St. Anne received into Heaven by the Holy Virgin," which are both of folio dimensions, will at least justify thus much of approbation, as would also the following subjects from the Life of Christ, which are all in small folio, and from his own compositions. "The Holy Virgin and Infant Christ;" "St. Joseph and St. John;" "The Penitent Magdalen;" "Jesus Christ disputing with the Doctors;" and "The Woman taken in Adultery."

Horatio Brun, or Brunette, was born at Sienna A. D. 1630, but resided chiefly at Rome. He worked principally with the graver, imitating, though not very successfully, the style of F. de Poilly. "The Golden Age," "The four Seasons," "The Prodigal Son guarding Swine," a set of animals, all in folio, and an allegorical print of still larger dimensions, which has been called "Nuna Pompeilius, and the Nymph Egeria," are among the best of his engravings.

Lorenzo Tinti was born at Bologna in the year 1634, and was a disciple of Andrea Sirani. He was a painter of some merit, and he engraved many prints, among which is the frontispiece to the Herbal of D. Hyacinthe Ambrosini, which was printed at Bologna in 1666. He worked for some time at the court of Modena, where he engraved the pompous funeral of Francis I. duke of Modena, from Francesco Stringa. He also engraved from the celebrated masters of the Bolognese school, and from the pictures of Elizabeth Sirani.

Francisco Vaccaro, or Vaccari, was born at Bologna A. D. 1636. He studied under Albano, and wrote a treatise on perspective, for which he engraved the plates, and dedicated the work to counsellor Beccatelli. He likewise engraved a set of twelve perspective views of ruins, fountains, and edifices in Italy. He continued to flourish as an artist until the year 1670, after which we hear no more of him.

Ciofello Zarlatti was born at Modena A. D. 1635, and learned

ITALIAN SCHOOL OF ENGRAVING.

learned the rudimental principles of art of J. B. Spezzini, a Genoese painter. He was an engraver of merit, and executed some plates in a very spirited and pleasing style. His heads were generally beautiful, and his attitudes elegantly chosen. It is to be regretted that he died early, and engraved but little; nor are we able to specify any of his works.

The name of Bartoli, (for whose life see *BARCOLI*.) should have been honoured with a more ample list of his best productions than we were able to give at the time of publishing the third volume. The collector will probably be highly gratified to possess the following.

Various Antiquities.—A set of thirty-three, intitled “*Admiranda Romanorum Antiquitatum ac veteris Sculpturæ Veiligia*,” with remarks by Bellori under each; a hundred and thirty-eight prints in folio, intitled “*Romanæ magnitudinis Monumenta*,” a set of fifty-two, intitled “*Veteres arcus Augustorum triumphis insignes*,” a set of seventy-eight in large folio, intitled “*Colonna di Marco Aurelio, con brevi note da Gio. Pietro Bellori*,” a set of one hundred and twenty-eight prints, intitled “*Colonna Trajana, di Alfonso Ciacconi*,” and another set, consisting of one hundred and thirty-two, intitled “*Sepolcri antichi Romani ed Etruschi, trovati in Roma; gli aqueducti which conducts the water from Civita Vecchia, with various views in and about Rome, in four large prints; a grand sepulchral urn of stone, from the Capitol; two subjects from the Aldobrandini Marriage, intitled “*Nova Nuptia in geniali Talamo*,” ninety-four in folio, intitled “*Le Pitture antiche delle Grotte di Roma del Sepolcro de Nasoni, intagliate da Pietro Santi Bartoli & Francesco Bartoli suo figlio, Roma; 1680 and 1706*,” a folio print, intitled “*Antiquissimi Virgiliani Codicis Fragmenta & Pictura*,” and a hundred and nineteen pieces, intitled “*Le Antiche Lucerne Sepolchrali*,” a collection of old pictures, correctly copied, from coloured drawings made by Bartoli, Paris.*

After various Italian Masters.—A set of fribzes, from the Bible, on the chimney-pieces of the Vatican, by Raphael, in twelve small pages; another set of the same, in fifteen leaves; another set, from Raphael, intitled “*Leonis X. admiranda virtutis imagines*,” a set of forty-three, of ornaments and figures, intitled “*Parerga atque ornamenta in Vaticanis Palatii Kiltis*,” by Raphael; a set of four, of the divinities in cars; “*Jupiter drawn by Eagles*,” “*Mars by Horses*,” “*Diana by Nymphs*,” and “*Mercury by Cocks*,” the history of Constantine in fribzes of different forms, from the Vatican. “*Giove che fulmina di Giganti*,” (Jupiter accompanied by all the Gods, destroying the Giants.) from the celebrated picture by Julio Romano, at the palace of T at Mantua, in nine leaves; “*The History of St. Peter*,” from Lanfranc, in folio.

Various separate Subjects from Italian Masters.—“*The Adoration of the Kings*,” from Raphael, (engraved on three plates,) of large folio; one of the finest productions of Bartoli; “*The Infant Jupiter nourished by the Goat Amalthea*,” from Julio Romano; “*Hylas stolen by the Nymphs*,” “*Sophoniba presented to Maffiniffa*,” “*The Continence of Scipio*,” all of folio size, from the same painter; “*St. John shewing Christ in the Desert*,” from P. F. Mola; “*The Birth of the Virgin*,” from Albano; “*The Marriage of the Virgin*,” from a picture by Nicolo Bertoni, in the church of St. Lorenzo in Borgo; “*Daniel in the Lion’s Den*,” after an altar-piece by P. de Cortona; “*The Virgin in Heaven with the Infant Jesus, and Saints*,” from L. Caracci, all of folio dimensions; “*The Mother and Wife of Coriolanus prostrate at his Feet*,” “*St. Charles Borromeus brought by an Angel to the Tomb of Vetallo*,” both from Ann. Caracci.

The following are from his own Designs.—An oval, in 4to. of “*St. Stephen receiving the Crown of Martyrdom*,” “*St. Bernard chaining Satan*,” a large folio print of the theatre erected in the cathedral of St. Peter, for the canonization of St. Peter of Alcantara, and “*Mary Magdalen*,” engraved conjointly with Falda; the sepulchral monument of pope Urban VIII. intitled “*Petr. Sancti. Bartolus del ec. &c.*,” and an ancient mausoleum, from Tivoli, with the figure of a lion, from P. de Cortona, in large folio.

The grand catafalco, or funeral procession of Sobieski, king of Poland, after Sebastian Cipriani, in large folio, was engraven by Francesco Bartoli, a Roman by birth, and the son, pupil, and successor of Pietro Sante, who sometimes worked on his father’s plates, but was inferior to him in talent and reputation.

Giovanni Battista Falda, a very excellent engraver of landscape and architecture, was born, in the year 1640, at Valduggia, in the Milanese, from whence he travelled, for professional improvement, to Rome. Whose disciple he was does not appear; but he executed his plates in a clear neat style, bearing no small resemblance to that of Israel Silvestre. He drew and engraved a great number of views of palaces, churches, gardens, &c. in Rome and its environs, which he enriched with small figures, drawn and engraved with great taste. And in the year 1676 he engraved a very large view of Rome on twelve plates. His works are numerous, and deservedly held in high estimation. Among them the following will be found to deserve the particular notice of the connoisseur. Two fine views of the square of Navonne, intitled “*Fontana in Piazza Navonna*,” and “*Altra Veduta in Piazza Navonna*,” erected by Bernini, in folio. Two other views, in large folio, of the Basilico at the Vatican, and the fountain of the Basilico. A very large view, lengthways, of St. Peter’s, with twelve of the most celebrated edifices in Rome, on the same plate, very rare. A view of the interior of St. Peter of the Vatican, with the beatification of St. Francis of Sales, in large folio; and a very large view of the castle and bridge of St. Angelo, from Bernini.

Matteo Thommaso Piccioni was born at Ancona A. D. 1637, and became a member of the Academy of St. Luke in the year 1655. Piccioni holds a distinguished rank among those artists who worked in Mosaic, and executed in that style the pictures of the cupola of the chapel of St. Peter at Rome, in conjunction with Fabius Christofori and Horace Manenti. He etched some few plates, among which are the following, all of folio size. “*St. Luke painting the Virgin*,” from a picture by Raphael; “*The Adoration of the Shepherds*,” from Paul Veronese; “*A Holy Family*,” from the same painter; “*The Virgin with the Infant Christ, who is represented sleeping, and St. John at his side*,” from Andrea Camaffi; and “*The Infant Moses carried by his Mother in the Ark of Bulrushes*,” from the same painter.

Dominica Maria Bonarera was born at Bologna about the beginning of the last century; he learned the principles of drawing and etching of his uncle, D. M. Canuti. Among his works, those that he executed after Titian for an edition of the anatomical work by Vesalius, for the use of students, are the most esteemed, many of which, after being etched, were finished with the dry point. A monogram, which was common to him and Dominic Barriere, will be found in our *Plate III.* of those used by the *Italian Engravers*; and the following are selected from the catalogues of his works, as those most worthy attention; “*St. Ann teaching the young Virgin Mary to read*,” from Dom. M. Canuti, in folio; “*St. Theresa with the Infant Christ*,” “*The*”

Martyrdom of St. Christiana," all of the same size, from Canuti; "St. John baptizing Christ in the River Jordan," from Albano, in large folio; "St. John preaching on the Banks of the Jordan," from L. Caracci; "Lot with his Daughters," from Ann. Caracci; and the dome of the cathedral church at Parma, representing "The Assumption of the Virgin, with the Apostles and Angels," from Correggio, all in large folio.

Ambrogio Beiozzi, or Bezutti, an eminent painter and engraver in aquafortis, was born at Milan A. D. 1649, and died in the same city in 1766. He studied for some time under Gioseffo D'inedi, called Montali, but afterwards went to Rome, where he studied from the antiques and the most celebrated pictures, and finally, in the school of Carlo Ferri. His greatest merit consisted in painting bas-reliefs, friezes, and other architectural decorations; but he etched some few plates, and among them the following. A portrait of Correggio, in profile, of 4to. size; and the apotheosis of a princefs, the bust of whom was engraved by Bonacina, and the remainder by Beiozzi, from Cesare Fiori, in folio.

Gioiomo, or Jerome Rossi, or de Rubeis, the elder, was born at Rome A. D. 1646. He learned the principles of art under Simon Cantarini, and J. B. Buoncone. He executed a few slight but meritorious etchings from various celebrated painters, among which are the following. A portrait of pope Pius V., from Scipio Gatani, in an oval; "Two Cupids playing together," a small upright plate from Guercino; "The Virgin and Child, accompanied by St. Francis and St. Jerome," a middling-sized upright plate, inscribed "Hieronymus de Rubeis pictor delineavit incidit;" "St. Charles Borromeus kneeling before a Cross," from Antonio Caracci, a rare print; and "St. Nicholas before the Virgin," from Francis Bonavini, both in large folio.

Gioiomo Rossi, or de Rubeis, the younger, was born at Rome A. D. 1685, and was probably a relation of the above-mentioned artist. He always resided at Rome, and engraved a considerable number of prints, after different Italian painters. He worked in a stiff heavy style, with the graver alone, without much effect or correctness of drawing, and engraved a considerable number of portraits of the cardinals of his time; forming a series, which has since been continued by Pazzi and others. Rossi likewise engraved some portraits of painters for the Florentine gallery. His best historical works are, "The Virgin and Child," from Correggio; "La Zingara, or the Repose in Egypt," where the Virgin is dressed in the Egyptian fashion, from a picture by Ann. Caracci, both in folio; and "The Martyrdom of St. Agapita," a large plate, lengthways, from J. Odazzi.

Giovanni Batista Teltana, was born at Genoa in the year 1649, and resided chiefly at Rome, where he engraved many plates from the pictures of various Italian masters. In conjunction with William Vallet and Stephen Picart, he executed the portraits of the heroes of antiquity, for Jean Angelo Canini, from antique gems and medals. He engraved in a very pleasing style, not unlike that of Mellan. The following prints afford satisfactory specimens of his talents. Two heads, of Socrates and Alexander; and another pair of Alpasia and Cleopatra, in 4to., for the work of Canini; "The Guardian Angel," in large folio, from Pietro da Cortona; and "The Baptism of Constantine the Great," from Aug. Caracci, of the same size.

Gioseffo Teltana was born at Genoa in the year 1650. Whether he was the brother, or how he was related to the above-mentioned artist, we are unable to ascertain. He resided at Rome, where he engraved many plates in the style of Giovanni Battista. He was employed in a work which appeared at Rome in 1680, under the title of "Portraits

of Cardinals now living," and from the rest of his works the following may be selected as affording specimens of his abilities both in portrait and history. A portrait of brother Jerome Comitibus, from P. de Cortona, in folio; "St. Margaret of Cortona kneeling before a Crucifix;" a subject of a Theses, representing a Hydra, and Religion hovering in the air, holding a portrait of pope Alexander VII. On a little streamer is the following inscription; "Accedite et illuminamini," both from Cortona, of folio size; and two portraits, Flavius Carl. Clusius, after M. Morandi, and Aloysius Card. Homodeus, Jos. Teltana del. et fecit. both in 4to.

Crecentius de Hunnfris, or de Onofris, was born at Rome in the year 1650, and died at Florence some time about the close of the seventeenth century. He was the pupil of Gaspar Poussin, and painted a great number of landscapes in the style of that master.

He also engraved landscape in a very good taste, and we have an engraving by him, from a picture by Carlo Maratti, of "Diana at the Chase," for the prince Livius Odescalchi, which is executed with freedom, and in a purity of style superior to most of the landscape engravings of that day. Thus, and a landscape with a waterfall; an Italian landscape with water and figures, (both in folio,) and two heroic landscapes, one with Jupiter and Mercury, the other with Apollo in the clouds, both in large folio, afford excellent examples of the talents of this artist.

Giovamo Gioseffo dal Sole, was a native of Bologna, and became both a painter and engraver of some eminence. He received his first instructions of D. M. Canuti, and afterwards became the pupil of Lorenzo Passignelli. He succeeded in engraving both historical subjects and landscapes; and died at Bologna A. D. 1719, aged sixty-five years. We have several etchings by him, from his own compositions, among which are, "Jupiter and Juno presenting Mars with a Duckler," from a ceiling by Passignelli, painted for General Monteculle, in folio; and "St. Francis Xavier preaching in the Indies," a large upright plate, from the same master.

Vincenz Vittoria, or Vittorie, was born at Valencia A. D. 1658. He travelled whilst very young to Rome, and frequented the school of Carlo Maratti, where he made great progress. He possessed considerable knowledge of anatomy, and his portraits are particularly esteemed. Vittoria is likewise celebrated as an antiquary and a connoisseur in works of ancient art; and possessed an excellent cabinet of gems, medals, and various antiquities; he was honoured with the titles of antiquarian to the pope, and first painter to the grand duke of Tuscany. Among other literary productions, Vittoria is the author of "Osservazioni, sopra la Felsina pittrice de Malvasia," a work which the celebrated J. P. Zanotti has endeavoured to refute. The portrait of our artist may be found in the collection of those of the great painters of the Florentine school. He died at Rome A. D. 1712, aged 51 years. Among many prints that he etched in a slight style, the following are the best, "The Virgin and Child in the Clouds, with John the Baptist, St. Francis, and other holy Persons, as below," from Raphael, inscribed "Vinc. Vittoria del. et sculpsit." rare; "The Last Supper," and "The Resurrection," both in large folio, from Carlo Ferri.

Giovanni Cristiano Frezza, was born at Canimorde, near Tivoli, in the year 1690. He learned engraving at Rome, under Arnold de Weterstein, and executed a great number of prints, after various Italian masters, in a neat careful style, finished highly with the graver; but without any force of chiaro-scuro, or boldness of execution. Some-times Frezza imitated that style of Mellan, which consists of single courses

ITALIAN SCHOOL OF ENGRAVING.

of lines, yet not very successfully, and we are obliged to say of his numerous productions, that the extremities of his figures in general are but poorly marked, and his drawing, though not very incorrect, is sometimes heavy. Among his engravings the following are held in most esteem. The Verolpian gallery, consisting of seventeen folio plates, including the title, from Albano, published at Rome in 1704; "The Virgin sitting under a Tree feeding the Infant Christ," from L. Caracci; "A Holy Family, with the Infant naked in the Arms of the Virgin," from Carlo Maratti, both in folio; "The Assumption of the Virgin," dedicated to pope Clement XI.; and "The Judgement of Paris," dedicated to the marquis Pallavicino, both from the same master, of folio size; "La Zingare," or the Repose in Egypt, where the Holy Virgin is represented in Egyptian attire, from Correggio, in large folio; a middling-sized upright plate of "The Descent of the Holy Ghost," from Guido, very rare; "Polyphe on a Rock, and Galatea on the Water with Nymphs," a folio print; "Polyphe harding a Rock after Acis and Galatea," in two plates. A set of six, including the title, from pictures in the chapel of St. Ann, in the church of the Madonna, at Monte Santo, from Nicolo Beretoni, in folio. The first and second plates for the Crozat collection, one representing "Venus," the other "Pallas," from antique paintings, in large folio, and the celebrated Centaurs (known by the name of Furiotto), done by Aridæus and Papias of Aphrodisium; and preserved in the museum Clementinum, from drawings by P. Battoni, and N. Honopri, in large folio.

Gioseffo Diamantini was born at Romania A. D. 1660, and spent the greater part of his life at Venice, where he died in the year 1722. Heinkeim, who has left us a catalogue of his etchings, seems to say of this matter, that his greatest praise was having instructed Rosa Alba Carriera. Yet, according to Strutt, who professes, however, to have seen but few of his works, "Diamantini etched in a free masterly style, with a fine point; the designs are spirited; the actions of the figures are often very graceful, and the heads and other extremities of them drawn in a superior style."

He was honoured with the title of chevalier, and hence he often marked his prints, "Eques Diamantinus in. f." The following are among the best of his works, almost all from his own compositions. "Hagar in the Desert," in an oval, of quarto size; "A Holy Family, with St. John," in folio; "The Marriage of Canaan," from Paul Veronese, in folio; "The dead Body of Christ, supported on the Tomb by an Angel," in an oval, dedicated to Gregorio Fab.; "Dido on the Funeral Pile, with Diana or Iris in the Air," in an octagon; "Venus, Ceres, and Pomona," dedicated to D. D. Ferdinand; "Mercury and Flora in the Air," dedicated to D. Aloysius Pisani; "Night pursued by Phosphorus, or the Morning Star," dedicated to Marc Angela Flavio C. mment; "The Sphere, or Astronomy," dedicated to Angelis, all of folio size; "Saturn, or a river God, with two Cupids," of octagon form; a middling-sized upright print of "The Fall of Phaeton;" a small octagonal print of "Mercury and Argus;" "Venus and Adonis," an octagon; another "Venus and Adonis," in quarto; a small octagon of "Jupiter and the Republic of Venice;" a small upright print of "Time, or a river God sitting, and a Child, with his Eyes bandaged, lying near him, accompanied by a Man;" a middling-sized upright print of "Time and Flora, crowned by a Genius;" "Strength, or Hercules fighting by a Nymph, accompanied by Pluto," in an octagon; and a small upright print of "Mars and Venus;" two more small uprights of "Diana and Endymion;" and

"The Sacrifice of Iphigenia;" "Boreas stealing away Orithæa," in a folio octagon; a small oval print of "Justice and Peace;" four small upright emblematical subjects; two large square ditto; and two other emblematical subjects, one a large hexagonal plate, and the other an oval.

Gioseffo Niccolò Naini was born at a short distance from Sienna, A. D. 1660. He learned the rudiments of art from his father Francisco Naini, but was sent to Rome at the age of eighteen, and entered the school of Ciro Ferri, under whom he studied two year, and acquired not only great command of the pencil, but a fine taste for design. He was recommended by his master to the grand duke Cosmo III., for whom he copied the pictures of Pietro da Cortona, in the Pitti palace; in which he succeeded so well, that the duke rewarded him very handsomely. He was likewise honoured with knighthood by the emperor Leopold, and had many other favours conferred on him by the great.

The style of Naini bears some resemblance to that of Paul Veronese. He died at Sienna in 1736, aged seventy-six. We have one small upright etching by this artist, representing "The Virgin with the Infant Christ and St. John," from a composition of his own.

Ceslar Fantetti was born at Florence A. D. 1660. The time of his decease has not been recorded, and of the events of his life it is only known that he worked at Rome after various Italian masters.

He engraved, in conjunction with Pietro Aquia, the paintings in the Vatican, known under the name of Raphael's Bible; the first thirty-six, and the fortieth, are etched by him, and the remaining fifteen by P. Aquia. Fantetti also engraved "Christ praying in the Garden of Olives," in folio, from L. Caracci; "Charity, with Two Children," from Ann. Caracci; "Latona insulted by Niobe," in large folio, from the same painter; "The Death of St. Ann," of the same size, from Andrea Sacchi; and "Flora surrounded with Cupids in the Air," from Ciro Ferri; in an oval of folio size.

Francisco Bruni was a native of Genoa, and an engraver. He was born in the year 1660, and died in 1726, but we are not acquainted with the particulars of his life, and we only know of the following print by him, "The Assumption of the Virgin," in large folio, from Guido.

Lodovico Mattioli was born A. D. 1662, at Crevalcone, in the principality of Massera, and died at Bologna in 1744. At an early age he was sent to study in the school of Carlo Cignani. He drew with a pen in a very pleasing style; and etched from his own compositions and those of the Caracci, and other great masters, but especially after G. M. Crespi, with whom he contracted a very intimate friendship. Among the etchings of Mattioli, the following will be found most worthy of notice: a landscape, with ruins and figures, in quarto; "The Annunciation," from L. Caracci, of the same size, a very rare print; "The Circumcision," in folio, from the same; "The Nativity," from Aug. Caracci, of the same size; "The good Samaritan," from Ann. Caracci; "The Death of St. Joseph," from Francechini; "The Martyrdom of St. Peter," from Crespi; a figure of "St. Anthony," and another of "St. Vincent Ferreri," all of folio size, from Crespi; "St. Luke," a note of invitation engraved by Crespi, and re-engraved by Mattioli. And the figures for the poem of Bertoldo con Bertoldino, in twenty sheets, were drawn by Crespi, and engraved under the direction of Mattioli.

William da Leone was born at Parma in the year 1664. He etched, from his own designs, two sets of animals, which are executed in a spirited style, and with some taste; we are able only to specify, in addition to these, the following engravings

ITALIAN SCHOOL OF ENGRAVING.

gravings by Leone: two landscapes, with animals, in quarto, and "Venus blinding Cupid," from Titian, in folio.

Luca Carlevarius, surnamed Zenobio, was born at Udine, in Italy, A.D. 1665, and died at Venice in 1729. He excelled in painting landscapes and marine subjects. He likewise engraved a set of views of Venice, consisting of one hundred large plates lengthways, which were published in 1705. His prints are slight, but bold and spirited etchings; and give us clear ideas of the places they are intended to represent. We can only specify the titles of the following two: a view of the church of St. Nicolas de Castello, at Venice; and one of St. Marie Formosa, at the same place, both in folio.

Of the family of CRESPI we have already spoken, as fee that article. Gioseffo Maria employed a long life of upwards of fourscore years, in the practice of the various arts of which imitation is the basis, in the course of which he etched several plates, which do credit to his general reputation, and which we omitted to mention in vol. x. Among them we venture to recommend the following as most worthy of the notice of the connoisseur.

A grand composition, in large folio, of "The Massacre of the Innocents;" two folio plates in the manner of Rembrandt, of which "The Resurrection" is the subject; "The miraculous Crucifixion of Pistoia;" "St. Anthony," also in the manner of Rembrandt, and of the oval form; a folio plate of "Two Shepherds," one of them asleep, and the other making the sign of silence. A set of five, in the taste of Salvator Rosa, of various mechanical occupations; and a very rare portrait of Michael Angelo Tamburini.

Pietro da Pietri, or Pitri, was born A.D. 1665, according to some authors, at Rome; others place his birth at Premia, in the Milanese territory. He learned the principles of art of Jos. Chezzi and Carlo Maratti, who employed him in copying some of the principal works of Raphael, and other celebrated Italian masters. He died at Rome in the year 1716.

Notwithstanding that Pietri employed great part of his time in copying, we have several meritorious historical pictures by him from his own compositions; those especially, which he painted for the church of St. Clement at Rome. He etched some few plates, and among them the two following will probably be found most worthy of notice. "The Assumption of the Virgin," a middling-sized upright; and "St. Lawrence the Jullinian," a small upright, both from his own compositions.

Francesco Antonio Lorenzini, known by the name of brother Antonio, was born at Bologna A.D. 1665. He was an ecclesiastic of the order of St. Francis; but turning his mind to the arts, he first studied painting under Lorenzo Passignelli: being, however, better pleased with etching, he was induced to throw aside his pencils for the love of aquafortis and copper.

In 1699 he travelled to Florence, where he engraved great part of the plates for the gallery of the grand duke of Tuscany, in conjunction with Theodore Ver-Cruys, Cosmo Mogalli, and Pichanti; and during his absence from Bologna, he was agreeably surpris'd by finding himself elected a member of the Clementine academy. Lorenzini was a very indolent man, and left a great number of prints from different masters: which, however, it must be acknowledged do him no great credit as an artist; among them the following are the best: "Moses striking the Rock," a large plate lengthways, from Bassan; "St. Anthony of Padua performing a Miracle," from Passignelli; "The Martyrdom of St. Ursula and her Companions;" "St. John preaching in the Desert," all of large folio size, from Passignelli; "Jesus

Christ in a Glory," with other figures, from L. Caracci; "The Virgin and Child," half figures, from Aug. Caracci, both in folio; "The Beatification of St. Dominic, accompanied by Jesus Christ, the Virgin, and Angels," from Guido, a large circular plate; "St. Philip Neri kneeling before a picture of the Virgin, surrounded by Angels," from Carlo Maratti; "St. John in the Clouds, surrounded by Angels," from Correggio, both in large folio; "The Annunciation," from Paul Veronese, in large folio; "The Baptism of our Saviour," of the same size; "The Refuscitation of Lazarus," on three large plates, all from Paul Veronese; "Jesus Christ on the Sea with St. Peter," from L. Cordi; "The Construction of Noah's Ark," from Jac. Bassano; "Venus with Two Cupids," from Carlo Cignani; "St. Augustino in the Air, surrounded by Rays of Glory," from Tintoret, all of large folio size; "Joseph sold by his Brethren," after Andrea del Sarto, in two large folio leaves; "Joseph in Egypt;" "Saul and David with the Head of Goliath," from Guercino; "The Pilgrims at Emmau;" "St. Peter delivered from Prison," both from the same painter, all in folio; "The Holy Women at the Sepulchre," from P. de Cortona, a circular print; and "St. Margaret of Cortona, to whom the Virgin appears in the Clouds," from Gab. Caliari, in large folio.

The monogram of Antonio Balestra will be found in our Plate III. of those used by the Italian Engravers. Of the leading events of his life we have already treated. (See BALESTRA.) His style of etching was bold and masterly, though slight; and his most esteemed prints are, a warrior's head, and two soldiers, both small plates; "The Holy Virgin seated in the Clouds, with the Infant Jesus and St. John, the Heads of three Cherubs appearing above;" "The three Angels visiting Abraham;" a vignette inscribed "Verona fidelis," all small uprights, and rare. His portrait of the architect Michel San Michell, surrounded with allegorical allusions, and marked with the engraver's monogram, is in small folio.

Benedetto Lutti was an eminent painter of Florence, who sometimes amused himself with etching, and whose works are generally and justly esteemed. He was born in the year 1666, studied under Antonio Domenico Gabbiani, and died at Rome in 1724.

Strutt says of this artist, that his merits procured him, from the elector of Mentz, the honour of knighthood, accompanied by a present of a cross enriched with diamonds; but specifies only two of his etchings, both of which are become extremely rare. The subjects of these etchings are, a landscape after Guercino, in small folio; and "The Crucifixion, with St. John and Mary Magdalen at the Foot of the Cross," a small upright, from a composition by Lutti himself.

Cosmo Mogalli was a native of Italy, and the disciple of Giovanni Battista Foggini, a Florentine sculptor. He was born at Florence in the year 1667, and died in the same city in 1730. He worked in conjunction with Antonio Lorenzini, (of whom we have recently treated,) and other engravers, on the plates from the Florentine gallery, for the duke of Tuscany. We likewise have by him many plates for a book of Etruscan antiquities, published by Thomas Dempster, at Florence, in 1724.

The following prints, from the Florentine gallery, are from the graver of the elder Mogalli, viz. "A Holy Family, or the Repose in Egypt," from Albano, a circular print in folio; another "Holy Family," from Correggio, of the same size; "The Supplication of Marfias," from Guercino, in large folio; "Eve presenting the Apple to Adam," from Gabr. Caliari, in folio; "The penitent Magdalen

Magdalen translated to Heaven by an Angel," from Caracci, in large folio; "Adam and Eve dismissed from Paradise," from Calari, in folio; "St. Benedict instituting his monastic Order," from P. Veronese; "Jesus Christ at the Table with the Pilgrims of Emaus," from Palma the elder; "The Marriage of St. Catherine," from Fra. Bartolomeo, all in large folio; "Virtutes Amor et Numen," an allegorical figure from Riminaldi, in folio; "David and Bathsheba," from Fr. Salviati; this and all the following are in large folio; "The Annunciation," from And. del Sarto; "The Adoration of the Shepherds," from Titian; a bacchanalian dance by four figures; and Philip II. king of Spain, also from the same painter.

Nicolas Mogalli was the son of Cosmo, and also an engraver. He was born at Florence in the year 1723, from whence, either for improvement or patronage, he travelled to Rome, where he engraved, with moderate success, from the cabinet of Portici, and the plates, after the designs of Cafanova, for "Les Monuments antichi inediti spiegati et illustrati da Giovanni Winkelmann," a folio work, which was published at Rome in the year 1767.

Jacques Maria Giovanni, or Juvanus, was born at Bologna in the year 1667, and died at Parma in 1717. He was the disciple of Antonio Roli, and became a painter of some eminence. He also practised engraving and etching, and executed many large works from L. Caracci and Correggio. The most considerable work he engaged in was a cabinet of medals for the duke of Parma, in several folio volumes. His prints are of very unequal merits. As far as they can be spoken of generally, they are executed with tolerable care and skill, but are deficient in chiaroscuro, and more or less so in drawing. The best of them are engraved from the pictures of the cloisters of St. Michael in Bosco, painted by L. Caracci, and other celebrated masters of his school, on 15 plates in folio; the cupola of the church of St. John of the Benedictines at Parma, representing "The Ascension of our Saviour," &c. &c. on 12 plates, from those justly famed pictures by Correggio, which can now only be known by the engravings, the paintings themselves being no longer in existence; the Holy Virgin in a landscape, with the Infant Christ in her arms, with St. Jerome and Mary Magdalen, the latter of whom is kissing the feet of the child (a subject commonly known under the name of "The Day of Correggio"); the Virgin seated on a pedestal with the Infant Christ, known by the name of "St. George," who is the principal figure, and by some esteemed the chief d'œuvre of Correggio; "St. Sebastian fastened to a Tree with his Hands behind his Back," in folio, from Caracci; "Jesus Christ giving the Communion to his Apostles," from France-schini, a very excellent print of large dimensions, and of the upright form.

Andrea Procaccini was born at Rome in the year 1667, and was the pupil of Carlo Maratti. He became a painter of some celebrity, and was chosen by pope Clement XI. to paint the twelve prophets of the Old Testament, for the church of St. John de Lateran. In 1720, he was invited to Spain, with the title of painter to the Royal Cabinet. Here he painted several pictures for the royal palace, and died at St. Ildefonso, A.D. 1734. We have several engravings by this master, both from his own compositions, and those of other painters, among which the following few are selected as most worthy of the notice of the collector:—"The Disciples at Emaus," from Raphael; "The Ascension of our Saviour," a large group of figures, with a youth carrying his father on his shoulders, both from Raphael; "The Birth of Bacchus," "Diogenes throwing away his Cup," and "Clelius and his Companions passing

the Tiber," all from Carlo Maratti, and of folio dimensions.

Giovanni Domenico Picchiatti was born at Venice A.D. 1676, and was the scholar of J. B. Foguini, a sculptor of some eminence. The productions of Picchiatti have no great share of excellence to recommend them, for he worked in a coarse slight style, and his drawing is rather mannered than correct. He engraved many of the plates from the pictures in the grand Florentine gallery, in conjunction with Lezzolini, Ver-Cruys, and Mogalli; and likewise some portraits, among which are, those of an unknown female, from Raphael, in folio, a whole length of Sebastian del Piombino, from Titian, and cardinal Bentivoglio, from Vanduyke; those of cardinals Louis de Rossi and Julius de Medicis, on the same plate, as from Raphael, and all are of large folio size.

The best historical works of Picchiatti are, "The Virgin sitting on a Chair," or the celebrated Madonna della Sedia of Raphael; a half figure of "The Virgin, with the Infant Jesus, and St. John," from Caracci, in folio; "Paying Tribute to Cæsar," commonly called "Il Cristo della Monetta," from Titian; "The Virgin and Child," from the same painter; and "Agar returning to the House of Abraham," from P. de Cortona, all of large folio dimensions.

Francisco Antonio Meloni was a native of Bologna, and born in the year 1670. At an early age he appeared fond of painting, and was accordingly placed under France-schini; but time discovered that his disposition was not formed for the attainment of excellence in that art, and he then took up the graver with much better success. He engraved chiefly from the pictures of his master, and other Bolognese painters; but the latter years of his life were spent at Vienna, where he died in the year 1713. The following are reckoned among his best engravings:—"The Adoration of the Shepherds," a middling-sized upright plate, from Carlo Cignani; and "Aurora," from a ceiling at Forli by the same master, both in folio.

Of the merits of FRANCESCO and PIETRO AQUILA we have already treated. (See those biographical articles respectively.) But of artists so distinguished it has been judged proper to subjoin, in this place, lists of the principal works on which their reputation has been founded. The best of those by the elder Aquila are "Saint Rosalie," from his own composition, in folio; "Mars binding his Arms to a Tree," in large folio; "Cardinal Casini as a Capuchin," in folio; "Cardinal Joseph Maria of Thomas," from P. Nelli, of the same size; "The Last Supper," from Albano, inscribed "Unus ex vobis. &c." in large folio; the first vaulted roof of mosaic in the church of the Vatican, from Ciro Ferri; two cupolas, one in the chapel of the Holy Sacrament, the other in the church of St. Sebastian of the Vatican, from P. de Cortona; another cupola, from the same master, painted in the church of St. Philip of Neri, all large circular prints; a group of heroes, to whom Minerva presents a crown of laurel, and Mars a sword, a folio print, from And. Bonfigli; "The Battle of Constantine and Maxentius," from And. Camassei; and "The Triumph of Constantine," both very large; "The dead Body of Christ across the Knees of his Mother, accompanied by Mary Magdalen and St. Francis," from Caracci, in large folio; "The Arrival of the Body of St. Helena announced by a Bishop to the Virgin," in folio; "The Repose," where the holy Virgin is represented seated under a tree with the infant, and in the background St. Joseph on his ass; "St. Peter's Bark," from Lanfranc, in large folio; a very large folio print of "Our Saviour in a Glory,"

with St. Ambrose, the Virgin, and St. Charles Borromeus, kneeling," from a grand altar-piece by Carlo Maratti; the vaulted ceiling of St. Francis Xavier at Naples, painted by Paul de Matheis, and engraved on three large plates, representing that saint overturning Idolatry, Herefy, and Mahometanism; "A Venus in the Air, flying Æneas his Arms fastened to a Tree," from Poussin.

The following are by Pietro Aquila, from his own designs: "The Adoration of the Kings," in folio; "The Flight into Egypt," dedicated to B. C. de Vingtimilliis, in large folio; "A Holy Family, where St. John kisses the Feet of the Infant Christ," half figures, in folio; "A Combat of two Lions," inscribed "Spe fuciat Iras," in folio; a portrait of Livio Odescalchi, with ornaments, in large folio.

From other Italian masters, Pietro has engraven "St. Luke," with the inscription "Ferox cum ferunt," &c. after Lazzaro Baldi, in folio; "The Sacrifice of Polixenes," from P. de Cortona, in large folio; "A Sacrifice of the Nymphs of Diana on their return from the Chace," "The Rape of the Sabinas," and "The Triumph of Bacchus," four very much esteemed prints, all from the same master, in large folio; a large subject on two plates of "The Battle between Alexander and Darius," from the same master; "Moses defending the Daughters of Jethro, at the Fountain," from Ciro Ferri; "Moses striking the Rock," both in large folio; "The Holy Virgin appearing to St. Alezio, who is repofing on a Bed, crowned with Stars," a large circular print; "The Vellars cherishing the sacred Fire, by the Orders of Augullus," a large upright print, all from Ciro Ferri; "The Holy Virgin in Heaven with five Saints, canonized by Pope Clement X.," from Carlo Maratti, in large folio; "The Triumph of Christianity, represented by Religion fitting on the Clouds, receiving the Homage of the four Quarters of the World," in large folio; "The Virgin fitting to St. Luke for her Portrait," in folio, all from Carlo Maratti; "Death and the Holy Virgin, with the Apostles," from J. Movandi, in large folio; the Bible of Raphael, inscribed "Imagines Veteris ac Novi Testamenti, a Raphaelæ S. nct. Urbini in Vaticano pictæ Jo. Jac. de Rubens fumiibus," in fifty-five leaves. Cesare Fantetti drew and engraved the first thirty-six subjects, and the fortieth; all the others are by P. Aquila. The Farnese Gallery, with the statues and ornaments, and a description in verse by J. P. Bellori, in twenty-five leaves, of large folio size; a room in the Farnese palace, with the ornaments and inscriptions, in thirteen plates, of folio size; "The Assembly of the Gods," painted in the garden of the prince Borghese near Rome, called "The Villa Picciniana," engraved "Deorum Conciilium ab Equite Joanno Lanfranco Parmensi, tum Spirantibus ad vivum Imaginibus, tum monocromatibus atque Ornaentis Artis," &c. on nine large folio plates.

Marco Ricci, the celebrated painter of landscape and ruined edifices, (for whose biography and general merits, see the article Ricci,) performed some etchings about this period, of which the best are a set of twenty-three, entitled "Varia Marci Ricci Pictoris præstantissimi Experimenta ab ipfomet auctore inventa delineata atque incisa et a me Carolo Orfolini Veneto incitore," &c. anno 1730, printed on folio paper, but of different sizes and shapes. They are feeble in chiarofcurò, and though not entirely successful, display no great knowledge of the art of engraving.

Antonio Maria Zanetti was of a noble Venetian family, born in the year 1700, and died in his native city in 1757, according to Huber; but according to Strutt, he lived ten

years longer. He acquired what is often termed a competent knowledge of drawing, at a very early age; and before he was fifteen, engraved some figures and some heads, which he dedicated to Dr. Mead, the celebrated English physician.

The works of Zanetti consist of etchings and engravings in chiarofcurò; and, in the estimation of our countryman Strutt, they "prove him to have been a man of great genius and found judgment."

Assisted by his relation A. M. Zanetti the Younger, and other artists, he engraved and published a large number of prints, taken from the drawings of Parmegiano, Raphael, and other great painters, which he purchased at the sale of the Arundelian Collection. They are divided into two sets; and both together consist of eighty-nine prints on copper and wood, with the portrait of Zanetti, engraved by Faldoni, from a painting by Rosalba."

We come now to what must be a reproach either on his "genius," or his "judgment," or on both. Strutt adds, that "in order to render this collection the more valuable he burnt the wooden blocks from which the chiarofcuròs were printed, and destroyed the copper-plates, after he had taken off such a number of impressions as he thought proper, which, we are informed, was by no means very large."

Now no principled engraver desires that his works should ever become rare from any other cause than the extensive demand for them among the public; and the substitution of nominal for intrinsic value, is an expedient worthy only of traffickers in art, and which "great genius" and "found judgment" would equally disclaim.

Zanetti resided for some time in London, and engraved here a set of twelve studies of heads, figures, &c. from his own drawings, which he tinted in a spirited style, and which, according to Strutt, do him great honour.

He also engraved in aquaforts another set of twelve plates, of which the subjects are animals and figures, after Castiglione; a set of the statues which adorn the library and palace of St. Mark at Venice; and a set consisting of eighty plates of the engraved gems of antiquity. His cypher will be found in Plate III. of the monograms of the *Italian Engravers*.

Zanetti the Younger was nephew to him of whom we have just closed the account, and was born at Venice A.D. 1720; but the year of his demise has not been mentioned. He engraved in the taste and style of his uncle, whom he assisted in his work after the statues at the palace of St. Mark, as well as in that after the drawings by Raphael, &c. which once formed part of the Arundelian Collection. And in the year 1760 he published an excellent work, adorned with eighty plates, engraved by himself, and intitled "Varie Pittore a fresco de principali Maestri Veneziani," &c.

Francesco Fontbasso was born at Venice A.D. 1681. He learned drawing in the Roman academy, and studied for a time under Seb. Ricci, whose style of painting he imitated with no inconsiderable degree of success, in the pictures which he painted for the Duodo palace, and the church of St. Salvador. In the year 1769 he travelled to Petersburg, with the view of bettering his fortunes, where presumptively he died, for we do not hear of his return.

He etched several plates with mediocre, but painter-like ability, among which are a set of seven whimsical subjects from his own compositions, in small folio; and "The Holy Virgin appearing to St. Gregory at prayer," an upright of the middle size, from Seb. Ricci.

Carlo Carloni, or Carbone, was born at the village of Searia, in the Milanese territory, A.D. 1686, and died at

ITALIAN SCHOOL OF ENGRAVING.

his native place in the year 1775. He was of a numerous family, of whom the greater part were artists. His father was a sculptor, and intended Carlo for that profession; but finding he had more inclination to become a painter, placed him under Julio Quaglio, under whose instruction he soon became remarkable for talent and industry, and occasionally both painted and engraved. In his pictures he produced a rich and agreeable effect, and made some advances toward combining the merits of the Roman and Venetian schools. Of his engravings, of which we cannot say quite so much, the following are held in most esteem: "A Holy Family, wherein St. John is kissing the Feet of the Infant Saviour;" and "The Miraculous Conception," both of 4to. size; "St. Charles Borromeus administering to the Sick, during the Plague at Milan," in folio; three plates of ceilings, in 4to., in one of which is a group of children with flowers; and the death of a saint, of folio dimensions.

Andrea Zucchi was born at Venice in the year 1680, where he engraved a set of twelve plates of Venetian habits, and many other subjects for the libraries. In 1726, he was invited to Dresden to paint theatrical scenes and decorations; and on his return to his native city he engraved most of the plates for the collection published by Lovisa, consisting in the whole of fifty-seven plates, from the most celebrated pictures at Venice; but his talents as an engraver never rose above mediocrity. Among his best productions are, "The Angel Raphael conducting the young Tobias," in large folio, from Titian; "St. John the Evangelist," of the same size, from the same painter; "St. Barnabas Vescova, St. Peter, St. John, and other Saints," from the picture which D. Varotari painted for the church of St. Barnabas; "St. John the Baptist," from P. Veronese; "The Martyrdom of Paul Erizzo," from P. Longhi; "The Nativity of the Virgin," from a picture by Nic. Bambini; "Manna gathered in the Desert," from Joseph Pons, a circular print; "Cybele on her Car drawn by Lions," from a fresco by Tintoret; and "Encaas saving his Father and Son from the Conflagration of Troy," after Seb. Ricci; all of large folio dimensions.

Francesco Zucchi was the younger brother of Andrea, under whose instruction he studied the elements of art. In the year 1750, he was invited to Dresden to paint for the electoral gallery, but was interrupted by the war, which obliged him to return to his native country, where he worked chiefly for the bookellers. He engraved several of the plates from the pictures in the Dresden gallery; among which the following will probably be found on the whole to deserve a preference; the portrait of Espagnac, from Rubens; ditto of a woman who resembles the first wife of Rubens, both in folio; ditto of Jacques Antonio Mirani, from Jean de Antona, in an oval of folio size; "St. Helena worshipping the Cross," from Bettini Cignaroli, in folio; "The Martyrdom of Religion," an allegorical subject, in folio; "Religion and the Sciences contemplating the Portrait of a Cardinal," in folio; and "Apollo with his Lyre," surrounded with ornaments, of large quarto size.

Lorenzo Zucchi was the son of Andrea, and was born at Venice in 1724. When his father was invited to Dresden, in the year 1726, Lorenzo accompanied him, and having been instructed in the elements of engraving, he continued to practise it in that metropolis with success, and was honoured with the title of engraver to the court of Dresden. Most of his productions are from the Dresden gallery, and among them the following have been thought the most worthy of notice.

Portraits.—Herman Charles Keyserling, count of the holy Roman empire, from Anna Maria Werner, in large VOL. XIX.

folio; John Frederick, prince of Sapidia; Donaventura Rossi, painter to Augustus III.; Louis de Silvestre, first painter to Augustus III.; L'Abbate Pietro Metastasio, Poeta, &c. all of large folio size.

Various Subjects from the Dresden Gallery.—"The seven Sacraments," from Joseph M. Crepini; "The Martyrdom of St. Peter and St. Paul," from Nic. del Abbate; (P. Tangui likewise engraved this picture, which engraving, as well as that of Zucchi, will be found in the collection from this gallery); "St. Catherine receiving the Crown of Imortality," after a copy by Erasmus Que'lina; from Rubens; "A grand Sacrifice to Venus," from G. Lairefle; "The Supplication of Marfyas," from J. B. Langens; all of large folio size; and "The Archangel Michael precipitating the Dragon," from Steff. Torelli; "St. Joseph, with the Infant Christ in his Arms," from Jos. Angelli, in the gallery of the count de Brühl; two landscapes, entitled "Soggiorno pastorale," and "Campagna aperta," from Jos. Reus; "The last of the Cæsars," two half figures, one of which represents Titian, marked Titianus f. L. Zucchi delin. et sculp. engraved in the style of Pitteri; and "David with the Head of Goliath," from L. Jordane, all of folio dimensions.

Jerome Ferroni was born at Milan in the year 1687. He painted the death of St. Joseph, for the church of St. Euforgio, and afterwards travelled to Rome, where he worked some time in the school of Carlo Maratti, after whose pictures he etched the following subjects, in the slight sketched style of a painter, but with great taste: "The Sun standing still at the Command of Joshua;" "Deborah singing the celebrated Canticle, after the Victory over Sifera;" and "The Death of Sifera," all in large folio; "The Chastity of Joseph," in quarto; and "Judith beheading Holofernes," in folio.

Giovanni Antonio Faldoni was born at Asolo in the year 1690. He learned painting under Antonio Luciani, and likewise practised engraving. Faldoni worked chiefly, if not entirely, with the graver, frequently imitating the style of Mellan with no inconsiderable degree of success; on the whole, he merits the encomium of having been an artist of ability. His best prints are the portraits of the doges of Venice, the procurators of St. Mark; various antique statues, making part of two volumes in folio, of Venetian antiques; part of the designs of Parmegiano, for the collection in two folio volumes published by Zanetti; a portrait of Antonio Maria Zanetti, from Rosalba, in folio; Marco Ricci, from Rosalba, in folio; "Sebastianus Ricci Beluensis Pictor, sue ætatis faciliæ primus, annus ægæ LX.," in folio; "A Holy Family in a Landscape, with Angels ministering," from S. Ricci, in large folio; "The Conception of the Virgin," from the same matter; "The Nativity of our Saviour," from P. de Cortona; "David playing the Harp before Saul," from Jos. Camerata the elder; "David dying from the Anger of Saul," from the same matter, all of folio size.

Antonio Baldi was a native of Cassa, in the kingdom of Naples, and was born in the year 1692. He studied the rudiments of painting under Solimene, and learned engraving of Miglior. He established himself as an engraver at Naples, and engraved for the most part after Solimene, but occasionally from his own compositions. The following are some of his best engravings; the portraits of the emperor Charles VI. in an oval of folio size; Don Carlos, king of the Two Sicilies, of the same size and form; Nicholas Cygnellus, a physician; Maria Avridia Carraccioli, a nun; St. Ignatius of Loyola, with his accessories; and Raphael Manca, accompanied by an angel, also in an oval; "The Communion of St. Mary the Egyptian," intobid

"*Divo Marco*;" "St. Philip of Neri, in Heaven before the Trinity," inscribed "Cui nomen dedit alma Trias;" "St. Emigde, interceding for the Neapolitans," inscribed "Divo Emigdo in terrâ motum, et Neopolis Patrono;" and "St. Gregory the Martyr, with the Subjects of his Miracles," all of folio dimensions.

Andrea Magliar was born at Naples in the year 1692. He engraved from the pictures of Solimene and other masters, but is very little known, and we are not able to specify any of his works. His son, Gioseffo Magliar, was the disciple of his father and of Solimene; and great expectations were formed, from the early specimens which he gave of his abilities, but he died young. There is a print by him, of "Christ appearing to St. William," of folio size, from Solimene, which certainly is a work of considerable merit.

Giovanni Dominico Campiglia, was born at Luques in the year 1692. At Florence he became the pupil of Thomaso Redi, and Lorenzo del Moro; and at Bologna he studied in the school of Gioseffo del Sole. He drew most of the statues, busts and portraits of the Florentine gallery, and composed the typographical ornaments for that work. Campiglia was invited to Rome, where he did the drawings of the sculptures of the Capitol, the first volume of which appeared in 1741. He has etched a great number of plates, with some taste, and among them the following portraits; Giovanni Lorenzo Bernini, Julio Romano, Salvator Rosa, Leonardo da Vinci, and Giovanni Antonio Razzi; all of folio dimensions.

Giovanni Battista Tiepolo, was born at Venice in the year 1697, and died at Madrid A.D. 1770. In his youth he frequented the school of Gregory Lazzarini, and after having worked at Milan, and in other parts of Italy, he travelled to Germany, and painted, in the episcopal palace of Wurzburg, the hall, the staircase, and two altar pieces. He afterwards went to Spain, and painted in conjunction with Mengs, who became jealous of him; but for the detail of his merits in this art, see the article TIEPOLO.

Tiepolo engraved fifty-six subjects in a very superior style, exceedingly neat, and with taste, correctness, and spirit, from which the following are selected. "The Adoration of the Kings," in folio, from his own composition, which is generally regarded as his chef-d'œuvre. A set of fancy subjects, consisting of twenty-four plates, in quarto. And another set of fancy subjects, in ten plates, smaller than the foregoing. All from his own compositions.

Giovanni Domenico Tiepolo was the son of the preceding artist, and was born at Venice A.D. 1726. He learned the principles of drawing and painting of his father, and in 1745, painted the figures of the cupola of the church of St. Paulin, and St. Jovita at Bresse.

He also occasionally took up the etching point as his father had done, working sometimes in a style which bears resemblance to the etchings of Calligione, and on other occasions in that of his father. His best prints are, a set of twenty-seven small plates, lengthways, representing, in series, "The Flight of the Holy Family into Egypt;" a set of twenty-six heads, of the same size, executed in the style of Calligione; "The Way to the Cross, or the History of the Crucifixion of our Saviour," in fourteen plates of quarto size; "The Miracle of St. Francis;" "The Miracle of St. Jerome," both in quarto; "The Republic of Venice receiving the Riches of Neptune," an allegory, in folio; "The Virgin in the Clouds appearing to St. Theresa, and two other female Saints;" and "St. Ambrose preaching to the People," both in large folio. The whole after the designs of the elder Tiepolo.

Lorenzo Tiepolo, brother to the above-mentioned artist, was also a painter, and etched in a style, and with a degree of taste which appears hereditary, from the designs of his father.

Giulio Giampiccoli, or Jampiccoli, was born at Venice A.D. 1700. We are ignorant under what master he learned engraving, but his style greatly resembles that of the school of Wagner. He mingled etching with the work of the graver, and engraved both history and landscape with success; the following few may be reckoned among his best productions. A set of thirteen landscapes, from Marco Ricci, in large folio. A set of pastoral subjects in four plates, each being inscribed with six Italian verses; and four landscapes after Marco Ricci, and F. Zuccarelli, in large folio.

Francisco Polanzani, or Polanfani, was born at Ardale, near Venice, A.D. 1700, and resided at Rome. The most considerable work we have by him, is a set of twenty-two plates, of which the subjects are from the life of the Virgin, either after Pouffin, or, more probably, from Jacques Stella (to whom Baillon attributed them). The following may also be reckoned among his best productions. The bust of a female, from C. Cignani. A bust of a blind musician, from Marco Benefiali. "Mater amabilis," from Jos. Nogari. Two other subjects from the same master, an old Man with a Bag of Money; and an Old Woman with a Hand Granade, all of quarto size. And "An Old Woman warming herself over a Chafing-dish;" from the same painter, in folio.

Giovanni Battista Pittoni, was born at Vicenza in 1690, and died at Venice A.D. 1767. He was the nephew and disciple of Francisco Pittoni, the Venetian painter, and his historical pictures are held in considerable esteem. There are some few etchings by this painter which are much valued by connoisseurs, and are marked sometimes with his initials, or at others Battista P. V. F. and sometimes with his name at full length, but we are unable to specify any of them.

Antonio Luciani was a native of Venice, and born A.D. 1700. He studied painting under Jacques Piccini, though he is better known as an engraver than as a painter. Luciani engraved from the works of Tiepolo, Caffana, Bombelli, and others, but his works are held in no very high degree of estimation, and it may therefore be sufficient to specify the two following prints by him. The portrait of cardinal Sforza Pallavicini, from Pietro Avogadro; and that of the Jesuit Tanbarni, from the same painter, in folio.

Domenico Rossetti was born at Venice in the year 1700. The prelate Giovanni Francesco Barbarigo, being very fond of this artist in his youth, took him to Verona, where he pursued his studies for some time. He practised architecture, as well as engraving both on copper and wood, and when some years had elapsed, and his reputation was established, Rossetti was invited to Dusseldorp, by the elector palatine, to engrave "The Triumph of Alexander," from G. Laireffe, on twelve large plates, which is become exceedingly rare, because, before many impressions had been printed, the elector had the plates gilt. This artist also engraved several of the plates for the collection of prints taken from the most curious pictures at Venice, which was published by Domenico Lovisa, and among which the following will probably be found most worthy of the notice of the connoisseur.

"Pope Alexander III. recognized by the Doge of Venice," after Paolo Veronese; "The Ambassadors sent by the Venetian Senate to the Emperor Frederic Barbaroussa," after the pictures of Carlo and Gabriel Cagliari, which are preserved in the hall of the grand council chamber at Venice.

Another

Another print, of which the subject is taken from the same embassy, after Tintoret, whose picture is also preserved in the same public hall; "The great Victory gained by the Venetians over the Imperialists," from the same master; "The Pope bestowing his Benediction on the Doge Zanii, previous to his Battle with Barbarouffa," after Francesco Bassano; "The Emperor Barbarouffa prostrate before Pope Gregory VIII.," after Frederico Zuechero, and another with the Italian title "Othone vien licenziato dal Pontefice e dal Doge perche vada al trattar la pace con l'Imperadore suo Padre," also after Zuechero.

The portrait of Thomaso Semachio, (a celebrated physician,) after S. Bombelli, is also engraved by Rossetti; and all the above are of large folio dimensions.

The names of some few of the engravers of Italy, who run their obscure and uninteresting careers about this period, have been purposely omitted, as being altogether unworthy of our records. Indeed, when we reflect on the advantages possessed by the artists of Italy, compared with those whose inferior fortune it is to exist in the other countries of Europe, we cannot but feel some surprise that in the course of the century through which we have just laboured with due obedience to chronologic order, so few engravers who are justly entitled to rank high in their profession, should have appeared in that highly favoured country. While France, Germany, and the Low Countries, with inferior opportunities, present a respectable display of talent in this art, and are even brightened with some rays of original genius, the history of Italian engraving is little better than a dull record of creeping mediocrity.

If the reader participates in our surprise, he will perhaps be led to reflect whether this effect may, with more justice, be ascribed to dearth of that particular kind of genius combined with patient assiduity which is required to excel in this art? or to paucity of Italian patronage? or that no philosophical view was then and there taken of the principles and practical energies of engraving, though painting and the art of the statuary were abundantly honoured with the literary attentions of their Italian professors and critics? or lastly, how far it was owing to the circumstance of engraving being less studied and practised in Italy, as a distinct profession than that of painting, than in the north of Europe?

The name and the works of Piranesi, which we now approach with all the refreshing pleasure with which wearied attention is inspired by the appearance of a worthy object, may shed some salutary light on the discussion of these questions, or will at least prove that the genius of Italian engraving had not fled for ever to less genial climates.

Giovanni Batista Piranesi was born in the Roman territory early in the eighteenth century; Huber says in the year 1707, and died in the city of Rome in 1778. He was at once architect, antiquary, draughtsman, and engraver, and in all, but more particularly in the latter art, evinced the most vigorous and original powers. He appears to have had no tutor, at least none has been mentioned by his biographers, and excepting a sound mathematical foundation, with which books or a master must presumptively have supplied him, he built his style of engraving on his own strong and keen observation of nature. In his practical knowledge of Perspective, as in his treatment of ruined edifices, he had no predecessor, and though he will always have numerous imitators, he has yet met with no rival in Italy, nor even in Europe, save and except our own Edward Rooker, and another, whom, with still more propriety, we *Cyclopedians* may call our own.

The authors of the French Encyclopedie say of Piranesi, that he was the best draughtsman of ruins, and the most pic-

tureque engraver that the country produced. This is no cold praise, though not warm enough for the ardour of the subject. His professional industry was unremitting, yet his mind and his hand have so far outstripped time, that though we know this, we remain in astonishment at the vast quantity of his works, which, when their number and magnitude are taken together, exceed the productions of any other engraver whatever. A pile of more than twenty large folio volumes, replete with taste and intelligence, seems to have to have been produced by the labour of a single individual, even after we have made ourselves acquainted with the rapidity of his powers; yet all these are etched from drawings made by himself, and some of these drawings, of which the subjects are the Greek temples at Pastum, and which attest the vivid feeling and wondrous powers of execution which Piranesi possessed in that branch of the art, are now in the country, having been purchased within these few years in Italy, by Charles Lambert, etc. of the Inner Temple.

Towards the middle period of his life, or rather before, our engraver became a member of the Roman academy of arts, but on account of some feuds, with the merits of which, if any merit attached to them, we are not acquainted, he was expelled by the voice of the majority of academicians. After some few years, however, had elapsed, and animosity was cool, motives were explained, or mistakes were discovered, and Piranesi was honourably invited by his brother artists to return. He was, about the same time, perhaps to give the greater eclat to his return, created a Roman knight, but was always better known by his name than his title.

Of many irrefragable proofs that might be adduced to render idle the sophisms of those who assert that engraving is not an original art, Piranesi is one, having never, to the best of the present writer's knowledge, engraved after any other pictures or drawings than were the production of his own hand, which sometimes present us with the magnificent remains of ancient Italy, and are sometimes the ready offspring of a mind stored with architectural wonders.

Wherefore, unless those arts which are capable of independent existence, might justly lose their claim to originality, by condescending to copy, where the general and inseparable interests of art and society require such condescension, no man, and no privileged body of men, should say of engraving that "it is not an original art," for no man of sense denies originality to a picture, because a sketch or cartoon of the same subject has previously existed, nor to the art of the sculptor, because he models in clay before he chisels in marble.

Though the human figures which he introduced into his landscapes, are extravagant in their attitudes, and ill drawn, they act the parts which they were intended to act; they serve to shew that the scenes he has represented were inhabited (if not by whom), and they are a scale whereby he induces the spectator unwittingly to measure the relative magnitude of those edifices which were the real and the sensible objects of his art. In his characteristic treatment of those edifices, and of the vases and other ornamental remains of antiquity, his line, varying as occasion admitted or required, was peculiarly expressive of stone, bronze, stucco, brick, and all the various materials of which Greek and Roman sculpture and architecture consist, discriminating with exquisite observation and inimitable skill, whether those materials retained their original sharpness of workmanship, or were mouldered by the hand of Time; or flamed by the weather; or split and cracked by the frost, by Vandals barbarity, or other sudden casualty; and whatever his subject, he always seems to have worked with easy vigour, with un-

limited freedom of hand, and as if "out of the abundance of his heart."

Trees do not often occur in the prints of Piranesi, but when they do, they in most instances too much resemble feathered: yet the wild ruggedness and unexpected forms which characterize both these and the clouds which float over his landscapes—and even his ill-drawn figures—have a certain air of enterprise, which accords with the forceful and chivalrous character of his chiaro-scuro, and rather augments than diminishes the general sentiment of romantic magnificence, which many of his compositions, and more especially the large frontispieces which fold into his large folios, inspire.

In some of the latter, all the grand architectural forms of Egypt, Greece, and Italy, appear to be assembled, as if by magic, and the mind of the spectator is led to wander, in poetic reverie, through irregular avenues of obelisks, sarcophagi, pyramids, columns, and triumphal arches. In others, which are of subterranean character, the author appears to have penetrated the cemeteries of departed greatness, and here, monstrous and forbidden things, are crawling and twining their slimy convolutions among mouldering bones, broken sculpture, and mutilated inscriptions, and an air of dankness and dilapidation, and sepulchral gloom, is diffused through the cavern, as if Time and Envy were beckoning to Oblivion, to break down what remained of the trophies of the brave, and obliterate the wisdom of the wise.

In his technical process, Piranesi was the first engraver who made free and abundant use of the ruler, as may be seen in his interiors of St. Peter's cathedral, his antique vases, and such other subjects as required it, or as admitted it only in certain parts; for he sometimes artfully contrasted, on the same plate, the widest fallies of the etching-point, in the broken or weathered parts of his lights, with ruled passages in his shadows, where the utmost regularity and perspicuity were preserved. Thought always accompanies his deeds, even where he seems most careless. The reflex lights of a bright climate might seem, to the inconsiderate in a humid one, to partake of flimsy transparency. In the works of Piranesi, they shew the justness of his observation. If he was stimulated by an adventurous spirit, he was restrained by judicious caution, which led so early on him, that he exerted it without the least seeming effort. In short, with the skill and conduct of a brave general, it was his to vary and adapt his mode of execution, and qualify his proofs, by the nature of the occasion which called it forth: he used the graver with boldness when he did use it, but used it only as an auxiliary to his etching. He knew that this was the main body of his native force, on which he could most depend. He doubtless felt that he was here the Alexander of his art, and that none could here, with any hope of success, dispute with him for the palm of victory.

To speak of the works of this artist in detail, would fill a volume: it would therefore here suffice to say, that among the best of them will be found the frontispieces or title pages to his large volumes of Italian antiquities, consisting, for the most part, of very rich compositions, formed of the fragments and monuments of antiquity. Several views of the Coliseum and arches of Constantine and Septimius Severus, at Rome; the pyramid of Cestius, with other Roman antiquities; the tomb of Cecilia Metella, on the Appian way; the fountain of Bernini, with the surrounding edifices; the facade of the Basilicum of St. Mary, with other buildings; ditto of St. Lorenzo on the Tiburtinian way; (an admirable mixture of regular with irregular mode of execution, in the treatment of the architecture;) interior and exterior views of the Pantheon of Agrippa; a very large and mag-

nificent view of the Sybil's temple at Tivoli; another view of the same temple, somewhat smaller; another, with the cascade at Tivoli; the bridge and castle of St. Angelo; the Ponte Mola; the square of the Capitol; the square of Monte Cavallo; the grand fountain of Trevi, and the temple of Jupiter Tonans; all of large folio dimensions, and some of them so large as to fold into his imperial folios.

Francisco Piranesi was the son of Giovanni Battista, and was born at Rome in the year 1748. He became an engraver of landscape and ruined buildings, in which he imitated the style of his father, but, like other followers, was always behind, though his engravings of this kind possess so much merit, that were his father's works annihilated, he would be entitled to hold rather an high rank in his profession. Francisco did not, however, confine the exercise of his talents to landscape and architecture, but engraved several plates of the celebrated statues of antiquity. He drew the human figure better than his father, but in his treatment of the antique was still an imitator, following, with much devotion, the style of engraving of Pitteri, of whom we shall presently speak.

Among the best of his prints are views of the Coliseum, the Pantheon, the baths of Salust, the baths of Dioclesian, and the temple of Isis at Pompeia, all in large folio; and in very large folio, the illumination of the chapel of Paulina, in St. Peter's cathedral; and among his statues the following are entitled to respectful notice, *viz.* the sitting Jupiter of the Museum Clementinum, the Venus de Medicis, the group of Cupid and Psyche, from the gallery of the Capitol, and Orpheus recognized by Electra, mistakenly called by some the young Papius and his mother, from the original sculpture in the Villa Ludovica, all of large folio dimensions.

Laura Piranesi, was the sister of the preceding artist, with whom she equally distinguished herself by engraving: the following views are by her hand, *viz.* the Capitol of Rome, the bridge of Salario, the temple of Peace, and the arch of Septimius Severus, all of 4to. size.

Giovanni-Marco Pitteri, was born at Venice A. D. 1703, and died in the same city in 1767. He studied engraving for a short time under Jos. Baroni, whom he soon quitted for J. A. Faldoni. The works of this admirable artist are executed in a very remarkable style, with single courses of lines, though very differently disposed from those of Mellan and his followers. They run perpendicularly from the top to the bottom of the plate, and the shadows are expressed by strengthening them as occasion required. The effect he has produced in this new mode of engraving is far more pleasing and harmonious than could have been expected, especially where, by partially notching his lines, he has imparted stony character and richness, to such parts of his prints as required it. This artist, being always occupied with engraving, never travelled out of his native place.

Among his works, the following are most worthy of notice.

Whole-length Portraits and Heads, all in large Folio.—A bust of himself, from Piazzetta; a bust of J. B. Piazzetta, a Venetian painter; Charles Goldini, a Venetian comic poet; John Moenigo, a Venetian nobleman; Joseph Nogari, a Venetian painter, with his hand on the hilt of his sword; and a young lady resting her head on her hand, all from the same painter; count de Schalenbourg, field-marshal of the republic of Venice, from C. F. Rusca; cardinal Quirini, marquis Scipio Maffei, Clara Isabella Fornari; and a set of heads on sixteen plates, which are presumptuously entitled God the eternal Father, our Saviour, the Virgin Mary, the twelve apostles, and St. Paul, all from Piazzetta,

Piazzetta, according to Huber, but, according to Strutt, the latter are from his own designs.

Various Historical Subjects.—"Christ expiring on the Cross," with the effect of night; "Religion and Heresy," an allegory, both from Piazzetta; "A Holy Family," from Pietro Longhi, in large folio; seven folio upright plates of the sacraments; six large folio plates representing chaces in the neighbourhood of Venice, from the same master; "St. Peter delivered from Prison by an Angel," after Espagnoleto; "The Martyrdom of St. Bartholomew," from the same master, both in folio, for the Dresden gallery; "St. Catherine of Siena," after J. B. Tiepolo; "The Penitent Magdalen," from the same, for the Dresden gallery; "The drunken King," after D. Teniers; and two rustic subjects, after the same painter, (the Shoe-maker, inscribed "Ne futor ultra crepidam," and the Miller, inscribed "Sudat rotator la forte contentus,") all in large folio.

Comte Pietro de Rotari was born of a noble family at Verona in the year 1707, and having a natural turn for the fine arts, together with the means of indulging it, became successively the pupil of Robert van Audenarde and Antonio Balestra. He studied with commendable assiduity, and travelled in quest of improvement, or of distinction as an artist, to Venice and to Rome, and afterwards to Vienna, Dresden, and Peterburg, in the latter of which cities, after a residence of eight years, he ended his career in 1764.

His engravings consist of light, spirited, painter-like etchings, which are much sought after by the curious, and are executed from his own compositions, or from those of his master, Balestra. From among these, the following will probably be found most worthy of selection. The portrait of Filippo Baldinucci writing; "St. Francis adoring the Crucifix," a middle-sized upright oval, from his own composition; "The Education of the Holy Virgin," of the same size; the head of an old man with a beard. Another head of an old man looking upwards, both in 8vo.; "The Three Angels entertained by Abraham;" "David with the Head of Goliath;" "St. Jerome;" and "The Interview between Venus and Eneas," all of 4to. size; and, of somewhat larger dimensions, three monks of the order of St. Francis, after Balestra. The count also arrived at some eminence as a painter of portraits and history.

David Antonio Foffato was born at Moreo, a bailiwick of Luggaris, in Switzerland, in the year 1708; but resided at Venice with an uncle, who was a merchant, and wished Foffato to become one also, but finding he had more taste for the arts, he gave up this design, and placed him under Vincent Mariotti, a good designer of architecture, and a master in perspective, with whom he made great progress. He afterwards travelled to Vienna with Daniel Gran, under whom he executed some very fine pictures, particularly a very superb ceiling for the Imperial library. He worked with great success, both in oil and fresco, in most of the towns of Rome and Germany; and likewise amused himself with the point. Among his best productions in that way, the following may be reckoned. A set of twenty-four folio landscapes of Venice and its environs, from M. Ricci, with a dedication to count Algarotti; "Diana and Callisto," from Solimene; "The Family of Darius before Alexander," from P. Veronese; "Jupiter thundering against the Vices," from the ceiling of the council chamber; "The Servant of Abraham with Rebecca," half figures, from Ant. Bacci; and "The Vocation of St. Peter to the Apostolate," from the same painter, all of folio dimensions.

George Foffato was born A. D. 1710, and was probably of the same family with the preceding artist. We are igno-

rant of whom he was the pupil; but he worked some time at Milan, and from thence went to Venice, where he died.

He etched the edifices which the celebrated architect Palladio erected at Padua, Vicenza, and other towns and cities of Italy, which was published by Pasinelli at Venice, during the years 1740 and 1745, in French and Italian, of large folio size. The etchings are well executed, and do honour to the taste and intelligence of our artist.

Jaques Leonardus was born at Parma A. D. 1712. He learned the rudiments of art of M. Benville, (a portrait painter), and J. B. Tiepolo. He engraved from the most celebrated pictures in Venice, and, with commendable regard to the public deficiencies, commonly made choice of those which had not already been engraved; though he generally succeeded so well in copying the characters and effects of his originals, that he need not to have been either afraid or ashamed of following other engravers, by working after the same pictures. The best of his productions are, "Cupids playing," after Julio Carpioni; "The Rejoicing of Silenus," from the same painter; "Neptune in a Car drawn by Tritons," from Seb. Conca; "The Rape of Europa," from the same master; two rustic subjects, one representing "A Village Fair;" and the other "A Crowd of Beggars at the Gate of a Town," from J. M. Creppi; two comic subjects representing "The Divisions of the Carnival at Venice," from Tiepolo; "The Golden Calf," from Tintoret; and "The Last Judgment," from the same master, all of large folio size.

Michael Sorello was born in Spain, but in what year is uncertain. He settled at Rome A. D. 1756, and studied engraving under Giacomo Frey, (for an account of whom see GERMAN School of Engraving,) and worked very much in the style of that very distinguished master. The most considerable work we have by Sorello is a set of eight prints, engraved from the tapestry of the Vatican, after Raphael; he likewise engraved, after other Italian masters, several meritorious plates for the Museum Florentinum. From the mass of his works, the collector may, with advantage, select good impressions of the following, for his Italian portfolio:—"The Nativity," where a shepherd, accompanied by his dog, is among the principal figures, from Corci; "The Purification of the Virgin;" and "St. Peter proclaimed Chief of the Church," from Carlo Maratti, all in large folio; and "The Descent of Christ into Hell," in small folio; "The Resurrection," dedicated to Antonio Colona; "The Disciples at Emmaus," in large folio; "Christ represented as a Gardener," or, the "Noli me Tangere;" "The Conversion of St. Paul," from C. Maratti; the frontispiece for the Monologium Græcorum, after Seb. Conca; and an "Annunciation of the blessed Virgin," from Felice de Castro, (a Spanish painter,) both in large folio.

Paul Pilaja, or Pilaia, was a native of Italy, and appears to have been born about the year 1718. The circumstances of his life have not been recorded, but he seems to have worked at Rome. He engraved the prints for a book entitled "Storia di Volsena," by the Abbé Adami, with the portrait of the author, after the Cavalier Odani; which book, according to Gandellini, was printed at Rome in the year 1737. He also engraved, in folio, the statue of the prophet Elias, from Aug. Cornacchini, erected at St. Peter's cathedral; the portrait of pope Benedict XIII. from J. B. Brughi, a Roman painter; "The Martyrdom of the Capuchin St. Fedele da Simaringa," from Seb. Conca, both of folio size; "The Miracle performed by St. Thoribio, archbishop of Lima, while preaching to the Indians,"

Indians," in large folio; "Liberality" with two children, in folio; and "Clodius, disguised as a Woman, discovered at the House of Cæsar," both from the same master, in large folio.

Niccolo and Antonio Billi were brothers, and born at Rome some time about the year 1719, or 1720. Of the family of this name, which were long known at Rome, as printfellers, and some of whom were engravers also, we shall mention only these brothers, who engraved many portraits and devotional subjects at Rome, and various plates for the volumes of the antiquities of Herculaneum, at Naples, executed in a stiff style, without much taste. Niccolo engraved many of the plates for the Museum Florentinum, and among his productions are also the portraits of Fredericus Zucharius, drawn by Campiglia; John Holbein, "se ipse pinxit;" Pietro Leonardo Ghezzi; John Maria Morandi; the cardinal Pompeo Aldrovandini, all in folio; the cardinal Joseph Spinelli Dom. Dupræ pinx.; "The Infant Jesus," in an oval, of 4to. size, from J. Conca; "St. Philip of Neri, kneeling before the Virgin," from S. Conca; "A Holy Family," half figures, from Caracci, in 4to; and "The Flight into Egypt," from Guido, in large folio.

Carlo Gregorio, or Gregori, was born at Florence in 1719, and died in the same city A.D. 1759. He learned engraving at Rome under the direction of Giacomo Frey, and worked for the greatest part of his life in his birth-place, after the celebrated painters of Florence. Part of the plates from the cabinet of the marquis Gerini, and some of those in the Museo Fiorentino, are by him, of which collections they constitute the best and greatest part. Among his productions the following may also be mentioned with approbation, viz. the portraits of Francisco Maria, grand duke of Tuscany, from Campiglia; his duchess, Eleonora Vicentina of Gonzague, from the same painter; and Scabalian Bombelli, painted by himself, all in folio; the statue of the Virgin, brought to Bologna by angels, from a design by dal Fratta; St. Catherine Jannen, from F. Bartolozzi, all of folio size; "L'Isitoria di Cesare, a cui nell'Egitto molte Nazioni presentarono vari donativi—Soldano d'Egitto," from Alexander Allovi, detto il Cruppino; "Opus Bernardini Barbatello, detto Poccetti, quod in facello S. S. Nerci & Achillei in Atrio Templi S. Magdalene de Pazzis Florentina adfervatur;" fourteen subjects from the Lives of the Saints, at the church of St. Magdalen at Florence; these were engraved in conjunction with his son Ferdinand, in large folio; "The Virgin and other holy Women at the Sepulchre," from a picture by Raphael, in the cabinet of lord Scarfdale, in folio; St. Padio, a bishop of Florence, from Sig. Betti, in 4to; St. Bonizella Cacciocanti, a half figure, from Ant. Bonfigli, in 4to; and the mausoleum of the princeess Elizabeth Charlotte of Lorraine, from Jos. Chamant, in folio.

Ferdinand Gregori was the son of Carlo, and born in the same city A.D. 1740. He learned the principles of drawing and engraving in his father's house, after whose death he travelled with Vincent Vangelisti to Paris, to finish his studies under Wille. He afterwards returned to his native country, and published several meritorious works, among which were a print of "The Death of St. Louis Gonzaga," after a design by J. B. Cipriani; and a portrait of Carlo Gregori, drawn and engraved by Ferdinand; "The Virgin suckling the Infant Jesus," from Carlo Maratti, in folio; "A sleeping Venus," from Guido, in large folio; "St. Sebastian fastened to a Tree," a half figure, from the same painter; "Venus discovering Cupid mounted on a Dolphin," from J. Cafanova, both in folio; two marble groups from Cellini, a Florentine sculptor, after

the designs of Allegranti, in large folio; "A Holy Family," from a painting in fresco, by Andrea del Sarto, in small folio, with a very good effect; and "St. Stephen stoned," from Louis Cardi, (whose picture has a grand character, which is very well preferred in the engraving,) of folio size.

Antonio Joseph Barbazza, was born at Rome A.D. 1720. The life and works of this artist are very obscure, and we can only specify, that he was a member of the *Bolognafe Academy*, and travelled to Spain in 1771. His pictures are less numerous than either his drawings or engravings, which are much esteemed by connoisseurs. Among his prints, four large heads from nature, in the style of pen and ink drawings, are justly intitled to high praise for their truth and originality; a group of musicians, among whom is a caricature of M. Perez, of musical celebrity, in 4to.; the plates for the book of father Bianchini, intitled "Istoria Ecclesiastica," in 4to.; and some plates for the work of Monaldini, who published new editions of Virgil, and other of the classic authors of antiquity.

Jean Elias Morghen was a native of Germany. He was born in the year 1712, travelled to Italy in his youth, and remained there during the greater part of his life, residing for the most part at Florence. He made all the drawings, and engraved most of the plates, for the work which was executed under the patronage of the marquis Gerini, after the pictures of Francefcchini and other celebrated masters, which decorate the ducal palace of Tuscany. He also engraved and published, in 1767, "The Antiquities of Pestum," on six plates, after drawings by Antonio Joleg.

Philip Morghen was the son and pupil of Jean Elias, and was born in Italy, probably at Florence, in the year 1740. He went, either for professional improvement or employ, to Naples, where he executed a great number of the plates for the antiquities of Herculaneum, including the portrait of the king of Naples, which serves as a frontispiece to the work.

Philip also engraved a set of twelve folio plates of statues at Florence, called the Apostles of Bandinelli, and thirty-one views of ruined edifices in and about the city of Naples.

His son, or his nephew Raphael Morghen, who has signalized himself by the production of Da Vinci's Last Supper, and other meritorious works, and who still lives and engraves at Florence, will become the worthy theme of future historians of the Italian school of engraving.

Francecco Londonio (whose name and merits appear to have been unaccountably overlooked by our countryman Strutt) was born at Milan A.D. 1723. He began his career in art with the study of historical painting, but soon abandoned the heroism and duplicity of man, for the honesty of the brute creation, and particularly attached himself to the painting and etching of domesticated animals, in both of which arts he was eminently successful.

In the year 1769 he travelled to Rome, Genoa, Naples, and other parts of Italy, and during his stay in the latter city, he made occasional journeys to the surrounding villages, and studied nature with great attention, particularly those rustic and unsophisticated actions and scenes, which were congenial with the simplicity of his own habits and feelings. Here he passed the greater part of his time in etching and engraving, and here, as is believed, he died of an apoplexy in the year 1783.

Londonio engraved a great number of rural and pastoral subjects, consisting for the most part of peasantry and cattle, with the accompaniments of picturesque banks, trees, and water, in a style which, though original, and evidently the offspring of his own observation and feeling, bears strong resemblance to the best etchings of Berghem and Vischer; using

ITALIAN SCHOOL OF ENGRAVING:

using the graver and dry-point, with great propriety, only as occasional auxiliaries to his etching-needle.

The works of this artist compose seven sets, confining in the whole of seventy-two plates, of which the subjects are the rural occupations of Italian peasantry, &c. One of these sets is dedicated to cardinal Pozzobonelli; another to the earl of Exeter, and the rest to different noblemen and gentlemen who had befriended their author, who were most of them Englishmen. London often times printed his plates on blue paper, and heightened his lights with white chalk, by which means he produced an agreeable effect.

A picture by this artist, of a Milanese peasant at the entrance of a hut, with geats, is now in the collection of the most noble the marquis of Stafford, at Cleveland house. His pictures are rare, and this is probably the only one in England: it has no very powerful chiaroscuro, but is painted with exquisite feeling, and great dexterity of pencil.

Gioseffo Camerata was born at Venice A. D. 1724. He studied engraving under John Cattini, and traveled to Vienna in 1742, where he learned miniature painting, which he ever after occasionally practised. In the year 1751, he was invited to Dresden, to engrave for the great work from the Electoral gallery in that metropolis, but the war breaking out he returned to Italy. When peace was proclaimed, he once more travelled to Saxony with the electoral prince; soon after which he was elected one of the professors to the Dresden academy.

This laborious artist engraved a great number of plates, many of which were from his own designs; among them are the portraits of Marco Foscarini, procurator of St. Mark, and doge of Venice; Simon Cantarini, another procurator of St. Mark, both of folio size; Sebastian Bombelli, in quarto; a whole length of Theresa Zamelli, a celebrated dancer, dressed in the Turkish style; and a large head of Mademoiselle Abuzzi, in folio.

For the *Dresden Gallery*, Camerata engraved two parables from the New Testament, after Fetti; "David with the Head and Sword of Goliath," in folio; "A Holy Family," after Julius Cesar Procaccini; "St. Roche relieving the People afflicted with the Plague," after Camillo Procaccini; "The Charity of St. Roche," after Caracci; "The Assumption of the Virgin," from the same painter, all of large folio size; "The Woman taken in Adultery," after Bicaino, in folio; "The Chastity of Joseph," from S. Cantarini, in folio; and the Old and New Testaments, after And. Vaccari, in large folio. Of his works of subsequent date, the following are to be preferred:—"A Holy Family," after Procaccini, in folio; "The Pentecost Magdalen," from a picture by P. Battini, in the Dresden gallery, in large folio; "A Sleeping Shepherd," from J. M. Crespi; "St. George refusing to sacrifice to the Idol," from Coine Rotoli, both in large folio. Two half length figures with long beards, after Dietrich; and a Magdalen, in miniature; from Vander Werff, of the same size as the original. This was Camerata's last engraving.

Joseph Canale was born at Rome in the year 1728, and became a professor of the academy at Dresden, and honorary member of that of Bologna. He studied engraving under the direction of that justly celebrated master Giacomo Frey, and also frequented the school of Cavalier Benicelli. At Dresden much of his time was taken up in making the drawings from the pictures which were to be engraved both by himself and others, for the publication of "The Dresden Gallery."

Canale had many pupils who did him honour; and his

engravings are very numerous. Among them the following are some of those which are held in most esteem.

Portraits.—Maria-Mattia Perini, a half figure, from Marco Benicelli, in quarto; Maria-Antonia Walburg, electress dowager of Saxony, from a painting by herself in crayons; the archbishop Donaventura Balthazi; Maria Josephina, queen of Poland, after Rotari; the profile of the prince Xavier, after Cafanova, all in folio; and the episcopal monument of cardinal Spinola at Rome, in large folio.

Historical Subjects.—"Imagina miraculosa della S. Virginia Maria trasportata nella Basilica Lateranense," in small folio; "The good Englishman," after Signora Rufiba, from the Crayon cabinet at Dresden, the same size; "The Philosopher," after Espagnolet; "Glory," after Dominichino; "A Sybil," after Angelica Kauffman; "Paris on mount Ida," after Vanloo; "Adam and Eve dismissed from Paradise," after Albanus; "Christ and St. John," after Vassler Werff; "Christ appearing to St. Thomas," after Martini, for the collection from the Dresden gallery. (This plate was only etched by Camerata and finished by Jean Beauvarlet.) "A Turkish Woman," half length, from Dietrich; and "Spring," a half figure, from the same matter, of which the last three plates are of folio dimensions.

Bartolomeo Crivellari was born at Venice A. D. 1725. He became the disciple of Wagner, and worked under his direction, from the pictures of Gaerardini, Tiarni, Tiepolo, and others, and he likewise engraved some plates for the Institution at Bologna, but attained no very high degree of eminence in his art. Among other engravings by this artist are the following: Portraits of Christian, prince royal, and elector of Saxony; and Mary-Ann, archduchess of Austria, both of folio size. Three subjects from the life of St. Peter of Petronius. Four from Nicolo del Abatte, in folio: viz. 1. A Company of Card Players. 2. A Group of Drinkers, diverting themselves, both half figures. 3. A Company of Musicians. 4. Another Group of Musicians, with a young Female playing the Harpsichord. "The Canonization of St. Alexander Saul," after Matteo Bartoloni; "A young Man and Female seated on a Couch," from Julio Romano, in small folio, from the gallery of the king of Prussia.

Gaetano Gandolfi was a native of Bologna, and the contemporary and fellow student of Crivellari. He engraved, after Nicolo del Abatte, "The Nativity," with "The Adoration of the Shepherds," inscribed "Opus hoc incunifumque expositum," &c. from a picture in fresco, at the palace Leoni at Bologna, in large folio, which latter engraving possesses so much merit as to make us regret that he engraved so little, and that we do not know more of this artist.

Giovanni-Baptista Profoloni or Brudoloni, was born at Venice in the year 1726. He always resided in the place of his birth, and was probably a pupil of Joseph Wagner. We are only able to specify the following engravings by him. The portrait of pope Benoit XIV. in an oval, a vignette with the same portrait; "St. Theresa in Rapture," in folio. A set of twenty views of Venice, etched after Ann. Canale, in folio. Another curious set of twenty large plates, from the same master, represent the ceremonies made use of at the election of the doge of Venice, and at the religious marriage with the sea.

Benigne Bossi was born, according to Puffin, at Prio d'Arcisato, in the Milanese territory, A. D. 1727. At the age of ten, his father took him to Nuremberg, where he learned the elements of design; and from thence, on the death of his father, he travelled to Rome, and afterwards Pompeus Batroni, Hutin, Dietrich, and Wessing. The latter advised him to practise etching, which he did till his death. The seven years' war, of which Saxony was amidst

the continual feat, obliged Boffi to return to Italy, and in 1760 he was received at the court of the duke of Parma, where he lived honorably, occupied with letters and the arts. The following are among the best of his works. A portrait of the engraver Boetius of Dresden; "The Presentation in the Temple," (published at Dresden); a set of heads and other subjects on forty small plates, etched with taste and in a very spirited style; a set of vases, and a masquerade, after Petitot; four subjects of trophies; the Attributes of the Four Seasons, inclosed in circular wreaths; two subjects of children, in small folio; a set of twenty-nine etched, and washed in with water colours to imitate the original drawings by Parmegiano; the cities of Piedmont; allegorical figures for an Epithaniam; and the celebrated St. Catherine, who was related to the house of Sanritali, engraved the size of the picture, and a very capital print.

Antonio Baratti was born at Florence in the year 1727. He worked for the collection of prints after the best pictures in the cabinet of the marquis Gerini, of which Mariette has given a description, and of which the first volume was published in large folio, A. D. 1759, at Florence. He likewise engraved after various Italian masters, and among others the portrait of Jean Bettini Cignarolli, after Della Rosa; of 4to. size.

Pietro Campana was born at Soria A. D. 1727. He learned engraving of Rocho Pozzi, and worked most part of his life at Rome and Naples. We find several of his engravings in the cabinets of Florence and Herculaneum; among which the following are most worthy of distinction: "St. Francis with Paul," a half figure; "Charity," in a small oval; "St. Peter delivered from Prison by an Angel," after Matt. Preti, from the Dresden gallery, in folio; the portrait of Pietro Berninini da Cortona, from the Florentine cabinet; and Bernardino Barbattelli, detto B. Poccetti pittore Ferretti, both in folio.

Carlo Orfolini was born A. D. 1724, in the city of Venice, where he generally resided, and where he carried on a considerable commerce in prints. He engraved for the Florentine Gallery, and among the best of his prints are "St. Jerome meditating," inscribed "pall multas lacrymas," &c. from Ant. Balestra, a much admired plate, in large folio. Four others from legendary stories of the saints Aloysius, Stanislaus, Francis, and Bernard, and the High-priest, all of folio dimensions.

Bernardino Belotti, surnamed Il Canaletto, was also born at Venice in the year 1724, and died at Varlovic in 1780. He was called Canaletto from his very distinguished uncle Antonio Canaletti, by whom he was instructed, and whose style he successfully imitated. After visiting Rome and other cities of Italy, he travelled to Germany, where he obtained the title of count Belotti, and made some stay at the courts of Vienna and Dresden.

The subjects of his prints, which consisted for the most part of etching, are landscapes, generally views, (or portraits of celebrated places,) which he treated in a picturesque taste, and which have been held in deserved esteem.

The most remarkable of these are, a set of six views of Vienna, &c. in folio; two other sets, each consisting of six architectural ruins in quarto; and a very large plate, entitled "The generous Turk," the whole of which were executed during his stay at Vienna.

Those which he engraved at Dresden are larger and more numerous. Among these we shall distinguish views of the port Wildstrasser Thor, with the ramparts, theatre, and public library; the gallery of Zwinger, with the bridge at the entry of Oltza; interior of the Zwinger, with the pavilions and galleries; the Catholic church with part of the

electoral palace; the bridge over the Elbe, with a profile of the Catholic church; the gallery and gardens of count Bruhl; the church of the holy Virgin, &c.; the picture gallery at the above church, &c.; the square before the grand guard-house; the old market at the side of the church of St. Cross; the church and street of St. Cross; the ruins of the belfry of the church of St. Cross, which fell on the 22d of June 1763, at the bombardment of Dresden; the ruins of a part of the suburbs of that city, before the port of Pirna; and two views of the new town and palace of Holland, with the equestrian statue of Augustus II.

Views in the Neighbourhood of Dresden.—The town of Pirna, on the side of the gate called Oberthor; the suburbs of the town of Pirna, before the waterman's gate; Pirna before the gate of Dohna; the façade of the castle of Sonnenstein on the banks of the Elbe, in the back-ground the city of Pirna; the ramparts of Sonnenstein, with the prisons, &c.; the fortrefs of Sonnenstein, from the road to Kenigstein; the rock and fortrefs of Kenigstein on the south-side; and the rock and fortrefs of the same city on the western side, with the castle of Lilienstein in view.

Views in Warsaw.—The abode of the Bernardin monks, as it presents itself from the gate of Cracow; Warsaw, from the palace of Sapieha, to the end of Szolle, and from thence to the castle of Villanova, with part of the town of Prague; the city of Warsaw, from the palace of the Ordinate to the royal castle.

Dominico Cunego was born at Verona in the year 1727. He learned the principles of drawing and painting in the school of Francesco Ferrari, but feeling a strong desire to become an engraver, he copied, without any previous instruction, various prints by the most celebrated engravers. His earliest engravings, (after these preparatory studies,) were the medals for the book of the marquis Giacomo Muselli Veronese.

He afterwards went to Rome with Mr. Adams, the English architect, where he engraved certain Roman antiquities, and we believe, some of the ruins of Dioclesian's palace at Spalatro, after Clerisseau; besides many other plates from celebrated Italian paintings; and most of the prints for the Schola Italica of Gavin Hamilton. Strutt supposes that he visited England, but this is perhaps a mistake into which he may have been led by the circumstance of Cunego's having engraved for Boydell's collection, and for the Messrs. Adams. When he was about sixty years of age, he was invited to Berlin, to work perhaps as preceptor, in an academy of engraving, established by an individual named Pascal; where he engraved a great number of portraits both in the line manner, and in aquatinta, after Cuningham; but this establishment not succeeding, he returned to Rome in 1789; in which metropolis, as is believed, he died within these few years. In the following list will be found mentioned all his works that are of any importance.

Portraits engraved after Cuningham.—Frederick II. king of Prussia, a whole-length figure, with the two favourite leversets of the king, in aquatinta; another portrait of king Frederick; two portraits of Frederick William, prince royal of Prussia; Frederica Charlotte, princess of Prussia, represented walking in a garden; and Frederick-Louis-Charles, Frederick-William, and the princess Frederica, whole-length figures, all of large folio size.

Subjects for the Schola Italica of Hamilton.—"The Creation of the Waters," in final folio; "The Creation of the Sun and Moon," in large folio; and "The Creation of Adam," in folio, all from Michael Angelo, in the Sistine Chapel; "Parnassus, the Muses of Raphael," after a picture by that master, at the palace Barberini, final 8vo size;

size; "Galatea on the Water," from Raphael, in the Farnese Palace, in large folio; "The Daughter of Robert Strozzi, a Florentine Nobleman," from Titian, in folio; "The Rape of Ganymede," after Titian, in small folio; a head, with a long beard, after Baffan; a bust of St. Jerome; St. Hieronymus, from Guido; bust of an old man after the same painter; a fine head of a Mary Magdalen, after the same, in small folio; a full-length portrait of an old man, after Guercino; "The Infant Prodigy," after a picture by the same master, in the palace Lanolotti, at Rome, all of folio size; "The Birth of St. John the Baptist;" and "Providence;" surrounded by children, both of large folio size, after J. Caracci; "Galatea on the Sea," after a picture by Augustino Carracci, in the Farn. G. Gallery; "Apollo and Semele," from Annib. Carracci; "A Penitent Magdalen lying on Phorus," after the same; "A young Man and Woman in Conversation," after Guercino; "Apollo supporting the wounded Iphigenia," after Dominichino, at Rome; "The Death of St. Cecilia," from the same master; and "Two Nereids, accompanied by three Cupids," from Albano, all of large folio dimensions.

Subjects after various Masters.—Benedictus Josephus Labre, Bolonensis, And. Blg. pinx. in large folio; Clement XIV. (Gauguelli) Gio. Dom. Campiglia pinx. in folio; Frederick Christian, prince royal of Poland, and elector of Saxony, drawn and engraved by Cuneo, at Verona, also in folio; Eques Antonius Raphael Mengs, seipsum pinx.; "The Virgin with the Holy Infant in her Arms," A. R. Mengs pinx. both in quarto; five large plates, from the pictures of Raphael Mengs in the library of the Vatican; "St. Basil celebrating the Greek Mass," after P. Subleyras; one of the altar-pieces of St. Peter's at Rome, executed in Mosaic, large folio size; "Juno with the Cætus of Venus;" and "Hebe presenting the Cup to Jupiter," (companions) of folio size, both after Gavin Hamilton; the P'Allegro and Il Penferoso of Milton, folio size; "Innocence, with a Lamb," a very interesting print, with much of truth, sincerity, and simplicity of character and expression, and which does honour both to the painter and engraver; "Briseis taken from the Tent of Achilles, who is regretting her Loss;" "Achilles mourning over the dead Body of Patroclus;" "Achilles dragging the dead Body of Hector at his Chariot Wheels;" "Achilles delivering the Body of Hector to Priam;" "Andromache mourning the Death of Hector," all of large folio size, from Gavin Hamilton; "Brutus swearing to revenge the Death of Lucretia," in folio, from the same painter; a half length of "The Virgin and Child," from J. B. Cignaroles; the same subject from Correggio; "A Magdalen," from the same painter; "The Apostle St. Andrew," after Guido Cagnacci; "St. Thomas of Villanova," from Ant. Cavazoni; "A Philosopher with a long Beard," from Cellini; "The Sick healed," after L. Carracci, all of folio dimensions; "Christ bearing the Cross," a very grand composition, after Raphael, in large folio; and "Christ laid in the Tomb," a very large upright plate, after Esp. goletto; "The Godhead in the Heavens, attended by Angels," from Dominichino, in folio; "The Annunciation," from the same painter, in large folio, from the chapel of Nelli; "The Visitation;" "The Nativity;" "The Circumcision," all in large folio size; "The Adoration of the Kings;" "The Prefatination in the Temple;" "The Flight into Egypt," of folio size, in a circle; "A dead Christ, with the two Marias and Angels," in large folio; and a very large upright plate of "The Virgin in a Radiance of Glory, surrounded by Angels, and crowned by the Holy

Trinity," all from Dominichino; "Rinaldo alleg. on the Car of Aretha, which is drawn by winged Dragons;" "Giulio da Camp. pinx. Rome, in J. P. S. Carracci, Dom. Cuneo sculpsit," of a very large folio size; "A young dissembling truth, in the composition, executed at Rome in the palace of the marquis C. C. in six large plates independent of the general plan of the design;" "The Last Judgment," from the S. J. de' Chapel of the Vatican, after Michael Angelo, a very large plate; the criers of the same chapel from the same painter; an antique tomb, on which is represented a bacchante leaning back, found in the Vault of Canali, in 1707, in folio; and thirteen views of antique edifices and churches, raised in Italy, after Cellini, on large plates, engraved with labour, but very inferior, in taste and style, to the best representations of such subjects, by Piranesi and Rooker.

Giovanni Battista Cipriani should not be left unmentioned among the Italian engravers of this period. Of his Engraving we have already treated. (See CIPRIANI) He etched several plates with considerable spirit, and a multiplicity of style in his handling, which borders on dryness, of which some are from his own composition, and some from those of other masters.

Among these are several portraits of distinguished characters, who lived in the time of Cromwell, of which four heads of Milton, which being taken at different periods of his life, from infancy to age, form an interesting physiological series, are particularly worthy of notice. They are rare, and intrinsically valuable prints, of 4to. or rather small folio size, in ovals, and are done from originals which were in the possession of T. B. Hollis, esq. and which, therefore, have every claim to authenticity.

He also etched, "The Descent from the Cross," after Vandyke; "The Death of Cosopatra," after Bovenanto Cellini; and "The Descent of the Holy Ghost," after Gabbiani; and, from his own design, "The Mother and Child," in folio, and some others.

Giuseppe Zucchi was born at Venice A.D. 1730, where he worked for some time in conjunction with Antonio Wagner, engraving for the same sets of rural and historical prints, in which appear the names of Wagner and Bartolozzi. He afterwards went to Florence, where he painted the ornaments of the principal pleasure houses and villas in that city and its neighbourhood, from which prints were engraved. Of these he himself engraved two, and in many of the other plates he etched the figures. He also engraved after different masters and from his own compositions, many other subjects, among which are the following:—A half figure of a man, with a furred hat on, in 4to.; rural conversation; "The Passage through the Red Sea," in large folio, supposed to be after Bourguignon; "The Virgin and Child crowned by Angels," after Guido, in 4to.; "Joseph sold by his Brethren;" "The Rape of Europa," after P. Perle; "The Mask of Vice taken from Hell;" after Balt. Franceschini; "Venus kissing Love by the Wings," from the same master, all of quarto size; "Offering to Ceres," after P. Corroni, in folio; "The Crown of Heretics," after the same painter, in folio; "The Three Graces," one of whom plays the lyre, while the other two are singing, after P. Cortona, of quarto size; and "Eneas descending to Hades," after Solimena, in small folio.

Giuseppe Zucchi, the younger, was born in the same city A.D. 1752, and was probably related to the former, as mentioned in our article. He came to London in quest of professional employment as an engraver; and here he became acquainted with Angelica Kaufman, with whom he travelled to Rome, and afterwards married. The engravings that we know of, by

this art, were all executed at London, from which it appears, that after he had once ingratiated himself into the good graces of Angelica, he engraved no more.

The subjects of Zucchi's prints are as follow:—"The Muse Erato," after Angelica Kauffman, in folio; "The Muse Urania;" "The Symbol of Simplicity;" "Calypto invoking Heaven and Earth to witness her Affection for Ulysses," in large folio, from Ang. Kauffman; "The Judgment of Hercules," from P. Cortona; "An Offering to Ceres," both in large folio; "Eneas and Dido taking refuge in the Grotto," after Guido; "The Virgin with the Holy Infant in the Clouds, surrounded by Angels," from the same master, in folio; "The Virgin and Child with St. John, between two Saints," Bartolomeo pinx.; "The Denial of St. Peter," from Guercino; "Jupiter and Europa accompanied by Nymphs;" and "Jupiter and Europa on the Waves of the Ocean, accompanied by Cupids," all of folio dimensions.

Giovanni (or John) Volpato, was born at Bassano, in the Venetian territory, in the year 1738, and in his early youth practised embroidery, which he learned of his mother, but afterwards applied himself to the study of engraving, which he followed for some time without any master, urged by the force of his own inclination, or attracted by such beauties of the art, as he saw in the print shops of Bassano.

He made a journey to Venice for the sake of obtaining information on what had now become the settled subject of his studies. Here, for some reason that has not transpired, perhaps from youthful affectation, perhaps from diffidence, he published his first plates under the assumed name of John Renard, and here he was first made known to the celebrated and benevolent Bartolozzi, who interrelated himself in the welfare of the young artist, and imparted to him the information of which he came in quest.

Volpato now felt more confidence; no longer withheld his name from the public, and soon produced engravings after Amiconi and Piazzetta, which obtained him approbation and encouragement, and were followed by others after Maiotto, Zuccarelli, and Marco Ricci.

From Venice our engraver travelled to Rome, where his abilities soon established him as a reputable engraver, and where his largest and best works were performed. A society of amateurs, very fortunately for him, had about this time conceived the project of patronizing the first engravers of the country, in the production of a set of large plates after Raphael's pictures in the Vatican; and among those who were engaged, none distinguished himself more by his industry, nor perhaps by his talents, than Volpato, who continued for many years to enrich the public with large plates, which have obtained him much praise from the critics and connoisseurs of the continent, and which are engraved after the very finest pictures that have been produced since the revival of art.

This was a noble race for an engraver to run, and his pupil and son-in-law Raphael Morghen is now following with superior brilliancy in the same course.

The works of Volpato have been the subject of eulogium with Roll, Huber, and some other of the German, French, and Italian writers upon art, but, in the estimation of the present writer, are deficient in richness and variety, and are more the result of mechanical care and patient industry, than of taste and feeling. His lights especially, when compared with those of Gerard Audran, Giacomo Frey, Sir Robert Strange, or his countryman Schiavonetti, of whom we are about to speak, are either papery, or cold and metallic. There is no playfulness of pencil; no evidence of a mind

that glows and moves through its work with painter-like felicity, but the spectator is perpetually reminded of the rigid and undeviating course of the graving-tool; and though the chaste forms and pathos of Raphael will always give a certain value to the works of Volpato, and even afford some argument in favour of the dryness of his style, posterity will not place him in the very first rank of engravers.

Indeed, so dead was our art to the more exquisite susceptibilities of his art, or so eager for the obtention of profit, that (like those in our own country who have converted Macbeth into a burletta) he joined with Du Cros, and his little school of petty colourers, in a scheme for painting over with water colours, his smaller sets of engravings from the gallery of Caracci at the Farnese palace, and the Loggia and Stanzas of Raphael at the Vatican, besides some sets of prints on a larger scale, of views in Rome and its environs.

Now, in works of this kind, the addition of colour, especially if some of the pigments employed be opaque, (as is the case in the coloured prints of Volpato,) inevitably destroys the beauty of the engraving, which in its turn mars that of the colours. It is, therefore, a mode of mutual destruction in art, which is justly regretted by those who know, or who believe, that the art of engraving is capable of becoming, of itself and without extrinsic addition, an appropriate vehicle for rendering every perfection that painting has yet attained.

In England we are but emerging from the mistakes into which coloured works of this kind, aided by the cupidity of dealers, had plunged the national taste, and we therefore may at least stand excused, if we dwell upon the misfortune to art that must ensue when a distinguished professor joins his efforts with those of the mistaken sons of commerce, to break down the natural barriers between one art and another, and obliterate the delicate lines of demarcation which the finger of science has traced upon the orb of the intellectual world.

"According to an ancient fable, which has an excellent moral, the blustering music of Pan did for a while seem successfully to silence the chaste harmony of Apollo; and as the senses of the vulgar, we know, are powerfully assailed by red, blue, and yellow, however "illy spread," it may yet be some time before the multitude are sufficiently informed, entirely to discard coloured engravings; but as even the tea-gardens have at length shut out coloured statues, we cannot despair. Though the gaudy bubble may float awhile in the dense atmosphere with which fashion has surrounded and chilled the sphere of British engraving, it will sooner or later burst; and though some few, perhaps more than a few, shallow and inaccurate observers may for a time be pleased to their cost, all mechanical modes of picture-making will eventually sink into contempt, and painting and engraving will triumph as distinct and separate arts.

"As we frequently hear the uninformed talk as if they conceived the highest effort of painting was merely to copy nature as nature appears to them, so it is very common to hear unreflecting people speak of engraving, as if it were no other than an art of copying that of painting; which, though a great mistake, is yet a very pardonable mistake on the part of those who have been led into it, when we consider the state in which the art of engraving has hitherto existed, and the difficulties, and the degradation, under which, in this country, it has hitherto laboured.

"Now engraving is no more an art of copying painting, than the English language is an art of copying Greek or Latin. Engraving is a distinct language of art; and though it may bear such resemblance to painting in the construction

ITALIAN SCHOOL OF ENGRAVING.

of its grammar, as grammars of languages bear to each other, yet its alphabet and idiom, or mode of expression, are totally different; if English be made the vehicle of the same thoughts which have previously been imparted to us by painting, it affords the means of affecting our minds in the same manner; this similar affection of the mind has led to the mistake, and little doubt may be entertained but that English would have been inconsiderately called an art of copying Greek, if we had never read any other English than translations from the Greek.

"The pretensions of engraving, as of all the arts denominated fine, are simple, chaste, un sophistication. Art ever disdains artifice, attempts no imposition, but honestly claims attention, as being what it is. A statue is to be looked at as being a statue, not a real figure; a picture, not as a portion of actual nature; a print, not as a copy of painting.

"Engravings, therefore, such as those of Volpato, are no more copies of Raphael's original pictures, than the same compositions, if sculptured, or modelled in low relief, would be copies. In both cases, they would be, not copies, but translations from one language of art into another language of art.

"But absurdity blossoms luxuriantly, when engrafted on an original stock of error; and this vulgar and erroneous notion, that an engraving is a copy of a painting, has been assiduously cultivated by the avarice or ignorance of the dealers in prints, who always follow and pamper the taste of the mob, be it ever so depraved, provided it be profitable. That grafts were green, and that soldiers' coats were red, was known to the most ignorant of the gaping multitude, and has given wings to credulity, and currency to empiricism. Neither is it of the smallest importance whether ignorance or the unprincipled love of gain have contributed most to the production of this effect, since the public taste in either case has equally suffered. It is error sufficient to call for admiration here, if the print-sellers, (possessing, or possessed by, this mistaken notion, and with the view of making the copy, in their own vulgar estimation, approach nearer to its original,) have caused colours to be literally and barbarously added to engraving: for to colour a legitimate engraving is not less palpably absurd to an eye of tasteful discernment, than it would be to colour a diamond, which, as every one knows, would but obscure the native brilliancy and beauty of the stone. And if a good engraving must thus suffer by being coloured, so neither can bad ones be thus converted to good pictures: at the utmost, nothing better than a sort of mule production, (such as those by Volpato and Ducros, which have suggested the introduction of these remarks) can thus be generated, though with much more of the aid than the horse in its constitution." Landseer's Lectures.

Again, these observations acquire force in a compound ratio to the merits in point of colouring, of the pictures from which coloured plates may be engraven. For example, Fyt, Teniers, and Vandyke are among the number of those painters who are justly esteemed inimitable for the beauty and harmony of their colours, and dextrous management of their pencils. If children could be brought, even in the way of copying, to pencil and colour like Fyt, Teniers, and Vandyke, those masters would lose their high reputation, and this part of the painter's art would be in consequence depreciated, as to become of very little value. To pretend, therefore, to emulate the merits of a lively coloured and beautifully pencilled picture, so as to meet the eye, and merit a place in the cabinet, of a man of taste,—and to do this on prints, by the score or by the hundred,—is little less ridiculous than to talk of a machine for playing on the violin or organ, or of a mill for making verses.

We shall notice the works of this popular engraver, nearly in the order in which they were produced.

While at Venice, and under the tuition of Bartolozzi, he engraved

Portraits, of the doge Foscarini, and the procurator Pascale, of folio size, after Bartolozzi; a set of four from the Old Testament, in folio, from drawings by Bartolozzi, after the original pictures by Amiconi, of which the subjects are, 1. "The Finding of Moses;" 2. Laban searching for his Idols;" 3. "The Servitude of Abraham;" and 4. "Moses erecting an Altar to the Lord." Eight conversational subjects, in small folio, after Maiotti; "The Orgies, or Feast of Bacchus," an historical landscape, designed for Wagner, after Zuccarelli; "A Philosopher prostrate before an Altar, surrounded by Ruins," from the same master, both in large folio; an Italian landscape, with fishers; and another landscape, and peasants; all from Zuccarelli; and two landscapes after the elder Brand, all of large folio size.

Plates engraved at Rome.—"The Four Sibyls of the Church of St. Mary of Peace," after Raphael, in large folio; "The Marriage of Alexander and Roxana," from the same painter; "Modesty and Vanity," after L. de Vinci, in square folio; "Perseus delivering Andromeda," from P. de Caravaggio; "Our Saviour praying on the Mount of Olives," from Coreggio, in large folio; "Mary Magdalen washing the Feet of Our Saviour at the Table of Simon the Pharisee," after P. Veronec; "The Marriage of Cana," after Tintoret, both of large folio size; and "The Gamblers," after M. A. de Caravaggio, in folio; all of which were for Hamilton's collection.

The Pictures of the Vatican, by Raphael, engraved in the line manner, on a very large scale.—"The School of Athens;" "The Dispute on the Holy Sacrament, or "Theology;" "Heliodorus chased from the Temple of Jerusalem;" "The Progress of Attila accredited at the Appearance of St. Peter and St. Paul;" "St. Peter delivered from Prison;" "Mount Parnassus;" and "The Burning of the City of Rome." "The Miracle of the Mifs of Bolfenna," belonging to this set, is by Raphael Morghen, the son-in-law and pupil of Volpato.

Subjects from various Italian Painters, all very large.—"The Descent from the Cross," from a painting by Raphael, in the Borghefe palace; "The Holy Virgin," named "La Saggiola of Florence," from the same painter; "The Holy Virgin of St. Mark," after Fra. Bartolomeo; "The Marriage of the Virgin," from Guercino; "Lucy, or the Virgin of Pity;" and "Aurora," both from pictures by Guercino, in the Villa Ludovisi; "Day" and "Night," which form a set with the Aurora, by the same painter; "The Crucifixion," from a picture by Guido, in the church of St. Lorenzo, in Luena; "The Venus" of Paolo Veronefe, from the gallery of the Colonna palace; two subjects, with children, from Mola; a pair from the first navigator of G. Gufer, after F. Guadri; another pair after the same painter, taken from Gufer's Idyllia; two landscapes from Claude Lorraine, of which the originals were in the Colonna palace; a set of six, or rather three pairs, after Gavin Hamilton, of which the subjects are 1. "The Death of Lucretia;" 2. "Innocence," a plate of considerable merit and beauty; 3. "Juno;" 4. "Hebe;" 5. "Il Penseroso;" 6. "L'Allegro," and the two prophets and two sibyls, from Michael Angelo's pictures in the Sistine Chapel.

The following are of smaller Dimensions.—A set of thirty-six, in small folio, from the antique statues, with the dimensions, &c. an elementary work for students in the arts; a set from the Farnese gallery, consisting of three larger and three smaller

ITALIAN SCHOOL OF ENGRAVING.

smaller plates, coloured; a set of eight views at Tivoli, coloured by Ducros and his assistants; another set of twenty views in Rome and its vicinity, coloured in the same manner, both sets books; another of fourteen ditto; another set of forty, from the Museum Clementinum; another set, printed on four large sheets, from Raphael and Julio Romano.

It is much to the honour of modern Italy, that we have to cloze our catalogue of its school of engravers with the mention of two stars, than which no brighter have shone in the hemisphere of the art.

Luigi or Lewis Schiavonetti, was born at Bassano, in the Venetian territory, in the year 1765. His father was a stationer, whose moderate circumstances enabled him to give to his eight children, the eldest of whom was Lewis, a useful but limited education. From his infancy he had a taste for drawing, and while his companions were at play, he was often seen kneeling on a stool in his father's shop, copying prints. By these, and such other means as he possessed, he attained such proficiency, that Julius Golini, (an able painter, to whom some of these early attempts were shewn,) undertook to instruct him in the art of drawing.

At the age of thirteen, Lewis was placed under his care, and the high opinion which he had formed of the boy's genius, was confirmed by the rapid progress he made, while his amiable disposition endeared him to such, that Golini loved him as his own son. After three years, he weaver, of useful instruction on the one part, and docile attention on the other, his tutor, unfortunately for our young artist, was attacked by a mortal disease. Lewis attended him during his illness with filial assiduity, received with becoming reverence his dying counsel and admonitions, and had the heart-piercing grief to see his master expire in his arms.

Being now left to pursue his own course, or assisted only by such advice as could be obtained in a town where Golini had been the only painter, he turned his views towards count Remaundin, who, though enrolled by this title, is proprietor (as it should seem) of an extensive typographical and chalcographical concern, and has inscribed on marble how much he feels himself honoured by having published some of the works of Bartolozzi and Volpato.

The works of these distinguished artists gave fresh impulse to young Schiavonetti's ardour for improvement, and becoming acquainted at out this time with one Lorio, an indifferent engraver, who was barely competent to teach the mechanical proceeds of the art, he applied to him for instruction. Unable to support himself and family by his graver alone, Lorio officiated as sacristan to a church, and could offer our artist no better accommodation for a study than the sacristy afforded, but which, his circumstances not allowing him to apply elsewhere, he was obliged to accept.

Schiavonetti remained, with this master about twelve months, when finding he had exhausted his fund of instruction, and feeling an aversion to studying occasionally among dead bodies, he resolved to alter his situation. A copy which he had executed in the line manner, of a Holy Family, from Bartolozzi's print after Carlo Maratti, gained him employment from count Remaundin, and attracted the notice of another print-seller of Bassano, of the name of Santacchi; and between these rival print-sellers it is probable that Schiavonetti might have long continued to exist on such patronage as consisted with their views of profit, but for the kinder and more advantageous notice of some Venetian noblemen, and the occurrence of those circumstances which ended in his migration to England.

As these circumstances have been detailed in print, in such a manner as to designate a certain naturalized subject of these realms with the reproach of having taken mean and

selfish advantage of the yielding simplicity of Schiavonetti and the credulity of Bartolozzi, with the view of converting to his own use and profit the abilities of the former, and the hospitality of the latter; and as the accused party has publicly required time for the collection of such documents as might exculpate him from the charge, which documents he has not yet produced:—in such a state of evidence, it may be sufficient to say of our engraver, that, after enduring some further difficulties and disappointments, and after residing a while under the roof, and receiving the instruction, of Mr. Bartolozzi, he, in concert with his brother Nicholas, commenced an independent establishment.

From Bartolozzi's house at Northend, he removed to Sloane square, and from thence to Brompton, where he continued, to the hour of his death, to cultivate and improve the talent that Providence had bestowed on him, uncheered by the sunshine of patronage:—or cheered, or chilled, by such patronage only as consisted with the purlieu views of commercial speculators, and exposed to the thousand nameless wrongs,

“That patient merit from th' unworthy takes.”

Some time about the year 1792, he entered into a partnership with certain print-fellers, of which he had soon reason to repent; and, the partnership being dissolved, and himself in possession of some few engraved plates, he dismissed a younger brother to the continent on a print-selling mission, which also ended in disappointment: for, the wretched vacillation of Prussian politics, and the inroads of French ambition, soon swept away the younger Schiavonetti from Berlin, which had been fixed upon as the head-quarters of their commerce.

During the short interval of peace between this country and France, he availed himself of the opportunity of visiting Paris, with the twofold object in view,—of improving his natural talent, of which he never lost sight,—and, obtaining such free access to the gallery of the Louvre, which was then thrown open to the public and supposed to contain the finest pictures in Europe, as might enable him to gratify himself with the pleasure and advantage of selecting one or more subjects to engrave, suited to his own abilities. This is a gratification in which engravers of genius are but too rarely indulged. The difficulties and delicacies of sollicitation, the demands of commerce, and the purlieu state of English patronage, (which, with all its benevolence, and all its power, has not yet emancipated itself from the mistakes and the fetters of trade,) are bars which, in this country, none have been able to overlook: yet nothing is more manifestly obvious, than that other men can only judge of the talents of an engraver by what he *has done*, while the feelings of the engraver himself, if he has any, inform him, at the sight of a gallery of fine pictures, what latent gems of genius or talent he may possess, adequate to the task of translating such of them as are suited with a spirit congenial to his own; what elements in the intellectual chaos of his untried powers may be called into existence; how far, through his means, the boundaries of the art itself may be extended.

The shortness, however, of that lucid interval, marred, in some degree, the excellence of our artist's design, and compelled him to compromise with the madnes of Europe, and his own untoward fortune. One of the subjects which he fixed upon was the Madré D'Isrofa of Van Dyke; but the return of war left him no alternative but to endeavour to satisfy himself as well as he could with a copy by another hand. The copy did not turn out very correct; yet from this indifferent copy, aided by Bollwert's print from the
fane

ITALIAN SCHOOL OF ENGRAVING.

fame original, and his own strong recollections of Vandyke's picture, has Schiavonetti produced an engraving of very extraordinary merit, though on a much smaller scale than he had originally projected. What he intended to have engraved on an ample scale, for himself and the public at large, he was compelled by circumstances, which legislators and patrons would do well to attend to, to engrave small, and part with to the proprietors of the French national museum.

A very few years before his death, he formed an intention, which he communicated to his friends, of returning to Italy, or at least of removing to a more southerly climate; not that any serious apprehensions were then entertained on the score of his delicate health, but because he felt the weight of taxes, and the want of encouragement; and, perhaps,—observing how well the quackeries of nonchuck pretension succeeded in this metropolis, and seeing how ill merit in his profession was rewarded,—he thought there was less of solid appreciation among us, than really existed. What delayed his departure, or altogether withheld him from going, the present writer can only conjecture; for he was shortly after disappointed of engraving a large plate from Mr. Devis's picture of "The Death of Lord Nelson,"—not because the fifteen hundred guineas, which he required for the performance of the task, was too much, — but because the sum which Mr. Bromley asked was too little. Perhaps he lingered here, and only delayed his departure on account of the continental war, and consequent difficulties of emigration; or, perhaps, he had rather literally to entertain a better opinion of the taste and appreciation of the British public than he had before conceived, and began to find himself less than he had been more an object of attention than his model had ill waded him to suspect.

That he did not go, is, on the whole, to be regretted, as the soft air and genial climate of Italy would probably have lengthened his life; and with length of life, his reputation would have increased, and the public at large have been proportionally benefited: for it has been justly said of his latter productions, that they were marked by a wonderful degree of improvement, and that, had his life been prolonged, the fruits of this improvement would probably have been multiplied in abundance. The circumstance of his premature death gives, therefore, fresh cause to lament that the patrimony and the acquisition of genius are undividable, and can never be bequeathed; and that talents, however rich, and however versatile, must inevitably perish with their possessor.

He died at his horse at Brompton, of a pulmonary complaint, which had for some time been gradually undermining his constitution, on the 14th day of June 1818, and was attended to his grave, in Paddington church-yard, by a long and numerous procession of artists and amateurs, who loved and honoured his merit as an artist, and his probity as a man.

In his person, Schiavonetti was rather tall; the fine proportion in the divisions of his figure gave him a graceful movement; his manners were gentle; in his address there was sweetness and affability; and persuasion hung on his lips. He was dignified without severity, and meek without indolence. His whole deportment was manly. His smile was modestly of character, equability of temper, and propensity to oblige, won the good will of all who saw and conversed with him. In company with his brother artists, he seemed unconscious of his own superiority: though invited to walk with the ladies, he exacted no distinction of notice, but kept himself on a level with the lowest; and by the deference with which he spoke his opinions, raised every one else at ease in his society. This urbanity of manners, is but too commonly an extrinsic accomplishment;

but in him it was the unaffected expression of innate goodness of heart, and liberality of mind. It was not the vanity of a coarse matter, but the polish of a fine one. Many acts of his private life might be adduced in support of what is here said in his praise:—one may be selected that exhibits a trait illustrative of his whole character. As soon as he began to derive profit from his profession, he devoted a portion of it to the support of his poorer relatives in Italy; and of late years he constantly remitted to his aged parent a stipend sufficient to ensure him comfort and respectability.

The same energy and elegant simplicity, which was observable in the personal character of our artist, predominated also in his engravings. He possessed, in very high perfection, that first requisite both in painting and engraving, freedom blended with accuracy of delineation. This power, united to the grace and dignity which characterized his style, enabled him to treat every subject on which he exercised his talents, with a truth, distinctness, and propriety of expression, rarely to be found in the works of other artists. By a varied choice of models, and a bold and independent habit of thinking, in particular, by fixing his attention strongly on the merits of the best works of our countrymen Strange and Sharp, he enfranchised his mind from the dogmas of school discipline, (which is said without any particular reference to his early tutors,) and stood forth an original, and not a self-taught, a self-formed engraver. In the works of common artists, we see only the labour of the hand; but in his, the hand is manifestly directed and controlled by the mind. What is their ultimatum, was only his instrument: he handed it with perfect command; he thought over it with nice determination; and as figurative of the world of art, as well as in the physical world, of genies corruption, and as *maner* is the exception of *gen*, Schiavonetti has entitled himself to all the praise that Mr. Cromek (from whose memoir of this artist our account is partly extracted) has bestowed on him, for the dignified ease with which he kept far aloof from that mechanical sameness on all occasions, which we denote by this term, and for always preferring that superintending mental delicacy, that store of knowledge, and that fine state of nerves, which enabled him to vary and adapt the language of his art to the peculiar beauties and merits of the various originals, which from time to time he had to transcribe. Scarcely of his life's informed critics have praised the *beauty* of his manual execution. It is beautiful; but to say so, is like praising the personal beauty of Lucretia. Dazzled by the sun-beams which glitter on its surface, they fathom not the depth, and know not the navigable benefits, of the current. But perhaps posterity will but gradually learn to appreciate his merits as they deserve.

That his powers were not less versatile than vigorous, may be seen by comparing his etchings with his chalk engravings, and both with his exquisitely finished plates in lines; of which latter, owing to the bad taste that has hitherto prevailed since his arrival in this country, the number is unfortunately small.

His principal engravings in the *Chalk manner*, are, two, of "The Five Senses," which, with the frontispiece, form a set of six plates, in small folio, all from his own designs; — "The Messiah holding Thunder," after R. Westall, R. S. for Byrdell's edition of Milton, large 4to.; — "The Bed of Tippoo Sultan" engraved by his Family, after the Captains of Seringapatam, from R. K. P. after, in large folio; a set of the Cruels of London, in large 4to.; three, of a set of the Beauties, after R. Westall; — "Lark, seated on a Moor," after Sir Joshua Reynolds; a set of four folio plates, from the design of Benardet, of "The Suburbs of Louis XVI. during his Cap-

twity in the Temple;" "Queen Elizabeth receiving News of the Death of Queen Mary of Scotland," after R. Weftal; "The red Slipper," from the same painter; two folio plates for *Boydell's Shakspeare*, of which, one in particular, "The two Gentlemen of Verona," after *Angelica Kauffman*, is a very capital print. The name and talents of *Schiavonetti* were but little known when he undertook this plate, and he engaged to engrave it for the low price of two hundred and eighty guineas. It is to the credit of the late Mr. *Boydell*, that he voluntarily increased this sum to three hundred. The portraits of *Albert Rubens*, after *Rubens*, in folio; the queen of Prussia, after *Tischbein*; and the duke of York, after *J. Bogle*, both in folio; Mrs. *Damer*, after *Cofway*, in 4to.; and the right honourable *W. Pitt*, and lady *Cawdor*, in small folio, after *Eldridge*.

But far beyond these in merit and importance, is a large folio print of "The Landing of the British Troops under Gen. *Abercrombie*, in Egypt," after *de Loutherville*, in which the fire, freedom, and vigorous chiaro-scuro of that master are most happily rendered, and for the production of which, the society in the *Adelphi* for the Encouragement of Arts, &c. did themselves the honour of presenting the engraver with a medal. By a judicious admixture of stippled hatchings, in imitation of chalk drawing when performed by the hand of a master, *Schiavonetti* has here revived with superior brilliancy and effect, the real chalk manner of engraving, which we call thus in contradistinction to *Ryland's* art of imitating stippled drawings, or what the French aptly term "en maniere de crayon noir," and has even enlarged the former boundaries of this mode of art. On the whole, this is probably the most perfect chalk-engraving that has yet been executed, and of itself, would be a monument of reputation in this branch of the art.

The chief of his etchings are, a set of twelve, in small folio, from drawings by *W. Blake*, of which the subjects are taken from *Blair's* poem of the Grave. These are works of great merit, and (as we venture to pronounce) of lasting reputation; and though it be too true, that, in the words of this poet

"The best concerted schemes men lay for fame
Die fast away; only themselves die faster;"

they yet prove, in opposition to his leading sentiment, that it is not

"Aburd to think to over-reach the grave,
And from the wreck of names to rescue our's."

Faithfully adhering to the character of art that is implied by the term *etching*, *Schiavonetti* is here slight and sketchy, and has produced his effects chiefly by the operation of aquafortis, with his usual fine feeling, and a congenial unstudied simplicity of style. The eye of discernment immediately sees that the same high finishing which he bestowed on his plates after *Vandyke*, was never intended, and that what was intended is precisely accomplished.

Of this series of meritorious etchings, which were printed with *Blair's* poem and an able preface by the professor *Fuseli*, and published by Mr. *Cronek*, the subjects are 1. The Descent of *Christ* into the Grave; 2. The Descent of *Man* into the Vale of *Death*; 3. *Death's* Door; 4. The strong and wicked *Man* dying; 5. The good old *Man* dying; 6. The *Soul* hovering over the *Body*; 7. The *Soul* exploring the *Recesses* of the *Grave*; 8. *The Counsellor*, *King*, *Warrior*, *Mother*, and *Child* in the *Tomb*; 9. The *Skeleton* re-animated; 10. The *Re-union* of *Soul* and *Body*; 11. A family *Meeting* in *Heaven*; and 12. *The Last Judgment*. These are preceded by a portrait of Mr. *W. Blake*,

the poetic designer of the work, after *T. Phillips*, *R. A.* in which our engraver has manifested great judgment and taste. It is also an etching, treated in the vignette style, with small assistance from the graver and dry-point, where a certain degree of mellowness or blending were wanted, and the whole brought to a focus in the animated and thinking countenance which is the proper subject of the print. Two etchings after *Caracci*, in folio, were afterward finished in aquatinta, for Mr. *Chamberlayne's* work from the *Royal* collection; two unpublished large folio plates of "The *Departure*, and the *Return*, of the *Savoyard* *Musicians*," slight, but performed with singular felicity.

Finished Engravings.—"The *Madre Dolorosa*," or dead *Christ* on the *Lap* of his *Mother*, after *Vandyke*, which he engraved in small folio, for the *French* publication, after their national gallery at *Paris*, is of a distinct class and character, from the above; more elaborate, more difficult of accomplishment, and combining merits of a loftier and more exquisite kind.

Here the mellow and harmonious mixture of etching, with the work of the graver and dry needle; the various combinations, by means of these instruments, of clear, broken, contrasted, and partially obscured, lines and stippling, by which he has expressed in their respective degrees of subordination to the purpose of the painter, rock, sky, hair, white and coloured draperies, and, above all, the anatomical markings, carnation tints, and fleshy texture, of the exquisitely finished naked figure of *Jesus Christ*, are truly admirable! and if not unparalleled, have certainly not been surpassed. Nor are the extremities of every figure in the composition rendered with less of taste, knowledge, or skill. *Bolswert* had engraved a larger print of this subject from *Vandyke's* original picture, a print of great merit; and to a nice observer, it is interesting to compare the details of the two engravings, and see how sedulously, and with what delicacy of discernment, the *Italian* artill has avoided every error, and improved every beauty, of the *Fleming*.

It is exceedingly to be regretted that among the works of *Schiavonetti*, we find so few of this inimitable class, for no man more than he, has united the excellencies which must enter into the constitution of a highly finished engraving. Another of these highly finished engravings, which is also after *Vandyke*, and of large 4to. size, is a portrait of the painter himself, habited as a peasant, and the same general observations will apply to both, for both are admirable epitomes of the powers of *Vandyke*; of the latter it has been truly said, that "its excellencies will be found to consist in its being at the same time a complete epitome of the original picture and of the powers which an engraver of genius can display upon so confined a subject as a half length figure, without landscape, sky, or any other accompaniment of back ground. It is throughout quite as well drawn as *Vandyke's* original; the texture of flesh is as perfectly expressed, with all its varieties and inflexions of surface and chiaro-scuro; nor is the drapery less well fit and understood, nor scarcely less skillfully engraven, than the naked parts of the figure; all are sufficiently finished, but without petty trickery, or vain labour, and the eye sparkles with all the fire of *Vandyke's*."

These remarks are taken from "The *Review of Art*," (vol. i. p. 40.) which proceeds to state what is equally applicable to both these engravings after *Vandyke*, namely, that "in addition to all their other perfections, they powerfully suggest the idea of colour, mingling its magic blandishments with those of light and shade; and present the most perfect example we have yet seen on paper of the style of *Vandyke's* pencilling, and *Vandyke* is in this respect the

very perfection of style, or at least approximates the nearest to it of any painter whatever, except perhaps Fyt, who exercised his powers on subjects of quite a different kind."

Another 4to. plate, which our artist engraved after a very excellent picture by R. Smirke, R. A. as an accompaniment to Joel Barlow's Columbiad, and of which the subject is "The Triumph of the Holy Inquisition;" some plates which he engraved for Sharpe's British Classics, and two for an edition of Homer, after the academicians Fuseli and Howard, possess merits of a similar kind, though, on account of the smallness of the scale, they could not be so effectually displayed.

The remainder of his finished engravings in lines, are the hovel scene in King Lear, after Smirke; and two or three other plates for the smaller edition of Boydell's Shakspeare, which are among the very best in that motley and undigested work; and some small portraits, particularly one of Mr. W. Cunningham (an Irish gentleman, distinguished for his taste and patronage of the fine arts); another, of a writing master, well known and distinguished in his profession, and a bust of Homer, from the celebrated marble in the Townslean Collection, all of 8vo. dimensions.

His folio print, engraved in the fourth remove from Michael Angelo's celebrated Cartoon of Pifa, is of a middle character, laborate than his prints from the pictures of Vandyke, though somewhat more so, than his etchings after the poetical sketches of Mr. Blake: in short, a graphic translation of a Cartoon, or preparatory study for a high-finished picture.
