CYCLOPÆDIA:

OR, A NEW

UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

INCREMENTS.

INCREMENTS, METHOD OF, called by the French *Calcul des Differences Finies*, is a branch of analysis invented by the learned Dr. Brook Taylor, particularly useful in the summation of series, and applicable to several subjects of mathematical investigation, where scarcely any other method can be successfully employed. Montucla observes, that had the human mind always pursued the path which appears the most natural, the theory of increments, or of finite differences, would have preceded that of fluxions, or the differential calculus; as it seems more natural for the mind to be carried from the consideration of finite differences, to that of differences indefinitely small, than that the latter should be the precursor of the former. Such, however, was the fact; for the first distinct notions of the method of increments did not appear till the year 1715, in a work entitled "*Methodus Incrementorum*," &c. by Dr. Brook Taylor, in which both the direct and inverse method of increments are treated of in a very learned manner, and an application of the same to various interesting problems; but the novelty of the subject, and the concise mode of expression employed by its author, together with the very complicated notation, rendered the work nearly unintelligible to any man less skilled in analysis than the author himself; even the enunciation of some of the propositions requires the greatest possible attention in order to comprehend their meaning; but in other respects, the work bears strong and evident marks of the lofty genius of its author, and contains, in the second part, many very excellent applications of the preceding theory to the solution of some of the most interesting and celebrated mathematical problems. Such, however, being the intricacy of the original work, it necessarily follows that it could only be read by the very first rate ma-

thematicians; and it was therefore fortunate that any of them would condescend to illustrate a subject in which they could only act a secondary part; such a person was however found in M. Nichole, of the Royal Academy of Sciences, who, having very early been in possession of a copy of Dr. Taylor's work, and perceiving, at once, its general utility, he undertook the task of illustrating the principles upon which it rested; and, by simplifying the notation and operations, rendered it intelligible to readers of an inferior order: his first paper on the subject was published in the *Memoirs of the Academy* for 1717, which was afterwards followed by two others in 1723 and 1724. Dr. Taylor himself also, in the *Philosophical Transactions*, undertook an explanation of certain parts of his work, and its farther application to some kinds of series beyond those treated of in the original: the same was also done by M. Montmort, in the *Transactions* for the years 1719 and 1720; which latter gentleman, it seems, had conceived some idea of the theory before Dr. Taylor's work appeared; and a trifling altercation took place between them as to the originality of some of the notions which was claimed by both parties. In 1763, Emerson published his "*Method of Increments*;" a work which, at least, does this author as much credit as any that he ever produced; but the notation resembles, in a great measure, that of Dr. Taylor, which renders it now almost obsolete. Emerson appears to have been extremely anxious to bring the theory of increments to perfection; and earnestly urged those who were qualified for the task, to pursue the paths he had opened to them. "I cannot," says he, "promise that I shall have time and leisure hereafter to prosecute this subject any farther. And as I have an earnest desire of advancing truth and improving science, let me here

INCREMENTS.

entreat the friendly mathematicians, who are lovers of science, to lend their kind assistance for the advancement of this uncultivated branch of knowledge, yet in its infancy, or rather, as yet, in the hands of Lucina, either according to the model I have here laid before them, or some better if it can be found, so that, by degrees, it may at length be brought to perfection." Hence it appears that this author was, in 1763, sensible of the neglect that had been paid to the theory of increments; and even now, near half a century after this date, the subject has not been advanced, nay scarcely touched upon by any English mathematician; while foreign authors are filling quarto volumes with the theory of *différences finies*, and its almost universal application to the most curious and important of mathematical inquiries. Euler, whose universal genius led him to the investigation of every subject that was useful and interesting, did not leave the theory of increments untouched, but has treated of it, in his usual masterly style, in a work entitled "Institutiones Calculi Differentialis," &c. in which he has given a new form, and much extended the bounds of this important branch of analysis; and subsequent authors have adopted his ideas, and rendered permanent the form he gave it. Various other works have since appeared to illustrate and render familiar the principles of this doctrine; the most complete of which is the "Traité des Différences," &c. par Lacroix. Boullé has likewise a chapter on this subject in his "Traité des Calcul Différentiel," where the theory is treated in a very elementary and comprehensive manner; and the same is also done by Cousin, in chapter 3, of the introduction to his "Traité de Calcul Différentiel," &c.

Having thus given a brief sketch of the history and progress of the method of increments, we shall now endeavour to explain the principles and application of it: in order to which, that we may prepare the reader for the more general theory, it will be useful to consider the same in a more limited form in the first instance, in doing which we cannot have a better model than that of M. Nichole above-mentioned.

The method of this author is extremely simple, but certainly less general than that of Dr. Taylor; it is, however, well calculated for conveying the first clear and connected ideas of this theory, and prepares the reader for more general reflexions, by leading him on, from step to step, with order and precision.

If we consider x as any variable quantity, which is continually increased by a constant quantity n , so that it becomes successively $x, x+n, x+2n, &c.$; and if y be any function of x , made up of factors, as $y = x(x+n)(x+2n)(x+3n)$, then the difference between this value of y , and that which it becomes when x is again increased by n , is the increment of y , or of $x(x+n)(x+2n)(x+3n)$; which increment is readily obtained, by observing, that

$$\begin{aligned} & (x+n) - x \dots \dots \dots = n \\ & (x+n)(x+2n) - x(x+n) \dots \dots = 2n(x+n) \\ & (x+n)(x+2n)(x+3n) - x(x+n)(x+2n) - 3n \\ & \quad (x+n)(x+2n); \text{ and hence generally, the increment of } x(x+n)(x+2n) \dots (x+rn) = (r+1)n \\ & \quad (x+n)(x+2n) \dots (x+rn); \text{ And hence again conversely, the integral of } (r+1)n(x+n) \dots (x+2n) \\ & \quad (x+rn) = n(x+n)(x+2n) \dots (x+rn); \text{ or more generally, the integral of } x(x+n)(x+2n) \dots (x+rn) \\ & \quad = \frac{x \cdot n \cdot (x+n) \cdot (x+2n) \dots (x+rn)}{r+1} : \text{ Again,} \end{aligned}$$

the increment of x^m , the difference between x^m and $(x+n)^m$. Now $(x+n)^m - x^m = mx^{m-1}n + \frac{m(m-1)}{1 \cdot 2}$

$$x^{m-2}n^2 + \frac{m(m-1)(m-2)}{1 \cdot 2 \cdot 3} x^{m-3}n^3 + \&c. ; \text{ and}$$

by means of this general expression, for the increment of x^m , we readily deduce the increment of any function of x , as $ax^m + a'x^n + b'x + \&c.$ Thus, for example, if it were required to find the increment of $x^3 + 3x^2 + 4x$, we have increment of $x^3 = 3x^2n + 3xn^2 + n^3$
 of $3x^2 = 6xn + 3n^2$
 of $4x = 4n$

$$\text{Hence the increment of } x^3 + 3x^2 + 4x = 3x^2n + x(3n^2 + 6n) + n^3 + 3n^2 + 4n.$$

It is therefore not necessary, when we proceed thus, that the proposed function should be made up of factors in arithmetical progression, as in the former rule.

Again, the increment $\frac{1}{x}$ is the difference between $\frac{1}{x}$ and

$$\frac{1}{x+n} = -\frac{n}{x(x+n)}; \text{ and in the same way we find the}$$

$$\text{increment of } \frac{1}{x(x+n)} = -\frac{2n}{x(x+n)(x+2n)}; \text{ of}$$

$$\frac{1}{x(x+n)(x+2n)} = \frac{-3n}{x(x+n)(x+2n)(x+3n)};$$

and generally the increment of

$$\frac{1}{x(x+n)(x+2n) \dots (x+rn)} = -\frac{(r+1)n}{x(x+n)(x+2n) \dots (x+r+1n)}.$$

And hence, again, conversely, the integral of

$$\frac{-1}{x(x+n)(x+2n) \dots (x+r+1n)}$$

$$= + \frac{1}{x(x+n)(x+2n) \dots (x+rn)}.$$

Or, more generally, the integral of

$$\frac{1}{x(x+n)(x+2n) \dots (x+rn)}$$

$$= - \frac{1}{x(x+n)(x+2n) \dots (x+r-1n)}.$$

This, as was before observed, is not the most general mode of considering the subject, but we are much mistaken if it be not the most obvious and natural; and therefore the best adapted for illustration, and for conveying to a beginner the first ideas of the theory. We will now shew the application of the above principles to an example or two, by way of elucidation, and then proceed to a more general and extended investigation of the method of increments, and its application to mathematical problems.

Ex. 1.—Let it be proposed to find the sum of 100 terms of the series

$$1 \cdot 2 + 2 \cdot 3 + 3 \cdot 4 + 4 \cdot 5 \dots 100 \cdot 101.$$

Each of these terms is of the form $x(x+1)$, and it is obvious that the next term to $100 \cdot 101$, that is $101 \cdot 102$, is the increment of the series; or, making $100 = x$, the last term is $x(x+1)$, and the succeeding one is $(x+1)(x+2)$; which is evidently the increment of the series, or the difference between the proposed series in the first case, and what it becomes when x is increased by the common difference 1; and therefore conversely, the integral of this increment, that is, of $(x+1)(x+2)$, will be the sum of

INCREMENTS.

the series fought. Now the integral of $(x + 1)(x + 2)$ is $\frac{x(x+1)(x+2)}{3}$; and since x in the present example = 100, we have $\frac{100 \times 101 \times 102}{3} = 343400$ for the sum required.

Ex. 2.—Required the sum of n terms of the series $1 \cdot 2 \cdot 3 + 2 \cdot 3 \cdot 4 + 3 \cdot 4 \cdot 5 + \&c. n(n+1)(n+2)$.

Here, by writing x instead of $n+1$, we shall have for the succeeding term $x(x+1)(x+2)$, which is the increment of the series, and therefore the integral of

$x(x+1)(x+2) = \frac{(x-1)x(x+1)(x+2)}{4}$ will be the sum required; which, by re-establishing the value of $x = n+1$, becomes $\frac{n(n+1)(n+2)(n+3)}{4} =$ the sum of n terms.

Ex. 3.—Required the sum of n terms of the natural series of squares $1^2 + 2^2 + 3^2 + 4^2 + \dots + n^2$.

Here writing x for n , the succeeding term is $(x+1)^2 = x^2 + 2x + 1 = x(x+1) + (x+1)$, which is the increment; and it consists of two parts. Now the

integral of $x(x+1) = \frac{(x+1)x(x+1)}{3}$;

integral of $x+1 = \frac{x(x+1)}{2}$.

And therefore since $x = n$, we have $\frac{n(n+1)}{2} + \frac{(n-1)n(n+1)}{3} =$ the sum required.

Ex.—Let it now be proposed to find the sum of the infinite series $\frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \&c.$

Here it will be necessary for us to consider the series as generated from the extreme term, which is 0, and therefore $\frac{1}{1 \cdot 2}$ as its last term, which will therefore be the increment

of the series $\frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \&c.$; and, consequently, the integral of this will be the sum of the series, wanting only the term $\frac{1}{1 \cdot 2}$. Make, therefore, $x = 2$, or

$\frac{1}{2 \cdot 3} = \frac{1}{x(x+1)}$; in which case the increment $\frac{1}{1 \cdot 2}$ becomes $\frac{1}{(x-1)x}$, and the integral of this = $\frac{1}{x}$ (because the increment is -1); therefore the sum of the series, beginning at the term $\frac{1}{2 \cdot 3}$ is $\frac{1}{2}$, to which adding the first term $\frac{1}{1 \cdot 2} = \frac{1}{2}$, we have the sum of the whole series = 1.

This will serve to explain the method pursued by M. Nicole in his first paper, and will be useful as an introduction to what follows: in which we shall not limit ourselves to considering the continual increase of x as constant as is done above; but as being variable like x itself; for it is under

this form, that the theory of increments becomes so universally applicable to almost every species of mathematical investigation.

Notation and Definitions.

1. As the increment of a variable quantity x is nothing more than the difference between that quantity in its first state, and what it becomes after a certain increase, this difference may be properly represented by Dx , or Δx ; and in the same manner, if y be any function of a variable quantity, Dy , or Δy , will represent the increment of y . And as in the fluxional or differential calculus, f is made the character of integration, so in the present instance, we shall employ it to represent the integral of any increment.

2. The increment of a variable quantity being, as we have observed above, only the excess of this quantity in one state, over the same quantity in the consecutive state, it follows that if a variable magnitude x become successively $x, x', x'', x''', \&c.$ we shall have $\Delta x = x' - x$; $\Delta x' = x'' - x'$; $\Delta x'' = x''' - x''$; $\Delta x''' = x^{(4)} - x'''$; $\&c.$

It may happen that an increment may be positive, or negative, according as the variable quantity of which it is the increment is augmented or diminished, with regard to some other magnitude or magnitudes which we suppose to increase, and of which the increments are therefore necessarily positive.

3. The increments of quantities being themselves quantities, if they be variable, we may take the increments of them, they are called *second increments*; and if these second increments be also variable, we may in like manner take the increments of these also; which are called *third increments*, and so on as long as the differences or increments are variable.

In all these cases, the condition of the increments being variable, is necessary; because if, in any case, they become constant, then it is obvious that the increments are 0, whether it be the first, second, third, &c. increment that thus become constant or invariable.

Thus the series of squares 1, 4, 9, 16, 25, &c. is an example of a case in which the second differences or increments are constant: for this series may be considered as generated by a variable quantity x ; which is such, that if the difference between the successive terms be taken, they will form a series of quantities in arithmetical progression, and consequently the differences of these differences, or the second increment of x^2 will be constant. In the same manner we find the third differences of the series of cubes, 1, 8, 27, 64, 125, or the third increment of x , is constant; and therefore the fourth increment = 0; for after any order of increments becomes constant, all the ulterior orders must, necessarily, become zero.

4. As Δx denotes the first increment of any variable quantity x ; so $\Delta^2 x, \Delta^3 x, \Delta^4 x, \&c.$ will represent the second, third, fourth, &c. increments of the same quantity x ; which expressions are sufficiently distinct from $\Delta x, \Delta^2 x, \Delta^3 x, \&c.$ which represent the powers of those increments; and if it be required to express the power of any increment past the first, as for instance the n th power of the second, third, &c. increment of x , that will be done thus, $\Delta^n \Delta x, \Delta^n \Delta^2 x, \&c.$

5. In some problems it is necessary to consider a certain order of the increments as constant; thus, in any arithmetical progression the first increments are constant. In the series of natural squares, the second increments are necessarily constant; as are also the third increments of cubes, &c. as we have seen above. But there is an in-

INCREMENTS.

finite number of questions, in which, from their nature, it is not necessary that any order of their increments should be constant: yet as we may attribute to a certain quantity whatever variation we please, providing that the variations of the other quantities depending upon the first be such as to accord with the variation we have attributed to it; it follows, that in any problem, we may at pleasure make any order of increments of a quantity chosen at will be constant; observing only, that the other quantities ought to vary in consequence; and, therefore, we cannot make another order of increments also constant, unless, from the nature of the problem, some other increment has a certain ratio to that which is so assumed.

6. The whole of the method of increments consists of two problems; viz. 1st. Finding the increments of all orders of any variable quantity, raised to any power; the product of different variable quantities; and generally of any function of variable quantities; which problem is always solvable, and presents but little difficulty in any case; and this is called the *Direct Method of Increments*. The other problem, which is the reverse of the preceding, is that of finding the integral of any given increment, which is frequently insolvable; at least, without infinite series, or some other mode of approximation; and this is termed the *Inverse Method of Increments*: which two problems we will consider under their distinct heads.

Of the Direct Method of Increments.

7. Since the increment of a variable quantity is the difference between the sums in any two consecutive states, it is obvious in general, that in order to find the increment of any function of variable quantities, we must suppose, that each of those quantities is increased or diminished by their respective increments; and substitute these quantities, thus changed, into the proposed function; and from this result, if there be subtracted the original expression, the remainder will be the increment sought.

Ex. 1.—Find the first increment of the sum $x + y + z$. These quantities, augmented by their respective increments, become

$$(x + \Delta x) + (y + \Delta y) + (z + \Delta z)$$

from which subtracting the original expression, there remains $\Delta x + \Delta y + \Delta z$, as is evident; since the whole increment must necessarily be equal to the sum of each particular one.

In the same manner we find the increment of $x + y - z$, or $\Delta(x + y - z) = \Delta x + \Delta y - \Delta z$.

And if we had to find the increment of $a + x + y - z$, we should have, considering a as a constant quantity,

$$\Delta(a + x + y - z) = \Delta x + \Delta y - \Delta z,$$

the same result as before, because the constant quantity a has no increment, or its increment is equal to zero.

Hence it appears, that if to the sum of any variable quantity we add or subtract any constant quantity whatever, the increment of the whole function will still be the same.

Ex. 2. Find the first increment of x^n .

This is, from what is observed above, the difference between $(x + \Delta x)^n$ and x^n ; which by the binomial theorem becomes $m x^{m-1} \Delta x + \frac{m(m-1)}{1 \cdot 2} x^{m-2} \Delta x^2 +$

$\frac{m(m-1)(m-2)}{1 \cdot 2 \cdot 3} x^{m-3} \Delta x^3 + \&c. \Delta x^m$. Thus we find

the increment of x^2 , or

$$\Delta(x^2) = 2x \Delta x + \Delta x^2$$

$$\Delta(x^3) = 3x^2 \Delta x + 3x \Delta x^2 + \Delta x^3$$

$$\Delta(x^4) = 4x^3 \Delta x + 6x^2 \Delta x^2 + 4x \Delta x^3 + \Delta x^4$$

&c. &c.

And if the proposed quantity, of which the increment is required, be ax^m , a being a constant multiplier, then it is obvious that

$$\Delta(ax^m) = \begin{cases} a(x + \Delta x)^m - ax^m = \\ a(x + \Delta x)^m - a(x^m) = \\ a[(x + \Delta x)^m - x^m] = a \Delta(x^m) \end{cases}$$

whence the increment $a \Delta x^m$ is equal to a times, the increment of x^m .

Ex. 3. To find the first increment of the product xy .

$$\begin{aligned} \text{Here } xy \text{ becomes } x + \Delta x \\ \text{and } y \text{ becomes } y + \Delta y \end{aligned}$$

whence the product $= xy + y \Delta x + x \Delta y + \Delta x \Delta y$; from which, subtracting the original quantity xy , we have $\Delta(xy) = y \Delta x + x \Delta y + \Delta x \Delta y$.

And in the same way we find

$$\Delta(xyz) = \{ yz \Delta x + xz \Delta y + xy \Delta z + x \Delta y \Delta z + y \Delta x \Delta z + z \Delta x \Delta y + \Delta x \Delta y \Delta z.$$

And in like manner may the increment of any other product be readily ascertained.

If the product was axy , $axyz$, &c., a being a constant quantity, we should have

$$\Delta(axy) = a \Delta(xy), \Delta(axyz) = a \Delta(xyz), \&c.$$

that is, we must find the increment as above, and multiply the result by the constant factor a .

Ex. 4.—To find the first increment of any quantity of the form $x(x+a)(x+2a)(x+3a)\dots(x+ra)$. It is obvious that this may be referred to the preceding example, by making $x+a = u$; $x+2a = y$; $x+3a = z$; &c. under which substitution, the function, of which the increment is required, reduces to $xuyz$, &c. and, consequently, $\Delta(xuyz)$ may be found as above. But if, without this substitution, we find the actual product, it is obvious that it will take the following form (where $A, B, C, D, \&c.$ represent constant quantities); viz.

$$x^r + Ax^{r-1} + Bx^{r-2} + Cx^{r-3} + Dx^{r-4} + \&c.$$

and hence by finding the increments of each of those terms by example 2, the sum of them will be the increment of the function proposed. Thus,

$$\Delta(x(x+a)) = \Delta(x^2 + ax).$$

$$\text{Now } \Delta(x^2) = 2x \Delta x + \Delta x^2;$$

$$\Delta(ax) = a \Delta(x) = a \Delta x;$$

whence $\Delta(x(x+a)) = (2x+a) \Delta x + \Delta x^2$.

And in the same manner

$$\Delta(x(x+a)(x+2a)) = \Delta(x^3 + 3ax^2 + 2a^2x).$$

$$\text{Now } \Delta(x^3) = 3x^2 \Delta x + 3x \Delta x^2 + \Delta x^3$$

$$\Delta(3ax^2) = 6ax \Delta x + 3a \Delta x^2$$

$$\Delta(2a^2x) = 2a^2 \Delta x.$$

The sum of which particular increments will be the increment of the original function proposed: and in exactly the same way, the increment of any similar function may be ascertained.

Ex. 5.—To find the first increment of the fraction $\frac{x}{y}$.

Here

INCREMENTS.

Here we have

$$\Delta \left(\frac{x}{y} \right) = \frac{\left\{ \frac{x + \Delta x}{y + \Delta y} - \frac{x}{y} \right\}}{(y + \Delta y - x \Delta y) (y + y \Delta y)^{-1}} = \frac{y \Delta x - x \Delta y}{y^2 + y \Delta y}$$

And therefore from the expansion of $(y + y \Delta y)^{-1}$ into a series, we have

$$\Delta \left(\frac{x}{y} \right) = \frac{(y \Delta x - x \Delta y)}{y^2} \times \left(1 - \frac{\Delta y}{y} + \frac{\Delta y^2}{y^2} + \frac{\Delta y^3}{y^3} + \&c. \right)$$

And if the proposed fraction be effected with any constant factor a , the whole of the above increment must be multiplied by a .

Ex. 6.—To find the first increment of the quantity $\sqrt[3]{(a^2 + x)}$.

Here it is obvious, on the same principles, that

$$\Delta \left(\sqrt[3]{(a^2 + x)} \right) = \sqrt[3]{(a^2 + (x + \Delta x))} - \sqrt[3]{(a^2 + x)}$$

$$\approx \left(\sqrt[3]{(a^2 + x)} + \frac{2x \Delta x + \Delta x^2}{3(a^2 + x)^{2/3}} \right) - \sqrt[3]{(a^2 + x)}$$

And if now we consider these two expressions as two binomials, to be raised to the power $\frac{1}{3}$, it is obvious that from the development of the first, there will be cancelled the first term, and the other terms will represent the increment required; and thus we have

$$\Delta \sqrt[3]{(a^2 + x)} = \frac{2x \Delta x + \Delta x^2}{3(a^2 + x)^{2/3}} - \frac{(2x \Delta x + \Delta x^2)^2}{8(a^2 + x)^{5/3}}$$

$$+ \frac{(2x \Delta x + \Delta x^2)^3}{16(a^2 + x)^2} - \&c.$$

Ex. 7.—Having given the equation $y^2 - ax + x^2 = 0$ which expresses the relation between the constant quantity a , and the two variable quantities x and y ; to find the equation which ought to express the relation between a , and the first increments of x and y .

Here we must substitute $x + \Delta x$ for x ; and $y + \Delta y$ for y ; which gives

$$(y + \Delta y)^2 - a(x + \Delta x) + (x + \Delta x)^2 = 0;$$

from which, subtracting the original equation, there remains

$$2y \Delta y - a \Delta x + 2x \Delta x + \Delta x^2 + \Delta y^2 = 0,$$

which is the equation required.

And in a similar manner the first increments of any quantities whatever may be ascertained, as also of any algebraical equation.

When it is required to find the second, third, &c. increments of any proposed function, it is only necessary to consider the preceding order of increments as variable quantities; and we shall thus pass from the first increments to the second, from the second to the third, from the third to the fourth, &c.; in the same manner as we pass from the original function to the first increment.

Ex. 1.—To find the second increment of x^2 .

Here we have, in the first place,

$$\Delta(x^2) = 2x \Delta x + \Delta x^2 \text{ the first increment.}$$

And if now, in this expression, we substitute $x + \Delta x$ for x , and $\Delta x + \Delta^2 x$ for Δx , we have

$$\Delta^2(x^2) = \Delta(2(x + \Delta x) + \Delta x^2) = 2(x + \Delta x)$$

$$+ \Delta(2 \Delta x + \Delta^2 x) + (\Delta x + \Delta^2 x)^2 - (2x \Delta x + \Delta x^2)$$

$$= 2 \Delta x^2 + 4 \Delta x \Delta^2 x + 2x \Delta^2 x + \Delta^3 x^2,$$

which is the second increment required.

And in the same way we find the third, fourth, &c. increments of a quantity or function, by substituting $\Delta^2 x + \Delta^3 x$ instead of $\Delta^2 x$; and $\Delta^3 x + \Delta^4 x$ instead of $\Delta^3 x$; and so on.

Remark.—If we consider the second increments as being constant, it adds very much to the simplicity of the operation; for, after having found the first increments, viz.

$$\Delta(x^2) = 2x \Delta x + \Delta x^2,$$

$$\Delta(x^3) = 3x^2 \Delta x + 3x \Delta x^2 + \Delta x^3,$$

$$\Delta(x^4) = 4x^3 \Delta x + 6x^2 \Delta x^2 + 4x \Delta x^3 + \Delta x^4,$$

&c. &c. &c.

we shall have for the higher order of increments,

$$\Delta^2(x^2) = 2 \Delta x^2, \Delta^2(x^3) = 0, \Delta^2(x^4) = 0, \&c.$$

$$\Delta^3(x^2) = 0, \Delta^3(x^3) = 6x \Delta x^2 + 6 \Delta x^3, \Delta^3(x^4) = 6 \Delta x^4,$$

$$\Delta^4(x^2) = 0, \Delta^4(x^3) = 0, \&c.$$

$$\Delta^4(x^4) = 12x^2 \Delta x^2 + 24x \Delta x^3 + 14 \Delta x^4,$$

$$\Delta^5(x^2) = 0, \Delta^5(x^3) = 36 \Delta x^3, \Delta^5(x^4) = 24 \Delta x^4,$$

$$\Delta^6(x^2) = 0, \Delta^6(x^3) = 0, \&c.$$

&c. &c. &c.

Scholium.—It is easy to find, on the same principles, the second increments of all sorts of functions. For example, to find the second increment of the product xy , without supposing any increment as constant, we must first find the first increment, which is,

$$\Delta(xy) = y \Delta x + x \Delta y + \Delta x \Delta y.$$

And substituting now in this expression,

$$x + \Delta x \text{ for } x, \text{ and } y + \Delta y \text{ for } y;$$

$$\Delta x + \Delta^2 x \text{ for } \Delta x, \text{ and } \Delta y + \Delta^2 y \text{ for } \Delta y,$$

it becomes

$$(y + \Delta y)(\Delta x + \Delta^2 x) + (x + \Delta x)$$

$$(\Delta y + \Delta^2 y) + (\Delta x + \Delta^2 x)(\Delta y + \Delta^2 y);$$

from which, subtracting the first increment, there remains

$$\Delta^2(xy) = y \Delta^2 x + x \Delta^2 y + 2 \Delta x \Delta y$$

$$+ 2 \Delta y \Delta^2 x + 2 \Delta x \Delta^2 y + \Delta^2 x \Delta^2 y.$$

And if we suppose Δx constant, this expression reduces to

$$\Delta^2(xy) = x \Delta^2 y + 2 \Delta x \Delta y + 2 \Delta x \Delta^2 y.$$

And similar methods apply in all cases; it will, therefore, be unnecessary to give any farther examples, except in the case of an exponential expression, which is somewhat different.

Let it be proposed, for example, to find the increment of the hyperbolic logarithm of x .

Let $y = b.l.x$; then, as x becomes $x + \Delta x$; so will y become $y + \Delta y$, that is,

$$y + \Delta y = bl(x + \Delta x);$$

and hence, since $y = b.l.x$, we have

$$y + \Delta y - y = b.l(x + \Delta x) - b.l.x, \text{ or}$$

$$\Delta y = bl(x + \Delta x) - bl.x = bl \left(1 + \frac{\Delta x}{x} \right).$$

Now, by the well-known logarithmic series, we have

$$b.l \left(1 + \frac{\Delta x}{x} \right) = \frac{\Delta x}{x} - \frac{\Delta x^2}{2x^2} + \frac{\Delta x^3}{3x^3} - \frac{\Delta x^4}{4x^4} + \&c.$$

$$\text{whence } \Delta y = \Delta(bl.x) = \frac{\Delta x}{x} - \frac{\Delta x^2}{2x^2} + \frac{\Delta x^3}{3x^3} - \frac{\Delta x^4}{4x^4}$$

+ &c. as required. And the higher order of increments of $b.l.x$ will be found as above, by taking the increments of the terms of this series.

Ex. 2.—Required the first increment of the exponential expression a^x .

Make $y = a^x$; then, when x becomes $x + \Delta x$, y will become $y + \Delta y$; whence

$$y + \Delta y = a^{x + \Delta x} = a^x \times a^{\Delta x}; \text{ but}$$

$$y = a^x = a^x;$$

$$\text{whence } \Delta y = a^x \times a^{\Delta x} - a^x = a^x (a^{\Delta x} - 1).$$

INCREMENTS.

Now, expanding $(a^{\Delta x} - 1)$ into a series, we have

$$(a^{\Delta x} - 1) = 1 + \frac{\Delta x (l.a)}{1} + \frac{\Delta x^2 (l.a)^2}{1 \cdot 2} + \frac{\Delta x^3 (l.a)^3}{1 \cdot 2 \cdot 3} + \&c.$$

Therefore Δy , or $\Delta (a^x) =$

$$a^x \times \left\{ \frac{\Delta (l.a)}{1} + \frac{\Delta x (l.a)^2}{1 \cdot 2} + \frac{\Delta x^2 (l.a)^3}{1 \cdot 2 \cdot 3} + \&c. \right\}$$

as required. And the higher order of its increments may be found by the usual method.

Of the Inverse Method of Increments.

8. In the inverse method of increments, the question is to find the integral, or function, from its increment being given. We must, therefore, examine with attention the steps by which we descend from a variable quantity to its increment; and then, by the reverse operation, we may ascend to the integral, when the increment is known. But this reverse operation is attended with the very same difficulties as the inverse method of fluxions, for, as in that, every fluent may be readily put into fluxions, so may the increment of any function be readily obtained; but it is frequently difficult, and sometimes impossible to find the fluent of a given fluxion; and so in the method of increments, there are many cases that will not admit of integration; we shall, however, give some of the most usual and obvious rules, and which will apply to the generality of examples.

Let us first attend to the powers of a variable quantity x .

1. Since $\Delta x = \Delta (x)$; therefore, reciprocally, $\int \Delta x = x$. And if we suppose Δx as constant (a supposition that has place in all that follows), we shall have $\int \Delta x \times 1 = x$, or $\Delta x \int 1 = x$; therefore $\int 1 = \frac{x}{\Delta x}$.

2. Since $\Delta (x^2) = 2x \Delta x + \Delta x^2$, therefore, reciprocally, $\int (2x \Delta x + \Delta x^2) = x^2$; or, which is the same, $\int 2x \Delta x + \int \Delta x^2 = x^2$; whence again also $\int x + \int \frac{\Delta x}{2} = \frac{x^2}{2 \Delta x}$; and hence, by transposition, $\int x = \frac{x^2}{2 \Delta x} - \int \frac{\Delta x}{2} = \frac{x^2}{2 \Delta x} - \frac{\Delta x}{2} \times \int 1 = \frac{x^2}{2 \Delta x} - \frac{x}{2}$.

3. Again, since $\Delta (x^3) = 3x^2 \Delta x + 3x \Delta x^2 + \Delta x^3$; therefore, reciprocally, $\int (3x^2 \Delta x + 3x \Delta x^2 + \Delta x^3) = x^3$; or, which is the same, $\int 3x^2 \Delta x + \int 3x \Delta x^2 + \int \Delta x^3 = x^3$; or dividing by $3 \Delta x$ $\int x^2 + \Delta x \int x + \frac{\Delta x^2}{3} \int 1 = \frac{x^3}{3 \Delta x}$; whence, again, $\int x^2 = \frac{x^3}{3 \Delta x} - \Delta x \int x - \frac{\Delta x^2}{3} \int 1$; or, which is the same, $\int x^2 = \frac{x^3}{3 \Delta x} - \frac{x^2}{2} + \frac{x \Delta x}{6}$.

We find in a similar manner, by continuing to suppose Δx as constant, and substituting always for the quantities contained under the particular sum their respective values; the following results for the integrals of the successive powers of x ; in which we have repeated the two preceding ones, for the sake of uniformity.

$$\begin{aligned} \int 1 &= \frac{x}{\Delta x}; \\ \int \Delta x &= \frac{x^2}{2 \Delta x} - \frac{x}{2}; \\ \int \Delta x^2 &= \frac{x^3}{3 \Delta x} - \frac{x^2}{2} + \frac{x \Delta x}{6}; \\ \int \Delta x^3 &= \frac{x^4}{4 \Delta x} - \frac{x^3}{2} + \frac{x^2 \Delta x}{2}; \\ \int \Delta x^4 &= \frac{x^5}{5 \Delta x} - \frac{x^4}{2} + \frac{3x^3 \Delta x}{12} - \frac{x^2 \Delta x^2}{12}; \\ \int \Delta x^5 &= \frac{x^6}{6 \Delta x} - \frac{x^5}{2} + \frac{5x^4 \Delta x}{12} - \frac{x^3 \Delta x^2}{12}; \\ &\&c. \&c. \qquad \qquad \qquad \&c. \&c. \end{aligned}$$

where it is only necessary to observe, that if the proposed increment have any constant multiplier, the integral above found must have the same.

Cor. 1.—Hence we may find the integral of any function composed of the powers of x , affected with any constant coefficients $a, b, c, \&c.$ For in order to find the integral of such an increment, it is only necessary to find those of the different powers of x , and their sum will be the integral required.

Ex. 1.—Required the integral of the increment $a + b \Delta x + c x^2$; considering Δx as constant.

$$\begin{aligned} \int a &= a \int 1 = \frac{a x}{\Delta x} \\ \int b \Delta x &= b \int x = \frac{b x^2}{2 \Delta x} - \frac{b x}{2} \\ \int c x^2 &= c \int x^2 = \frac{c x^3}{3 \Delta x} - \frac{c x^2}{2} + \frac{c x \Delta x}{6} \end{aligned}$$

And hence by addition,

$$\int (a + b \Delta x + c x^2) = \frac{a x}{\Delta x} + \frac{b x^2}{2 \Delta x} - \frac{b x}{2} + \frac{c x^3}{3 \Delta x} - \frac{c x^2}{2} + \frac{c x \Delta x}{6}.$$

Ex. 2.—Required the integral of $a x^3 - b x^2$, considering Δx as constant.

Here we have

$$\begin{aligned} \int a x^3 &= \frac{a x^4}{5 \Delta x} - \frac{a x^3}{2} + \frac{a x^2 \Delta x}{3} - \frac{a x \Delta x^2}{30} \\ \int -b x^2 &= \frac{-b x^3}{3 \Delta x} + \frac{b x^2}{2} - \frac{b x \Delta x}{6} \end{aligned}$$

the sum of which expressions will be the whole increment sought.

Cor. 2.—When it is required to find the integral of a quantity of any of the following forms, (Δx being supposed constant), viz.

$$\begin{aligned} (x + a) \\ (x + a) (x + 2a) \\ (x + a) (x + 2a) (x + 3a) \\ (x + a) (x + 2a) (x + 3a) (x + 4a) \end{aligned}$$

we arrive at them by taking the actual product of those quantities, and finding successively the increments of each of the terms; thus,

$$\begin{aligned} 1. \int (x + a) &= \int x + \int a = \frac{x^2}{2 \Delta x} - \frac{x}{2} + \frac{a x}{\Delta x} \\ 2. \int (x + a) (x + 2a) &= \int (x^2 + 3ax + 2a^2) = \end{aligned}$$

$\int x^2$

INCREMENTS.

$$\begin{cases} \int x^3 = \frac{x^4}{4\Delta x} - \frac{x^3}{2} + \frac{x\Delta x}{6} \\ \int 3ax = \frac{3ax^2}{2\Delta x} - \frac{3ax}{2} \\ \int 2a^2 = \frac{2a^2x}{\Delta x} \end{cases}$$

Whence $\int (x+a)(x+2a) = \frac{x^2}{3\Delta x} - \frac{x^2}{2} + \frac{x\Delta x}{6} + \frac{3ax^2}{2\Delta x} - \frac{3ax}{2} + \frac{2a^2x}{\Delta x}$.

3. Again, $\int (x+a)(x+2a)(x+3a) = \int (x^3 + 6ax^2 + 11a^2x + 6a^3) =$

$$\begin{cases} \int x^3 = \frac{x^4}{4\Delta x} - \frac{x^3}{2} + \frac{x\Delta x}{6} \\ \int 6ax^2 = \frac{6ax^3}{3\Delta x} - \frac{6ax^2}{2} + \frac{6ax\Delta x}{6} \\ \int 11a^2x = \frac{11a^2x^2}{2\Delta x} - \frac{11a^2x}{2} \\ \int 6a^3 = \frac{6a^3x}{\Delta x} \end{cases}$$

Whence by addition, we have $\int (x+a)(x+2a)(x+3a) = \frac{x^4}{4\Delta x} - \frac{x^3}{2} + \frac{x^2\Delta x}{2} + \frac{2ax^3}{\Delta x} - \frac{3ax^2}{2} + \frac{ax\Delta x}{2} + \frac{11a^2x^2}{2\Delta x} + \frac{6a^3x}{\Delta x} - \frac{11a^2x}{2} + \frac{6a^3x}{\Delta x}$; and so on of other similar quantities.

And if it be required to find the integral of quantities of the form

$$\begin{aligned} & x(x+a) \\ & x(x+a)(x+2a) \\ & x(x+a)(x+2a)(x+3a) \\ & \text{\&c. \&c. \&c.} \end{aligned}$$

we have in the same way

$$\begin{aligned} 1. \int x(x+a) &= \int x^2 + \int ax = \frac{x^3}{3\Delta x} - \frac{x^2}{2} + \frac{x\Delta x}{6} + \frac{ax^2}{2\Delta x} - \frac{ax}{2} \\ 2. \int x(x+a)(x+2a) &= \int x^3 + 3a\int x^2 + 2a^2\int x = \\ & \begin{cases} \int x^3 = \frac{x^4}{4\Delta x} - \frac{x^3}{2} + \frac{x\Delta x}{6} \\ 3a\int x^2 = \frac{3ax^3}{3\Delta x} - \frac{3ax^2}{2} + \frac{3ax\Delta x}{6} \\ 2a^2\int x = \frac{2a^2x^2}{2\Delta x} - \frac{2a^2x}{2} \end{cases} \end{aligned}$$

the sum of which will be the increment required.

And, in a similar manner, we may find the integral to any other quantity of these forms.

9. Remark.—Before we proceed any further on this subject, it will be proper to attend to the correction of my integral, when from the nature of the problem under consideration such becomes necessary.

As the increments of any variable quantities x , and $x+a$ are both expressed by Δx , the constant part a having no increment, so, reciprocally, the integral of the increment Δx may be x , or $x+a$; therefore, when we have found the integral of any increment, we must add to it a constant quantity, which will be zero, if the integral needs no correction.

but a real quantity, positive or negative, in other cases, which must be determined from the nature of the problem. This remark will be of considerable importance in what follows.

10. Let us then consider those products, of which the factors are continually increased by a constant difference; viz.

$$\begin{aligned} & x(x+\Delta x) \\ & x(x+\Delta x)(x+2\Delta x) \\ & x(x+\Delta x)(x+2\Delta x)(x+3\Delta x) \\ & \text{\&c. \&c. \&c.} \end{aligned}$$

Here it is obvious that the increment of $x(x+\Delta x)$; or $1 \Delta(x(x+\Delta x)) = (x+\Delta x)(x+2\Delta x) - x(x+\Delta x)$; whence, by multiplication and subtraction, we have $\Delta(x(x+\Delta x)) = 2\Delta x(x+\Delta x)$.

In the same manner we find, $\Delta(x(x+\Delta x)(x+2\Delta x)) = 3\Delta x(x+\Delta x)(x+2\Delta x)$; And thus again, $\Delta(x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)) = 4\Delta x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)$

and so on of other similar products. Whence it appears, that in order to find the increment of any product of the above form, we must suppress the first factor x , and write in its place the increment Δx , effected with a co-efficient equal to the total number of factors; all the other part of the expression remaining as before.

Whence again, conversely, the integral to any increment of this form, will be found from the reverse operation.

- Thus for example,
1. $\int 2\Delta x(x+\Delta x) = x(x+\Delta x)$
 2. $\int 3\Delta x(x+\Delta x)(x+2\Delta x) = x(x+\Delta x)(x+2\Delta x)$
 3. $\int 4\Delta x(x+\Delta x)(x+2\Delta x)(x+3\Delta x) = x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)$
- and so on of others.

Whence, in order to find the corresponding integral to any increment of the above form, which may be represented generally by

$$a\Delta x(x+\Delta x)(x+2\Delta x) \dots (x+n\Delta x),$$

we must change Δx in the first factor into x , and divide the whole by the number of factors; that is,

$$\frac{\int a x(x+\Delta x)(x+2\Delta x) \dots (x+n\Delta x) = a x(x+\Delta x)(x+2\Delta x) \dots (x+n\Delta x)}{n+1}$$

This part of the theory has been before considered in the preceding pages, in describing the method employed by Mr. Newth of the Academy of Sciences, published in 1717.

11. Let us now consider those fractions, the denominators of which are composed of factors similar to those above described, viz.

$$\frac{1}{x(x+\Delta x)}$$

$$\frac{1}{x(x+\Delta x)(x+2\Delta x)}$$

$$\frac{1}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x) \dots \&c.}$$

in which Δx is constant.

INCREMENTS.

Here, by taking the differences as before, we shall have

$$1. \Delta \left\{ \frac{1}{x(x+\Delta x)} \right\} = \frac{1}{(x+\Delta x)(x+2\Delta x)} - \frac{1}{x(x+\Delta x)}$$

$$= -2\Delta x \times \frac{1}{x(x+\Delta x)(x+2\Delta x)}.$$

And in the same manner we find the increment, or,

$$2. \Delta \left\{ \frac{1}{x(x+\Delta x)(x+2\Delta x)} \right\} = -3\Delta x$$

$$\times \frac{1}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)}$$

$$3. \Delta \left\{ \frac{1}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)} \right\} = -$$

$$4\Delta x \times \frac{1}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)(x+4\Delta x)}$$

and so on of others. Whence it follows, that in order to determine the increment of any expressions of the above form, we must increase the denominator by one factor, and multiply the new fraction by the constant increment taken negatively and affected by such a co-efficient, as is equal to the number of factors in the denominator of the resulting fraction.

And hence, again, conversely, in order to find the integral corresponding to any increment of the form

$$\frac{a\Delta x}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)\dots(x+n\Delta x)}$$

we must suppress the last factor in the denominator, and afterwards divide the resulting fraction, taken negatively, by the product of Δx , into the number of factors comprised in the denominator of the said fraction; thus,

$$\int \frac{a\Delta x}{x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)\dots(x+n\Delta x)}$$

$$= \frac{-a}{n\Delta x(x+\Delta x)(x+2\Delta x)(x+3\Delta x)\dots(x+n-1\Delta x)}$$

12. On the same principles we find

$$\Delta \left(\frac{1}{x+n\Delta x} \right) = \frac{1}{x+(n+1)\Delta x} - \frac{1}{x+n\Delta x}$$

and, therefore, reciprocally,

$$\int \frac{1}{x+(n+1)\Delta x} - \int \frac{1}{x+n\Delta x} = \frac{1}{x+n\Delta x};$$

The integration of these two latter expressions cannot be effected separately, but the difference of them is evidently

equal to the algebraical fraction $\frac{1}{x+n\Delta x}$

Whence it appears, that quantities may sometimes admit of integration, by being decomposed into many parts; which, though they will not admit of it in their state of separation, may, notwithstanding, be so combined with each other, that the final result shall be algebraical; a circumstance that commonly happens in practical operations.

Examples of Integration.

13. *Ex. 1.*—Find the integral of the increment

$$\frac{3x+2\Delta x}{x(x+\Delta x)(x+2\Delta x)}.$$

This quantity admits of the following decomposition:

$$\frac{3x+2\Delta x}{x(x+\Delta x)(x+2\Delta x)} = \frac{1}{\Delta x} \frac{1}{x} + \frac{1}{\Delta x} \frac{1}{x+\Delta x}$$

$$- \frac{2}{\Delta x} \frac{1}{x+2\Delta x} = \frac{1}{\Delta x} \times \frac{1}{x} + \frac{1}{\Delta x} \times \frac{1}{x+\Delta x}$$

$$- \frac{2}{\Delta x} \times \frac{1}{x+2\Delta x};$$

each of which parts is evidently of the form that has been investigated in the preceding paragraph. By making first $n=0$, $n=1$, and $n=2$; thus we have

$$\int \frac{1}{x} = \int \frac{1}{x+\Delta x} - \frac{1}{x};$$

by which means the integral of the proposed quantity takes the following form: *viz.*

$$\frac{2}{\Delta x} \left\{ \int \frac{1}{x+\Delta x} - \int \frac{1}{x+2\Delta x} \right\} - \frac{1}{x\Delta x}.$$

But the above formula gives also

$$\int \frac{1}{x+\Delta x} - \int \frac{1}{x+2\Delta x} = \frac{-1}{x+\Delta x};$$

whence the whole integral is

$$\frac{1}{\Delta x} \times \left(\frac{-2}{x+\Delta x} - \frac{1}{x} \right) = -\frac{3x-\Delta x}{x\Delta x(x+\Delta x)}$$

as required.

Ex. 2.—Required the integral of the quantity

$$\frac{3\Delta x}{x(x+3\Delta x)}$$

Here we have $\frac{3\Delta x}{x(x+3\Delta x)} = \frac{1}{x} - \frac{1}{x+3\Delta x}$;

and, consequently, the integral of the quantity will be

$$\int \frac{1}{x} - \int \frac{1}{x+3\Delta x}.$$

Now the above formula gives

$$\int \frac{1}{x} = \int \frac{1}{x+\Delta x} - \frac{1}{x}$$

$$\int \frac{1}{x+3\Delta x} = \frac{1}{x+2\Delta x} + \int \frac{1}{x+2\Delta x};$$

whence the whole integral is expressed by

$$\int \frac{1}{x+\Delta x} - \int \frac{1}{x+2\Delta x} - \frac{1}{x} - \frac{1}{x+2\Delta x}.$$

But $\int \frac{1}{x+\Delta x} - \int \frac{1}{x+2\Delta x} = \frac{-1}{x+\Delta x}$

by the same formula, and, consequently, we have at length

$$\int \frac{3\Delta x}{x(x+3\Delta x)} = -\frac{1}{x+2\Delta x} - \frac{1}{x+\Delta x} - \frac{1}{x}.$$

Such are the elements of the direct and inverse method of increments, and which will be found to embrace a very great number of cases; but those who wish for a more complete development of the principles, cannot consult a work better calculated to convey the necessary information, than the third volume of the "Traité du Calcul Différentiel, &c." par La Croix. We shall now conclude this article,

by

INCREMENTS.

By shewing the application of the foregoing theory a few examples.

Application of the Method of Increments.

14. The summation of series, by the inverse method of increments, is founded generally on this principle; that if we have any series of quantities, as

$$a, b, c, d, e, \&c.$$

which are derived from each other according to some known law; each term may be considered as the increment of the sum of all those which precede it. Thus,

$$\begin{aligned} \text{let } a + b + c + d + e &= x \\ \text{and } a + b + c + d + e + f &= x': \end{aligned}$$

then it is obvious, that $x' - x = \Delta x = f$; and therefore, conversely, the integral of any one of those terms, considered as an increment, will represent the sum of all the preceding part of the series.

This being premised, we may proceed to the solution of the following examples.

Ex. 1.—Required the sum of n terms of the natural series

$$1 + 2 + 3 + 4 + 5 + \dots + n$$

Here, by writing x instead of n , the term next in order will be $x + 1$, which being the increment of the series, we shall have $\int (x + 1) =$ the sum required.

Now $\int (x + 1) = \int x + \int 1$; and by art. 8,

$$\int x = \frac{x^2}{2 \Delta x} - \frac{x}{2}; \text{ and } \int 1 = \frac{x}{\Delta x}.$$

And since in this case $\Delta x = 1$, we have

$$\int (x + 1) = \frac{x^2}{2} - \frac{x}{2} + \frac{x}{1} = \frac{x^2 + x}{2} = \frac{n^2 + n}{2}$$

by writing again n instead of x , which is the sum of n terms of the proposed series, as is also evident from other considerations.

Remark.—This example offers an easy illustration of what has been observed at art. 9, of the correction of an integral, which is necessary in many cases, the same as the correction of a fluent is in the fluxional or differential calculus. Suppose for example, that instead of the preceding series beginning at unity, it had commenced from any other term, as 7; the general law of formation would have been the same, and the increment would still have had the form $x + 1$; and consequently the integral, in the first instance, would be represented as above; *viz.*

$$\int (x + 1) = \frac{x^2 + x}{2}.$$

But here a correction of the integral is necessary, for from the nature of the series, when $x = 7$, the sum of the series is 7; this being the term at which the series commences; whereas, without a correction, we should have the sum = 28; we must, therefore, write

$$\int (x + 1) = \frac{x^2 + x}{2} + c; \text{ } c \text{ being the correction, and}$$

since when $x = 7$, $\frac{x^2 + x}{2} + c = 7$; or $\frac{49 + 7}{2} + c = 7$,

we find $c = -21$; after which the sum of any number of terms of the proposed series is readily obtained. Thus for example, let $n = 16$, then the sum of the series beginning with the term 7 becomes

$$\frac{16^2 + 16}{2} - 21 = 115 \text{ as required.}$$

Ex. 2.—Find the sum of the series of squares $1^2 + 3^2 + 5^2 + 7^2 + \&c. n^2$.

Here the general term of the series is $(x + 2)^2$, and therefore the sum required will be expressed by the integral of $(x + 2)^2$.

Now $\int (x + 2)^2 = \int x^2 + \int 4x + \int 4$; and by article 8

$$\int x^2 = \frac{x^3}{3 \Delta x} - \frac{x^2}{2} + \frac{x \Delta x}{6}$$

$$4 \int x = \frac{4x^2}{2 \Delta x} - \frac{4x}{2}$$

$$4 \int 1 = \frac{4x}{\Delta x}$$

And since in this case $\Delta x = 2$, we have

$$\begin{aligned} \int (x + 2)^2 &= \frac{x^3}{6} - \frac{x^2}{2} + \frac{2x}{6} + \frac{4x^2}{4} - \frac{4x}{2} + \frac{4x}{2} \\ &= \frac{x^3}{6} + \frac{x^2}{2} + \frac{x}{3} = \frac{n^3}{6} + \frac{n^2}{2} + \frac{n}{3} \end{aligned}$$

by making $x = n$.

But here again, if the series do not begin at unity, it will require a correction, which will be found generally, thus: suppose the series to commence at any term p ; and let $x = p$, then the above formula gives the sum of the series to the

term $p = \frac{p^3}{6} + \frac{p^2}{2} + \frac{p}{3}$, whereas it ought to be p^2 ; the

correction therefore becomes $-\left(\frac{p^3}{6} + \frac{p^2}{2} + \frac{p}{3} - p^2\right) = -\left(\frac{p^3}{6} - \frac{p^2}{2} + \frac{p}{3}\right) = c$; and, therefore, the general expres-

sion for any number of terms of this series, between the limits p and n , will be

$$\frac{n^3}{6} + \frac{n^2}{2} + \frac{n}{3} - \frac{p^3}{6} + \frac{p^2}{2} - \frac{p}{3}.$$

Cor.—This example will also furnish the solution of the problem, when the roots of the squares differ from each other by any constant quantity m ; for it will only be necessary to make

$\Delta x = m$, and the same formula will give $\int (x + m)^2 = \int x^2 + 2m \int x + m^2 \int 1$

$$\int x^2 = \frac{x^3}{3 \Delta x} - \frac{x^2}{2} + \frac{x \Delta x}{6}$$

$$2m \int x = \frac{2m x^2}{2 \Delta x} - \frac{2m x}{2}$$

$$m^2 \int 1 = \frac{m^2 x}{\Delta x}$$

And since in this case we have $\Delta x = m$, the sum of these expressions becomes

$$\int (x + m)^2 = \frac{x^3}{3m} + \frac{x^2}{2} + \frac{m x}{6} + c, \text{ the correction; and}$$

therefore the general formula for the sum beginning at any term p , will be

$$\frac{n^3}{3m} + \frac{n^2}{2} + \frac{m n}{6} - \frac{p^3}{3m} + \frac{p^2}{2} - \frac{m p}{6}.$$

Ex. 3.—Required the sum of the natural series of cubes $1^3 + 2^3 + 3^3 + 4^3 + \&c. n^3$.

INCREMENTS.

Here the general term is $(x+1)^2$; and the integral of this, that is, $\int (x+1)^2 = \int x^2 + 3 \int x + 3 \int x + \int 1$, is computed as follows:

$$\begin{aligned} \int x^2 &= \frac{x^3}{4 \Delta x} - \frac{x^2}{2} + \frac{x^2 \Delta x}{4} \\ 3 \int x &= \frac{3x^2}{3 \Delta x} - \frac{3x^2}{2} + \frac{3x \Delta x}{6} \\ 3 \int x &= \frac{3x^2}{2 \Delta x} - \frac{3x^2}{2} \\ \int 1 &= \frac{x}{\Delta x} \end{aligned}$$

And here, since $\Delta x = 1$, we have

$$\int (x+1)^2 = \frac{x^3}{4} + \frac{x^2}{2} + \frac{x^2}{4} = \left(\frac{x^2 + x}{2} \right)^2$$

Or, by making $x = n$, the sum required is $\left(\frac{n^2 + n}{2} \right)^2$

Hence a very curious property with regard to the sums of consecutive cubes beginning at 1; viz. that this sum is equal to the square of the sum of all their roots.

$$\begin{aligned} \text{Thus, } 1^3 + 2^3 &= (1 + 2)^2 \\ 1^3 + 2^3 + 3^3 &= (1 + 2 + 3)^2 \\ 1^3 + 2^3 + 3^3 + 4^3 &= (1 + 2 + 3 + 4)^2 \\ &\text{\&c.} \end{aligned}$$

As to the correction in those cases that required it, it will be found as in the preceding example; as also the sums of any number of cubes whose roots are in arithmetical progression, having any common difference m . And the sums of any powers whatever are attainable upon the same principles.

Ex. 4.—Required the sum of any proposed number of terms in the series of triangular numbers

$$1, 3, 6, 10, 15, \&c.$$

In this case the general term is $\frac{x(x+1)}{2}$,

and it will therefore be necessary to find the integral of $\frac{(x+1)(x+2)}{2} = \frac{1}{2} \int (x+1)(x+2)$ but (art. 10)

$$= \frac{1}{2} \int (x+1)(x+2) = \frac{x(x+1)(x+2)}{6 \Delta x} = \frac{n(n+1)(n+2)}{6}$$

by making $x = n$, and $\Delta x = 1$.

The same may be otherwise found from art. 8; thus,

$$\begin{aligned} \frac{1}{2} \int (x+1)(x+2) &= \frac{1}{2} \int x^2 + \frac{1}{2} \int 3x + \frac{1}{2} \int 2 \\ \frac{1}{2} \int x^2 &= \frac{x^3}{6 \Delta x} - \frac{x^2}{4} + \frac{x \Delta x}{12} \\ \frac{1}{2} \int 3x &= \frac{3x^2}{4 \Delta x} - \frac{3x}{4} \\ \int 1 &= \frac{x}{\Delta x} \end{aligned}$$

And since $\Delta x = 1$, this sum becomes

$\frac{1}{2} \int (x+1)(x+2) = \frac{x^3}{6} + \frac{x^2}{2} + \frac{x}{3} = \frac{x(x+1)(x+2)}{6}$. And the sums of any order of polygonal and figurate numbers may be found in the same manner.

Ex. 5.—Required the sum of any number n terms of the series

$$1 \cdot 2 + 2 \cdot 3 + 3 \cdot 4 + 4 \cdot 5 + \&c. n(n+1)$$

Here the general term of the series is $x(x+1)$, it is therefore required to find the integral of $(x+1)(x+2)$. First by art. 10. we have

$$\int (x+1)(x+2) = \frac{x(x+1)(x+2)}{3 \Delta x} = \frac{n(n+1)(n+2)}{3}$$

by writing $x = n$, and $\Delta x = 1$.

The same may also be found, as in the example above, by article 8; but it is needless to repeat it, as it only differs from that in its constant factor.

We have in neither of the foregoing examples any correction, for it is obvious that when $x = 0$, the formula $\frac{x(x+1)(x+2)}{6} = 0$, as it ought to be, and therefore the integral needs no correction.

Ex. 6.—Required the sum of any number of terms n , of the series

$$1 \cdot 4 \cdot 7 \cdot 10 + 4 \cdot 7 \cdot 10 \cdot 13 + 7 \cdot 10 \cdot 13 \cdot 16 + \&c. n(n+3)(n+6)(n+9)$$

Here the general term of the series is $x(x+3)(x+6)(x+9)$, and we have therefore to find the integral of $(x+3)(x+6)(x+9)(x+12)$. Now, by art. 10.

$$\int (x+3)(x+6)(x+9)(x+12) = \left\{ \frac{x(x+3)(x+6)(x+9)(x+12)}{5 \Delta x} = \frac{n(n+3)(n+6)(n+9)(n+12)}{15} \right.$$

by writing $x = n$, and $\Delta x = 3$.

Ex. 7.—Required the sum of the infinite series

$$\frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{2 \cdot 3 \cdot 4} + \frac{1}{3 \cdot 4 \cdot 5} + \frac{1}{4 \cdot 5 \cdot 6} + \&c.$$

Here the general term of the series is $\frac{1}{x(x+1)(x+2)}$; and the most simple idea is now

to consider the series as generated from its extremity, which is infinitely distant; under which circumstance each term will be the increment of all those which follow it in the above arrangement; and therefore, in order to find the sum beginning at any term $\frac{1}{x(x+1)(x+2)}$, we have

simply to find the integral of $\frac{1}{(x-1)(x)(x+1)}$ taken negatively, because the increment x , that is, $\Delta x = -1$. Now, by art. 11,

$$\int \frac{1}{(x-1)(x)(x+1)} = \frac{1}{\Delta x} \times \frac{-1}{2x(x+1)} = \frac{1}{2x(x+1)}$$

because $\Delta x = -1$; that is, the sum of the above infinite series beginning at any term $\frac{1}{n(n+1)(n+2)}$

is equal to $\frac{1}{2n(n+1)}$; and therefore when $n = 1$, the whole series becomes $= \frac{1}{2}$.

Cor. Having thus found the sum of the whole series, we may readily find the sum of as many terms as we please, for we have seen that the sum beginning at the n th term from the first, is $\frac{1}{2n(n+1)}$; and therefore, beginning at the

$(n+1)$ th term, the sum will be $= \frac{1}{2(n+1)(n+2)}$; which last sum taken from the whole sum $\frac{1}{2}$, will leave that of the first n terms, that is,

$$\text{sum } n \text{ terms} = \frac{1}{2} - \frac{1}{2(n+1)(n+2)} = \frac{(n+1)(n+2) - 2}{4(n+1)(n+2)}$$

Thus, if $n = 1$, sum = $\frac{1}{6}$; if $n = 2$, sum = $\frac{1}{4}$; if $n = 3$, the sum = $\frac{2}{5}$, &c.

Ex. 8.—Find the sum of the infinite series

$$\frac{1}{1 \cdot 5} + \frac{1}{5 \cdot 9} + \frac{1}{9 \cdot 13} + \frac{1}{13 \cdot 17} + \dots + \frac{1}{n(n+4)}$$

Here the general term of the series being $\frac{1}{x(x+4)}$; we shall, on the same principles as in the preceding example, have to find the integral of $\frac{1}{(x-4)x}$.

Now by art. 11.

$$\int \frac{1}{(x-4)x} dx = \frac{1}{\Delta x} \times \frac{-1}{x} = \frac{1}{4x}; \text{ because } \Delta x = -4.$$

Making, therefore, $x = 1$, we have $\frac{1}{4}$ for the sum of the whole series, beginning at the first term. We might have added here a variety of other examples, had the limits of the article admitted of it, but such as are given will be found to apply in a number of cases; and will indicate to the intelligent reader the method of application in many others, which are reducible to similar principles. It will be proper, however, before we dismiss this subject entirely, to say a few words on the celebrated theorem of Dr. Taylor, the learned author of this theory. This theorem may be expressed as follows:

Let Y represent any function whatever of the variable quantity x ; then if x be increased by any difference Δx , the value Y , that is $Y + \Delta Y$, becomes (adopting the differential notation) $Y + \Delta Y = Y + \frac{\Delta x dY}{1 \cdot dx} + \frac{\Delta x^2 d^2 Y}{1 \cdot 2 \cdot dx^2}$

$$+ \frac{\Delta x^3 d^3 Y}{1 \cdot 2 \cdot 3 \cdot dx^3} + \frac{\Delta x^4 d^4 Y}{1 \cdot 2 \cdot 3 \cdot 4 \cdot dx^4} \text{ \&c. or, } \Delta Y = \frac{\Delta x dY}{1 \cdot dx} +$$

$$\frac{\Delta x^2 d^2 Y}{1 \cdot 2 \cdot dx^2} + \frac{\Delta x^3 d^3 Y}{1 \cdot 2 \cdot 3 \cdot dx^3} + \dots \text{ \&c. where the}$$

law of continuation is obvious, and requires no farther development; it must, however, be remarked, that when Δx is negative, the terms of the above series must be taken plus and minus alternately; and it will therefore be more generally expressed by

$$\pm \Delta Y = \frac{\Delta x dY}{1 \cdot dx} \pm \frac{\Delta x^2 d^2 Y}{1 \cdot 2 \cdot dx^2} + \frac{\Delta x^3 d^3 Y}{1 \cdot 2 \cdot 3 \cdot dx^3} \pm \dots$$

In order then to find the increment of any function of a variable quantity, we must take the successive order of its fluxions, by which means all the fluxional parts in both the numerator and denominator will disappear; and we shall have the value of ΔY expressed in terms of x and Δx ; and this expression will always be finite, unless the function be transcendental.

Let us propose the function $Y = ax + bx^2 + x^3$ to find the value of Y , when x becomes $x + \Delta x$.

$$\begin{aligned} d \cdot Y &= a dx + 2 b x dx + 3 x^2 dx \\ d^2 Y &= 2 b d x^2 + 6 x dx^2 \\ d^3 Y &= 6 dx^3 \\ d^4 Y &= 0 \end{aligned}$$

Now these values being substituted in the general series, we shall have for the increment of Y ,

$$\Delta Y = \Delta x (a + 2 b x + 3 x^2) + \Delta x^2 (b + 3 x) + \Delta x^3$$

Again, given $Y = ax + bx^2 - cx^3 + x^4$, to find the increment of Y .

$$\begin{aligned} d \cdot Y &= a dx + 2 b x dx - 3 c x^2 dx + 4 x^3 dx \\ d^2 Y &= 2 b d x^2 - 6 c x dx^2 + 12 x^2 dx^2 \\ d^3 Y &= -6 c dx^3 + 24 x dx^3 \\ d^4 Y &= 24 dx^4 \\ d^5 Y &= 0 \end{aligned}$$

Whence making these substitutions in the general theorem, we have

$$\Delta Y = \left\{ \begin{aligned} &\Delta x (a + 2 b x - 3 c x^2 + 4 x^3) + \Delta x^2 (b - 3 c x + 6 x^2) \\ &+ \Delta x^3 (c + 4 x) + \Delta x^4 \end{aligned} \right.$$

These examples will explain the method of applying the theorem to any case that may arise, it being as universal in its application in the theory of increments, or differences; as the binomial theorem is in the expansion of roots and powers; but, like the latter, it was left by its author without demonstration: it has, however, received many success from several able mathematicians, though there is no one of them perhaps that is quite so satisfactory as might be wished; Maclaurin's rests upon the fluxional calculus, which it would be desirable not to introduce, if it could be obtained from more evident and obvious principles. Another demonstration of this theorem, and which is considered the most satisfactory of any that has yet appeared, is given by l'Huilier of Geneva, in his work entitled "Principiorum calculi diff. et integr. expositio elementaris," in 4to. published in 1795.

INCROACHMENT, in *Law*. See ACCROCHING.

INCrustation, the lining or coating of a wall, either with glossy stones, rubrics, marble, pottery, or flue-cork-work; and that either equally, or in panels and compartments.

INCrustation, in *Natural History*, is one of the modes in which organic remains are preserved in the earth: the petrifying or incrusting matter, forming so thin a coat or crust around the extraneous fossil, that its external form is nearly preserved on the stony incrustation. Mr. William Martin classifies these among the artificial genera of reliquia, and observes, "Outlines," p. 177, note, that "the common calcareous incrustations of our rivers, &c. have been ranked as petrifications; but, with more propriety, may be considered as incipient matrices." If the coat of mineral matter be too thick to exhibit externally the exact figure of the fossil which it covers, such are called by this author sub-incrustating matrices, of which ironstone nodules inclosing leaves of plants, &c. are well-known examples. The petrifying springs of Derbyshire, (for a list of which, see Mr. Farey's Report on that county, vol. i.) and other calcareous districts, are well known for the curious and whimsical incrustations which are there in a short time produced.

INCruSTED, or INCruSTATED *Column*. See INCruSTATED COLUMN.

INCUBATION, in *Comparative Anatomy*, is the term applied to the conduct of most birds in sitting upon their eggs, in order to communicate to them the necessary degree of warmth for the excitement of their internal parts, and the development of the fetus.

The phenomena produced by incubation are so interest-

INCUBATION.

ing, on account of their exhibiting in a palpable manner the progress of fetal existence, that they have been studied by almost every respectable physiologist. Writings have been left upon this subject by Aristotle, Hippocrates, Fabricius ab Aquapendente, Aldrovandus, Coiter, Velling, Harvey, Langly, Schrader, Theod. Aldes, Stenon, Needham, Malpighi, Maitre Jan, Haller, Hunter, Monroe, &c. besides some later observations by Blumenbach, Leveille, and other continental anatomists. Notwithstanding the labours of so many eminent men, some of the most important points in the history of incubation remain still undetermined. The best treatises are those of Malpighi, Maitre Jan, and Haller, but even in these authors there are many errors to correct, and, except some detached figures that have been published to illustrate particular parts of this subject, we do not possess any tolerably good plates.

The deficiency and doubts that still remain, with respect to several parts of the history of incubation, prove how difficult it is to investigate the subject.

The membranes of the egg, and the organs of the chick, are in general so tender, that they do not admit of being easily or satisfactorily examined; and when prepared by immersion in spirits, acids, or other astringent liquors, their natural appearances and connections are much obscured.

The progress in the growth of the membranes is found to be in many circumstances unlike what would be expected, and what it appears to be; and the attachments of the membranes to each other are extremely intricate and perplexing. This part of the anatomy of the incubated egg, therefore, principally requires improvement. In the following article we have endeavoured to supply, by our own observations, what was deficient in the history of incubation, but, we must confess, not with as much success as we could wish; there are several anatomical points upon which we are obliged to speak doubtfully, and we have not been able to satisfy ourselves respecting the uses attributed to some of the parts of the incubated egg, although we believe others will be found to be elucidated by the experiments we have made, and which are here related.

Most writers upon incubation, appear to us to have paid too much regard to the dates or periods at which they have observed the different events of incubation to occur. Much exactness with respect to dates is not of material consequence, and if it were, it is not practicable, for the progress of incubation depends so much upon climate, season, and the diligence of the parent, with many accidental circumstances, that hardly any two eggs agree precisely in their state of growth, at any given period of incubation; we are not, therefore, to wonder at the difference amongst writers upon this subject with respect to chronology.

The proper heat for the hatching of hens' eggs is 104° of Fahrenheit, to which degree the surface of the body of the hen will raise the thermometer when she sits upon her eggs. In those birds that do not sit constantly, but trill to the heat of the sun, the temperature of the eggs is probably below 104 degrees.

The full period of incubation by the hen, in this country, is well known to be 21 days. In warmer climates it is said to be a day or two less. The periods of incubation vary much in different species of birds: we introduce the following table, which has been compiled from different authors by count Morozzo, in a letter from him to Læcæpède, to shew the periods of incubation compared with those of the life of certain birds.

Names of Birds.	Periods of their Incubation.	Duration of their Life.	Authority.
	Days.	Years.	
Swan	42	about 200	Aldrovandi.
Parrot	40	— 100	Wolmaer.
Goose	30	80 or more	Willoughby.
Eagle	30	} period of life not known.	
Bustard	30		
Duck	30		
Turkey	30		
Peacock	26 to 27	45 to 28	{ Aristotle and Pliny.
Pheasant	20 — 25	18 — 20	{ A Treatise on Pheasants.
Crow	20	100 or more	Hesiod.
Nightingale	19 to 20	17 to 18	Buffon.
Hen	18 — 19	16 — 18	Buffon.
Pigeon	17 — 18	16 — 17	{ Several observations.
Linnet	14	13 — 14	Willoughby.
Canary	13 to 14	13 — 14	{ A Treatise on these Birds.

Crane and heron, as well as *ostrich*, hatch their eggs chiefly by the heat of the sun. Journ. de Physique Ventos. an. 10.

The usual mode of examining the progress of incubation, is to gently fracture the shell, and pick it carefully off in pieces with a pair of forceps. This should be done at the large end, as it is there the changes of incubation commence, and at all periods it will be found the most convenient place for breaking the shell, on account of the air-cell being interposed between it and the fluids of the egg. For particular purposes other modes of preparation must be employed. If it be our object to study the formation of the membranes, these must be separated from the humours, and after being cleaned by being passed through several waters, they are to be floated in weak spirits over a blue paper, or some other dark coloured substance. The strongest spirits, distilled vinegar, or a solution of alum, are necessary to render the organs of the fœtus sufficiently plain for examination. The only use of boiling the contents of the egg, is to shew the relative situation and magnitude of different parts.

In many observations, it is necessary to magnify by glasses the subjects of investigation; we would however recommend, that the sight be only assisted by the single lens. When a higher power is employed it is liable to deceive.

After the egg has been sat upon for 12 hours, the quantity of air contained between the two layers of the membrane that lines the shell, is found to be a little increased.

No evident change is yet to be observed with respect to the bulk or consistence of the humours.

The white spot on the superior surface of the yolk, which contains the *cicatricula* of the ancient anatomists, or the *follicle* of Haller, is now somewhat enlarged. There appears, in its interior, a small white body of an elongated and indistinct figure, which is surrounded by a line of a deep yellow or greenish colour. If this part of the membrane be removed and examined with a lens on the under surface, after being a short time immersed in spirits or vinegar, it will be discovered that the elongated white body is the rudiment of the *fœtus*, which is already inclosed in the *amnios*. The greenish appearance would seem to depend partly upon the existence of the *amnios*, and partly upon a depression of the substance

INCUBATION.

substance of the yolk, which is the origin of the head of the chick. We cannot determine whether this depression contains a fluid or not. The part of the white spot which surrounds the depression that contains the fetus, is occasioned by the substance of the yolk having a peculiar organization. At that point it is white, and has a curdy or coagulated appearance. Malpighi believed that he could discern the fetus as early as the sixth hour, and even before the egg had been fat upon; but most other observers have not been able to see any appearance, which they thought deserved to be considered as the fetus, before the 12th hour. It is, however, probable, that the embryo of the chick is formed after impregnation, although from its extreme tenderness and obscurity of figure, it cannot be detected until it is a little developed by incubation.

The *amnios* appears to be coeval with the chick.

The *rings* or *circles* (*balones*) that surround the cicatrícula, are now somewhat enlarged, and more defined in their outline. They also assume a little of an oval figure. The external circle is undulating, or forms waves, through which the colour of the yolk appears. Maitre Jan describes four *balones*, Haller only three; we have found the number vary. This appearance of circles is not easily accounted for. We have thought it arose from the separation of the membranes into their proper layers.

First Day, or after 24 Hours.—Upon opening an egg at this period, it is perceived that the space formed for the admission of air between the layers of the external membrane is a little more enlarged.

The *external white* appears scarcely diminished; it is fluid and transparent, and runs out at the opening if the egg be inclined to that side.

The *yolk* is found to float higher in the principal white than before incubation, and appears a little flattened upon the upper surface.

The *balones* are more extended, particularly the outer one. The internal one has acquired a little of a heart-shape, and is surrounded by a more defined line of a greenish colour, which is the first appearance of the outline of the venous area. There are also some faint and imperfect traces of green vessels, or rather elongated points, to be detected in different parts of the space inclosed by this line, which are the rudiments of the vessels that are to compose the area.

The *amnios* is well formed, and composed of two circles which unite two straight lines, resembling the figure of a pettle.

The *fetus* has a more determined figure; it is larger at both extremities than in the middle; but the end which corresponds to its head is larger than the other, and forms an oval mass. Maitre Jan states that if an egg, after being under the hen for 24 hours, be put into water, it will float with the small end downwards, which is a proof that a part of its fluids is lost, and replaced by the admission of air into the air-cell at the great end of the egg.

After 36 hours we have found the greenish line, already mentioned, to have still more plainly the appearance of a vessel. It encompasses a larger area, and assumes more completely the contour of a heart. The greenish points also now are continued into each, and put on the appearance of vessels, which are most numerous next the circumference of the area, but present no evident connection with the fetus. Some of these vessels are seen to contain red blood, more particularly those which pass between the head of the chick and the upper part of the vessel in shape of a heart. In some eggs, at this period, we have found these red vessels approach the chick but not join it; in others they were collected by a single branch, which passed behind the head of the chick.

This branch Leveille has called the meningo-cardiac vein, and others the vena ascendens. There is considerable variety with respect to the period at which red vessels begin to appear. We have seen them before the 36th hour, but oftener, perhaps, not before the 40th, or even later. Authors differ extremely on this point. Malpighi represents the commencement of the vessels at the 30th hour (Append. figs. 18 and 19.), and even delineates them at the 12th hour. (Épist. 1. fig. 5.) Stenon observed them at the 71st hour; Vesling at the 43d, but saw the points at the 42d hour. Alrovandus found them the third day. Maitre Jan described the first appearance of vessels at the 38th hour, and represented them distinctly formed, and carrying red blood at the 44th hour. (P. 53 and 58, and fig. 10.) Haller noticed some reddish points at the 36th hour, and to the 48th, but did not perceive perfect red vessels before the end of the third day. Memoire 2d sur la Formation du Cœur dans le Poulet, &c. p. 23.

These contradictory accounts depend in some degree upon their authors not having sufficiently attended to the existence of colourless points and vessels before the formation of red blood.

Haller states, that he observed, at 3½ hours, the head of the *fetus* to have the appearance of being split, which he attributed to the vessels of the brain having a small degree of opacity, whilst the membranes composing the cranium were so transparent as to be seen through. Malpighi also represented this appearance. We have not noticed it.

Haller likewise describes the head of the chick to begin to form at a right angle with the tail at the 40th hour.

After 48 hours, or two days, the external *balones* occupy a considerable extent upon the surface of the yolk, and become fainter in their appearance.

The *liquid* or *external white* is somewhat diminished.

The *principal white* begins to subside to the bottom and small end of the egg.

The *yolk-bag* appears flatter upon the upper surface, and its contents are a little more fluid than before incubation.

The *chalazæ*, which were originally situated at the two poles of the yolk-bag, are now found somewhat below them, and consequently rather nearer to each other.

The *vascular area* (*figure veineuse* of Haller) is now in general completely formed with colourless and red vessels. The number of the latter is very variable. We have found them at this period in very different states of advancement, but always discoverable by the greenish vessels which precede them. The area has very perfectly the figure of a heart, except that the part corresponding to the basis is formed by the outline of the two sides being considerably curved before their junction in the middle, at which place the outline of the area forms a pointed projection downwards, which nearly reaches to the head of the fetus. It is this part of the area which receives the branches of the meningo-cardiac vein already mentioned. The vessels are now also connected with the chick by means of their principal trunks.

The *pulsation of the heart* is evident at this period, and even in some hours before, according to Maitre Jan's observations. It appears to be produced by the alternate contraction and dilatation of two or sometimes three vessels. This appearance is the *punctum saliens* of the older anatomists, and has been commonly, but erroneously, reputed the first action of life.

One mode of preparing eggs for examination is to remove a portion of the membranes including the fetus and vascular figure around it, and having washed off any pieces of the yolk that may adhere to them, immerse them for a short time in strong spirits or distilled vinegar, by which means the

INCUBATION.

pulpy substance that composes the chick is rendered opaque and visible, and the structure of the membranes more distinguishable.

If this step be taken with the egg at the present period, or even before it, a fine glossy transparent membrane will be found upon the external surface of the yolk-bag, which is very readily detached, leaving the fetus and the vascular area beneath. This membrane, we conceive, is the same which, strengthened by the vesicula umbilicalis, becomes the one which at last entirely envelopes the contents of the incubated egg.

The membrane, containing the *vascular area* at the second day, may be distinguished to be composed of two layers; the external is smooth, and receives the vessels; the internal is a little thickened and spongy. The remaining portion of the yolk-bag is not separable into different layers. From hence it would appear that the division into layers is the consequence of vessels being distributed to the membrane.

The *amnios* is now found a little larger, and the transparent fluid with which it is filled in greater quantity. The superior circle also, or that which incloses the head of the chick, is larger than the lower.

The *fetus* has altered its shape a little. The head has acquired something the figure of the ace of clubs, the anterior prominence of which corresponds to the nose and mouth; and the two other projections are the vesicles containing the brain in a very soft pellucid state. Maitre Jan states that the eyes also are visible at this period. (P. 77.) Haller did not see the eyes before the 51st hour, at which time they had not any colour, and were merely distinguishable from the other parts of the head, by their prominences and situation. Sect. xii. Second Memoir.

The *heart*, before the chick is removed from the membranes, and rendered opaque by immersion in spirits, appears to be situated on the outside of the body, and the pulsating points seem unconnected with each other; but upon a close examination it is seen that the heart is not uncovered, although, from its projection, and the natural transparency of the parietes of the chest, it had every appearance of being so. The heart altogether resembles a horse-shoe in form, or a portion of a circle, of which the convexity is turned forwards, and the limbs backwards, one being directed to the upper part of the chest, and the other to the lower. The heart at this time consists of an auricular canal, a ventricle, and a bulbous enlargement belonging to the aorta. The two last are the salient points, and when the chick is so far advanced that the auricle is formed and pulsates, which is sometimes the case at the 48th hour, there are three salient points to be seen. Maitre Jan describes four salient points, and supposes that they are the rudiments of the two ventricles and two auricles of the heart. At other times, he says he has sometimes seen but three pulsating points, or perhaps two, or only one. Haller, who paid particular attention to the development of the heart of the chick, contradicts Maitre Jan's account. At the 45th hour he could discover but two salient points; at the 50th hour he saw three, but on no occasion more than that number. He supposes that when there are two salient points the auricle does not pulsate, and when only one the bulb of the aorta is without motion. *Memoire* t. p. 83.

The End of the third Day, or Seventy-two Hours.—This is a very important period in the history of incubation.

The separation of the layers of the external membranes for the admission of air continues to increase.

The *halones* are scarcely to be discovered. The *yolk* is more extended, and the *white* continues to gravitate to the lower parts of the egg.

The *vascular area* is now generally found to be perfected with red vessels. The contour of the area is more extensive, particularly in the transverse direction. The diameter being now about an inch and a quarter, it has therefore less the shape of a heart: the pulsation of the three vessels, and distribution of the blood-vessels, are very clearly seen through the transparent membrane which covers them.

The *amnios* begins to assume the figure that it is afterwards to possess. The two circles which encompass the head and the tail of the fetus become enlarged, principally on the fore-part, or the side next the right-hand of the observer; but the sac is a little contracted on the same side opposite to the umbilicus of the chick, thus tending, in a degree, to give the *amnios* the form of a kidney.

The *fetus* has a curved position forwards, and its body appears larger in proportion to its head, than on the preceding day.

We have forbore to describe particularly the *heart* and *blood-vessels* of the chick and area until the present period, when they are more distinctly seen.

In order to discern perfectly these parts, the membrane including the fetus and vascular area should be removed from the yolk-bag, floated in clear water, and examined with a lens. The vascular area contains four or five principal venous branches, which ramify upon the membrane, and produce a very close and intricate network towards the circumference of the area. These branches appear, when the chick is in the natural situation, to be so many distinct trunks. Two of them are seen to come from the sides of the chick, a third from under the tail, and one, or sometimes two, branches from under the head of the chick. The two first are commonly called the *umbilical* vessels, as they come out of the chick at the umbilicus: they would, perhaps, with more propriety, be called mesenteric veins, as we have much reason for supposing that they are the same which are so plainly branches of the mesenteric vein in the latter stages of incubation. At the present period they terminate in the vein which corresponds to the vena cava and vena portae. Both the branches which emerge from under the tail and head of the fetus are found to be given off from the umbilical veins just outside the body of the chick. This origin is concealed from view until the lower surface of the membranes and chick are carefully examined. Several anatomists seem to have published errors with respect to the superior and ascending vessels of the vascular area. They are often described as distinct branches, which are lost on each side of the notch or chink, which has been already mentioned to exist during the first days of incubation in the contour of the vascular area. They were, therefore, sometimes supposed to be separate vessels. Langly represented them to be at first distinct branches, which united at the 61st hour; but Malpighi, Maitre Jan, Haller, &c. state that these two branches always unite into one behind the head of the fetus when they do not sooner. Malpighi, Maitre Jan, and others, however, represent this vessel as coming from the heart: Maitre Jan even supposes it may be the ascending aorta. Our observations, nevertheless, lead us to agree with Haller respecting this vessel, who states it to be a branch of the umbilical vein. It is this vessel to which Leveille has given, as we conceive improperly, the name of *meningo-cardiac vein*.

The vessel which forms the contour of the vascular area has been commonly described as a single vein: Malpighi, however, represented it as being composed of an intertexture, or plexus of the ultimate branches of the veins which are spread over the vascular figure. There appears to be some foundation

INCUBATION.

tion for both these accounts, according to our observations: thus we have sometimes seen with a lens the appearance described by Malpighi, and at the same time the single trunk nearly transparent from wanting red blood, and enveloped and concealed by the intricate and close plexus formed by the extremities of the veins of the external part of the area. We believe, however, that there is in every case originally a single vessel which makes the outline of the venous figure or area, and which exists previously to the vessels which communicate with the chick. It is not uncommon to find this vessel deficient at some parts of the circumference of the area, more especially at the superior part, where the outline makes the pointed projection inwards towards the head of the chick. Sometimes a vein is seen to pass across the chink formed by the outline at this part.

The arteries which go to the vascular area bear no proportion to the veins. They are so small that they are not easily seen, and even have been by some supposed not to exist. The left umbilical artery is in general much more considerable than the right; indeed we have sometimes doubted whether the latter existed or not. They accompany the veins in their course, but are not supposed to have any immediate connection with the vessel which forms the contour of the area. Besides the small size of the arteries at this period of incubation, they are difficult to discover on account of all the blood-vessels of the egg carrying blood of the same colour. During the first days the blood is a bright scarlet, or possesses an arterial character. The parts composing the heart of the chick, although formed several hours before, are now particularly evident. The vein, which in the first periods conveyed the blood from the vascular area to the horse-shoe dilatation corresponding to the heart, is now seen to be the vena cava, or rather it should be considered as the vena portae and cava together. At the superior part of this vein a dilatation is formed, which is prolonged transversely forwards, and inclines a little downwards. This dilated part, in which the vena cava ends, is the origin of the single auricle of the heart of the fœtus, and is the first vessel in order which is seen to pulsate.

Towards the end of the third day, according to Haller, the enlargement of the head of the vena cava becomes greater, and is distinguished from the rest of the vein by a whitish-coloured interval; it is still, however, but a single cavity: its greatest diameter is across from the right to the left side of the fœtus. The canal which conveys the blood from the auricle into the ventricle (*le canal auriculaire* of Haller), exists, as already mentioned, before the vena cava becomes dilated to form the auricle, at which time it might be considered as the continuation of the cava. This canal is, therefore, one of the first formed parts of the heart. It is most long and slender when it first appears, and gradually contracts in length, until it is lost in the substance of the heart. It is smallest where it arises from the auricle, and widest where it opens into the ventricle: its diameter, however, is always less than that of the latter. It enters the ventricle on the left side, for which purpose it descends a little, and therefore crosses the aorta, which arises from the ventricle on the right side and ascends backwards. There arises from the decussation of these two vessels the appearance of a kind of knot, and the auricular canal seems to double upon itself, in order to be continued with the aorta in the opposite and concealed side of the knot.

When the auricular canal is viewed on the right side, its extremity is concealed, and the manner in which it opens into the ventricle cannot be perceived: it seems rather as if separated from the ventricle by a line which is the border of

the heart. But if it be viewed on the left side, there is no difficulty in discovering its communication with the ventricle.

The *ventricle* is a single cavity during the first four or five days of incubation; or rather, the left ventricle exists only at that period. When the two ventricles make their appearance, it is in consequence of the right ventricle being added to that which had already been formed. The left, or single ventricle, arises out of the ring-shaped vessel, which constitutes the first appearance of the heart, and probably is the first point which pulsates. It is an oval vessel, with transparent parietes in the commencement; but it soon acquires more of a conic figure, with a pointed apex, and greater thickness and muscular power: it is, however, very nearly oval at the present period.

The *aorta*, as already mentioned, is coeval with the first appearance of the heart, and exists before the formation of the auricle. It is then very long, and its arch is much greater in proportion to the length than in the succeeding periods of incubation, as in the adult bird. It makes an extensive curve backwards, in order to enter the chest, immediately under the head, and composes a considerable part of the ring which represents the heart. On the left side this artery appears as if cut off by a line which terminates the heart. The auricle, when formed, is surrounded by the arch of the aorta, which is superior, and more forwards.

A few hours after, the part of the aorta which appears to be outside the chest, becomes shorter, and some inequality is perceived in its diameter. The part of the aorta, which immediately arises from the ventricle, is more contracted than any other; and the wave of blood which is seen to pass through it is very slender. Haller gives the name of the *filait* (*le d. trait*) to this part.

The next part of the aorta is a dilatation, to which Haller has given the name of the *bulb* of the aorta. This portion of the vessel, as already mentioned, constitutes one of the pulsating points, and is seen to beat even before the auricle. The bulb of the aorta has been mistaken by Malpighi for the left ventricle, which, considering its lively and early pulsation, was not unnatural. He likewise was led by the same error to take the single ventricle, which is actually the left for the right, or pulmonary ventricle of the heart.

The third portion of the aorta is cylindrical; its direction is changed, and it represents with the preceding a point or beak. It is smaller than the bulb, but larger than the branches which go to produce the dorsal aorta. Haller calls this part the *bec de Paorie*.

Soon after the present period, and before the end of the fourth day, there are branches seen to arise from the beak of the aorta, in order to form the dorsal portion of that vessel.

The three parts which compose the heart of the fetal chick pulsate so rapidly, when examined immediately after the egg is opened, that the eye cannot follow them; but in proportion as the chick becomes cold and feeble, the intervals between the pulsations become longer. The pulsations may be thus gradually reduced to fifteen, to ten, to five, or two, or at last even to but one in a minute; nevertheless, the celerity with which each contraction is performed is scarcely diminished.

When the pulsations of the heart are rendered sufficiently slow to be counted, they are perceived to follow each other in a regular succession. The auricle always beats the first of the three vessels. In its systole the point descends, and the sides are approximated: it scarcely ever appears to expel

INCUBATION.

entirely the drop of blood it contains, and therefore it retains almost constantly a degree of red colour.

The wave of blood which proceeds from the auricle appears to vanish, as one cannot see its course into the ventricle unless the heart be beheld obliquely from above: then the blood will be seen to pass along through the auricular canal, which, as before observed, is concealed by the ventricle.

The contraction of the ventricle succeeds to that of the auricle: it approximates its sides, and becomes narrower and shorter. The ventricle frequently becomes quite pale during its contraction, owing to the entire expulsion of its contained blood.

After the contraction of the ventricle follows that of the bulb of the aorta, which pulsates as quickly and perfectly as the ventricle itself. It empties itself completely at each contraction, and therefore appears quite pale at these moments.

The pulsatory movement terminates at the origin of the three vessels which go to form the dorsal aorta, and this vessel declines very much in bulk opposite to the umbilicus; the branches which go to supply the inferior parts of the fœtus being very insignificant.

The different membranes become more distinct at the end of the third day than they were before. At this period also the first appearance is seen of that remarkable membrane, which is called by some *Allantois*, and by others *vesicula umbilicalis*.

When a portion of the membrane is removed containing the vascular area and the chick, and washed and spread out in clear water, it is found to contain four layers. The first is thin, transparent, and shining, and resembles that which forms the yolk-bag before incubation. It very readily separates from the other layers. The second is also transparent, and still thinner than the first, but is more adherent to those underneath it. The third is the membrane in which the blood-vessels are distributed that form the vascular area; and the fourth is the internal or spongy membrane of the yolk-bag. The third membrane seems to grow with the vascular area, by which it appears to be bounded: the internal membrane of the yolk-bag is at this period a little spongy or villous at every part, but much more so under the vascular area than at any other place.

The chick inclosed in the amnios is situated between the two first and two last of these membranes.

The *vesicula umbilicalis*, when first discovered, makes its appearance as a small spherical transparent bag, which projects out of the opening into the abdominal cavity of the chick, that is left by the reflection of the amnios inwards. At this period, and for some time afterwards, it is distended by a clear fluid.

The end of the fourth day, or ninety-six hours, the appearance of *balanus* is in general no longer to be perceived.

The vascular area is so much extended that it occupies near the half of the superficies of the yolk: the outline has no remains of the heart shape, but has assumed an oval figure, the greatest diameter of which is in the transverse direction of the chick.

The air-cell continues to enlarge at the great end of the egg.

The external or liquid white appears to be all consumed.

The principal white is chiefly to be found in the lower parts of the egg, and when poured out is seen to adhere a little to the internal layer of the membrane of the shell at the small end of the egg.

The yolk-bag is still flatter in its figure than before, and its contents are evidently more fluid than they were previous to incubation.

The *chalazæ* continue to approach each other below the poles of the yolk-bag.

The amnios is considerably increased, contains more fluid, and forms a deeper bed for the chick on the membrane of the yolk-bag.

The *vesicula umbilicalis* has made a rapid progress since the end of the third day. It now projects considerably beyond the fœtus. It appears flatter, and less full of fluid than at first; and at this period, by examination with a magnifying glass, a vessel may be seen to ramify upon it.

Upon opening the yolk-bag, and washing off the yolk, the spongy coat is seen to be elevated in the course of the blood-vessels of the vascular area: this is the first appearance of the valvular structure of the yolk-bag, of which more hereafter.

The fœtus is still more curved in its form, the prominence corresponding to the bill being bent down upon the breast. The rudiments of the upper extremities are apparent: they are two white buds or short projections. The lower limbs are likewise produced, but without any more form. The cerebral vesicles are more eminent; and, when opened, their contents are found, though still pellucid, to be mixed with some whitish fibres, which form opaque clouds, and are the commencement of the brain.

Haller found the heart beginning to undergo some changes about this period. The auricle, when viewed in the usual manner on the right side of the fœtus, is seen to contain two femicircles. The most posterior of these, or the one nearest the vertebrae, is the largest, and terminates the auricle. The anterior femicircle is smaller, and divides the auricle as a kind of septum. This is the first appearance of the distinction of the auricles into two. That which is to be called the left is the larger, and projects over the right posteriorly. The latter, which is the smaller, has a femilinear termination, which is comprised in the breadth of the left auricle. The vena cava and the auricular canal are inserted in the interval of the two auricles.

The distinction of two auricles is likewise to be seen on viewing the heart on the left side. That which is to become the left is oval, wider than the other, and passes beyond the auricular canal.

At the end of the fourth day, or soon afterwards, the two auricles become more separate from the vena cava and the auricular canal. They project over these vessels, and are elevated from the two sides of the base of the heart into a pointed top. The whole of the auricle, or the united reservoir of the right and left auricles, appears then as a sac with two pointed horns: each of these pointed tops has a separate drop of blood. The border of both the auricles appears at this time notched. Mem. 2d sur la Formation du Cœur dans le Poulet, &c. par M. de Haller, p. 70.

The auricular canal, towards the end of the fourth day, passes more in a direction from above downwards than formerly.

According to Maitre Jan, the rudiments of the lungs are visible at this period; but Haller asserts that they do not appear before the 138th hour. The former author describes at this time, in the neighbourhood of the heart, little reddish clouds, apparently of a spongy nature, which appear more or less red, alternately, as the heart moves, and which remain of an uniform colour when the heart has ceased to beat. Maitre Jan admits that the pulmonary vessels cannot yet be discerned, but supposes from the above effect of the heart's motion, that they do exist, although they are not visible. (Observat. sur la Formation du Poulet, par Maitre Jan, p. 115 and 122.)

—Not having examined this point, we cannot decide between these authorities, but we should judge it improbable that the

pulmonary vessels could regularly transmit blood to the lungs, and yet not be visible.

Both Haller and Maitre Jan agree that the *liver* makes its appearance towards the end of the fourth day. It is seen as a viscous cloud of a reddish yellow colour, situated between the umbilical vessels and the descending aorta. It is rendered more visible and opaque by moistening it with distilled vinegar.

The *eye* of the fetus appears black, the choroid coat being formed; and the superior part of the eye chiefly presenting itself to view, the pupil is situated in the inferior portion of the eye.

The *end of the fifth day, or 120 hours, the vascular area* is so much extended as to cover generally more than half the superficies of the yolk-bag. The trunks of the vessels are proportionally increased in size, but the branches near the circumference are not so much advanced. Some additional vessels are seen to proceed from the umbilicus of the chick towards the left side of the area. These appertain to the vesicula umbilicalis, as will be better understood hereafter. All the blood-vessels of the area, which were in the first days of incubation of a fine scarlet, are now commonly found of a dusky red colour.

The *amnios* continues to increase in magnitude, and contains so much fluid, that the chick appears to be surrounded by a green liquor.

The *chick*, especially when excited by a little external heat, can be perceived to move its limbs.

When the external membrane is removed, the *vesicula umbilicalis* is found to be considerably larger than it was the preceding day. It is likewise perceived to have contracted some adhesion with the external membrane, which however is undone by a slight force, particularly after the membranes have been a short time immersed in vinegar or spirits.

The branches of blood-vessels which are distributed upon the vesicula, belong to a trunk that comes out through the opening of the abdomen at the umbilicus of the chick. The vesicula is connected with the fetus by means of a neck, or contracted part, which is likewise received into the abdomen at the umbilicus.

Maitre Jan describes at this period a number of fine branches of blood-vessels upon the skin of the chick: we have not, however, observed these so early.

When the internal surface of the *yolk bag* is examined, it is found that the eminences upon it, already mentioned, have assumed the form of vessels ramifying from the centre, where the chick is situated, to the circumference of the vascular area. This appearance has been mistaken by many of the older anatomists for real vessels distributed upon the inner surface of the yolk-bag, and were supposed by some to be designed to convey the yolk to the chick. When the appearance of the yellow vessels of the yolk-bag is first presented, it is very difficult to detect the real occasion of it, but as it advances, it becomes plain that the effect is produced by the inflection or doubling of the inner membrane of the yolk-bag, in the course of the real blood-vessels of the bag. By a careful examination of the matter with a lens, even at this period, we have always perceived the appearance of yellow vessels to arise from the blood-vessels running in grooves, or reflections of the inner membrane. When the two tunics of the bag are separated, the blood-vessels are found to belong to the external, upon the inner side of which they appear as eminent lines; while upon the external side of the inner coat there are corresponding grooves or impressions.

The *heart* at this period begins to undergo the changes by which it approximates in structure the heart of the adult bird. It becomes perpendicular, or in the line of the fetus,

from being placed in a transverse direction. The point is recurred between the two lobes of the liver.

The *auricles* become more distinct, and the interval between them white.

The *auricular canal* is considerably shortened.

The *second or right ventricle* begins to be formed before the termination of the fifth day. It appears as a little sac under the bulb of the aorta. It is much shorter than the original ventricle, above which it is placed. Its figure is oval, and it has a red colour. In a short time the new ventricle is seen in its proper situation, that is, on the right side of the heart. Haller states that he found it placed on the right as early as the 117th hour. There are then two distinct drops of blood in this part of the heart of the fetus, and a white line is perceived between them.

The *aorta* arises from the left ventricle. The branches, which are furnished in order to form the dorsal aorta, have an inclination downwards, and unite in an acute angle. At this period also the bulb of the aorta begins to diminish, and to retire into the flesh of the heart.

The *liver* is more distinct than at the end of the preceding day; it is divided into lobes, and is of a pale or yellowish red colour. Its vessels receive blood.

Haller first perceived the rectum at this period, although the stomach and other intestines were not yet formed. It appears in the shape of a trident, the lateral processes of which are produced by the rudiments of the two cæca.

The End of the 6th Day, or 144 Hours.—Eggs placed so long under the hen are considerably diminished in weight, which is even perceivable on taking them into the hand. The shell begins to appear more dry, and opaque coloured, and is more fragile than before incubation.

The diminution of weight depends upon the enlargement of the air-cell, which now extends over a considerable part of the great end of the egg. Maitre Jan has taken some pains to prove that the air contained in the egg is not derived from the atmosphere. He supposed that the fluids filtered through the inner layer of the membrane which lines the shell, and that by the action of heat, they were volatilized or converted into air. This opinion is not only improbable, but refuted by particular facts. On opening the air-cell, we do not find its surface to possess any moisture; that layer of the membrane which lies next the humours of the egg, although less thick, is smoother, denser, and less porous than the layer immediately in contact with the shell, and therefore less fitted to admit the transpiration of either fluids or air. The chemical properties of the gaseous contents of the air-cell seem to put it beyond all doubt that the atmospheric air passes into the egg. (See the article *Egg*.) We shall only add, that when we have varnished the external surface of the shell the air-cell no longer increased in size.

Upon opening an egg at this period of incubation, it is not unusual to see the chick turned upon its back, instead of lying, as before, upon its left side. This circumstance seems to depend upon the amnios having so much increased in size that the fetus may roll round within it.

The membranes around the chick begin to acquire more strength and firmness, which is the consequence of the vesicula umbilicalis becoming more closely and extensively united to the external membrane.

The *vesicula* is now found to be very much increased in magnitude, and to cover a considerable portion of the yolk-bag. When the membranes surrounding it are cut open, and the vesicle exposed, its neck or peduncle may be traced as a fine transparent tube to the rectum, by a careful examination, particularly if the parts have been rendered opaque, by

INCUBATION.

being a short time steeped in vinegar or strong spirits. Where it opens into the rectum it is dilated.

The connection that exists between the vesicula umbilicalis, and the end of the rectum, by means of a tube analogous to the urachus, has induced Haller and others to consider this bag as the reservoir of urine.

We shall find in the subsequent periods of incubation, that the vesicula umbilicalis performs very important and other functions than those of a reservoir of urine, in which, nevertheless, it does not perhaps materially differ from the allantois of quadrupeds.

It is necessary here to notice an error which two of the best writers upon the subject of incubation have fallen into with respect to the vesicula umbilicalis. Both Malpighi and Maitre Jan supposed it to be a part which afterwards became the stomach of the chick. This mistake appears to have been occasioned by the vesicula becoming, as we shall afterwards describe, so much extended as to lose the figure of a bag, and from being united to other membranes, only to be distinguished with difficulty. Its being visible nearly three days before the stomach; acquiring even then a much greater size than that viscous possesser, and differing essentially in figure and texture, should however have prevented these two parts from being confounded with each other.

The chick, on the sixth day, has assumed a good deal of its natural form. The extremities are so much developed, that the divisions of these members are visible. The wings have their bent figure, and the legs are added to the thighs.

This period is likewise marked by the first appearance of most of the important organs of the body, besides some changes in those already formed.

Haller states that he could discern the *pericardium* at this time.

The two *auricles* are still more distinct than at the end of the preceding day.

The *auricular canal*, which had before begun to retire within the flesh of the heart, is now not visible.

The *ventricles* are better formed, and broad at their base.

The *bulb*, the *frons*, and the *bulk* of the aorta, which gave origin, in the early periods, to the principal arterial trunk, are in general not apparent at the end of the sixth day. This vessel is seen to come forth from the basis of the heart itself.

The *pulmonary artery* was seen by Haller first, about the middle of the sixth day. This vessel is less firm and opaque than the aorta; it arises from the left side of the basis of the heart with a little bulb. It is usually of less diameter than the aorta. Almost at its exit from the heart it divides into two branches.

The branch on the left side forms an arch, in order to reach the lung of that side in passing behind the bronchia; it joins the aorta, towards the third vertebra of the back. The branch of the pulmonary artery, which is inserted into the dorsal aorta, is longer than the *dorsal arteria* of quadrupeds, to which it is analogous. It should, however, receive the name of *left*, as birds have a similar arterial duct upon the right side. The left lung receives a considerable branch from the ductus while on its way to join the aorta.

The other principal branch of the pulmonary artery passes transversely to the right side, under the aorta; to which it adheres. It furnishes the artery to the right lung, and descends behind the bronchia, in order to open into the aorta, higher than the left branch already mentioned. The right arterial duct is much smaller than the left.

These arterial ducts are two of the three branches, which

have been described in the preceding days as contributing to form the dorsal aorta. The right duct is larger in appearing than the other, and hence, when the aorta is first discovered, it is observed to be only formed by two branches.

About this period the *lungs* have sufficient confidence to be visible. When they are rendered opaque by vinegar, they are found to be not so small, that they might not have been seen some time before if their transparency had permitted it. Their figure is cylindrical; they are attached posteriorly to the back, and connected with the two sides of the heart.

The *liver* has acquired more of its future form than it had the preceding day.

The *stomach* is apparent at this time. It is very thin and tender, and resembles a good deal the form of the human stomach; its orifices are, however, nearer to each other. The stomach is received between the lobes of the liver.

The fluid contained in the *cerebral vesicles* has acquired by this time some confidence.

The *kidneys* are discovered during this day as long reddish granulated lines or traces in the reins.

The *End of the 7th Day, or 168 Hours*.—Upon opening an egg at this period, we perceive that the changes already mentioned in the form, confidence, and situation of the humours have continued to increase.

The *cobite* tends more towards the lower part and small end of the egg; it continues to diminish, and to become more tenacious in its composition.

The *yolk* is more fluid, more spread out, and apparently of a larger size than before. Haller nevertheless found it at this date to possess its original weight.

The *blood-vessels* which are distributed upon the membranes, and which were in the first days, as before mentioned, of a brilliant scarlet, are now in most eggs found to be all of the purple or venous colour. The uniformity of colour makes it difficult to distinguish the arteries; they can indeed be only ascertained by dissecting the membranes and pursuing the course of the vessels into the body of the chick.

The *amies* are still larger at this than any previous period; it preserves its kidney form, and its fluid is transparent, and cannot be rendered opaque, or coagulated by vinegar or spirits.

The *vesicula umbilicalis* goes on increasing in size, and its vessels acquire strength.

The *chick* has its members more developed. The *feet* are added to the posterior extremities, and even the *toes* are discerned. Ossification has commenced. Haller states that he prepared the *four* and *tibia* at the 146th hour. The *two mandibles* begin to form at the under part of the head, leaving an aperture between them, which is to be the mouth.

Haller at this period observed the first convolutions of the *small intestines*, which were so extremely tender as not to admit of being touched, although the rectum was apparent two days before.

The *stomach* now first makes its appearance. Haller supposed that he could likewise discern the *renal capsules* and *ovaries*.

The intermediate of the three vessels which arise from the heart to form the dorsal aorta, is, about this time, seen to furnish the *two carotids*; it is the same vessel which becomes the *descending aorta*, when the structure of the pulmonary artery is completed. Haller states that the pulsation of the aorta ceases after the 154th hour.

The *eye* of the fœtus is considerably developed at the present period. The three humours exist: the *vitreous* is extremely

extremely abundant, upon which depends the great bulk of the eyes of the chick about this time. The *lens* is small. The *iris* is formed, but is very transparent. The trunks of the *optic nerves* and *retina* are visible. The latter is transparent and plaited, and seems to go as far as the lens. The radiated black lines which form the *corona ciliaris* are seen through the retina, placed around the external part of the lens.

The End of the 8th Day, or 102 Hours.—The *vascular arca* has increased so much by this time, that it very nearly covers all the superficies of the yolk-bag, except what is in contact with the white. The branches of vessels, however, begin to decline or disappear in some parts, particularly towards the circumference, although the trunks are larger than at any former period.

The blood-vessels belonging to the *vesicula umbilicalis* are considerably enlarged and extended, and are now seen to turn backwards, to be reflected upon themselves in the direction of the chick. The reflected portion of the vessels of the vesicula appears to be distributed to the superior half of that bag which is now in contact with the external membrane. This membrane, which was in the first periods of incubation, as already mentioned, perfectly transparent, by its connection with the vesicula becomes vascular, and acquires strength, and contributes to form a complete sac, which envelops in the latter days all the humours and the chick, as will be hereafter described.

The *vesicula umbilicalis* is found at the present period to have a considerable extent, according to our observations much greater than has been represented by anatomists in general, who do not seem to have been acquainted with the uses of this bag in the later stages of incubation.

The *chick* is a very pale pink colour, or white slightly tinged with red, in consequence of the vascularity of the surface preparatory to the formation of the skin and feathers.

When the *head* of the *chick* is viewed posteriorly, it presents the appearances of four emences, which are an opaque white, and are joined to each other by transparent membranes. Maitre Jan considers them as the rudiments of the bones of the cranium in a cartilaginous state, and the transparent parts as corresponding to the sutures and fontanel. Haller speaks of these emences as four lobes of the brain. We conceive the account of Maitre Jan to be more correct.

The *head being opened* at this period by Maitre Jan, he says that he distinguished the *membranes*, the *sinuses*, and the *eyalls* of the brain, and that the substance of the *cerebrum* and *cerebellum* was well formed, the *convolutions* even being apparent. This observation, according to our experience, is premature.

The *structure of the eye* is more perfect than before. The *ciliary zone*, according to Haller, is as perfect at the present period as at any time afterwards. Its description, however, is easier some days later.

The *bill* of the chick is cartilaginous. The animal occasionally opens it in the water of the amnios as if attempting to swallow.

The *brail* of the *fetus*, which was covered by a thin membrane, that in the first days was so transparent, as to give rise to the mistake of the heart being outside the chest, has at the present time become flesh upon it. About this period also the rudiments of the *sternum* and of the *clavary* be discovered.

The *gall-bladder* makes its first appearance towards the end of the 10th day, at which period, and for a few days afterwards, it is very small and without colour.

About this time the reflections of the inner tunic of the

yolk-bag, which we have described at the end of the fifth day, as putting on the appearance of yellow vessels, acquire more decidedly the form of valves. They still preserve the same situation and course, commencing under the bed of the *fetus*, and extending outwards in a radiated manner towards the circumference of the vascular area, where they terminate. They are made of a number of plaits or folds which have a transverse direction, and which are more prominent, or have deeper folds in proportion as the valvular lines approach the circumference of the circle. They form merely waves where they commence, and at the present period they are on every part of the yolk-bag much less marked and striking than they become towards the end of incubation.

The End of the 9th Day, or 216 Hours.—Maitre Jan mentions the appearance of some new parts at this period which we have not met with so early. He describes the *kidneys* as secreting a milky fluid, which he saw distending the *ureters*. He discovered about this time the *crap* and the *trabæ* and was not only able to distinguish the principal divisions of the brain, but states that he could discern the *convolutions* with the *emences* they contained, and even the *plexus choroides*. He likewise saw upon the basis of the brain the greater number of the *nervi* that arise there, more particularly the *optic* and *auditory nerves*, and found the *spinal marrow* to be split or composed of two parts at its origin. He distinguished the nerves of the spinal marrow, which, although very small, he states to be much more firm than those which take their origin from the brain. Observ. sur la Formation de Poulet, p. 189.

The surface of the *fetus* exhibits now a number of pores; these are principally situated upon the thighs, the back, the neck, and the wings, and are the apertures of the cells in which the *feathers* are formed.

The *eyes* are larger than the vesicles of the brain; their form is not spherical, but flattened upon the anterior and posterior sides.

The *iris* is still thin and transparent; but there are seen through it and the transparent cornea five or six white points which form a circle. When the eye is opened carefully with a lancet, these points are found to be elongated, and to form little lines, or ciliary fibres, which at this period are white.

Maitre Jan states the *eyelids* to be formed at this time, but to be so transparent as to be invisible, unless after preparation by a strong acid.

The *testicles* are now so firm, that they can be examined without danger of breaking them.

The *yolk-bag*, according to Maitre Jan, begins to form two lobes, a larger and a smaller; but we have not observed this change to take place before the 11th or 12th day.

Maitre Jan made the experiment of boiling an egg at this period, after having fixed it upon a plate of lead with its small end downwards. When despoiled of the shell, and the chick removed, the depression in which the amnios lay was fully exposed, and found to be very considerable. He then made a section of the egg in the vertical direction, dividing the depression of the yolk through the middle, when there appeared a round space about the eighth of an inch in diameter, filled with a whitish curdy matter, and another space around this of a larger extent, containing a firmer matter than the first, and of a paler yellow than the rest of the yolk. Maitre Jan, very erroneously in our opinion, supposed the white curdy substance to be the intellines of the fetal chick. These do not project from the abdomen in sufficient quantity to account for the appearance, admitting that they had been separated from the chick, and had ad-

hered to the yolk during the boiling of the egg. This appearance, we believe, arises from the same change of organization in the yolk being continued, which in the early periods of incubation produced the whitish appearance under and around the bed of the chick. The firm, pale yellow texture of the yolk which encompasses that just mentioned, Maitre Jan accounts for by supposing that the fluid parts of the yolk in the neighbourhood of the chick had passed into the amnios. There can be no doubt that different parts of the substance of the yolk are differently constituted, which difference is preserved notwithstanding the motions that eggs may experience; a fact that cannot perhaps be fully explained, but which proves that animal fluids have their peculiar organization, which they can maintain as well as the solids. When the fluids change this composition, it is often by some vital action in themselves, instead of a fermentative process, or the mechanical operation of the solids upon them, as is commonly supposed.

In making the experiment of boiling eggs at this period, Maitre Jan did not find that the amnios was coagulated, although Haller stated that the liquid of the amnios is coagulable at the 19th hour.

The *vascular structure* upon the internal surface of the *yolk-bag* is more prominent, and when minutely examined, it is found to receive branches of the blood-vessels which are given off at right angles with the plane of the surface of the bag, and having penetrated towards the edge of each valve, there unite and form a single vessel, which runs within that edge. This structure is better seen a few days afterwards.

The End of the 10th Day, or 240 Hours.—The *vesicula umbilicalis* has now a very considerable extent, occupying the greater part of the surface of the vascular area, which last is spread over almost the whole of the yolk-bag. The portion of the bag that is applied to the white, is not at this date the $\frac{1}{3}$ th of the whole. The chalazae, therefore, are much nearer to each other than when we last mentioned them. The white is confined almost entirely to the lower part of the egg, and its mass continues daily to diminish, while, on the contrary, the bulk and quantity of the yolk appears to be increased.

The *external membrane* is firm and fleshy where it is strengthened by the *vesicula umbilicalis*. Some of its vessels are seen to extend to the white, upon which a fine pellicle may be observed to grow, and which is the first appearance of a membrane to this humour, notwithstanding some authors speak of the *membrana albuminis* as an original structure, and others, amongst whom is Blumenbach, describe the membrane which lines the shell as belonging to the white.

The *amnios* is larger, its membrane more firm, and the fluid less clear and limpid than before. It has contracted some adhesions with the *vesicula umbilicalis*, and by that means, with the external membrane. These adhesions are particularly in the course of the blood-vessels, that are distributed to the *vesicula* and external membrane. One of these vessels is always seen to pass across the back of the chick, at which place it is involved in a reflection of very fine membrane, which is connected with that of the amnios.

The *chick* is very much curved at this period: its beak is usually doubled down between its feet. The *feathers* are apparent.

The external form of the *head* bears a greater resemblance to that of the full-grown bird, except that the eyes are still enormously large.

The *eyelids* are evidently formed, and are occasionally

moved by the chick. The *membrana nictitans* is likewise to be seen.

Haller prepared at this period the *ciliary zone* and radiated appearance called the *crown*, with the membrane on which the latter is sustained, although he states that these parts are formed on the 8th day, or before it.

He says he has seen on the 7th day the *corona ciliaris*, or *corpus ciliare* of Morgagni. At this epoch the retina, which is in thick folds, appears to go as far forwards as the crystalline lens, behind the *corona ciliaris*, with which it is covered, and which is dimly seen across it. He believes, notwithstanding, that the retina does not proceed to the lens; that the appearance of its doing so arises from its thickness and folds leaving so small a space between it and the lens, and that the membrane which supports the ciliary zone and crown, and is attached to the crystalline, is different from the retina.

The *corona ciliaris* is a row of black lines arranged alternately, long and short, in some degree parallel, but converging as rays proceeding from the external circumference of the uvea to the crystalline lens. The ciliary crown is not formed entirely in the same manner in quadrupeds and birds. In the former it appears, when examined by a microscope, to be composed of a plicated membrane, upon which some ramified vessels advance towards the crystalline. In birds there are only some serpentine lines folded upon themselves, which are very numerous in the contour of the ciliary crown, and of which many unite to form single ones: they are joined together by these branches, and are covered with a black pigment.

The figure of the ciliary zone and crown is not a perfect circle, but it is broader on one side than the other.

The greater number of anatomists have described the *corona ciliaris* as resting immediately upon the membrane of the vitreous humour. Others have believed that the retina extends to the crystalline, and that the corona is supported upon it. Since Zinn's publication upon the anatomy of the eye, the structure of the ciliary body in man and quadrupeds has been well understood; but in birds the lamina, which serves for the base of the *corona ciliaris*, does not come from the membrane of the vitreous humour.

The membrane, which is placed under the *corona ciliaris* in birds, is to be seen from the 8th day. It is radiated, opaque, and a little ash-coloured; more thin than the retina, and thicker than the membrane of the vitreous humour. It is of the same dimensions as the *corona ciliaris*, and in a degree attached to the corona, and much more firmly united in the latter days of incubation; and after the exclusion of the chick, it adheres by its posterior extremity to the great circle of the retina, and by the other to the crystalline lens.

The retina terminates by a distinctly formed circle, which is a little strengthened at the circumference of the *corona ciliaris*, and at that of the zone. The plane of the retina is continued with that of the corona; the zone is placed more posteriorly than the retina. Its external part, which rests upon the vitreous humour, is nearly horizontal, and its internal part becomes straight again in order to be attached to the crystalline lens. It does not adhere to the membrane of the vitreous humour when the chick is but little advanced. It remains often placed upon that membrane without being attached to it, and when the chick is more formed, or after incubation is finished, it quits the membrane of the vitreous humour, in order to remain connected to the *corona ciliaris*, with which it becomes inseparably united in the end.

The circumference of the ciliary zone, in the latter days of incubation, can be separated from the membrane of the vitreous

INCUBATION.

vitreous humour without leaving any fibres. It is distinguished from the retina by its fineness and being separable from the latter without being torn; but it is continued with the posterior and inferior part of that membrane. It differs still more from the membrane of the vitreous humour; it is thicker, it has more brown and less blue in its colour. Acids, when applied to it, affect its colour more than they do that of the vitreous membrane. It is situated anteriorly upon that membrane, in another plane, and evidently sustained by it, and consequently ought not to be confounded with it.

The canal of Petit does not exist. The membrane of the vitreous humour proceeds, without stopping behind the ciliary zone to be attached to the crystalline lens, that it sustains, and which remains in its place even when the corona ciliaris has been raised.

The ciliary zone is easy to prepare even in the chick but little advanced. One method is to cut off the cornea and iris; and having washed away the black pigment with which the corona ciliaris is covered, it will appear between the intervals of the ciliary rays; and if some of those rays be elevated, it will be seen in its proper place. It is practicable to make the lens come forth from its depression, and to elevate it with the corona ciliaris, with which it is connected; and sometimes it may be possible to leave the zone resting upon the membrane of the vitreous humour.

An easier mode of preparation is to cut the sclerotic coat through the middle, and to plunge the anterior half of the eye into vinegar. After some hours immersion in that fluid, if the back of a fine scalpel be insinuated between the retina and the choroid coats, and the vitreous and crystalline humours be removed, one sometimes succeeds in obtaining the ciliary zone alone, the corona remaining attached to the choroid. It is rare to have the zone entire, but a considerable part of it is commonly preserved, and particularly the whole of the external circle. When the experiment fails, it is the interior circle which remains attached to the corona.

In the above account of the ciliary zone and crown, we have anticipated many facts that are observable during the last days of incubation, and even after that process terminates, in order to render the history of those parts more intelligible. We have also been induced to borrow the preceding description from Haller, who made the structure of the ciliary zone and crown in the chick a particular subject of investigation, as we have not much attended to the progress of the eye during incubation. See Mem. sur la Format. du Cœur dans le Poulet, sur l'Œil, &c. Observ. 180, 181, 182, 101, 102, 193, 215, 216, 226, 228, 231, 239, 240, 247, 249, 253, 254, 256, 261, 262, &c. and sect. xii. Mem. second par M. Haller. The *small tubercle*, from whence the aorta and pulmonary arteries arise, and which appears to have been a remnant of the bulb of the aorta, entirely disappears about the present period.

The *right ventricle* of the heart is still about the one-fourth of its length shorter than the left.

Those *bands* of the chick, according to Haller's observations, which are now formed, are merely in a cartilaginous state; even the *cranium*, which was apparent some time before the present.

The *umbilical opening*, through which the urachus and the blood-vessels communicate with the interior of the body of the chick, forms a projection, or a sort of tube, which in a few days becomes more striking. Some of the convolutions of the intestines may be seen in this opening, but the greatest part of the intestines is contained in the body of the fœtus.

The end of the 11th day, or 264 hours, the external membrane goes on strengthening, by its connection with the *vesicu-*

la umbilicalis. This last is now so extensively united to the external membrane and the amnios, that it is only by great care, and after being macerated in spirits, that it can be liberated from its connections, and exposed as a distinct bag, pendent from the umbilicus. When thus separated by dissection, it is seen to be a large sac, composed of a thick fleshy membrane and hardly containing any fluid. The strength of the bag appears to depend upon a reflection of some of the other membranes covering and being inseparably adherent to it, for at the umbilicus the vesicula is thin. Haller traced the urachus from the vesicula to the rectum after the present period, and even until the last day of incubation; but in our observations it has appeared that the connection of the vesicula with the chick, except by means of the blood-vessels, after this time, is very obscure.

The whole of the body of the chick is now seen to be covered with *feathers*.

Haller at this period first discovered the *tongue*.

The substance of the *brain* is still found to be a very soft pulp.

The *liver*, in most instances, has a yellow colour, but in some the red predominates.

Bile is evidently secreted: the *gall-bag* is green, and a greenish or yellow fluid is commonly found in the stomach. The intestines likewise appear to contain bile, or at least a bitter fluid.

The *renal capsules* are evident; they have, according to Haller, the form of an S.

The tube or sheath which projects at the umbilicus is better formed.

The *blood-vessels*, which come out at this place, are easily traced from different sources. Those which are distributed to the external membrane and vesicula come from the loins, and those belonging to the yolk-bag are from the abdomen.

The end of the 12th day, or 288 hours, the chick has more of the figure of the adult bird than at any preceding period. The extremities are larger, and the head smaller, in proportion to the rest of the body. The bill is more pointed, and of a harder substance.

The *stomach* has gained greater strength; it contains a white coagulated or curd-like substance.

There is *bile* found in all the intestines, which is very bitter.

On the outside of the umbilical sheath there are some folds of the intestines, with one of which the yolk-bag is seen to be connected by a short process, which is evidently the continuation of the alimentary canal into the yolk-bag. This part has commonly, and as we shall hereafter see very deservedly, received the name of *ductus vitello-intestinalis*. Although we have not observed the duct before the present date, there is every reason to suppose that it is coeval with the intestines.

Matpighi states that he saw the *stomach* of the chick on the outside of the umbilical sheath; but this would seem to be an error. The stomach, it is true, is situated low down in the belly, but, as far as our observation goes, it never is protruded from that cavity.

The structure of the *eye* is the same that is described on the 11th day. It is proper to remark, that at no period is there to be found in the chick a *membrana pupillaris*.

The *yolk-bag*, according to our observations, begins in general to alter its figure. Before this date it was an irregularly round mass, containing two depressions; one for accommodating the chick and amnios at the upper side, and another at the lower part of the yolk, in which the white is partially lodged. The latter is a regular depression, and before this period contracts in breadth, although it becomes somewhat greater.

INCUBATION.

greater in depth; an alteration which arises from the diminution of the white, and from the chalazae tending to approach each other, and thereby to bring the two poles of the yolk, at which these bodies were originally attached, together on the lower surface of the yolk. The approximation of the chalazae seems likewise to occasion, in the first instance, the division of the yolk-bag into lobes. At the present period the bag forms two lobes, one large and one small. These afterwards, by the compression of the chick, are usually moulded into three, but in the egg of some other birds into a greater number: thus the yolk-bag in the *Guinæa fœcal* is divided into six or seven lobes.

The End of the 13th Day, or 312 Hours.—Upon opening an egg at this period, and removing the contents from the shell, the *white* is found to have assumed a greenish hue, and to have more confidence than at any of the former periods; and it is inclosed entirely by a fine film, which retains it in one position, and in strict connection with the depression on the inferior surface of the yolk-bag. The external vessels are distributed over the whole white.

The yolk-bag has still more of the lobulated figure, and the chick lies obliquely across the bag in the superior depression between the two lobes.

The *vascular structure* on the internal surface of the yolk-bag, which we have noticed before, has now arrived at perfection. The valves are more eminent, form numerous folds or coils, their edges appear to be covered by tubes which are calculeated upon themselves in the manner of intestines. These have been called by Haller the *vermiform and intesliniform tubes*, and have been described both by him and other anatomists as real vessels: but they have always appeared, in our examinations, as reflexions or processes of the valvular structure, in the substance of which the real blood-vessels ramify. Maitre Jan speaks of them as vessels which collect the fluid of the yolk, and which afterwards terminate in the blood-vessels. Haller considers the blood-vessels which run in the edge of the valves as a distinct order of vessels, that end in the trunks of the veins of the yolk-bag, and which take their origin at the circle, that exists in the latter days of incubation around the line where the yolk and white are joined to each other. We have already said that the vessels upon the edges of the valves have numerous communications with those that run along the roots or bases of the valves, and which belong to the external tunic of the yolk-bag, and were originally the same vessels that formed the vascular area. The venous circle of the yolk-bag, we have no doubt, is the same that in the early stages of incubation has been described as the contour of the vascular area: and the vermiform tubes appear to be the villos or spongy processes of the external surface of the yolk-bag, which appeared in the first days greatly extended, and grown into the form now described.

The *chick*, at the present period, has still more of its perfect form; its head is much curved, and the bill is placed under the wing, which position is preserved throughout incubation.

The *bill* is pointed and has its natural figure. Haller states, that the chick is often perceived to open and shut the bill about this period and afterwards. Maitre Jan, on the contrary, although the chick moves its limbs frequently and strongly, asserts, that it does not open its mouth. We have not attended to this circumstance, from considering it of little consequence, and no way explaining the mode in which the chick is nourished.

The *internal organs* of the chick are considerably advanced towards perfection. The *brain*, although still soft and pulpy, is well formed. The *kidneys* and *testes* are completed in their

figure. The *spleen* resembles a conglobate gland. The *lungs* are of greater size than the heart.

The first branch that the aorta gives after its exit from the heart is the *left carotid*, which gives off the *subclavian artery* of that side. The trunk of the aorta then forms an arch, which turns to the right. It sends off the *right carotid*, and approaches the vertebrae in passing behind the right lung: it is united to the ductus arteriosus above the liver.

The right ventricle of the heart is still shorter than the left; it is of an oval figure, but the latter ends in a point.

The end of the 14th day, or 336 hours, the changes in the humours and the formation of the organs of the chick are found to have made progress since the preceding day.

We have already stated that the membrane which is external to the chick and the yolk-bag, and which is scarcely palpable in the first days of incubation, gains strength and receives vessels after the vesicula umbilicalis has acquired some size, and has adhered to it. The magnitude of the vessels, and the thickness of this membrane, increase in proportion as the vesicula umbilicalis grows: we therefore conceive that the development of this membrane depends upon its connection with the vesicula and the blood-vessels which it derives from that bag. We have observed, that some days before the present period, the external membrane begins to extend over the white, which it usually incloses about the 14th day: it therefore forms a perfect sac, containing the chick in its amnios, the yolk-bag, and the white.

The vesicula umbilicalis about this period has arrived at a very great size; its extent cannot be easily ascertained, as it is so much incorporated with the external membrane, that they cannot be separated or accurately distinguished: but we should conceive that the vesicula exceeds in size the yolk-bag, as there is the appearance of the external membrane being thickened and strengthened by one under it as far as the yolk extends.

The manner in which the vesicula concurs to form a membrane which invests all the contents of the egg, appears to be similar to the reflection of the serous membranes of the thorax and abdomen, in order to cover the viscera and line the parietes of these cavities. It should however be observed, that when it is opened, there is no appearance of its forming an immediate tunic similar to the pleura pulmonalis, but it seems to be a simple bag, holding the contents of the egg, and only united to them by some reflexions of very fine membrane, which are chiefly attached to the back of the amnios, and in the course of the trunks of the blood-vessels. This circumstance has embarrassed other observers, and has led many to overlook the share that the vesicula umbilicalis has in the formation of the common membrane of the parts of the egg.

The *blood-vessels* which are distributed to the external membrane, are, even at the present period, much larger than those of the yolk-bag. There are four long branches, which feed out numerous ramifications, that become so minute as to evade the sight; but when this membrane is viewed with a magnifying glass, it presents a beautiful spectacle. The situation of the four great branches is not constantly the same; as they are dispersed upon a loose membrane, which varies in some degree its position according to circumstances: one of them, if not two, is always seen, however, to cross the back of the amnios. The four branches are arteries, and are formed immediately on the outside of the umbilicus of the chick from the two iliac arteries; they, therefore, correspond to the *umbilical arteries* of mammiferous animals. The left iliac artery is always of much greater size than the right; it even appears larger than the aorta, of which it is the termination.

INCUBATION.

nation. The right iliac artery is often a mere filament, and in some instances it seems to be wanting altogether.

The *venous branches* which accompany the umbilical arteries are so small that they are hardly distinguishable, although the former are of sufficient magnitude to be injected, and have a visible pulsation. There is, therefore, a quantity of blood sent to this membrane which is not returned to the fœtus. The colour of the blood, both in the umbilical arteries and veins, is a purple.

The vascular membrane, above described, has received different names. By the older anatomists it was usually called the *chorion*, to which perhaps it is most analogous. Haller gave it the name of the *umbilical membrane*, and Leveillé has lately called it the *lax-flopped membrane* (*membrane fœciforme*), from the circumstance of its enveloping all the parts of the egg. We have hitherto called it the *external membrane*, until it should be defined; but hereafter we shall speak of it as the *chorion*. In the account of the unincubated egg, the membrane, on which the shell is moulded, is called the *external*, which it strictly is. It should not be confounded with the *chorion*, from which it differs so much in figure, structure, and use. See Egg.

Haller appears to have not distinguished the chorion from the membrane of the yolk-bag, which contains the vascular area. The progress of these two membranes is exceedingly different, and the system of vessels belonging to each is perfectly distinct. The vascular area is confined to the surface of the yolk-bag, and is intimately connected with it, membranous, and the vascular apparatus already described. The vessels of the area are chiefly venous, and are formed independently of the heart of the chick. They are most numerous in the early periods of incubation, although they increase in size along with the other parts of the chick. They go to terminate in a large vein which proceeds directly to the auricle of the heart in the first days, but, after the liver appears, is seen to pass behind it, and when the intestines are formed is found upon the mesentery, and constitutes the largest branch of the vena porta.

The arteries of the vascular area are insignificant, until towards the end of incubation. When first perceived, they are given off from the dorsal aorta, and after the development of the intestines they are discovered to be branches of the mesenteric artery. The vessels distributed to the area appear, therefore, analogous to the omphalo-mesenteric arteries of quadrupeds, although their destination and functions may differ.

The *veins* of the *chorion*, as we have already said, are branches, or rather, in the fetal state, the trunks of the veins extended upon this membrane. They do not exist previous to the appearance of the vesicula umbilicalis, with the growth of which they keep pace. The arteries of the chorion exceed the size of its veins in the same proportion as the veins of the yolk-bag exceed the arteries of that part. The vascular area, therefore, collects and transmits the blood to the fœtus, while the arteries of the chorion dispose of a great portion of it in an extraneous circulation, and in the formation of a thick and extensive membrane.

Haller and others have described, at this date, an appearance of white vessels upon the albumen. Maitre Jan reckons seven of these white lines or vessels. They arise from a little circle which is in the centre of the white; they divide into branches in advancing towards the vascular circle of the yolk-bag, which forms at this time the boundary of the septum between the yolk and the white. Maitre Jan describes them as passing beyond the septum and extending to the yolk. Haller conjectures that the use of these vessels may

be to absorb the white and convey it into the yolk. Observ. 226. Mem. 1.

We have not made such an examination of these white lines, as to enable us to pronounce whether they are vessels or not, or what their use may be.

The *water* of the *amnios* appears to diminish about this period of incubation. It also becomes gradually less pure. It is stated by Maitre Jan, that when the fluid of the *amnios* is boiled at this date, the greater portion of it acquires the hardness that the white of the egg possesses after being boiled, although previous to the experiment it is much more fluid than the albumen; from whence Maitre Jan conjectures that some of the fluid of the white is conveyed into the sac of the *amnios*, but he does not pretend to explain the means by which this is effected.

The *card-like substance*, already mentioned as being found in the stomach and intestines, is now met with also in the crop and œsophagus. According to Haller, boiling water makes this substance hard in the same manner as it does the white of an egg.

The *end of 15 days, or 360 hours*, the membrane of the *chorion* continues to increase in strength, and its arteries in size. Haller speaks of having sometimes found the latter of a lighter red than the veins, which does not accord with our observations. We have generally perceived the arteries and veins to be similar in colour, or at least when a difference did exist it was immaterial, and sometimes the arteries, and sometimes the veins were the lighter coloured vessels. The vessels of the chorion have always appeared darker in our observations than those of the yolk-bag, but the character of all the blood is venous in the incubated egg during the latter periods. The reflections of membrane which accompany the principal vessels of the chorion, are now more firm than before, and continuous with them appears a fine transparent membrane that envelops the yolk as far as the vascular circle on the edge of the white, and extends over part of the *amnios*, to which membrane it adheres, so as to cover an irregular triangular portion of the chick in its *amnios*, and inclose more loosely the umbilical sheath with the convolutions of the intestines which project from it and the neck of the yolk-bag. This membrane does not appear to have been well understood by the older anatomists.

They sometimes speak of it as a layer of the yolk-bag, and at others as the vesicula umbilicalis, or allantois. The best description of it has been given by Leveillé, who has also named it very appropriately *entero-choriynne*, or the *membrana containing both intestines and yolk*.

The origin of this membrane is still involved in a degree of obscurity. Leveillé described it when perfectly formed, but has thrown no light upon the history of its growth. The present date is the first at which it has appeared to us to be perfected, but we conceive that it is one of the original membranes and the second layer, that in the first days comes off the vascular area as a very fine pellicle. It seems to be completed, or rather continued into the peritoneum, lining the *amnios* in the late periods of incubation, of which we shall see farther proofs hereafter. There is no reason for supposing this membrane to be the vesicula umbilicalis, or allantois, as the vesicula is a stronger membrane in the middle of incubation than this membrane is several days afterwards, when it is completely formed. The proper contents of the allantois also are found, throughout incubation, within the cavity of the chorion, to the formation of which we have supposed that bag contributes, but never under the membrane that incloses the intestine and yolk-bag.

Haller states that he examined the *waters* upon the inner surface of the *yolk-bag* with a lens, and distinctly saw the

intelligiform

INCUBATION.

intestineform tubes upon the edges of the valves most beautifully curled and folded upon themselves. He failed to see the aperture of these tubes. By maceration in water they were detached from the valves, and swam in the water. The valves themselves, by a longer maceration, were also separated.

The *chick* increases regularly in size, though not so rapidly as during the early part of incubation. Haller observed the feathers upon the *eye-lids* at this period, and that the *spleen* had acquired the figure it preserves through life.

The *curdy*, or *coagulated substance* is now found in the œsophagus and the crop, as well as in the stomach and intestines. Harvey found this substance principally in the stomach: this appears to be the case, and when met with in other places, it would seem to have proceeded from the stomach to them.

The *end of 16 days, or 384 hours*, the space between the two layers of the membrane lining the shell, for containing air, is much increased since the period at which we have last mentioned it. About one-sixth of the whole cavity of the egg is occupied by air.

This circumstance depends upon the diminution of the substance of the white, which is at present reduced to a very small size.

The texture of the *white* continues to become firmer.

Upon removing the chorion, which now completely encloses the white, that humour is found to possess a thin tunic, which is proper to it. This membrane is evidently of a late growth, and appears to be formed by the vessels of the yolk-bag extending beyond the septum, or that portion of the bag which is bounded by the vascular circle, and which is in contact with the white.

The fluid of the *amnios* is somewhat diminished.

The *yolk-bag* in the egg of the hen is generally formed into three lobules, although many authors speak only of two lobes at this time; one, which is the most distinct, but the smallest, lies upon the side of the body of the chick, between the head and the thigh: the two others are placed at the two ends of the chick.

Maitre Jan describes the yolk-bag as being formed only into two lobes, but ready to enter the abdomen, of which he gives a figure at this period, and of a fissure that ascends from the umbilicus, between the two recti muscles of the belly of the chick. He likewise describes the ductus vitello-intestinalis for the first time, which, with the yolk-bag, he succeeded in inflating from the crop of the chick; and he says this part is not to be demonstrated at an earlier period than the end of the 16th day, on account of its extreme tenderness; but, as already mentioned, we have found the duct on the 13th day.

Haller found the intestines before this period to be irritable. When stimulated, they contracted into knots.

The blood-vessels of the yolk-bag appear fewer and smaller, owing, in part, to their being so much more involved in the valvular coat than they were in the middle periods of incubation. The branches of the blood-vessels of the yolk-bag are larger than the trunks, and the veins are still vastly greater than the arteries. Haller states that the vein going upon one of the valves, is a larger vessel than the trunk, from whence all the arteries of the yolk-bag take their origin.

The *End of 17 Days, or 408 Hours*—Haller admits the appearance of three lobes of the yolk at this date, which we have seen before.

The *arteries* of the *chorion* are extremely large; we have succeeded in introducing a pipe into them, and injecting them with coloured size, which makes a beautiful preparation. Haller, in his observation of this date, found both

the arteries and veins of the chorion to be a purple colour, and the veins more violet than the arteries.

It now appears that there are two series of vessels belonging to the yolk-bag. The branches, which are spread upon the external membrane of the bag, appear to be the same which formed the vascular area in the early periods of incubation. The vessels of the internal coat are distributed to the valves. Both series contribute to the vascular circle, which, as we have before stated, is the remains of the vein that formed the contour of the vascular area. Maitre Jan says there are several layers of the membrane which contains the yolk, but it is probable that he mistook for one that membrane which incloses the yolk-bag, the intestines, and a part of the chick.

Ceiter has found the *yolk-bag* within the belly of the chick at the 17th day; but the ingurgitation of the yolk is a later event, according to the observation of other writers.

There is now a circular arrangement of muscular fibres around the opening into the belly of the chick at the umbilicus. This sphincter was not apparent before, and, as we shall soon find, is a very essential structure in the last periods of incubation.

If the *yolk-bag* be opened, and the valvular membranes cleaned by frequent ablation and floated in clear water, the sides of the valves will be found to be perforated by a great number of foramina, so as to give the valves the appearance of lace. The intestineform tubes also upon the edges of the valves will be partially detached; and the portions that remain resemble pieces of cylindrical tubes.

Many of the blood-vessels upon the external surface of the yolk-bag contain apparently but little blood, and have a greenish colour, as if conveying a yellow or green fluid.

The *End of the 18th Day, or 432 Hours*.—The two layers of the external membrane, which immediately lines the shell, are separate for about one-third of their extent, and can with little pains be detached from each other until near the small end of the egg. The quantity of air contained between these layers, although much increased, is less than might be supposed, as the layers are not far asunder, except at the great end of the egg.

The *coater* of the *amnios* is a good deal diminished, and its membrane is applied in folds to the surface of the chick.

The *chorion* has attained a very considerable strength, admitting of examination and dissection, without being previously hardened by spirits or vinegar. When this membrane is laid open, there is some tough lymphous substance found under it in layers or streaks, which has been mistaken for a membrane by some anatomists. There is generally mixed with this substance a certain quantity of calcareous matter. It has, therefore, been supposed to be a kind of excrement, or the secretion of the kidneys. These white flakes are what have been called *strie reticulatae urinae* by Malpighi, and were described by him as being found in the allantois.

When the chorion is opened and turned down off the contents of the egg, it appears to be a distinct bag, and only connected to the other parts by reflections of fine membrane. These are chiefly in the course of the trunks of its blood-vessels, and at the junction of the yolk and white.

The *yolk-bag* is now often found gathered into more lobules than three, some of which have entered the abdomen of the chick, through the aperture at the umbilicus. The forming of the yolk-bag into lobes and lobules, appears to be owing to the contraction of the membrane that contains it, and the intestines of the chick; for, when the yolk-bag is taken out of this membrane, it spreads out into nearly its original figure, except that there is a marked depression where the white is joined with it, and that the neck of the bag is somewhat elongated

INCUBATION.

gated. It seems likewise to be the contraction of the fame membrane which urges the yolk-bag into the cavity of the abdomen of the chick.

The *yolk* appears to be somewhat less than in the preceding days; but on the closest examination we have not been able to discover any of it in the intestinal canal. We have observed at this period, although it probably exists much sooner, an appearance of yellow vessels accompanying on each side the blood-vessels of the yolk in the same manner as the small veins generally attend arteries. We have not been able to determine whether this appearance be caused by real vessels filled with a yellow fluid, or by the inner coat of the bag being seen through the outer, producing on the edge of the tract of the real blood-vessels an appearance of yellow lines.

The *chick* has now attained nearly the utmost size that it will possess while in the egg. Its form is entirely that of the excluded chick, except that its abdomen is enlarged in proportion to the quantity of the yolk-bag which is admitted into that cavity.

The different organs of the chick are very perfect. The convolutions of the *intestines* which were outside are taken into the belly with a portion of the yolk-bag, as before mentioned. Maitre Jan states that he found about this period the *sympanum* and the *labyrinth* of the *ear* hard, and nearly of their full size. All the *bones* have acquired ossific matter and considerable hardness.

The *bile* contained in the *gall-bag* is an intense green, and gives that bag a blue colour.

The end of the 19th day, or 456 hours, the *air-cell* extends round one-half of the cavity of the egg.

The *amnion* is in some instances found to be ruptured by the bill of the chick.

According to Haller, the chick begins to cry about this period. Harvey and Langly also heard the piping of the chick at this date. Some other authors have not noticed the chick to cry until the twentieth day, which agrees with our observations. Still, however, the time at which the chick begins to cry is subject to vary, according to the degree of heat to which it is exposed. Thus, in an egg from which no sound issues while it is in the nest, if placed upon warm water the piping of the chick will be heard.

The *chorion* begins to appear a little faded, the circulation of blood upon the membrane being carried on more sluggishly. This change seems to be preparatory to the destruction of that membrane which is about to happen.

More than two-thirds of the *yolk-bag* and its contents have been received into the abdomen. If that cavity be opened, it will be seen that the bag is pressed in amongst the different viscera, to which its figure is capable of being perfectly accommodated in consequence of its folds and lobules.

The *ovibite* is reduced to a few irregular-shaped knots, which generally contain some calcareous matter that appear to remain after all the liquid parts of the albumen have been removed. The knots are composed of the chalazæ, and the membrane of the white compressed together.

Maitre Jan very readily succeeded in distending the yolk-bag and the ductus vitello-intestinalis, by blowing air into the œsophagus, but did not yet perceive that any of the yolk had passed through the duct into the intestine.

Haller describes at this date the effects produced upon the valvular structure of the yolk-bag by maceration in water for some days.

Having first washed the face containing the yolk with several waters, he found the edges of the valves covered with the vermiform tubes before described, which separate and

form curves; these elongate and expose the interval of their two curvatures. They break at the end, and the two ends become nearly straight, remaining attached to the edge of the valve. The breadth of these little membranes appears also covered with cylindrical tubes, sometimes branched and separated by the reticular intervals. The day after, the yolk-bag having been steeped in water, he saw the appearance of cylindrical tubes forming a net-work upon the membrane which makes the breadth of the valves, and continuous with the vermiform tubes of the edges. He further saw that the vessels of the valves, having arrived there, were covered with some very fine small tubes resembling a powder. The following morning, he saw some of the tubes which ascended from the base of the valves, and which were continued with the tubes of the edge. They were cylindrical as far as he could perceive, and joined in form of a net-work. The straight vessels went evidently as far as the vascular circle of the yolk-bag.

The fourth day many of the tubes had disappeared, and there only remained on the edge of the valves the membrane which covered the trunk of the vessel. With respect to the nature of the tubes on the sides of the valves, he found it difficult to pronounce with certainty. By examination with a strong lens he perceived that there were some real tubes upon the sides of the valves, which ascended in a serpentine manner; but those which are the most numerous, and which form the net-work on the breadth of the valves, were not determined to be tubes, although they are most probably so, as they appear cylindrical under every point of view, and are continuous with the tubes of the edge.

The fifth day, the vessels of the edge appeared all uncovered: these vessels preserved some breadth, and a round figure at the edge, and an undulating course. It was more easy to distinguish the real vessels which descend from the edge in a serpentine manner, and traverse obliquely the breadth of the membrane, in order to return into the plain between the valves. Haller also saw very evidently some branches which proceed from the vessels between the valves, and which ascend in a serpentine manner by the side of the valves, and communicate with the trunk which runs along the edge. The remainder of the valve was become an open net-work of extreme beauty.

The sixth day many of the valves had disappeared, and others presented only a plaited border, like a meneltery, from which the intestines had been removed. Mem. 1. p. 379.

The *chick* at the present date is about the size that it is immediately after exclusion from the shell. It lies coiled round with its head under the right wing.

The *blood-vessels* in the interior of the chick have attained more of their proper size in proportion to the parts they supply. The left branch of the aorta, however, which forms the principal umbilical artery, is still nearly equal in magnitude to the aorta itself.

Haller observed at this period the *vena cava* beat between the lobes of the liver.

The end of the 20th day, or 480 hours, the *shell* is extremely dry, and very fragile, which is occasioned by the more extensive detachment of the membrane which is immediately under it. The brittleness of the shell is a very convenient circumstance at this period, when it is about to be ruptured by the efforts of the chick.

It is usual at the present date to find the greater number of the eggs in a hen's nest cracked or chipped near the great end. This is attributed by common people to the parent, who is supposed, by a particular instinct, to know the proper period for the liberation of the young chick. Malpighi likewise

INCUBATION.

supposed that the shell was broken by the hen, in which opinion Haller seems to concur. He states that he found a fissure in the shell, and the membranes which inclosed the chick, at the same time entire. Maitre Jan, on the contrary, ascribes the fracture of the shell to the chick. He found the beak had lacerated the membranes before the shell was broken; and having watched the eggs at the time the chicks began to cry, he did not perceive the hen touch them with her bill, but that the shell was ruptured from the inside, and the fractured portions were pushed outwards. This account of the mode in which the shell is opened, exactly accords with our observations. We have seen the shell evidently broken from within; besides, the fact of birds being hatched by artificial heat, proves decidedly, that the assistance of the hen is not necessary for the fracture of the egg.

After the shell is broken the chick is always heard to cry, and the point of its beak is seen to project out of the egg for several hours before the chick attempts its liberation.

It is reported by common people who have the care of fitting hens, and it is even asserted by some anatomists, that the cries of the chick are heard before there is any aperture made in the shell. Haller relates that he took an egg, in which he discovered the piping of the chick, and which was at the same time unbroken, and having carefully removed the shell, piece by piece, he found that the opaque membrane, which lines the shell, was alone entire, but that there was an opening in the chorion opposite to the beak of the chick. He does not state whether the bill had penetrated into the air-cell, but it most probably did, as at this period the two layers of the membrane lining the shell are separated beyond the situation of the beak of the chick. In another observation Haller found the chorion entire under the fissure in the shell, which was on the opposite side of the egg to the bill of the chick; and therefore he supposes the shell to have been cracked by the hen. We cannot positively contradict the assertion of the chick uttering sound before it has the means of freely respiring, but we should conceive it extremely improbable; and upon every occasion where we have heard the piping of the chick issue from the egg, we have found that there was a crack or fracture in the shell.

Where the chorion is lacerated by the beak of the chick there is always some blood shed, but the edges of the membrane soon dry, which prevents any farther hæmorrhage; for the circulation is not yet interrupted in the chorion by the contraction of the sphincter at the umbilicus, although Maitre Jan describes the passage of the yolk, and the destruction of the chorion, as events of the same date.

When incubation has proceeded regularly, the whole of the yolk-bag at this period is found within the cavity of the abdomen, which is closed by the contraction of the circular fasciculus, of muscular fibres placed around the umbilicus; but, as already mentioned, this does not, until near the exclusion of the chick, compress the umbilical vessels, so as to destroy their circulation.

The ingurgitation of the yolk causes a great tumefaction of the belly of the chick. The animal resembles one in a gravid state, but the belly is less swollen than might have been supposed from the bulk of the yolk-bag. The latter does not lie in the front of the cavity, but is pressed in between all the viscera, and therefore occupies the least possible space.

It is remarked by Maitre Jan, that more chicks die about this period than at any other of incubation, which he attributes to the distention of the abdomen by the yolk-bag; but we should suppose that it is the cessation of the external circulation upon the membrane of the chorion, which causes the great fatality towards the end of incubation.

Maitre Jan states that he discovered the fluid of the yolk at the 48th hour mixed with the contents of the small intestines; but some other anatomists, who admit the passage of the yolk through the ductus vitello intestinalis, do not pretend to have detected it in the intestine so early.

The chick, about this period, is sometimes observed to remain for a while perfectly motionless. Harvey supposed that it was asleep on these occasions. How far he was correct we cannot pretend to say.

According to Haller the weight of the yolk is not sensibly diminished before its entrance into the belly of the chick. He weighed the entire yolk-bag at the 500th hour, and found it to be three drachms and two grains. He states that the weight of the yolk, before incubation, was three drachms and ten grains. This diminution of weight is, therefore, not greater than might have been expected from evaporation, or from an original difference in the bulk of the two eggs that were the subjects of the experiment.

Haller, in seeking for the *allantoides*, or *vesicula umbilicalis*, at this period, states, that he could not distinguish it from the chorion, or rather from a fine membrane he raised from the internal surface of the chorion by inflation; but he found a little sac in the form of a pear, extremely vascular, full of a yellow mucus, and terminated by a peduncle which was not an inch long. We have already described the *vesicula umbilicalis* as being lost in the formation of the chorion long before the present period. Malpighi, likewise, supposed this part to have the same destination in the latter periods of incubation: and in none of our observations have we met with the pear-shaped bag mentioned by Haller. We have turned back the chorion at the present date, and have found it to be a perfect sac, such as we have previously described it, and connected with the adjoining membranes by reflections of a very delicate texture. These were readily detached, and left the chorion pendent by its vessels from the umbilicus of the chick. Besides the blood-vessels, we could discover a transparent filament passing to the inverted bag, which appeared to be tubular, and perhaps was the urachus.

The End of 21 Days, or the full Period of the Incubation of the Hen.—When the progress of incubation has been regular, the chicks are now generally found to have abandoned the eggs, leaving the shells with the shreds of the chorion and annios behind them. It happens, however, occasionally, that some of the chicks have been backward in their growth, from the unfavourable position of the eggs in the nest, or the negligence of the hen. These are sometimes found about this period within the broken shell, having the remains of the membranes still attached to the umbilicus.

The separation of the membranes does not appear to be effected by a process of slough or of ulceration. They appear rather to be torn off, as some shreds and a short portion of the trunks of the blood-vessels are seen to project at the umbilicus. The hæmorrhage from these vessels also is not entirely suppressed by the contraction of the sphincter muscle, but in a degree by the assistance of a clot of blood, which forms in the ends of the torn vessels.

We have not been able to observe whether the complete fracture of the shell, previous to the exclusion of the chick, and the detachment of the membranes, are accomplished by the efforts of the chick alone, or with the assistance of the hen.

The belly of the chick, after exclusion, is much enlarged, though less tumid than it was when the yolk-bag was first taken into the abdomen. It would, therefore, appear that the yolk begins to diminish immediately after it is admitted into the belly of the chick, although some observations of Haller

INCUBATION.

Haller would lead to a different conclusion. He weighed the egg and its different contents at the 526th day, and found the entire egg to be 13 drachms and as many grains; the weight of the yolk, with some light membranes that adhered to it, was four drachms. The fetus weighed five drachms and 14 grains. In an egg which had not been fat upon, he found the weight of the entire egg to be 10 drachms and three-sixths, and that of the yolk three drachms and 10 grains. This account of the weight is obviously incorrect. See Egg.

Many anatomists state that they have been able to detect the fluid of the yolk in the intestines at this period, and some supposed that they found it had passed into the alimentary canal, even before the exclusion of the chick. Haller found yolk in the intestines at the end of the 21st day, in one instance where the chick had not left the egg. Maitre Jan saw it after 20 days and six hours. Needham describes the gradual passage of the yolk into the intestine at the end of incubation. Langly also found it in the intestine at the same time. Theod. Alder states that before the chick was excluded, he could not press the fulbrance of the yolk into the gut, but that immediately afterwards he was able to do so. Stenon succeeded in pressing the yolk through the ductus vitello intestinalis.

Notwithstanding the testimony of so many anatomists, we are inclined to believe, that the fulbrance of the yolk is not conveyed into the intestine. We have scrupulously examined the intestines of chicks, both before and after the exclusion from the egg, and in no instance could we discover with certainty any yolk in them. In the last periods of incubation, and until the chick has taken its natural food into the stomach, the alimentary canal is filled with a yellow fluid, which it is scarcely possible to distinguish from the yolk; therefore, all direct observations respecting the passage of the yolk into the intestines must be attended with a degree of doubt. There are, nevertheless, many reasons besides actual examination; for supposing that the yolk is not conveyed into the system of the chick by passing first into the intestinal canal, which we shall state in speaking of the uses of the different parts of the egg, we are further supported in our opinion by the authority of Blumenbach, who asserts positively, that the yolk does not pass into the intestine. We might also quote the same opinion held by Leveille; but he advances it upon false grounds, as he describes the ductus vitello intestinalis as a ligament, by which the yolk-bag is suspended to the body of the chick, notwithstanding the tubular structure of this part is so palpable.

The substance of the yolk at the end of incubation is extremely tenacious or gluey in its consistence, and of a deep green colour, particularly in the centre.

The network of the valves upon the inner membrane is very visible at this period. We have thrown coloured size into the blood-vessels of the yolk, and afterwards softened by maceration, and by frequent ablution detached the inner membrane; when we found that the basis of the lace-like or reticulated structure of the valves was formed by real blood-vessels, which presented the most beautiful vascular apparatus that we have ever seen. This mode of preparation shews, that the organization of the internal membrane depends upon the growth of the blood-vessels of the external membrane of the yolk-bag, and confirms the account we have already given of the formation of the valves. Haller considered the vessels distributed in the valvular structure of the bag as being chiefly, if not entirely, venous; but we found them most easily injected from the aorta of the chick. In the early periods of incubation we know that the branches

of the veins of the yolk-bag are larger and more numerous than those of the arteries, but we are inclined to believe the arterial branches predominate towards the end of incubation. Further observations, however, are necessary to explain the vascular system of this membrane.

Several anatomists speak of a new membrane being found upon the yolk-bag towards the end of incubation, which is continuous with the skin of the chick. Haller, in some observations, describes this membrane in a manner which leaves no doubt of its being the same that we have already noticed as including the yolk-bag and intestines of the chick, when they are on the outside of the body.

We, as well as others, have found the appearance of a new transparent membrane covering the yolk-bag after it has entered the abdomen of the chick. This membrane seems to be the continuation of the peritoneum. It adheres to the inside of the umbilicus, and to that point of the yolk-bag where the white and chalaazæ were attached. We have not had it in our power to investigate completely the connections of the yolk-bag with the peritoneal coat of the parietes of the belly, but we believe at present that any appearance of a third tunic to the bag is derived from the peritoneum.

Haller states observations made upon the *allantois* or *vesicula umbilicalis*, even to the last day of incubation. He mentions that he found under the chorion an extremely fine membrane which was incorporated with the tissue of white filaments or streaks that we have spoken of before. He describes this membrane as giving an immediate covering to the chick: it was so tender that inflation burst it. He supposes it to be either the amnios or the allantois. In the next paragraph he says, he sought the centre of the yolk, and found the urachus there without having any connection with the allantois. He inflated it, one part of the air went out at the anus; another elevated the membranes of the rectum. He next passed an extremely fine probe into the urachus, and found an orifice on the left side, between the anus and that vessel that the urachus produced by inflation in the rectum: the probe would not enter the plicated muscular sac, which is behind the rectum and at the side of the vagina.

This account appears to us to be very inaccurate in some points. The membrane which Haller took for the allantois was most probably that which envelops the yolk-bag and intestines. The urachus at the periods of incubation, when it can be found, has no connection with the yolk-bag. The foramen on the left side of the anus appears to have been made by the probe, and the muscular sac he speaks of was the *burba Fabricii*.

Changes which take place in the Structure of the Chick after Incubation.—These chiefly relate to the disappearance of the yolk, and the degeneracy of the arterial ducts, which in the fetus conveyed the blood from the pulmonary artery into the aorta.

In two days after exclusion from the egg, the yolk is very sensibly diminished in quantity, and its consistence is even more tenacious or gluey than it was before.

The *right ductus arteriosus*, which is the first obliterated, becomes so small as a filament. The *left* is, according to Haller, diminished three times the size it had during incubation.

In four days after exclusion, the yolk is found to be reduced two-thirds of its bulk. In proportion as the substance of the yolk disappears, the membranes forming the bag also diminish. The adhesion which we have mentioned, the yolk-bag to have with the internal part of the umbilicus, after its admission into the abdomen, is now undone. It would appear that this attachment is produced by the con-

INCUBATION.

traction of the sphincter muscle upon the remnant of the vessels and of the membranes connected with the centre of the yolk-bag.

It is now particularly easy to see the origin and course of the proper *blood-vessels* of the yolk. The *veins* belong to a single trunk, which is continued along the mesentery, and ends in the vena portæ; it is evidently a branch of the mesenteric vein. The *arteries* are also derived from a single trunk, which is the principal branch of the mesenteric artery. This trunk, in some points of view, appears to be double; it divides, passes on each side of the intestine, and then unites to form a single vessel previous to its distribution in the membranes of the yolk-bag. These vessels, and the ductus vitello intestinalis, are connected together by some fine folds of peritoneum, which are the continuation of the mesentery.

The cavity of the *right ductus arteriosus* is completely obliterated, but the *left* is scarcely more diminished than it was on the second day.

In eight days after exclusion, the yolk is reduced to the size of a hazel nut. The *ductus vitello intestinalis* becomes thicker, and more resembles the intestine than it did before.

The valvular structure upon the internal surface of the yolk-bag is no longer apparent.

The *right ductus arteriosus*, although reduced to the size of a filament, is enlarged where it enters the aorta.

The *left duct* is likewise obliterated at its origin from the pulmonary artery; it is a filament, but is inferiorly white, opaque, and larger. Both these ducts, therefore, decline first at the superior part, where they come from the pulmonary artery.

The gizzard of the chick, especially if the animal has had the opportunity of picking up small stones with its food, is thick and muscular; and the internal coat, which during incubation was soft and spongy, is now become firm and dry.

In 16 days after exclusion, according to Haller, the substance of the yolk is entirely consumed; there remains but a small thin sac, less than a pea, containing a granular substance, which is partly of a calcareous nature, and which is the dregs of the substance of the yolk.

Twenty-seven days after exclusion, Haller found both the *right ductus arteriosus*, and the *left*, still remaining in the form of filaments. The *right* was smaller than the *left*. The latter was still open at its junction with the aorta.

In three months after exclusion, the *ductus vitello intestinalis* is found to be turned down upon the side of the intestine, to which it evidently forms an appendix. At its extremity may still be seen the remnant of the yolk-bag, reduced to nearly the size of the head of a pin. It is usually dark coloured, from the nature of its contents.

In the adult bird, Stenon, Needham, and Maitre Jan, have recognized the *ductus vitello intestinalis* in the form of a small cæcum. It is situated on the alimentary canal, about midway between the stomach and the anus.

Needham describes it as being half an inch long, but this is incorrect with respect to any of the *gallinaceous* tribe, but in some other birds we have found it of a very remarkable size.

In the *snipe* it exceeds in length the cæca of the large intestine.

In the *curlew* it is about an inch long, and very capacious.

In the *woodcock* it is nearly as large.

It is above an inch long, and very slender, in the *black*

coot: the cæca of the great intestines are also singularly long and slender in this bird.

In all the passerine birds it is small.

In the *swan*, *goose*, and *duck* it is of a moderate size.

It is remarkably small in the *heron* and in the *hawk*.

In all the birds we have examined, there exists during life some remnant of the yolk-bag at the end of the cæcum, formed by the ductus vitello intestinalis. This is more particularly remarkable in the *passerine* and *accipitrine* birds. The *nightingale* has a little sac, about the size of a small pea, attached to the end of this process of the intestine.

Although there is so much variety with respect to the figure and size of the cæcum of the small intestines of birds, the structure of this part is constantly the same in every species. It appears to possess but two coats; one is the continuation of the peritoneum, covering the intestine: the other corresponds to the mucous membrane of the gut. The internal surface of the cæcum exhibits small cells similar to those points of the alimentary canal on which the mucous glands are congregated. This structure exists whether the internal membrane of the intestine be plicated or villous.

We have not found the appendix produced by the ductus vitello intestinalis to receive, in any instance, the contents of the alimentary canal. It is filled with a mucous fluid, which appears to be secreted from its internal surface. There is, therefore, every reason to suppose that this appendix performs the office of a mucous gland in the adult bird. The great size which it possesses in the *snipe*, *curlew*, *woodcock*, and *coot* is probably dependent upon the nature of the food of these birds, although we cannot at present perceive in what manner this part is so particularly useful to them. See Phil. Trans. part ii. 1811.

In the *Plate* designed to illustrate the incubation of the egg, *fig. 1.* exhibits an egg with a portion of the shell and the membrane underneath it, removed at the great end: *a* is the first appearance of the fœtus as it is seen in the cicatricula, through the membrane which covers it; around it are the concentric circles or waves (*balones*).

Fig. 2. represents an egg opened in the same manner in order to expose the fœtus when it is a little more advanced, with the commencement of the vascular area; *a*, the fœtus somewhat formed with the head like the top of a club; *b*, the contour of the vascular area assuming the heart-shape: it does not yet circulate red blood, but within it are seen the rudiments of vessels containing a greenish fluid. Some of these points are of a darker colour, and are the first appearance of the real blood.

Fig. 3. is an egg also with the shell of the great end removed; *a* is the fetal chick; *b* refers to the pulsating points that constitute the heart; *c* represents the appearance of the vascular area after the circulation of blood is perfected in it.

Fig. 4. exhibits a magnified view of the portion of the membranes at the great end of the egg, including the chick and vascular area about the fourth day of incubation; *a* is the thin glistening membrane which readily separates at this period from the rest, turned back; *b* is the fine transparent membrane immediately under the first, also turned a little off; *c* the chick contained in the amnios; *d* the vesicula umbilicalis attached to the chick; *e* the external membrane of the yolk-bag on which the vessels composing the vascular area are seen to spread; *f* is the internal pulpy membrane of the yolk-bag which afterwards produces the valves, the preceding membrane being partially removed to expose it.

Fig. 5. exhibits a portion of the yolk-bag with the chick and vesicula umbilicalis considerably magnified; *a* the chick; *b* the amnios; *c* the membranous connection the amnios has with

INCUBATION.

With the vesicula umbilicalis; *d* the vesicula, the neck of which is seen to enter the opening at the umbilicus of the chick.

Fig. 6. is a magnified view of the heart of the chick as it appears when first formed; *a* indicates the horse-shoe dilatation mentioned in the description of that organ on the second day.

Fig. 7. shews the heart and large vessels of the chick magnified after these parts are more perfectly formed; *a* is the vena cava; *b* the auricle; *c* the auricular canal; *d* the single ventricle; *e* the bulb of the aorta; *f* the principal artery.

Fig. 8. is a view, also magnified, of the heart, pulmonary arteries, lungs, and aorta of the chick; *a* is the heart seen on the posterior side; *b, b,* the two arteries which send off the pulmonary arteries, and afterwards concur towards the formation of the abdominal aorta. These vessels, after parting with their branches to the lungs, are analogous to the ductus arteriosus of mammalia; *c, c,* are the pulmonary branches of the vessels last mentioned; *d* the third vessel of the heart, which corresponds to the superior part of the aorta; *e* the abdominal aorta, formed as already described; *f, f,* the two lungs.

Fig. 9. is a view of the internal surface of the yolk-bag after the valves have begun to form upon it.

Fig. 10. shews a similar view of the internal membrane of the yolk-bag, when the valvular apparatus is completely formed; *a, a, a,* indicate some of the intelliform tubes upon the edges of the valves; *b, b,* the appearance of vessels in the intervals between the valves. The valvular projections themselves are sufficiently evident.

Fig. 11. shews a portion of one of the valves of the yolk-bag magnified; *a* the basis of the valve, where the principal vessel runs; *b* the plaits or folds upon its side; *c* the intelliform tubes upon the edge of the valve.

Fig. 12. is a magnified view of a portion of a valve of the yolk-bag after it had been converted into a fine lace, the vessels injected, and the internal membrane washed, so that the real blood-vessels alone remain; *a* is the principal vessel that runs along the base of the valve; *b* the one which goes along the free edge; *c* the lace-like ramification of vessels between these two.

Fig. 13. represents the yolk-bag, and the portion of the intestine with which it is connected, taken out of the chick a few days after incubation; *a* is the yolk-bag very much reduced in size, and of an irregular form; *b* the piece of intestine to which the yolk-bag is attached; *c* the ductus vitello intestinalis imperfectly seen, as it is partly covered by the blood-vessels of the yolk-bag; *d* the branch of the mesenteric vein, which furnishes, in the early periods of incubation, the veins of the vascular area; *e* the branch of the mesenteric artery, which goes to the yolk-bag. It divides, passes on each side of the intestine, and unites again before it ramifies upon the yolk-bag.

Fig. 14. shews the chick after the yolk-bag had been taken into the belly; *a* the umbilical opening surrounding the aperture, which is closed, in the present instance, by the contraction of this muscle; *b* some lacerated vessels, and a portion of the chorion hanging from the umbilical aperture; *c* the belly of the chick distended in consequence of the admission of the yolk-bag.

Fig. 15. is a plan of the relative position and magnitude of the contents of the egg about the ninth day of incubation. The view is procured by first boiling the entire egg, and afterwards making an equal section; *a* the edge of the shell; *b* the cavity left between the two layers of the membrane that lines the shell to contain air. This cavity is

considerable at the present period; *c* the chick in its amnios; *d* the yolk; *e* the cut edge of the yolk-bag; *f* the white which has descended to the small end of the egg and diminished; *g* the chalazae, much nearer each other than they were before incubation.

Fig. 16. exhibits a view of the contents of the egg, with the chorion cut open and turned down off the other parts; *a* the chick seen obscurely, as it is in some measure covered by the membrane that includes the yolk-bag and intestines, besides being surrounded by the amnios, the fluid of which, at the present period is greenish; *bb* the amnios seen at each end of the chick; *c* indicates the yolk-bag, which is divided into three lobes; one of them is seen to lie upon the side of the chick; the blood-vessels of the yolk appear small, and are indistinctly seen; *d* some folds of the membrane which envelops the yolk-bag, intestines, and a part of the chick; *e* the white contained in its proper membrane, and very much reduced in size; *f* the chorion turned down, and therefore the surface that is seen is the internal; *g, g, g,* reflections of fine membrane which attach the chorion to the other membranes; *b, h,* the two trunks of the umbilical arteries, which each divide into two branches, and are distributed to the chorion.

Fig. 17. is intended to explain the formation of that membrane which includes the yolk bag and the intestines of the chick, and for this purpose the chorion is entirely removed; *a* is the chick contained in the amnios; *b* indicates the membrane of the yolk-bag and intestines; it is seen to cover a certain extent of the amnios and chick; it descends posteriorly to be connected to the septum, between the yolk-bag and the white; anteriorly it is laid open, in order to turn out the yolk-bag, which was before contained in this membrane. Within the chick made by the incision are to be seen the intestines of the chick perfectly uncovered and denigrated by *c*. The yolk-bag hangs by the ductus vitello intestinalis and its blood-vessels, and is marked by the letter *d*.

Fig. 18. shews an egg with the great end fractured previous to the exclusion of the chick: some more pieces of the shell are removed in order to bring into view the membranes that are lacerated by the bill of the chick; *a* is that portion of the membrane under the shell which forms the air-cell, and in which there is a small aperture. The chorion and amnios are torn to a greater extent to permit the bill of the chick to appear on the outside of the shell; *b* the bill of the chick: beside it are seen some points of feathers projecting out of the opening made in the outer membrane.

Fig. 19. is a portion of the small intestine taken from the adult bird, on which the appendix is placed, that we have described as the remnant of the ductus vitello intestinalis; *a* the intestine; *b* the appendix or caecum; *c* is a little knot which was, during fetal life, the yolk-bag.

In some of the preceding figures, the form of the chick is represented at different ages, which the reader will understand without the letters of reference.

Of the Uses of the different Parts of the Egg during Incubation, and after the Exclusion of the Chick.—Although there can be no doubt that the chick derives its nutriment from the humours of the egg, the mode in which this is effected is involved in considerable obscurity. Anatomists have entertained very different opinions upon the subject. Some have supposed that both in mammiferous animals and birds, the fetus is nourished by swallowing or absorbing the liquor amnii.

Heister, in his Compendium of Anatomy, states, that after the contents of the uterus of the cow were frozen, he found
a piece

INCUBATION.

a piece of ice of the thickness of a finger extended from the concealed amnios into the mouth of the fœtus, and down the œsophagus as far as the stomach.

There have been sometimes seen also in the stomach of the *fœtal calf* the same kind of fatty concretions, that usually exit in the amnios of this animal. The hairs of the *calf* have been discovered in the neconium. New-born infants have been observed to vomit a fluid resembling the liquor amnii.

It has been remarked by Harvey, Haller, and several other writers upon incubation, that the fœtal chick frequently opens and shuts its mouth while inclosed in the amnios, as if it were performing the act of swallowing.

The preceding facts leave no doubt that the water of the amnios passes into the stomach of the fœtus, but by no means proves that it contributes to the nourishment of the young animal, but rather the contrary, as if it were either digested in the stomach, or consumed by absorption, it could not be found towards the end of gestation, or after-birth, in the quantity reported.

Those who give credit to the nutrition of the fœtus by the liquor amnii, cite some remarkable cases in which the umbilical cord is said to have been destroyed before birth, or in which the infant has been born with the cicatrix at the umbilicus perfectly formed. See Observ. rarior cent. post. pars 1. obs. 32.—Journal des sçavans, année 1673, p. 69. Observat. communij. par Chatton.—F. Hoffmann & Triller Dissert. de pinguid e succo nutr. superfl. p. 10. and Rommel Ephemer. nat. eur. dic. 2 à 7, obs. 209.

It should be remarked, that of these observations, some are related in a manner which makes their accuracy very doubtful; and others, even if correctly stated, do not prove the point they are proposed to establish. Thus the infant with the cicatrized navel was not seen by Chatton until five months after birth; and in some of the cases where the cord was said to be injured or putrid while the child was alive, it does not appear that the circulation had been destroyed.

We should not have noticed the doctrine of the nutrition of the fœtus from the liquor amnii, as it is generally discredited, had it not been advanced with some limitation by Lobstein in a modern publication. This author does not pretend that the fœtus swallows the liquor amnii, he allows that the young animal exhales and increases in growth, before the digestive organs or even the mouth are formed. He is also aware, that there have been monsters produced in whom the head was wanting. He therefore supposes, that the fluid of the amnios is taken into the body of the fœtus by the absorbents of the skin, which opinion he grounds upon the following circumstances: Many of the cold-blooded animals, he says, have no placenta, but in every species the fœtus floats in a clear liquor, analogous to that of the amnios. This fluid, he remarks, diminishes in proportion to the growth of the fœtus; it likewise remains uncorrupted during fœtal life, which fact, he thinks, can only be explained by its passing successively into the body of the young animal. (Lobstein sur la Nutrition du Fœtus, § 88.) Our reply to this reasoning would be, that the liquor amnii is not a nutritive fluid perhaps in any instance; that when first perceived, it is in a very small quantity: it is, in the higher classes of animals, contained in a membrane which is continuous with the skin of the fœtus, and which membrane further derives its blood-vessels from the fœtus. It is, therefore, a secretion of the young animal. During several days of incubation it increases as the chick grows, and in the latter periods does not perhaps actually diminish in quantity, but ceases to increase in proportion to the development of the chick; for

which reason it appears less than it did when the chick was small. The quantity of the liquor amnii at any given time, even admitting that it is not secreted by the fœtus, would be quite insufficient for the formation of the latter. The principal part of this fluid also is lost when the membrane that contains it is ruptured, previous to the liberation of the young animal from the uterus or the egg. We should, on all these grounds, deny that the liquor amnii is destined to sustain the fœtus in any circumstances.

In all oviparous animals, there is no necessity for supposing the liquor amnii to be a nutritive fluid, as there are other humours provided for the purpose of nourishing the fœtus. The sources of nutriment, during fœtal life, are particularly evident in the ovum of birds.

In the history of incubation it will be found, that the albumen begins to diminish as soon as the fœtus becomes apparent, that it continues to decrease regularly as the chick grows, and that this fluid is entirely consumed at the end of incubation: there is, therefore, no doubt that the white of the egg is the substance from which the chick is formed. It has been supposed by some writers, that the yolk also contributes to the support of the chick while in the egg. This opinion rests chiefly upon the circumstance of the yolk becoming larger and more fluid after the white begins to diminish, which has been attributed to the albumen passing into it, that the two fluids might be mixed together, and afterwards converted into the substance of the chick. Mairre Jan, Leveille, and others believed, that the white is absorbed by the chalazæ, and thus conveyed into the yolk-bag, and Leveille has even pretended to demonstrate the tubular structure of one of the chalazæ. We have already stated, that by the strictest examination we could not perceive the structure described by Leveille; we are therefore led to conclude, that the fluidity of the yolk, during incubation, is occasioned by the organization of that humour undergoing a change from the application of heat. We have found also the yolk become fluid when eggs were fat upon, which had not been fecundated by the cock, and in which the white was not sensibly diminished. The weight of the yolk at the end of incubation, almost proves that it is not concerned in the nourishment of the chick, until after the animal is excluded from the egg.

We confess, however, that we are unable to form a decided opinion with respect to the manner in which the albumen is carried into the body of the chick. Throughout incubation the white tends to the lower and small end of the egg; the chick is placed at the upper and great end. There is, therefore, no direct communication between the chick and the albumen. The blood-vessels of the egg have apparently no immediate connection with the white, until its proper membrane is formed, at which time this humour is already much reduced, and even then there are only a few wandering vessels spread over its membrane. These facts afford reason for the supposition that the white passes into the yolk-bag, through the chalazæ; but, on the other hand, it is scarcely credible that the white, after being mixed with the yolk, should alone be absorbed during incubation, and the latter fluid left undiminished.

The chalazæ, whether they perform the office of absorbents or not, act as ligaments to the yolk-bag, and have the effect of keeping, throughout incubation, that surface of the bag uppermost on which the chick is situated, in order that it may receive heat from the hen. See EGA.

The use of the vesicula umbilicalis is a subject on which no satisfactory theory has been yet made out.

The older anatomists supposed this part to be a reservoir of urine, and gave it the name of *allantois*. Lobstein considers

ders the fluid of the vesicula and the allantois as the nutriment of the fetus during the first periods of its existence. Soemmerring and Blumenbach supposed that the vesicula umbilicalis is intended for the nourishment of the fetus in the human subject. Although it does not appear that this use of the vesicula or allantois has been in any degree proved, the arguments employed are conclusive against it being a reservoir for urine, and particularly so with respect to birds and the human subject.

The vesicula umbilicalis attains a considerable size, and is filled with its proper fluid before the kidneys exit; and although the membrane continues to increase, the quantity of the fluid it contains by no means keeps pace with the growth of the kidneys. We cannot admit the reasoning of Haller, who concludes that the existence of fluid in the allantois is a proof that the kidneys secrete urine before they are visible. It has not yet been ascertained that the fluid contained in the allantois is urine even in quadrupeds, where this bag communicates so plainly with the bladder. Lobstein found, after the allantois had acquired a very considerable bulk, that the kidneys were small and pale, and resembled organs which had not yet been called into action. The bladder also was contracted. He very judiciously remarks, that if the allantois were distended to the size that it is known to possess in the early periods of gestation and incubation by the secretion of the kidneys, it would become before birth a most prodigious sac. It is extremely improbable that the secretion of urine should diminish or be suspended after the kidneys were perfectly formed, by which supposition alone the smaller relative size of the allantois in the latter periods of fetal life could be explained.

We may further observe, that there is no reservoir provided for any of the other secretions of the fetus, and that even the gall-bag is not remarkably distended, although it evidently contains bile some time before birth, and notwithstanding the liver is the largest gland in the body.

In describing the progress of incubation, we have mentioned, that the vesicula umbilicalis of birds contributes to the formation of the membrane called the chorion; that its fluid disappears, leaving behind it some layers of a soft calcareous substance, resembling the excrement of birds, or rather the solid parts of the urine of those animals. This excrementitious matter has been considered a proof of the vesicula being the receptacle of the urine, but it should be observed that the same sort of substance is found after the consumption of all the fluids of the egg.

The functions of the vesicula umbilicalis in birds, if there be any peculiar to it, are lost in those of the chorion.

By recurring to the history of incubation, it will be found that the external membrane of the yolk-bag, on which the vascular area is spread, and the chorion, receive a vastly larger quantity of blood than circulates at any one moment in the body of the chick. The chorion is not originally a vascular membrane; its vessels arise with the vesicula umbilicalis, by which they are conducted from the body of the fetus. The vascularity of the chorion in some degree succeeds that of the vascular area; it appertains chiefly to the arterial system, whilst that of the area is almost entirely produced by veins.

The use most commonly ascribed to these two great systems of extraneous vessels, is the oxydation of the blood of the fetus, for which purpose it is also believed that the air is admitted into the great end of the egg. We have, however, been led to entertain a different opinion of the offices of the vascular area, chorion, and air-cell, in consequence of some experiments we have made, which we shall lay before the reader.

Experiment 1.—Two eggs of a hen were opened at the great end by destroying the shell and outer layer of the membrane composing the air-cell. The blood-vessels were seen through the membrane of a deep purple colour. Being exposed to the atmospheric air, they became, in a few minutes, a vivid scarlet. The same eggs were then placed in a jar filled with fixed air, and their blood very soon re-assumed its original purple colour; and upon the eggs being again brought into the common air, the scarlet colour of the blood was speedily revived. One of these eggs had its blood rendered venous and the other arterial, in the manner above-mentioned. Both were then placed in a vessel of water, in which they remained all night, and on the next morning each continued to preserve its proper colour.

Ex. 2.—We took an egg which had been sat upon 18 days, and having removed a square portion of the shell and membrane forming the air-cell, about a quarter of an inch in size, it was placed in a jar of carbonic acid gas, over a bath of quicksilver, which was kept throughout the experiment, as nearly as possible, at the temperature of 104° Fahrenheit. The motions of the chick cause an egg to roll upon a smooth surface, but in this instance no motion was perceived. After the egg had remained an hour in the fixed air it was taken out, and the aperture of the shell was carefully closed with paper and glue, and two hours elapsed before the egg began to roll upon the surface of the mercury. Upon this occasion, therefore, the chick appeared to have been submitted three hours to the influence of carbonic acid gas without being destroyed.

Ex. 3.—An egg, at the 18th day of incubation, was deprived of the greatest part of the shell, and of the membrane that lines the shell, so that the vessels of the chorion were fully exposed. The membrane of the chorion was moistened to increase the effect. The egg was suffered to remain for 25 minutes in the fixed air, during which time the chick shewed no motion; but upon being removed into atmospheric air it struggled as usual.

Ex. 4.—The air contained in the cells, during the latter stages of incubation, was collected from a number of eggs, and subjected to experiment in a graduated glass tube. It afforded, as nearly as may be, the same products that are obtained from atmospheric air, after it has been spoiled by respiration; from which it would appear, that it was the presence of undiluted fixed air in the 2d and 3d experiments that caused the motions of the chick to cease, and not the absence of oxygen gas.

Ex. 5.—Being aware of the fatal effects upon the chick, which have been reported to follow covering the shell of the egg, so as to stop the further admission of air into it, we varnished the surface of several eggs at different periods of incubation. The result of this experiment was nearly the same in every instance. The chick always died; not, however, immediately, but in two, three, or four days, and apparently not in consequence of being unsupplied with fresh air, but from being unprovided with any kind of air to occupy the space caused by the expenditure of the fluid contents of the egg in the formation of the chick; for, in these cases, we found the yolk more or less disorganized, the membranes sometimes ruptured, and the fetus always malformed or imperfectly developed. If the death of the chick had been occasioned by the deprivation of oxygen, it would have been immediate, and unattended with any change in the structure of the fetus.

The gradual admission of air into the eggs of birds takes place as a matter of necessity, because the shell, being hard and unyielding, cannot accommodate its form to the bulk of its contents in proportion as they diminish; for the parts originally

INCUBATION.

nally contained in the egg occupy a much larger space, as already mentioned, than when the chick is fully formed.

The preceding experiments prove that the air does not pass into the egg for the purpose of effecting any change in the blood of the fetal chick, similar to the process of respiration, as has been generally supposed. It is true, nevertheless, that when the blood is first exposed to the air contained in the great end of the egg, it becomes oxydized by it; and hence, during the first days of incubation, all the blood-vessels of the vascular area are observed to be of an arterial colour: but as there are no means of expelling the air as it becomes spoiled, and as the supply of pure air afterwards is too small in quantity to produce any effect upon the blood, all the vessels are of the purple or venous colour in the latter periods of incubation. This appearance of the blood has been observed to exist by many writers upon incubation, and coincides with the experiments we have related above.

It may be asked, what end is answered by the distribution of so much blood to the membranes of the egg, if it be not for its exposure to oxygen gas? This is a question which, perhaps, cannot be solved by direct experiments.

We conceive, however, that it is necessary, during fetal life, to have a greater quantity of blood formed than is employed in the organs of the young animal. The functions of the blood-vessels of the fetus are almost confined to the creation of its body; but in the adult animal the principal part of the mass of blood is consumed in furnishing the various secretions. The vascular membranes of the ovum may be considered as performing the office of the various secretory organs, the actions of which are dormant, at least during the early periods of fetal life. By this means also the organs of the body are accustomed to the preparation and presence of a quantity of blood which is wanted immediately after the young animal leaves the uterus or the egg: indeed, without such a provision, it would seem to be impossible for the fetus to assume, in a moment, the functions of an independent state of existence.

Further, the extraneous circulation on the membranes appears to be the means by which the nutritive fluids of the egg are converted into blood. This is almost demonstrated in the vascular area, in which the red blood appears before its vessels have any visible connection with the body of the chick.

The *membrane* containing the vascular area, therefore, we deem the organ of nutriment and assimilation. It corresponds to the different viscera which convert the food into blood in the full-grown or perfect animal. The *chorion* of birds supplies the place of the viscera, which return the particles of the adult body to the common stock of nature. We could draw many arguments in support of this theory from the anatomy of the lower classes of animals, and from the structure of the vascular system in particular animals of a higher rank; but it does not seem consistent, with the nature of the present article, to enter into an extensive physiological discussion.

If it be admitted that the blood of the fetus does not receive that effect from the air which gives the arterial character, it becomes desirable to ascertain the power of the fetus for generating animal heat. With this view we have instituted the following experiments.

Ex. 1.—An egg, on which the hen had sat 17 days, was placed upon a bath of mercury heated to 104° of Fahrenheit, and kept at that temperature for several hours. The heat of the room was 75°. The upper surface of the membranes, when the shell was broken to admit the thermometer, raised the instrument to 92°. The interior of the egg was 95°; and

on the instrument being thrust down so as to touch that part of the shell in contact with the mercury, it did not rise higher than 100°. From this experiment, the standard heat of the chick appeared to be about 95°.

Ex. 2.—An egg, at the same period of incubation as the last, had the shell entirely removed, and was placed upon a mercurial bath at the heat of 83°; the air of the apartment being 75°. The centre of the egg preserved the instrument at 88°, and when pushed down upon the membranes next the mercury, it did not fall below 85°.

Ex. 3.—A chick, about 18 days old, was removed from the egg and its membranes, and exposed for some time upon the surface of a bath of quicksilver at the temperature of 79°, and becoming gradually cooler as the heat of the surrounding air was 75°. The thermometer was introduced into the thorax of the chick, and stood at 80° for a short time, even after the chick had died.

The heat of the different parts of the incubated egg cannot be expected to correspond with each other as long as external heat or cold is applied to one surface only, but the three last-mentioned experiments, notwithstanding, appear to us conclusive, with respect to the fetal chick possessing an independent temperature, and being capable of resisting, to a certain extent, both foreign heat and cold.

It is proper to observe, that we have made some experiments with respect to the oxydation of the blood, and the animal heat of the fetus in mammalia, which entirely correspond in their results with those above related; and, therefore, fortify our opinion with regard to the absence of any process analogous to respiration during fetal existence, and likewise prove that the young animal has an independent temperature.

We have already mentioned that the yolk loses very little, if any, of its original weight during incubation; but that after the chick is excluded from the shell it is speedily consumed. This humour, therefore, is obviously designed for a provisional nutriment to sustain the chick until it is able to procure a sufficient quantity of its natural food. This disposition of the yolk is particularly necessary to those birds that live in a wild state, but is useful to all.

Anatomists are divided with respect to the manner in which the yolk is conveyed into the system of the chick. Some assert that it passes into the alimentary canal, through the ductus vitello intestinalis, where it is digested previous to its being absorbed by the lacteals. Others deny that it is to be found in the stomach or intestines, and believe that it is absorbed immediately from the yolk-bag. We are disposed to adopt the latter opinion, both from never having been able to discover any yolk in the intestinal canal, and from a number of reasons, which indirectly go to disprove the passage of the yolk through the ductus vitello intestinalis.

In the first place, there does not seem to be any power by which the yolk can be transmitted into the intestine. The yolk-bag itself has no muscular coat, and the mere pressure of the parietes of the abdomen of the chick, even if sufficiently strong, would be exerted as much upon the intestines as the yolk-bag, and might therefore as readily urge the contents of the former into the latter, as the yolk into the gut; for the ductus vitello intestinalis does not penetrate the coats of the intestine obliquely, so as to produce the effect of a valve, but has merely a slight contraction at the orifice, which must operate equally on both sides.

There would appear to be no necessity for the yolk to pass into the alimentary canal, or to be subjected to any process of digestion or assimilation previous to its entering the

the system of the chick. It is already a vital fluid, which is proved by Mr. Hunter's experiments upon the temperature of eggs. (See Egg.) If the humours of the egg did not possess vital properties, they would very soon become putrid from the heat of incubation.

When we contemplate the structure of the yolk-bag, it must be perceived to be not only continuous with the intestinal canal, but to resemble the latter in organization, except that the muscular coat is wanting. The external membrane of the bag differs in no respect from the peritoneal coat of the intestines; and the internal membrane is so analogous to the villous coat, that we cannot hesitate to allow them the same functions. No advantage, therefore, would be gained by the passage of the yolk into the intestine.

The absorption of this humour, by the valvular or internal membrane of the yolk-bag, seems proved by the organization of the yolk undergoing a change upon the surface which is in contact with the membrane, while the central part is unaltered. The circumstance also, of a concrete substance, resembling the residue of the albumen, being left in the yolk-bag after the nutritious parts of the yolk are consumed, affords a strong evidence that the latter are removed by a process of absorption; for if the yolk passed through the ductus vitello intestinalis, it would disappear without distinction of parts.

The authors who believe that the yolk is carried into the system without a previous preparation in the alimentary canal, attribute the office of absorption to the red veins. In proof of this opinion Blumenbach and others state that they have detected upon some occasions a yellow fluid in the veins of the bag, which they have supposed to be the yolk in its passage. Notwithstanding this appearance, which we have sometimes also seen, it appears to us most probable that the yolk is absorbed by the same system of vessels which take up the chyle from the small intestines. The yolk-bag and intestinal canal, as already mentioned, are continuous parts, and similarly organized. The yolk-bag is, in fact, a process of the intestines, and should be considered as a portion of the body of the chick. It is supplied by the same blood-vessels as the intestines; why should we therefore deny it the lacteal vessels?

Another argument against the absorbing function of the veins of the yolk-bag may be deduced from the size of these vessels at different periods. During the early part of incubation they are large and numerous; but after the yolk-bag passes into the abdomen of the chick, where their absorbing function ceases; if not entirely, exists, if it does at all, they become smaller and fewer than the arteries. The vessels of the yolk-bag, when they constitute the vascular area, are the organs of languification for the chick. After incubation they appear to become the nutritious vessels of the bag itself.

It may seem not easy to assign a use for the ductus vitello intestinalis, unless we grant it to be for transmitting the substance of the yolk into the alimentary canal. If, however, this should not be the case, still a communication would probably exist between the yolk-bag and the intestine; for it is without example, we believe, for the continuity to be interrupted by two adjoining cavities that have a similar organization. The ductus vitello intestinalis we think, therefore, would exist as a matter of course, independently of any offices it might perform. We have described the purposes this part serves in the full grown bird; it is not, therefore, without its uses.

For the history of fetal life in oviparous animals in general, see OVUM.

INCUBUS, in Medicine, from the Latin *incubare*, to lie or sit upon, the same with the English *night-mare*, signifies a state of imperfect sleep, accompanied with an oppression of the breathing, and frightful dreams.

By the Greeks this affection was designated by a name of similar import, *ἐπιπληξ*, *epiphalex*, from the verb *ἐπιπληξαι*, *I leap upon*; and it has received various other appellations expressive of the sense of weight and oppression of the chest, the laborious respiration, &c. as well as indicative of the hypotheses by which its occurrence was explained. Thus it has been called *ἰππῶδες πνεύμα*, *epiphlexa nocturna*, *asthma nocturnum*, &c.; and by Piius, *ludibria suavi*, from the same notion which dictated the more modern appellations of *bag-riding*, *wizard-pressing*, *mare-riding*; *dier mahr*, or *das reiten der mahr*, of the Germans; *cochenar* of the French; *night-mare*, &c.

This disorder seizes persons, while sleeping, who imagine that they feel an extraordinary compression or weight about the breast and stomach, which they cannot by any effort shake off. In this agony they sigh, groan, and utter indistinct sounds; sometimes they cry out, but more frequently they attempt to speak, or to move in vain. These feelings give rise to various frightful suggestions of the imagination: the patient fancies himself to be struggling with strong men or devils, or to be in a house on fire, or in danger of being drowned in the sea or some river; and in attempting to run away from danger, or climb up a hill, he fancies he falls back as much after every step as he had advanced before. At length the sensations of oppression become intolerable, and the patient awakes; but the terror excited by the frightful ideas attending the night-mare, leaves often a palpitation of the heart, with great anxiety and languor, and sometimes a tingling of the ears, and a tremor over the whole body.

It is altogether unnecessary to attempt an enumeration of the numerous hypothetical explanations which have been attempted to be given of the phenomenon of *incubus*, and which have been detailed by Awen, Bond, and other writers. (See Awen, *Posit. inaugur. de Incubo*. Argentorat. 1676. Bond, *Essay on the Incubus or Night-mare*, 1753.) The disorder has commonly been supposed to proceed from a stagnation of the blood in the sinuses of the brain, or in the vessels of the lungs, or from too great a quantity of blood being sent to the head. The horizontal posture, in time of sleep, and the pressure of the stomach upon the *aorta*, in a supine situation, have been thought sufficient to occasion a more than usual dilatation of the *sinuses* and other vessels of the brain; and the weight of the heart, pressing on the left auricle and large trunks of the pulmonary veins, may, it is supposed, prevent the easy return of the blood from the lungs, and thus produce an oppression and sense of weight and fluctuation in the breast. (See Bond, chap. ii.) But without entering into a particular examination of these opinions, which are far from being satisfactory, we may observe, with Dr. Whytt, that, if they were true, some degree of the night-mare ought to happen to every body that lies upon his back, especially after eating a full meal. Further, if a horizontal situation could overcharge the brain with blood, so as to occasion the *incubus*, how comes it that people, who remain for some time in an inverted posture, do not feel this disease beginning to attack them? And why does a slighter degree of the night-mare sometimes seize people who sleep in an erect situation in a chair? a circumstance which sometimes occurs, not only after eating, but when the stomach is out of

order, and troubled with wind. As the weight of the stomach, even when filled with food, can have scarcely any effect upon the motion of the blood in the *aorta*, so the pressure of the heart is by much too small to be able sensibly to retard the motion of that fluid in the pulmonary veins, otherwise, people exhauited by tedious diseases, who generally lie on their back, would be constantly affected with the *incubus*.

We know that certain medicines or poisons, worms, and even corrupted bile, or other humours, by disagreeably affecting the nerves of the stomach, produce an oppression about the breast, wild imaginations, frightful dreams, raving, and insensibility; and there is no doubt that low spirits, melancholy, and disturbed sleep, often proceed from a disordered state of the stomach. It seems, therefore, more probable that the seat of the night-mare is principally in that organ. It is well ascertained that some forms of epilepsy, and of hysterical fits, originate from disorder in that *viscus*; and Galen considered the *incubus* as a nocturnal or slighter epilepsy. People troubled with nervous and hypochondriac affections, and who have delicate or flatulent stomachs, are more peculiarly subject to this disorder; and it is observed, that a heavy or flatulent supper greatly aggravates the night-mare, in those who are predisposed to it. The sympathy of the stomach with the head, heart, lungs, and diaphragm, is so remarkable, that there can be no difficulty in referring the several symptoms of the *incubus* to a disagreeable irritation of the nerves of the stomach.

The *incubus* is most apt to seize persons when lying on their back, because, in this position, on account of the stomach and other abdominal viscera pressing more upon the diaphragm, we cannot inspire with the same ease as when we sit up or lie on one side. Further, in that situation of the body the food seems to lie heavier on the stomach, and wind in it does not separate so readily by the *esophagus* and *pylorus*, as in an erect posture, when these orifices are higher than the other parts of the stomach. The night-mare only occurs in the time of sleep, because the strange ideas excited in the mind, in consequence of the disordered feelings of the stomach, are not then corrected by the external senses as they are when we are awake; nor do we, by an increased respiration or other motions of the body, endeavour to shake off any beginning uneasy sensation about the stomach or breast. The *incubus* generally occurs in the first sleep, and seldom towards morning, because at the earlier period the stomach is more loaded with food, and that in a more crude and indigested state than in the morning. A lesser degree, amounting only to frightful dreams, is almost a constant concomitant of overloaded stomach in some habits. See DREAM.

In fact, if the night-mare were owing to a stagnation of the blood in the lungs from the weight of the heart, or in the sinuses and other vessels of the brain from the horizontal posture of the body, it would become greater the longer it continued, and would scarcely ever go off spontaneously. But we know that this disease, after affecting people for some time, often gradually ceases, and is succeeded by refreshing sleep: for as soon as the load of meat, or wind, or other cause disagreeably affecting the nerves of the stomach is removed, the oppression and weight on the breast, wild imaginations, frightful dreams, &c. vanish; as all these proceed originally from the disorder of the stomach. It may be remarked, however, that, as neither flatulency, phlegm, nor crudities in the stomach, ever produce the symptoms of *hypochondriasis*, unless the nerves of that organ be indispensed; so neither a horizontal posture, sleep, nor heavy suppers, ever

produce the night-mare, at least in any considerable degree, unless the person be already predisposed to the complaint, from the particular condition of the nerves of the stomach.

But although the stomach is the part commonly affected primarily in the case of *incubus*; yet symptoms like those of the night mare may sometimes arise without any fault of the stomach, when the lungs, or even the brain, are affected. Thus Dr. Whytt observes, that asthmatic patients, whose lungs are much obstructed, are sometimes disturbed, in time of sleep, with distressing dreams, and oppressed with a sense of suffocation. Startings and oppressions about the præcordia, with painful dreams, are indeed common occurrences from *hydrothorax*, chronic coughs, and other pulmonary obstructions; but they are not strictly analogous to the common night-mare. Dr. Lower mentions a patient, who, though he could sleep pretty easily with his head inclined forward; yet, in the opposite situation, he was always soon awaked with horrid dreams and tremors; the cause of which appeared, after his death, to have been a great quantity of water in the ventricles of the brain. At all events, a plethoric state of habit, by rendering the circulation through the lungs less free, may help to produce, or at least increase, the oppression of the breast in the night-mare.

The Cure.—As *incubus*, then, is only a symptom of disordered or loaded stomach, and arises out of the irritation and morbid feelings which are thus produced during sleep, the relief of the disease, generally speaking, lies within a narrow compass. *Temperance* in eating and drinking, especially at late hours; taking, in fact, either extremely light suppers or none at all; and when the dinner is so late as to be only a supper with another name, being cautious that that also should be moderate in quantity, and easily digestible and unstimulating in its nature; drinking thin, sub-acid liquors, where these are agreeable to the constitution,—these are the principal remedies required. Brisk active exercise, by which the digestive powers may be aided and the stomach strengthened, is also advisable. It were useful, too, to sleep with high pillows, and to lie on the side as much as possible, in preference to the back. If the functions of the stomach are much disordered with flatulency, heart-burn, acidity, or oppression, with pain, or nausea, after taking food, the remedies recommended for *indigestion* (which see) must be resorted to. The bowels should be kept open. See Whytt on Nervous Disorders, chap. vi. § 18.

INCUMBENT, in *Law*, a clerk resident on his benefice, with cure.

He is called incumbent of such church, because he ought to bend his whole study to discharge his cure. See RECTOR and VICAR.

INCUMBRAVIT. See QUARE *incumbavit*.

INCURABIL, the name of one of the celebrated conservatorios or music-schools at Venice, where orphan girls, or girls of worthy parents in indigence, used to be well educated and regularly bred to music as a profession. Galuppi was master of this conservatorio in 1770, when the composition and performance were exquisite.

INCURVATION, the act of bending a bone, or other body, from its natural shape.

INCURVATION of the Rays of Light. See LIGHT, and REFRACTION.

INCUS, in *Anatomy*, one of the small bones contained in the cavity of the tympanum. See EAR.

INCUSU, in *Geography*, a town of Africa, in the kingdom of Congo; 80 miles S. of St. Salvador.

INDAL, a town of Sweden, in the province of Medelpad,

pad, on a river of the same name. N. lat. 62° 34'. E. long. 16° 23'.

INDEA, a town of Africa, in the kingdom of Yemina, on a river of the same name.

INDEBITATUS ASSUMPSIT, in *Law*. See ASSUMPSIT.

INDECIMABLE, INDECIMABILIS, is applied to things not tithable, or which by law ought not to pay tithes.

INDEFEASIBLE, or INDEFEAZABLE, signifies what cannot be taken, or made void. As, a good and indefeasible estate. No one, who considers our laws, constitution, and history, without prejudice, and with any degree of attention, will assert, that the doctrine of hereditary right implies an indefeasible right to the English throne. See *Right of Crown*.

INDEFINITE, INDETERMINATE, that which has no certain bounds, or to which the human mind cannot affix any. Des Cartes uses the word, in his philosophy, instead of infinite, both in numbers and quantities, to signify an inconceivable number, or number so great, that an unit cannot be added to it; and a quantity so great, as not to be capable of any addition.

Thus, he says, the stars, visible and invisible, are in number indefinite; and not, as the ancients held, infinite; and that quantity may be divided into an indefinite number of parts, not an infinite number.

INDEFINITE is also used, in the *Schools*, to signify a thing that has but one extreme: for instance, a line drawn from any point, and extended infinitely.

Thus, what they call *eternity a parte ante*, or *eternity a parte post*, are indefinite durations.

INDEFINITE, in *Grammar*, is understood of nouns, pronouns, verbs, participles, articles, &c. which are left in an uncertain indeterminate sense, and not fixed to any particular time, thing, or other circumstance.

INDEFINITE Proposition, in *Logic*. See PROPOSITION.

INDELAVOY, ENDELAVOY, or *Indelvai*, in *Geography*, a town of Hindoostan, in Golconda, lying in the route between the Godavery and Hydrabad; 75 miles N. of Hydrabad. N. lat. 18° 26'. E. long. 78° 40'.

INDELIBLE, formed from *delere*, to blot, with the preposition *in*, taken negatively, that which cannot be blotted out, or effaced.

Thus baptism, and the order of the priesthood, are said to convey indelible characters.

INDEMNITY, formed from the negative *in*, and *damnum, loss*, in *Law*, an act by which one promises to guarantee, or save harmless some other person from any loss or damage that might accrue to him on any particular account.

When a church is appropriated to an abbey, or college, the archdeacon loseth his induction money for ever; in recompence whereof he shall have yearly, out of the church so appropriate, one or two shillings, more or less, for a pension, as was agreed at the time of the impropriation; and this pension is called an indemnity.

INDEMNITY, with regard to estates. See WARRANTY.

INDEMNITY. See *Act of GRACE*.

INDEN, in *Geography*, a town of Switzerland, in the Valais; 18 miles E. of Sion.

INDEN-HOTUN, a town of Chinese Tartary, the capital of the Mantchew Tartars, where they began to establish their empire over China. N. lat. 41° 46'. E. long. 124° 36'.

INDENTATIONS of the Coast of the Ocean, in *Geology*, or the peninsulas, headlands, points, bays, gulfs, ciliaurics,

&c. which occur on the shores of most islands and continents, are phenomena worthy the attentive consideration of geological observers. M. de Luc, in his *Geological Travels*, vol. i. p. 333 and 336, has considered many of the circumstances attending the headlands and gulfs of the northern coast of Europe, and very properly represents, that they arise from the system of vallies and hills, which are seen inland, continuing down much below the present level of sea, even to the greatest fathomable depths in some instances: and Mr. Farcy, who has remarked on this part of M. de Luc's work in the *Philosophical Magazine* (vol. xxxvi. p. 7.), observes, that the hills all evidently ran out in headlands into the sea, just as they would into a sea at a level considerably above the present, of which a perfect idea may be obtained by tracing an extended level line in any country; and that the operations of the tides and waves have a powerful tendency, in most instances, to lessen the indentations of the coasts, by washing away the projecting points of hills, and throwing up the alluvial matters therefrom in the intervening gulfs, where marshes are accumulated; and that the coasts, where cliffs or precipices occur at the headlands only, have not originated, in most instances, from faults or depressions of the strata under the sea beach, but are occasioned by the falling and washing away of the points of the hills. It is evident, that where rocky cliffs fringe the borders of the gulfs, as well as the headlands of a district, such cliffs have a different origin from those which are confined to the headlands. See ENCROACHMENT of the Sea.

INDENTED, INDENTEE, in *Heraldry*, is when the outline of a bordure, ordinary, &c. is notched, in form of the teeth of a saw.

INDENTED Leaf. See *Serrated LEAF*.

INDENTED Line, in *Fortification*. See REDENS.

INDENTED Medals and Wheel. See MEDALS and WHEEL.

INDENTURE, in *Law*, a writing which comprises some contract between two, at least; being indented at top answerable to another part, which has the same contents. See DEED.

INDEPENDENT Company and Troop. See COMPANY and TROOP.

INDEPENDENTS, in *Ecclesiastical History*, a sect of Protestants in England and Holland: so called, as denying not only any subordination among their clergy, but also all dependency on any other assembly.

They maintain, that every separate church, or particular congregation, has in itself radically and essentially every thing necessary for its own government; that it has all ecclesiastical power and jurisdiction; and is not at all subject to other churches, or their deputies, nor to their assemblies, or synods.

Robinson, the founder of the sect, makes express use of this term in explaining his doctrine relating to ecclesiastical government: "Cætum quemlibet particularem," (says he, in his *Apologia*, cap. 5. p. 22.) "esse totam, integram et perfectam ecclesiam ex suis partibus constantem, immediate et independentem (quoad alias ecclesias) sub ipso Christo." It may probably have been from this very passage that the title of independents was originally derived. The disciples of Robinson, originally called *Brownists* (which see), because John Robinson, the founder of this sect, was pastor of a congregation of Brownists that had settled at Leyden, did not reject the appellation of Independents. It was certainly utterly unknown in England before the year 1640: at least it is not once mentioned in the ecclesiastical canons and con-

stitutions that were drawn up during that year, in the synods or visitations held by the archbishops of Canterbury, York, and other prelates, in which canons all the various sects that then subsisted in England are particularly mentioned. See Wilkins's *Concilia Magnæ Britannicæ et Hibernicæ*, vol. iv. cap. 5. p. 548.

It is true, that not long after this period, and more particularly from the year 1642, we find this denomination very frequently in the English annals. The English Independents were so far from being displeas'd with it, that they assum'd it publicly in a piece, which they published in their own defence at London, in the year 1644, entitled "Apothegical Narration of the Independents." But in process of time, in order to avoid the odium of sedition and anarchy charged on this sect, the true and genuine Independents renounc'd this title, and call'd themselves "Congregational Brethren;" and their religious assemblies "congregational churches." The first independent, or congregational church in England, was set up in the year 1616, by Mr. Jacob, who had adopted the religious sentiments of Robinson. The Independents, though sprung originally from a congregation of Brownists, were much more commendable than the latter, both in the moderation of their sentiments, and the order of their discipline. The Brownists, as we have already mention'd under that article, allowed all ranks and orders of men promiscuously to teach in public, and to perform the other pastoral functions; whereas the Independents had, and still have, a certain number of ministers, for the most part regularly educated, chosen respectively by the congregations where they are fix'd; nor is any person among them permitted to speak in public, before he has submitted to a proper examination of his capacity and talents, and been approved of by the congregation to which he ministers. The charge alleg'd against them by our historian Rapin, (*Hist. of England*, vol. ii. p. 514. fol. ed.) who says, that they could not so much as endure ordinary ministers in the church, &c. is, therefore, evidently false and groundless. He was led into his mistake by confounding the Independents and Brownists. There are other charges, no less unjustifiable, that have been urg'd against the Independents by this celebrated historian, and others of less note. Rapin says, that, with regard to the state, they abhorred monarchy, and approv'd only a republican government. This might have been true with regard to several persons among the Independents, in common with those of other sects; but it does not appear from any of their public writings that republican principles form'd the distinguishing characteristic of this sect. On the contrary, in a public memorial drawn up by them in 1647, they declare, that "they do not disapprove of any form of civil government, but do freely acknowledge that a kingly government, bounded by just and wholesome laws, is both allowed by God, and also a good accommodation unto men." The Independents, however, have been generally distinguished by the denomination of regicides, under a notion that they were chargeable with the death of Charles I. Whether this fact be admitted or denied, and this is not a place proper for the investigation of it, no conclusion can be fairly drawn from the greater prevalence of republican principles, or from violent proceedings at that period, that can affect the distinguishing tenets and conduct of the Independents in general; and especially of the fact that bears this denomination in our times. It is certain that our Independents are ready friends to a limited monarchy. Rapin is farther mistaken, when he represents the religious principles of the Independents as contrary to those of all the rest of the world. It appears from two

confessions of faith, one compos'd by Robinson, on behalf of the English Independents in Holland, and published at Leyden in 1619, entitled "Apologia pro Exulibus Anglis, qui Brownitæ vulgo appellantur," and another drawn up in London in the year 1658, by the principal member of this community in England, entitled "A Declaration of the Faith and Order owned and practis'd by the Congregational Churches in England, agreed upon and consented unto by their Elders and Messengers, in their Meeting at the Savoy, Oct. 12, 1658;" as well as from other writings of the Independents, that they differed from the rest of the reformed in no single point of any consequence, except that ecclesiastical government; and their religious doctrines were almost entirely the same with those that are adopted by the church of Geneva. During the administration of Cromwell the Independents acquired very considerable reputation and influence; and he made use of them as a check to the ambition of the Presbyterians, who aim'd at a very high degree of ecclesiastical power, and who had succeeded, soon after the elevation of Cromwell, in obtaining a parliamentary establishment of their own church government. But after the restoration of Charles II. their cause declined; and in the year 1691, under the reign of king William, they enter'd into an association with the Presbyterians residing in and about London, under certain heads of agreement, compriz'd in nine articles, that tend'd to the maintenance of their respective institutions. These may be found in the second volume of Whitton's *Memoirs of his Life and Writings*; and the substance of them in Mosheim, *ubi infra*.

At this time the Independents and Presbyterians, call'd from this association the United Brethren, were agreed with regard to doctrines, being generally Calvinists, and differ'd only with respect to ecclesiastical discipline. But, at present, though the English Independents and Presbyterians form two distinct parties of Protestant dissenters, they are distinguished by very trifling differences with regard to church government; and the denominations are more arbitrarily us'd to comprehend those who differ in theological opinions. The Independents are generally more attach'd to the tenets distinguish'd by the term orthodoxy or calvinism, than the Presbyterians.

Independentism is peculiar to Great Britain, the United States of America, where it was carried first in 1620, and by successive Puritan emigrants in 1629 and 1633, from England, and the United Provinces. One Morel, in the sixteenth century, endeavour'd to introduce it into France; but it was condemn'd at the synod of Rochel, where Beza presided; and again at the synod of Rochel, in 1644.

On the subject of this article, see Mosheim's *Ecc. Hist.* by Maclean, vol. v. p. 398, &c. 8vo. Neal's *Hist. of the Puritans*, vol. ii. p. 107, &c. vol. iii. p. 547, &c. vol. iv. p. 187, &c. Burnet's *Hist. of his Own Times*, vol. i. p. 46, &c.

INDERGEREE, in *Geography*, a river on the N. E. coast of Sumatra, which runs into the sea. S. lat. 6° 35'. E. long. 103° 20'.

INDERGUR, a town of Hindoostan, in Guzerat; 15 miles E. of Damann.

INDERMAY POINT, a cape on the N. coast of Java. S. lat. 6° 12'. E. long. 108° 18'.

INDERSKAIA, a town of Russia, on the river Ural; 72 miles N. of Gurev.

INDERSOUL, a town of Hindoostan, in Baglana; 12 miles E. of Bihblong.

INDER-TAUPPLITZ, a town of the duchy of Stiria, on the Enus; 14 miles W. of Rottenman.

INDERVA,

INDERVA, a small island in the Persian gulf; 50 leagues W. of Ormus.

INDETERMINATE, in *Geometry*, is understood of a quantity either of time or place, which has no certain or definite bounds. See INDEFINITE.

INDETERMINATE *Analysis*, is a particular branch of algebra, in which there is always proposed a greater number of unknown quantities than there are equations; whence, from what we have seen under the article ALGEBRA, the questions become unlimited; but in this species of equations, the solutions must always be given in integers, or rational fractions; and this condition frequently fixes a limit to the number of answers that an equation admits of, and even sometimes renders the problem impossible; though, in the generality of cases, the number of solutions is indefinite. When, amongst the unknown quantities, there are none that exceed the simple power, the equation is said to be of the *first degree*: when the second power enters into the equation, it is said to be of the *second degree*: and when the third power or cube enters, it is of the *third degree*; and so on.

Every indeterminate equation of the first degree, as

$$ax \pm by \pm cz \pm d \pm \&c. = 0$$

is solved by means of the more simple equation

$$ap - bq = \pm 1.$$

And every indeterminate equation of the second degree has its solution, if not absolutely depending, at least intimately connected with the solution of the equation

$$p^2 - Nq^2 = \pm 1.$$

Before, therefore, entering upon the general solution of indeterminate problems, it will be proper to consider more particularly the two equations above-mentioned.

PROP. I.

To find the values of x and y , in the equation

$$ax - by = \pm 1.$$

First, it may be observed, that this equation is always possible under either condition of the ambiguous sign \pm , provided that a and b be prime to each other; and without this, the equation is always impossible; because, in that case, the first side of the equation will be divisible by the common divisor of a and b ; whereas the second side, ± 1 , has no divisor; and, consequently, no equality can obtain. But when a and b are prime to each other, the solution may always be obtained by the following rule: Divide the greatest of the two given numbers a and b by the other, and then always the last divisor by the last remainder, as in the usual method of finding the greatest common measure of two numbers, and let the successive quotients arising from this operation be denoted by $\alpha, \beta, \gamma, \delta, \&c.$ See COMMON *METHOD*.

With these quotients, placed in one horizontal row, make the following calculation; and the terms of the last fraction but one will be the values of x and y required; thus

$$\text{quot}^a \quad \beta \quad \gamma \quad \delta \quad \&c.$$

$$\text{frac}^x \quad \frac{\alpha}{1}, \frac{\alpha\beta + 1}{\beta}, \frac{(\alpha\beta + 1)\gamma + \alpha}{\gamma\beta + 1}, \frac{[(\alpha\beta + 1)\gamma + \alpha]\delta}{(\gamma\beta + 1)\delta + \beta} \&c.$$

which may be otherwise expressed in words: thus, having arranged the successive quotients, as above, the first fraction will have α for its numerator, and 1 for its denominator; the second will have $\alpha\beta + 1$ for its numerator, and β for its denominator; and all the other numerators will be found by multiplying the numerator of the last fraction by the following quotient, and adding thereto the preceding numerator, and the denominators are found exactly in the same

manner, as is evident in the foregoing fractions. See RATIO.

Ex. 1.—Find the values of x and y , in the equation

$$16x - 41y = 1.$$

$$\begin{array}{r} \text{First } 16)41(2 \\ \underline{32} \\ 9)16(1 \\ \underline{9} \\ 7)9(1 \\ \underline{7} \\ 2)7(3 \\ \underline{6} \\ 1)2(2 \\ \underline{2} \end{array}$$

quotients 2, 1, 1, 3, 2

fractions $\left\{ \frac{2}{1}, \frac{3}{1}, \frac{5}{2}, \frac{18}{7}, \frac{41}{16} \right.$

Here the last fraction but one is $\frac{18}{7}$, and therefore this gives the values of x and y ; that is, $x = 18$ and $y = 7$, which renders $16x - 41y = 1$, as required.

Ex. 2.—Find the values of x and y , in the equation

$$17x - 15y = -1.$$

$$\begin{array}{r} \text{First } 15)17(1 \\ \underline{15} \\ 2)15(7 \\ \underline{14} \\ 1)2(2 \\ \underline{2} \end{array}$$

Quotients 1, 7, 2

Fractions $\left\{ \frac{1}{1}, \frac{8}{7}, \frac{17}{15} \right.$

Therefore $x = 7$, and $y = 8$, which gives

$$17x - 15y = -1.$$

The demonstration of this rule belongs properly to continued fractions, which the reader will find very ably treated of, in the English edition of Euler's Algebra; and in most of the French writers on that subject, particularly in the "Essai sur la Theorie des Nombres, par Legendre."

Having thus shewn the general method of solving the indeterminate equation $ax - by = \pm 1$; it only remains to make a few observations relating to it, and to shew, that one solution being obtained, an infinite number of other solutions may be deduced from the one known case.

In the above examples we found $ax - by = +1$, and $ax - by = -1$, as the questions required; but we are frequently led to the solution $ax - by = +1$, when the question requires -1 , and the contrary; which seems at first to destroy the generality of the rule; but this difficulty is easily surmounted from the following considerations.

Let $ap - bq = +1$, the values of p and q being known, to find, from this equation, the value of x and y , in the equation $ax - by = -1$.

Since $ap - bq = 1$, we have only to make $x = bm - p$, and

and

INDETERMINATE ANALYSIS.

and $y = am - q$, and it is obvious that this substitution will give

$$a(bm - p) - b(am - q) = -1;$$

and here, by means of the indeterminate m an indefinite number of values of x and y may be determined.

If from one known case, as $ap - bq = +1$, the general values of x and y in the same equation $ax - by = +1$ were required; we should only have to make $x = mb + p$, and $y = ma + q$, and we should have still

$$a(mb + p) - b(ma + q) = ap - bq = +1,$$

where, by means of the indeterminate m , an indefinite number of values of x and y may be obtained. We will now illustrate what has been taught by an example, and then proceed to the more general equations; each of which, however, will be found to depend upon the one we have been considering.

Ex. 3.—Find the general values of x and y , in the equation

$$13x - 19y = 1.$$

$$\begin{array}{r} 13)19(1 \\ \underline{13} \\ 6 \\ \underline{6}13(2 \\ \underline{12} \\ 1)6(6 \\ \underline{6} \end{array}$$

Quotients	1, 2, 6
Fractions	$\left\{ \begin{array}{l} \frac{1}{1}, \frac{3}{2}, \frac{19}{13} \end{array} \right.$

we have therefore $p = 3$, and $q = 2$; and this gives

$$13p - 19q = 1.$$

Therefore the general values of x and y are

$$x = 19m + p, \text{ and } y = 13m + q, \text{ or}$$

$$x = 19m + 3, \text{ and } y = 13m + 2.$$

Assuming therefore $m = 0, 1, 2, 3, 4, \&c.$; we have the following values of x and y ,

$$\begin{array}{l} m = 0, \quad 1, \quad 2, \quad 3, \quad 4, \quad 5 \quad \&c. \\ x = 3, \quad 22, \quad 41, \quad 60, \quad 79, \quad 98 \quad \&c. \\ y = 2, \quad 15, \quad 28, \quad 41, \quad 54, \quad 67 \quad \&c. \end{array}$$

which series may be continued at pleasure.

If the proposed equation had been $13x - 19y = -1$, then having found $p = 3$, and $q = 2$, as above; we must have made

$$x = 19m - 3; \text{ and } y = 13m - 2;$$

and then, by assuming m as before, we should have

$$\begin{array}{l} m = 0, \quad 1, \quad 2, \quad 3, \quad 4, \quad 5 \quad \&c. \\ x = -3, \quad 16, \quad 35, \quad 54, \quad 73, \quad 92 \quad \&c. \\ y = -2, \quad 11, \quad 24, \quad 37, \quad 50, \quad 63 \quad \&c. \end{array}$$

where it may be observed, that the successive values of x and y , in both cases, form a series of arithmeticals, and may therefore be continued with great facility.

PROP. II.

To find the general values of x and y , in the equation $ax - by = \pm c$.

In the first place we must have either a and b prime to each other, or if they have a common measure, c must have the same, for otherwise the equation will be impossible; and in this latter case, the whole equation may be divided by that common measure, and thus reduced to one in which a and b

are prime to each other: it will, therefore, only be necessary to consider the quantities a and b as prime to each other. Also, after what has been taught in the foregoing proposition, we may always suppose that we know the case $ap - bq = \pm 1$; it will therefore be sufficient in this place to show how the general values of x and y , in the equation $ax - by = \pm c$, may be deduced from the known case $ap - bq = \pm 1$.

In the first place it is obvious, that since

$$ap - bq = \pm 1,$$

we shall have

$$acp - bcq = \pm c;$$

but this furnishes only one solution, and in order to have the general values of x and y , we must substitute $x = mb \pm cp$; and $y = ma \pm cq$; which give

$$a(mb \pm cp) - b(ma \pm cq) = \pm c;$$

the ambiguous sign \pm , in the two values of x and y , being $+$ when $ap - bq$ has the same sign with c , but $-$ when it has a contrary one.

Ex. 1.—Find the values of x and y , in the equation

$$9x - 13y = 10.$$

First, in the equation $9p - 13q = \pm 1$, we have $p = 3$, and $q = 2$, which gives $9p - 13q = +1$; and this being the same sign with 10 in the proposed equation, the general values of x and y are

$$\begin{cases} x = 13m + 3c, \text{ or} \\ y = 9m + 2c, \text{ or} \end{cases} \text{ and } \begin{cases} x = 13m + 3c, \\ y = 9m + 2c \end{cases}$$

And by assuming here $m = -2, -1, 0, 1, 2, \&c.$ we have the following values of x and y :

$$\begin{array}{l} m = -2, \quad -1, \quad 0, \quad 1, \quad 2, \quad 3 \quad \&c. \\ x = 4, \quad 17, \quad 30, \quad 43, \quad 56, \quad 69 \quad \&c. \\ y = 2, \quad 11, \quad 20, \quad 29, \quad 38, \quad 47 \quad \&c. \end{array}$$

each of which values has the required conditions, for

$$\begin{array}{l} 9 \cdot 4 - 13 \cdot 2 = 10 \\ 9 \cdot 17 - 13 \cdot 11 = 10 \\ 9 \cdot 30 - 13 \cdot 20 = 10 \\ 9 \cdot 43 - 13 \cdot 29 = 10 \\ \&c. \quad \quad \quad \&c. \quad \quad \quad \&c. \end{array}$$

Ex. 2.—Find the values of x and y , in the equation

$$7x - 12y = 19.$$

First in the equation $7p - 12q = -1$, we have $p = 5$, and $q = 3$; where -1 has a different sign from 19 in the proposed equation; therefore the general values of x and y are

$$\begin{cases} x = 12m - 5 \cdot 19; \\ y = 7m - 3 \cdot 19 \end{cases} \text{ or } \begin{cases} x = 12m - 95; \\ y = 7m - 57 \end{cases}$$

where, by taking $m = 9, 10, 11, \&c.$ in order that x and y may be positive, we have

$$\begin{array}{l} x = 13, \quad 25, \quad 37, \quad 49, \quad 61, \quad 73, \quad 85 \quad \&c. \\ y = 6, \quad 13, \quad 20, \quad 27, \quad 34, \quad 41, \quad 48 \quad \&c. \end{array}$$

and in a similar manner may any possible equation $ax - by = \pm c$ be resolved.

PROP. III.

To find the general values of x and y , in the equation $ax + by = c$.

In the foregoing proposition, where the difference of two quantities was the subject of consideration, we found that the number of solutions was infinite, provided that a and b were prime to each other; but in considering the sum of two quantities,

INDETERMINATE ANALYSIS.

quantities, as in the present case, the number of solutions is always limited, and in many cases the equation is impossible; it may however be demonstrated, that the equation always admits of at least one solution, if $c > ab - a - b$, a and b being prime to each other; and it is proposed in the present proposition to ascertain the exact number of possible solutions that any equation of this kind admits of in integer numbers, and to point out more accurately the limits of possibility.

The solution of the equation $ax + by = c$, depends, like that in the foregoing proposition, upon the equation $ap - bq = \pm 1$, though its connection with it is not so readily perceived.

Let $ap - bq = 1$; then we have also

$$a \cdot ep - b \cdot eq = c;$$

and it is evident that we shall have the same result if we make

$$x = ep - mb; \text{ and } y = eq - ma;$$

for this also gives

$$a(ep - mb) - b(eq - ma) = c;$$

assuming, therefore, for m such a value, that $eq - ma$ may become negative, while $ep - mb$ remains positive, we shall have

$$a(ep - mb) + b(ma - eq) = c;$$

and consequently $x = ep - mb$; and $y = ma - eq$; but if m cannot be so taken that $eq - ma$ may be negative, while $ep - mb$ remains positive; it is a proof that the proposed equation is impossible in integer numbers. And on the contrary, the equation will always admit of as many integral solutions as there may be different values given to m , such that the above conditions may obtain.

And hence we are enabled to determine *a priori* the number of solutions that any proposed equation of the above form admits of; for since we must have $ep > mb$, and $eq < ma$, the number of solutions will always be expressed by the

greatest integer contained in the expression $\left(\frac{ep}{b} - \frac{cq}{a}\right)$;

as is evident, because m must be less than the first of those fractions, and greater than the second, and therefore, the difference between the integral part of these fractions will express the number of different values of m ; except when $\frac{ep}{b}$ is a complete integer, or, which is the same, we must consider $\frac{ep}{b}$ as a fraction, and reject it, but not $\frac{a}{a}$, the reason for which is obvious.

Ex. 1.—Required the values of x and y , in the equation

$$9x + 13y = 2000,$$

and the number of possible solutions in integers.

First, in the equation $9p - 13q = 1$, we have at once $p = 3$, and $q = 2$; therefore the number of solutions will be expressed by

$$\frac{2000 \times 3}{13} - \frac{2000 \times 2}{9} = 461 - 444 = 17.$$

And these are readily obtained from the formulæ

$$\begin{cases} x = ep - mb, \text{ or} \\ x = 6000 - 13m; \end{cases} \text{ and } \begin{cases} y = ma - cq, \text{ or} \\ y = 9m - 4000 \end{cases}$$

in which, assuming $m = 445, 446, \&c$; in order that $9m > 4000$, we shall have the following solutions, each of which is deduced from the preceding one, by adding suc-

cessively 9 to the values of y , and subtracting 13 from those of x ; thus

$$\begin{array}{l} x = 215, 202, 189, 176, 163, 150, 137 \ \&c. \\ y = 5, 14, 23, 32, 41, 50, 59 \ \&c. \end{array}$$

that is;

$$\begin{array}{l} 9 \cdot 215 + 13 \cdot 5 = 2000 \\ 9 \cdot 202 + 13 \cdot 14 = 2000 \\ 9 \cdot 189 + 13 \cdot 23 = 2000 \\ 9 \cdot 176 + 13 \cdot 32 = 2000 \\ \&c. \qquad \qquad \&c. \qquad \&c. \end{array}$$

Ex. 2.—Given the equation $11x + 13y = 190$, to find the number of solutions, and the values of x and y .

First in the equation $11p - 13q = 1$, we have $p = 6$, and $q = 5$; therefore

$$\frac{190 \cdot 6}{13} - \frac{190 \cdot 5}{11} = 87 - 86 = 1;$$

whence it follows that the equation admits of only one integral solution, and this is obtained from the formulæ

$$\begin{cases} x = ep - mb, \text{ or} \\ x = 190 \cdot 6 - 13m; \end{cases} \text{ and } \begin{cases} y = ma - cq, \text{ or} \\ y = 11m - 190 \cdot 5 \end{cases}$$

where, by taking $m = 87$, in order that $ma - cq$ may be positive, we have $x = 9$, and $y = 7$, which gives

$$11 \cdot 9 + 13 \cdot 7 = 190, \text{ as required.}$$

PROP. IV.

To find the values of x, y , and z , and the number of integral solutions of any equation of the form

$$ax + by + cz = d$$

In the first place we may observe, that if any one or more of the co-efficients a, b , or c , be negative, the number of answers is indefinite. For let b be negative, then the equation may be put under the form

$$ax + cz = by + d;$$

in which, by means of the indeterminate y , an infinite number of values may be given to the second side of the equation; and consequently also to x and z . We need, therefore, only consider equations of the form above given, in which the quantities are all connected with the sign +.

Now in this equation, as in those of the two foregoing propositions, if a, b , and c , have each a common divisor, which d has not, it becomes impossible; but if only two of them, as a and b , have a common measure, the equation is still possible, as we shall see in what follows.

The solution of the equation,

$$ax + by + cz = d,$$

is resolved by means of the equation

$$ap - bq = \pm 1,$$

as we have seen is the case in the preceding examples. For let one of the three terms, as cz , be transposed to the other side of the equation; then we have

$$ax + by = d - cz,$$

in which the values of x and y , determined as in the last proposition, will be

$$x = (d - cz)p - mb; \text{ and } y = ma - (d - cz)q,$$

that is, by only substituting $d - cz$ instead of c , which is the only respect in which this equation differs from that in the foregoing problem: and here the only limits to be observed are,

if, $cz < d$; $2d, mb < (d - cz)p$; $3d, ma > (d - cz)q$

may

INDETERMINATE ANALYSIS.

may be obtained. But as these questions generally admit of a great number of solutions, the object of enquiry is not so much to find the values of the intermediate quantities, as to determine *a priori* the number of them that the equation admits of; and this, therefore, shall form the subject of our future investigation.

Now we have seen, that in the equation

$$ax + by = c,$$

the number of solutions is generally expressed by

$$\frac{cp}{b} - \frac{cq}{a},$$

p and q being first determined by the equation

$$ap - bq = 1.$$

If, therefore, in the equation

$$ax + by = d - cz,$$

we make successively $z = 1, 2, 3, 4,$ &c. the number of solutions for each value of z will be as below; *viz.*

$$ax + by = d - c, \text{ number of solutions } \frac{(d-c)p}{b} - \frac{(d-c)q}{a}$$

$$ax + by = d - 2c \dots \dots \dots \frac{(d-2c)p}{b} - \frac{(d-2c)q}{a}$$

$$ax + by = d - 3c \dots \dots \dots \frac{(d-3c)p}{b} - \frac{(d-3c)q}{a}$$

&c. &c. &c. &c.

the sum of which will be the total number that the given equation admits of; and therefore, in order to find the exact number of solutions in any equation of this kind, we must first ascertain the sum of all the integral parts of the arithmetical series

$$\left\{ \frac{(d-c)p}{b} + \frac{(d-2c)p}{b} + \frac{(d-3c)p}{b} + \frac{(d-4c)p}{b} + \dots \right\} \text{ and}$$

$$\left\{ \frac{(d-c)q}{a} + \frac{(d-2c)q}{a} + \frac{(d-3c)q}{a} + \frac{(d-4c)q}{a} + \dots \right\} \text{ and}$$

the difference of the two will be the exact number of integral solutions.

Now in both these series, we know the first and last term, and the number of terms; for the general term being

$$\frac{(d-cz)p}{b}, \text{ and } \frac{(d-cz)q}{a},$$

we shall have the extreme terms by taking the extreme limits of z , that is $z = 1$, and $z \leq \frac{d}{c}$; which last value of z also expresses the number of terms in the series.

Hence then, having the elements of the progressions given, the sum of the whole series is readily obtained; and if therefore we also find the sum of the fractional parts in each, we shall have, by deducting it from the whole sums, that of the integral part of the series as required. The latter part of this problem is readily effected, for the denominator in each term being constant, the fractions will necessarily recur in periods; and the number in each can never exceed the denominator; it will therefore only be necessary to find the sum of the fractions in one period, which being multiplied by the number of periods, will give the sum of the fractional part of the terms; and these taken from the total sum, will give the sum of the integral part of the series; and then, from what has been before observed, the difference of the two sums will be the number of integral solutions required. It may also be ob-

erved, that when the number of terms do not consist of an exact number of periods of circulation, the remaining terms or fractions must be summed by themselves, which is also readily effected, as they will be the same as the leading terms of the first period; and it must also be remembered,

that $\frac{b}{b}$ is to be considered as a fraction in the first series;

but not $\frac{a}{a}$ in the second, as is explained in the foregoing proposition.

Ex. 1.—Given $5x + 7y + 11z = 224$, to find the number of solutions that the equation admits of in positive integers.

Here the greatest limit of z is $z < \frac{224}{11} = 20$; also in

the equation $5p - 7q = 1$, we have $p = 3$, and $q = 2$, also $a = 5$, and $b = 7$; and therefore the two series, of which the sums are required, beginning with the least term in each, are

$$\left\{ \begin{array}{l} \frac{3 \cdot 4}{7} + \frac{3 \cdot 15}{7} + \frac{3 \cdot 26}{7} + \frac{3 \cdot 37}{7} + \dots + \frac{3 \cdot 113}{7} \\ \frac{2 \cdot 4}{5} + \frac{2 \cdot 15}{5} + \frac{2 \cdot 26}{5} + \frac{2 \cdot 37}{5} + \dots + \frac{2 \cdot 113}{5} \end{array} \right.$$

the common difference in the first being $\frac{3 \cdot 71}{7}$; and in

the second $\frac{2 \cdot 11}{5}$; also the number of terms in each 20.

Whence we have 930 for the sum of the first; and - 868 for the sum of the second.

Again, the first period of fractions, in the first series, is

$$\frac{5}{7} + \frac{3}{7} + \frac{1}{7} + \frac{6}{7} + \frac{4}{7} + \frac{2}{7} + \frac{7}{7} = 4;$$

and in the second series, the first period of fractions is

$$\frac{3}{5} + 0 + \frac{2}{5} + \frac{4}{5} + \frac{1}{5} = 2;$$

$\frac{7}{7}$ being considered as a fraction in the first, but not

$\frac{5}{5}$ in the second.

Now the number of terms in each series being 20, we have 2 periods and 6 terms in the first series = $2 \times 4 +$ the first 6 fractions = 11 for the sum of all the fractions; and therefore $930 - 11 = 919$, which is the exact sum of the integral terms. And in the second, we have 4 periods = $4 \cdot 2 = 8$, and therefore $868 - 8 = 860$, which is the sum of the integral terms in this; and hence according to the rule

$$919 - 860 = 59;$$

which is the number of integral solutions.

Remark.—Simpson, in his algebra, makes the number of solutions to this question 60; but he has evidently introduced one (*viz.* $x = 10, y = 14,$ and $z = 14,$) which does not obtain.

Ex. 2.—Having given $7x + 9y + 23z = 9999$, it is required to find the number of its solutions in positive integers.

Here the greatest limit of $z < \frac{9999}{23} = 434$; also in

the equation $7x - 9p = 1$, we have $p = 4$, and $q = 3$,

INDETERMINATE ANALYSIS.

$a = 7$, and $b = 9$; also $9999 - 23 \cdot 434 = 17$; therefore the series whose sums are required, will be

$$\text{1st. } \frac{4 \cdot 17}{9} + \frac{4 \cdot 40}{9} + \frac{4 \cdot 63}{9} + \&c. \dots \frac{4 \cdot 9976}{9}$$

$$\text{2d. } \frac{3 \cdot 17}{7} + \frac{3 \cdot 40}{7} + \frac{3 \cdot 63}{7} + \&c. \dots \frac{3 \cdot 9976}{7}$$

the common difference in the first being $\frac{4 \cdot 23}{9} = 10 \frac{2}{9}$;

and in the second $\frac{3 \cdot 23}{7} = 9 \frac{6}{7}$; also the number of terms in each 434; that being the greatest limit of x .

Hence we have the sum of the first series = $963769 \frac{3}{9}$

and of the second - - - - - 929349

Also the first period of fractions in the first series, is

$$\frac{5}{9} + \frac{7}{9} + \frac{9}{9} + \frac{2}{9} + \frac{4}{9} + \frac{6}{9} + \frac{8}{9} + \frac{1}{9} + \frac{3}{9} = 5;$$

and $\frac{434}{9} = 48$ periods, and 2 terms = $5 \cdot 48 + \frac{5}{9} + \frac{2}{9} = 241 \frac{7}{9}$

And in the second series, the first period of fractions is

$$\frac{2}{7} + \frac{1}{7} + 0 + \frac{6}{7} + \frac{5}{7} + \frac{4}{7} + \frac{3}{7} = 3;$$

also $\frac{434}{7} = 62$ periods; and therefore $62 \cdot 3 = 186$.

Hence $963769 \frac{3}{9} - 241 \frac{7}{9} = 963528$ integral terms

and $929349 - 186 = 929163$ integral terms

whence the difference 34365 is the number of integral solutions required.

In the foregoing examples we have had two of the terms prime to each other; but when this is not the case the following transformation will be necessary.

Ex. 3.—Let there be proposed the equation,

$$12x + 15y + 20z = 100001,$$

to find the number of solutions.

Here no two of the co-efficients are prime to each other, and we must therefore proceed as follows.

Divide the whole equation by 5, and transpose z , and we have

$$4x + 3y = 33334 - 7z + \frac{z-1}{3}$$

which last must be an integer; make therefore $\frac{z-1}{3} = u$,

and we have $z = 3u + 1$; substituting now this value of z , the original equation becomes

$$12x + 15y + 20(3u + 1) = 100001;$$

or, dividing by 3,

$$4x + 5y + 20u = 33327,$$

the number of solutions in which will be the same as in the equation proposed, which will be found as in the foregoing examples, except that here the least value of $u = 0$, because we shall then still have $z = 1$, and by proceeding as in the preceding examples, it will be found that the number of integral solutions that may be given to this question, amounts to no less than 138861.

PROP. V.

Having given any number of equations, less than the number of unknown quantities that enter therein, to determine those quantities.

Let there be proposed the two equations

$$\begin{cases} a'x + b'y + c'z = d' \\ a''x + b''y + c''z = d'' \end{cases}$$

to find the values of x, y , and z .

Multiply the first by a'' , and the second by a' , whence, by subtraction, we obtain

$$(a'b - a'b')y + (a'c - a'c')z = a'd - a'd''$$

Or, dividing each of these known co-efficients by their greatest common divisor, if they have any, and representing the results by b'', c'' , and d'' , this equation becomes

$$b''y + c''z = d''.$$

Find now the values of y and z in this equation; and these being substituted for them in the equation

$$x = \frac{d - cz - by}{a}$$

will give the corresponding values of x , of which those, of course, must be rejected that render x fractional, and also those that give $(cz + by) > d$.

Ex.—Given the equations

$$\begin{cases} 3x + 5y + 7z = 560 \\ 9x + 25y + 49z = 2920 \end{cases}$$

to find all the integral values of x, y , and z .

Multiplying the first by 3, we have

$$\begin{cases} 9x + 15y + 21z = 1680 \\ 9x + 25y + 49z = 2920 \end{cases}$$

whence

$$\begin{cases} 10y + 28z = 1240, \text{ or} \\ 5y + 14z = 620 \end{cases}$$

And here the values of y and z are found to be

$$\begin{aligned} y &= 110, 96, 82, 68, 54, 40, 26, 12 \\ z &= 5, 10, 15, 20, 25, 30, 35, 40 \end{aligned}$$

and of these, the only two that give

$$x = \frac{560 - 7z - 5y}{3}$$

an integer, are as follows,

$$\begin{cases} z = 15, y = 82, x = 15 \\ z = 30, y = 40, x = 50 \end{cases}$$

which are the only two solutions the equations admit of in integers.

The method above given will never fail of producing all the possible solutions in equations of the above form; but there are other methods that may be followed in particular cases which sometimes shorten the operations. The reader will find explained in vol. ii. of Euler's Elements of Algebra.

PROP. VI.

To decompose a given numerical fraction, having a composite denominator, into a number of simple fractions having prime denominators.

This is, in fact, only an application of the foregoing propositions to this particular problem; for let $\frac{m}{n}$ be the given fraction; and suppose, in the first instance, that it

INDETERMINATE ANALYSIS.

denominator consists of two prime factors, or $n = ab$, it will then be found

$$\frac{m}{ab} = \frac{p}{a} + \frac{q}{b}, \text{ or } aq + bp = m,$$

in which equation, having determined the values of p and q ,

we shall have $\frac{p}{a} + \frac{q}{b}$ for the fractions required; and as

many different ways may any such fraction be decomposed into two others, as the equation $aq + bp = m$ admits of integral solutions. If the given fraction be $\frac{m}{abc}$, then we may first resolve it into two fractions, and one of these into two others; thus, let

$$\frac{m}{abc} = \frac{p}{bc} + \frac{q}{c};$$

then we have

$$abq + cp = m;$$

and having, from this equation, found the values of p and q ,

$$\text{we shall have } \frac{m}{abc} = \frac{p}{ab} + \frac{q}{c}.$$

Again, let $\frac{p}{ab} = \frac{r}{a} + \frac{s}{b}$, or $as + rb = p$, find r and s in this equation, so shall we have

$$\frac{m}{abc} = \frac{r}{a} + \frac{s}{b} + \frac{q}{c},$$

as required; and in the same manner may any fraction that admits of decomposition be resolved into others of which the sum shall be equal to the original fraction.

Ex.—What are those two fractions whose sum is equal to $\frac{19}{35}$.

Since $35 = 5 \times 7$, we may make $\frac{19}{35} = \frac{p}{7} + \frac{q}{5}$, which produces this equation,

$$5p + 7q = 19,$$

in which the value of $p = 1$, and $q = 2$ are readily found;

and therefore the fractions sought are $\frac{1}{7} + \frac{2}{5} = \frac{19}{35}$.

PROP. VII.

To find the least number, that, being divided by given numbers, shall leave given remainders.

Let N represent the required number, such that, being divided by a, a', a'' &c. the remainders shall be respectively b, b', b'' , &c. that is,

$$N = am + b = a'n + b' = a''p + b'' \text{ \&c.}$$

and it is required to find the least value of N , that answers these conditions.

First since $am + b = a'n + b'$
we have $am - a'u = b' - b$.

Find, therefore, in this equation, the least values of m and n by Prop. II., then will $am + b$, or $a'n + b'$, express the least number that fulfils the first two conditions. Let now this number be called c ; then it is evident that every number of the form $a'a'g + c$ will also fulfil these conditions; and we must proceed to find $a'a'g + c = a''p + b''$; or,

$$a'a'g - a''p = b'' - c;$$

that is, the least value of p and g in this equation; so shall we have $a'a'g + c$ for the least number that answers the

first three conditions, and so on for as many others as may be proposed.

Ex.—Find the least number, that, being divided by 28, 19, and 15, shall leave for remainders respectively 19, 15, and 11.

Here we have $28m + 19 = 19n + 15 = 15p + 11$. Now, in the equation $28m - 19n = -4$, the least values of m and n are $m = 8$, and $n = 12$; whence $28m + 19 = 19n + 15 = 243$; and it now remains to find $28 \cdot 19g + 243 = 15p + 11$; or, $532g - 15p = -228$.

In which equation $p = 512$, and $g = 14$, whence $532g + 243 = 15p + 11 = 7691$, which is the least number having the required conditions.

Having thus treated of the solution of indeterminate equations of the first degree, to as great an extent as our limit will admit of, we shall proceed to those, in which one, at least, of the unknown quantities enter in the square power, which constitute the class of indeterminate equations of the second degree; and as we have seen that every equation of the first class has its solution depending upon that of the equation $ax - by = \pm 1$; so in those that we are about to investigate, the solution is intimately connected with that of the equation $p^2 - Nq^2 = \pm 1$; this, therefore, is what shall first engage our attention.

PROP. VIII.

To find the integral values of p and q in the equation

$$p^2 - Nq^2 = \pm 1,$$

N being any given number whatever, not a complete square.

In order to obtain the general solution of this equation, which is always possible (at least with the positive sign) we must shew the method of extracting the square root of any number N , not a complete square, in continued fractions; but as this operation belongs properly to the latter subject, we shall only in this place indicate the method, and must refer the reader for the demonstration to vol. II. of Euler's Algebra, and to Barlow's Elementary Investigations. See also SQUARE ROOT.

The transformation of the \sqrt{N} , to continued fractions, is performed by means of the following formula.

Let a be the greatest integer contained in \sqrt{N} ; then make

$$\begin{array}{l} \sqrt{N + 0} = a \\ \frac{1}{\sqrt{N + m}} = u \\ \frac{n}{\sqrt{N + m'}} = u' \\ \frac{n'}{\sqrt{N + m''}} = u'' \\ \frac{n''}{\sqrt{N + m'''}} = u''' \\ \text{\&c. \&c.} \end{array} \quad \left\{ \begin{array}{l} a - 0 = m; \quad \frac{N - m^2}{n} = n \\ \frac{1}{n} = m'; \quad \frac{N - m'^2}{n'} = n'' \\ u n - m = m'; \quad \frac{N - m'^2}{n'} = n'' \\ u' n' - m' = m''; \quad \frac{N - m''^2}{n''} = n''' \\ u'' n'' - m'' = m'''; \quad \frac{N - m'''^2}{n'''} = n'''' \\ \text{\&c.} \quad \text{\&c.} \end{array} \right.$$

In these formulæ $u, u', u'',$ &c. are the greatest integers contained in the corresponding fractions, which quantities are the quotients, whence the converging fractions are to be deduced, by the same rule as is given in Prop. I. for the quotients $\alpha, \beta, \gamma, \delta,$ &c.; and by continuing the above operations, we shall be finally led to a quotient equal to $2a$, at which term we must stop, and the corresponding fractions to the last quotient before this will give the required values of p and q .

INDETERMINATE ANALYSIS.

Ex. 1.—Required the values of p and q in the equation

$$p^3 - 19q^2 = -1.$$

By the above rule,

$\frac{\sqrt{19+0}}{1} = 4 = a$	$4 \cdot 1 - 0 = 4$	$\frac{19-4^2}{1} = 3$
$\frac{\sqrt{19+4}}{3} = 2 = u$	$3 \cdot 2 - 4 = 2$	$\frac{19-2^2}{3} = 5$
$\frac{\sqrt{19+2}}{5} = 1 = u'$	$5 \cdot 1 - 2 = 3$	$\frac{19-3^2}{5} = 2$
$\frac{\sqrt{19+3}}{2} = 3 = u''$	$2 \cdot 3 - 3 = 3$	$\frac{19-3^2}{2} = 5$
$\frac{\sqrt{19+3}}{5} = 1 = u'''$	$5 \cdot 1 - 3 = 2$	$\frac{19-2^2}{5} = 3$
$\frac{\sqrt{19+2}}{3} = 2 = u'''$	$3 \cdot 2 - 2 = 4$	$\frac{19-4^2}{3} = 1$
$\frac{\sqrt{19+4}}{1} = 8 = u''''$	$\&c.$	$\&c.$

Having thus arrived at the quotient $8 = 2a$, we have only to compute the fractions by the proposition above quoted; thus,

quotients	4,	2,	1,	3,	1,	2,	8
fractions	$\left\{ \frac{4}{1} \right.$	$\frac{9}{2}$	$\frac{13}{3}$	$\frac{48}{11}$	$\frac{61}{14}$	$\frac{170}{39}$	$\left. \right\}$

which last fraction gives the values of p and q ; that is, $p = 170$, and $q = 39$; for

$$170^3 - 19 \cdot 39^2 = -1, \text{ as required.}$$

Ex. 2.—Find the values of p and q in the equation

$$p^2 - 13q^2 = -1.$$

First,

$\frac{\sqrt{13+0}}{1} = 3$	$3 \cdot 1 - 0 = 3$	$\frac{13-3^2}{1} = 4$
$\frac{\sqrt{13+3}}{4} = 1$	$4 \cdot 1 - 3 = 1$	$\frac{13-1^2}{4} = 3$
$\frac{\sqrt{13+1}}{3} = 1$	$3 \cdot 1 - 1 = 2$	$\frac{13-2^2}{3} = 3$
$\frac{\sqrt{13+2}}{3} = 1$	$3 \cdot 1 - 2 = 1$	$\frac{13-1^2}{3} = 4$
$\frac{\sqrt{13+1}}{4} = 1$	$4 \cdot 1 - 1 = 3$	$\frac{13-3^2}{4} = 3$
$\frac{\sqrt{13+3}}{1} = 6$	$\&c.$	$\&c.$

And having thus arrived at the quotient $2a$, or 6 , we have for

quotients	3,	1,	1,	1
fractions	$\left\{ \frac{3}{1} \right.$	$\frac{4}{1}$	$\frac{7}{2}$	$\frac{18}{5} \left. \right\}$

that is, $p = 18$ and $q = 5$, which give

$$18^2 - 13 \cdot 5^2 = -1, \text{ as required.}$$

Ex. 3.—Find the values of p and q in the equation

$$p^2 - 17q^2 = -1.$$

First $\frac{\sqrt{17+0}}{1} = 4 = a \left\{ \begin{array}{l} 4 \cdot 0 = 4 \\ \frac{17-4^2}{1} = 1 \end{array} \right.$

$\frac{\sqrt{17+4}}{1} = 8 \left\{ \right.$

Here we have, at the first step, arrived at the quotient $2a$, whence the first fraction, $\frac{4}{1}$, is the one sought; for $4^2 - 17 \cdot 1^2 = -1$, as required.

Ex. 4.—Find the values of p and q in the equation

$$p^2 - 14q^2 = 1.$$

First,

$\frac{\sqrt{14+0}}{1} = 3$	$3 \cdot 1 - 0 = 3$	$\frac{14-3^2}{1} = 5$
$\frac{\sqrt{14+3}}{5} = 1$	$5 \cdot 1 - 3 = 2$	$\frac{14-2^2}{5} = 2$
$\frac{\sqrt{14+2}}{2} = 2$	$2 \cdot 2 - 2 = 2$	$\frac{14-2^2}{2} = 5$
$\frac{\sqrt{14+2}}{5} = 1$	$5 \cdot 1 - 2 = 3$	$\frac{14-3^2}{5} = 1$
$\frac{\sqrt{14+3}}{1} = 6$	$\&c.$	$\&c.$

Whence we have, quotients

fractions	$\left\{ \frac{3}{1} \right.$	$\frac{1}{1}$	$\frac{11}{3}$	$\frac{15}{4} \left. \right\}$
-----------	-------------------------------	---------------	----------------	--------------------------------

which gives $15^2 - 14 \cdot 4^2 = 1$, as required.

It will be observed, that in the foregoing examples we have obtained for each only one solution; whereas they all admit of an indefinite number of solutions. Moreover, it does not appear, from the first three examples, how we should have found the values of p and q , if they had been put equal to $+1$ instead of -1 . This shall, therefore, be considered in the following proposition.

PROP. IX.

To find the general values of x and y in the equation $x^2 - Ny^2 = \pm 1$, from one known case $p^2 - Nq^2 = \pm 1$. In the first place it may be demonstrated, but our limits will not allow of it, that the equation $x^2 - Ny^2 = 1$ is always possible for every value of N , providing it be not a complete square; and the values of x and y are always deducible, both from $p^2 - Nq^2 = 1$, and from $p^2 - Nq^2 = -1$; but if the operation above given does not produce the equation $p^2 - Nq^2 = -1$, the equation $x^2 - Ny^2 = -1$ is always impossible. The present problem, therefore, divides itself into three cases; *viz.* to find the general values of x and y in the equation $x^2 - Ny^2$, under the following conditions:

1st, $x^2 - Ny^2 = 1$,	from one known case $p^2 - Nq^2 = 1$
2d, $x^2 - Ny^2 = 1$,	$p^2 - Nq^2 = -1$
3d, $x^2 - Ny^2 = -1$,	$p^2 - Nq^2 = -1$

Case 1.—Resolve $p^2 - Nq^2 = 1$, and $x^2 - Ny^2 = 1$ into

the factors $\left\{ \begin{array}{l} (p + q\sqrt{N})(p - q\sqrt{N}) = 1 \\ (x + y\sqrt{N})(x - y\sqrt{N}) = 1 \end{array} \right.$

then we have also,

$$(p + q\sqrt{N})^m (p - q\sqrt{N})^n = 1;$$

equating these, with the factors in x and y , we have

$$(p + q\sqrt{N})^m = x + y\sqrt{N}$$

$$(p - q\sqrt{N})^m = x - y\sqrt{N}$$

whence $x = \frac{(p + q\sqrt{N})^m + (p - q\sqrt{N})^m}{2}$;

and $y = \frac{(p + q\sqrt{N})^m - (p - q\sqrt{N})^m}{2\sqrt{N}}$;

which values of x and y will always be integral, and will be the general values sought; and these are evidently indefinite in number, because the power m is indefinite.

Case 2.—The same method may be followed here, as in the preceding case, except that the powers must be even,

INDETERMINATE ANALYSIS

in order to convert -1 into $+1$, as is obvious from inspection; and, therefore, the general values of x and y will be

$$\begin{cases} x = \frac{(p+q\sqrt{N})^{2m} + (p-q\sqrt{N})^{2m}}{2} \\ y = \frac{(p+q\sqrt{N})^{2m} - (p-q\sqrt{N})^{2m}}{2\sqrt{N}} \end{cases}$$

Case 3.—Here, again, we have evidently the same result as in the former cases, except that the power m must now be odd for every odd power of $-1 = -1$; and, therefore,

$$\begin{cases} x = \frac{(p+q\sqrt{N})^{2m+1} + (p-q\sqrt{N})^{2m+1}}{2} \\ y = \frac{(p+q\sqrt{N})^{2m+1} - (p-q\sqrt{N})^{2m+1}}{2\sqrt{N}} \end{cases}$$

Let us now propose an example in each of these three cases.

Ex. 1.—In the equation $x^2 - 14y^2 = 1$, we have $p = 15$ and $q = 4$, to find a second value of p and q , or of x and y , in the equation $x^2 - 14y^2 = 1$.

Make

$$\begin{cases} x = \frac{(15+4\sqrt{14})^2 - (15-4\sqrt{14})^2}{2} = 449 \\ y = \frac{(15+4\sqrt{14})^2 - (15-4\sqrt{14})^2}{2\sqrt{14}} = 120 \end{cases}$$

which give $449^2 - 14 \cdot 120^2 = 1$; and other values may be found by assuming any other power above the second.

Ex. 2.—Given $p = 4$, and $q = 1$, in the equation $p^2 - 17q^2 = -1$, to find the values of x and y , in the equation $x^2 - 17y^2 = 1$.

Here we have, again,

$$\begin{cases} x = \frac{(4+\sqrt{17})^2 + (4-\sqrt{17})^2}{2} = 33 \\ y = \frac{(4+\sqrt{17})^2 - (4-\sqrt{17})^2}{2\sqrt{17}} = 8 \end{cases}$$

whence $33^2 - 17 \cdot 8^2 = 1$; and other values may be found by assuming any other even power instead of the second.

Ex. 3.—Given $p = 4$, and $q = 1$, in the equation $p^2 - 17q^2 = 1$, to find the values of x and y , in the equation $x^2 - 17y^2 = -1$.

Assume

$$\begin{cases} x = \frac{(4+\sqrt{17})^3 + (4-\sqrt{17})^3}{2} = 268 \\ y = \frac{(4+\sqrt{17})^3 - (4-\sqrt{17})^3}{2\sqrt{17}} = 67 \end{cases}$$

whence, $268^2 - 17 \cdot 67^2 = -1$, and other values may be obtained, by assuming other odd powers instead of the third.

PROP. X.

To ascertain the possibility or impossibility of every equation of the form $x^2 - Ny^2 = \pm A$; and to find x and y in the former case, A being $< N$.

The rule for this purpose, is to convert \sqrt{N} into a series of quotients, as in Prop. VIII.; and if A be found in the denominator of any of the quotients, that is, if A be found amongst any of the numbers, which in the proposition above quoted are represented by $n, n', n'', \&c.$ the equation is possible, and the converging fraction corresponding to the quotient preceding this will give the values of a and y ;

but if A be not so found, then is the equation impossible. This theorem cannot be demonstrated in this place, as it belongs to the theory of continued fractions, and the reader is therefore referred for a proof of the rule to Le Genérese's *Essai sur la Théorie des Nombres*.

Ex. 1.—Required the values of x and y , in the equation

$$x^2 - 23y^2 = 2.$$

Here by the rule Prop. VIII.

$$\begin{array}{l|l} \frac{\sqrt{23+0}}{1} = 4 & 1 \cdot 4 - 0 = 4; \quad \frac{23-4^2}{1} = 7 \\ \frac{\sqrt{23+4}}{7} = 1 & 7 \cdot 1 - 4 = 3; \quad \frac{23-3^2}{7} = 2 \\ \frac{\sqrt{23+1}}{2} = 3 & \end{array}$$

Having thus arrived at the denominator 2, it follows that the equation is possible, and the values of x and y are found from the same calculation as at Prop. VIII.; thus

quotients	4,	1,	3
fractions	{ $\frac{4}{1}$,	$\frac{3}{7}$,	$\frac{2}{2}$

whence $x = 5$, and $y = 1$, which gives $x^2 - 23y^2 = 2$.

Ex. 2.—Required the values of x and y , in the equation

$$x^2 - 19y^2 = 5.$$

First

$$\begin{array}{l|l} \frac{\sqrt{19+0}}{1} = 4 & 1 \cdot 4 - 0 = 4; \quad \frac{19-4^2}{1} = 3 \\ \frac{\sqrt{19+4}}{3} = 2 & 3 \cdot 2 - 4 = 2; \quad \frac{19-2^2}{3} = 5 \\ \frac{\sqrt{19+2}}{1} = 4 & \end{array}$$

Having therefore found the denominator 5, the equation is possible, and we have

quotients	4,	2,	1
fractions	{ $\frac{4}{1}$,	$\frac{2}{3}$,	$\frac{1}{5}$

whence $x = 9$, and $y = 2$, which gives $x^2 - 19 \cdot 2^2 = 5$, as required.

Ex. 3.—It is required to ascertain the possibility, or impossibility, of the equations

$$\begin{cases} x^2 - 17y^2 = \pm 2 \\ x^2 - 17y^2 = \pm 3 \end{cases}$$

First

$$\begin{array}{l|l} \frac{\sqrt{17+0}}{1} = 4 & 1 \cdot 4 - 0 = 4; \quad \frac{17-4^2}{1} = 1 \\ \frac{\sqrt{17+4}}{1} = 8 & 1 \cdot 8 - 4 = 4; \quad \frac{17-4^2}{1} = 1 \\ \frac{\sqrt{17+4}}{1} = 8 & 1 \cdot 8 - 4 = 4; \quad \frac{17-4^2}{1} = 1 \end{array}$$

whence it follows, that since only 1 enters into the denominators of these quotients, no one of the proposed equations are possible.

Cor.—By means of this proposition, we may demonstrate generally the impossibility of all equations falling under any of the following forms;

$$\begin{cases} x^2 - (a^2 + 1)y^2 = \pm A \\ x^2 - (a^2 - 1)y^2 = \pm A \\ x^2 - (a^2 + a)y^2 = \pm A \\ x^2 - (a^2 - a)y^2 = \pm A \end{cases}$$

in which $A > 1$, and $< a$.

Cor.

INDETERMINATE ANALYSIS.

Cor. 2.—It is also deducible from similar principles, that the following equations are always possible; N being a prime number, of the form placed opposite the respective equations.

$$\begin{aligned} x^2 - N y^2 &= -1 \text{ possible when } N \text{ of the form } 4n + 1 \\ x^2 - N y^2 &= -2 \dots\dots\dots N \dots\dots\dots 8n + 3 \\ x^2 - N y^2 &= 2 \dots\dots\dots N \dots\dots\dots 8n - 1 \end{aligned}$$

And in a similar manner, are deduced the three following theorems:

1. If M and N be both of the form $4n + 3$, and not equal to each other, the equation

$$M x^2 - N y^2 = \pm 1$$

is always possible in integer numbers: that is, under one or other of the signs $+$ or $-$.

2. If M and N be both of the form $4n + 1$; then one of the equations

$$\begin{cases} x^2 - M N y^2 = -1, \text{ or} \\ M x^2 - N y^2 = \pm 1 \end{cases}$$

will always be resolvable in integers.

3. If M and M' be two prime numbers of the form $4n + 3$, and N a prime number of the form $4n + 1$, it will be always possible to satisfy one of the equations

$$\begin{cases} N x^2 - M M' y^2 = \pm 1 \\ M x^2 - M' N y^2 = \pm 1 \\ M' x^2 - M N y^2 = \pm 1 \end{cases}$$

PROP. XI.

To find the general values of x and y in the equation

$$x^2 - N y^2 = \pm A$$

from one known case $p^2 - N q^2 = \pm A$.

Find the values of m and n in the equation $m^2 - N n^2 = 1$, by Prop. VIII.; then it is evident that the product

$$(p^2 - N q^2) \times (m^2 - N n^2) = \pm A;$$

and it will be found, upon the development of the following formulae, that

$$(p^2 - N q^2) \times (m^2 - N n^2) = \begin{cases} (pm + Nqn)^2 - N(\rho n + qm)^2 \\ (pm - Nqn)^2 - N(\rho n - qm)^2 \end{cases}$$

we have, therefore, only to make,

$$\begin{cases} x = pm + Nqn & \text{or} & \begin{cases} x = pm - Nqn \\ y = pn + qm \end{cases} \\ y = pn + qm & & \begin{cases} y = pn - qm \end{cases} \end{cases}$$

and having before shewn how to find the general values m and n in the equation $m^2 - N n^2 = 1$; it is obvious, that by means of these formulae we may derive different values of x and y , in the proposed equation, to any extent at pleasure.

Cor.—It appears also from this proposition, that if the rule in the foregoing one give $p - N q = -A$, when the equation proposed be $+A$; that this may be converted to the latter sign by means of the equation

$$m^2 - N n^2 = -1.$$

Ex. 1.—Given the values of p and q , in the equation $p^2 - 7 q^2 = 2$; viz. $p = 3$, and $q = 1$, to find the general values of x and y , in the equation $x^2 - 7 y^2 = 2$.

First in the expression $m^2 - 7 n^2 = 1$, we have $m = 8$, and $n = 3$; whence by the above formulae is obtained

$$\begin{cases} x = pm \pm N q n = 3 \cdot 8 \pm 7 \cdot 1 \cdot 3 = 3 \text{ or } 45 \\ y = pn \pm q m = 3 \cdot 3 \pm 1 \cdot 8 = 1 \text{ or } 17 \end{cases}$$

so that the second values of x and y are, $x = 45$, and $y = 17$; which give $45^2 - 7 \cdot 17^2 = 2$. And assuming these again as new values of p and q , other values x and y may be found in *infinitum*: or the original values of p and q may

be retained, and new values found for m and n , which answers the same purpose.

Ex. 2.—Find the general values of x and y , in the equation $x^2 - 11 y^2 = 5$; the known case being $p^2 - 11 q^2 = 5$, or $p = 4$, and $q = 1$.

In the equation $m^2 - 11 n^2 = 1$, we have $m = 10$, and $n = 3$, therefore by the formulae

$$\begin{cases} x = pm \pm N q n = 4 \cdot 10 \pm 11 \cdot 1 \cdot 3 = 7 \text{ or } 73 \\ y = pn \pm q m = 4 \cdot 3 \pm 1 \cdot 10 = 2 \text{ or } 22 \end{cases}$$

that is $x = 7$, and $y = 2$, are two new values of x and y , as are also $x = 73$, and $y = 22$; for each of these give

$$\begin{cases} 7^2 - 11 \cdot 2^2 = 5 \\ 73^2 - 11 \cdot 22^2 = 5 \end{cases}$$

and in the same manner, other values may be found to any required extent.

As our limits will not allow of a very full and explicit investigation of the several elegant rules that have been introduced into the indeterminate analysis by Euler, Lagrange, Legendre, and other distinguished mathematicians; we must refer the reader for the investigation of the methods employed in the following propositions to the authors above-mentioned, and must content ourselves with barely stating the operations, without entering into the demonstration of the theorems themselves.

PROP. XII.

Every indeterminate equation of the second degree falls under the general formulae

$$a x^2 + b x y + c y^2 + d x + e y + f = 0,$$

and this may always be transformed to the more simple form

$$u^2 - A t^2 = B.$$

The method of performing this transformation will be seen from the following partial example, and the formulae we have given it being universally the same in all cases.

Assume $b d - 2 a e = g$; $d - 4 a f = b$; $(b y + d)^2 - 4 a (c y^2 + e y + f) = t$; $b^2 - 4 a c = A$; $A y + g = u$; $g^2 - A b = B$.

Then it will be found, by the development of these expressions, that

$$a x^2 + b x y + c y^2 + d x + e y + f = u^2 - A t^2 - B = 0,$$

becomes $u^2 - A t^2 = B$.

And having found the values of u and t in this last equation, those of x and y are readily derived in the equation proposed.

For $y = \frac{u - g}{A}$, and $x = \frac{t - d - b y}{2 a}$;

or, substituting for y in the last, we have the following values;

$$\begin{cases} y = \frac{u - g}{b - 4 a c} \\ x = \frac{(t - d)(b^2 - 4 a c) - (u - g)b}{2 a (b^2 - 4 a c)} \end{cases}$$

Ex. 1.—Transform the equation $3 x^2 + 8 x y - 3 y^2 + 2 x - 5 y = 110$ to its simplest form.

Here $a = 3$, $b = 8$, $c = -3$, $d = 2$, $e = -5$, $f = -110$.

Whence $\begin{cases} b^2 - 4 a c = A = & 100 \\ b d - 2 a e = g = & 46 \\ d - 4 a f = b = & 1324 \\ g^2 - A b = B = & -130284 \end{cases}$ and

INDETERMINATE ANALYSIS.

and thus the reduced equation becomes

$$u^2 - 100t^2 = -130284.$$

In which, having found $u = 346$, and $t = 50$,

$$\text{we have } \begin{cases} y = \frac{u-g}{A} = \frac{346-46}{100} = 3, \\ x = \frac{t-by-d}{2a} = \frac{50-8 \cdot 3-2}{6} = 4, \end{cases}$$

therefore $x = 4$, and $y = 3$, are the values of x and y in the original equation.

It will be observed that we have employed here the most general form that equations of this kind admit of, and therefore the formulæ are more complex than they usually occur in practical cases, for when any of the co-efficients a , b , c , &c. become zero, the expressions are much simplified, as appears from the following example.

Ex. 2.—Reduce $7x^2 + 5xy + y^2 = 67$ to its simplest form.

Here $a = 7$, $b = 5$, $c = 1$, $d = 0$, $e = 0$, $f = -67$, whence, omitting those quantities that are zero, we have

$$\begin{cases} b^2 - 4ac = A = 29; \text{ and } g = 0 \\ d^2 - 4af = b = 1876 \\ g^2 - \Lambda b^2 = 29 \cdot 1876^2 = B \end{cases}$$

and thus the reduced equation is

$$u^2 - 29t^2 = 29 \cdot 1876^2.$$

And in a similar manner may any indeterminate equation of the second degree be reduced to the form $u^2 - \Lambda t^2 = B$.

Having therefore shewn the method of reducing every indeterminate equation to the form $u^2 - \Lambda t^2 = B$; it follows that the solution of this simple form involves with it the solution of every equation of this kind that can be proposed; we shall therefore, in the following proposition, attend to the solution of this particular case. But it may be proper to state, that there are an infinite number of equations of this kind that are impossible; and will admit of no solution, either in integers or fractions; and therefore before we proceed farther in the investigation, it will be useful to lay down a rule, whence their possibility, or impossibility, may be ascertained; as we may thus frequently save much unnecessary labour.

PROP. XIII.

To ascertain the possibility or impossibility of every indeterminate equation of the second degree.

Rule.—Reduce the proposed equation to the form

$$u^2 - \Lambda t^2 = B,$$

and find all the remainders arising from dividing each of the

squares $1^2, 2^2, 3^2, 4^2$, &c. $\left(\frac{A-1}{2}\right)^2$ by A ;

and also the remainders arising from dividing each of the

squares $1^2, 2^2, 3^2, 4^2$, &c. $\left(\frac{B-1}{2}\right)^2$ by B ;

and again, divide the greatest of these numbers A, B , by the least of them, and observe the remainder.

Then if B be greater than A , this last remainder will be found amongst those of the upper series; and the number A will be found amongst those of the lower series, if the equation be possible.

And conversely, if these conditions have not place, the proposed equation will admit of no solution, either in integers or fractions.

Again, if $\Lambda > B$, then the remainder arising from $\frac{A}{B}$ will

be found in the lower series, and the number B in the upper series of remainders, if the equation be possible; and if these conditions have not place, the proposed equation is impossible.

Note.—It is to be observed, that equations falling under the possible form are not always solvable in integers, the proof extending only to their solvability in rational numbers, which may therefore sometimes be fractional; but when they fall under an impossible form, they will admit of no solutions either in integers or fractions.

Ex.—Required the possibility or impossibility of the equation

$$x^2 - 7y^2 = 11$$

squares $1^2, 2^2, 3^2$ divided by 7

remainders $1, 4, 2$

squares $1^2, 2^2, 3^2, 4^2, 5^2$ divided by 11

remainders $1, 4, 9, 5, 3$

$\frac{11}{7} = 1$ and remainder 4.

Now 4 is found in the upper series of remainders, but 7 is not found in the lower; therefore the equation cannot have place either in integers or fractions.

And for the same reason, the equation $x^2 - 7y^2 = 11x^2$ is also impossible, for if this was possible, so would like-

wise $\frac{x^2}{x^2} - 7 \frac{y^2}{x^2} = 11$; which we have seen is impossible.

Ex. 2.—It is required to ascertain the possibility or impossibility of the equation

$$x^2 - 13y^2 = 12$$

squares $1^2, 2^2, 3^2, 4^2, 5^2, 6^2$ divided by 13

remainders $1, 4, 9, 3, 12, 10$

And the same squares, divided by 12, give for

remainders $1, 4, 9, 4, 1, 0$

also, $\frac{13}{12} = 1$ and remainder 1.

And here, since 12 is found in the upper series, and 1 in the lower, the equation is solvable.

Note.—If the equation proposed be of the form

$$x^2 - \Lambda y^2 = -B,$$

we must employ, instead of the positive remainders arising from Λ , the negative remainders of the same, that is, taking the quotients in excess. And if the equation have the form

$$x^2 + \Lambda y^2 = B,$$

then we must employ the negative remainders of B . Having thus given an idea of the method of judging of the possibility of every equation of the form $x^2 - \Lambda y^2 = B$; and having also shewn how any indeterminate of the second degree may be reduced to this form, it only remains to shew the method of solution of the above equation; or, which is still a more general form, of the equation

$$x^2 - \Lambda y^2 = Bz^2;$$

but in this, as in the other propositions, we can only indicate the method, without attempting to investigate the rationale of the operation; as this would carry us much beyond our limits. Now it is shewn under the article DIOPHANTINE, that

INDETERMINATE ANALYSIS.

the solution of the equation $x^3 - y^3 = Cz^3$ is always to be obtained; and in the following proposition, with which we shall conclude this article, it will be seen that every equation of the form $x^3 - Ay^3 = Bz^3$, which is possible, may be transformed to another of the form $x^2 - y^2 = cz^2$; and that x , y , and z , in the original equation, will be dependent upon those of x' , y' , and z' , in the transformed equation; and therefore these last being known, the former will be known also.

PROP. XIV.

To transform every possible equation of the form $x^3 - Ay^3 = Bz^3$, to another dependent equation of the form $x^2 - y^2 = cz^2$.

Ex. 1.—It is required to transform the equation $x^3 - 5y^3 = 11z^3$, to another of the form $x^2 - y^2 = cz^2$.

Having first ascertained the possibility of the equation by the foregoing proposition, the transformation may be effected in the following manner.

Assume $x = ny - 11y'$, and this substituted for x , gives

$$\left(\frac{n^3 - 5}{11}\right)y'^3 - 2ny'y' + 11y'^3 = z^3.$$

Take n , so that $n^3 - 5$ may be divisible by 11; that is, let $n = 4$, and our equation becomes

$$\frac{y^3 - 8y'y' + 11y'^3 = z^3}{(y - 4y')^2 - 5y'^2 = z^2}$$

or, by making $y - 4y' = x$, we have

$$\frac{x^2 - 5y'^2 = z^2}{x^2 - z^2 = 5y'^2}, \text{ as required,}$$

that is, the equation has been reduced from the form $x^3 - 5y^3 = 11z^3$, to another of the form $x^2 - y^2 = cz^2$; or, at least, to $x^2 - z^2 = 5y'^2$; which differs from the foregoing only in the letters.

And, by means of the values of x , y' , and z , in this last, we readily arrive at those of x , y , and z , in the one proposition;

$$\text{for } x' = y - 4y', \text{ or } y = x' + 4y'.$$

$$\text{and } x = ny - 11y', \text{ or } x = 4y - 11y'$$

Now we have seen, under the article *DIOPHANTINE*, that the general values of x' and z , in equations of the form $x^2 - z^2 = 5y'^2$, are

$$\begin{cases} x' = p^2 + 5q^2 \\ z = p^2 - 5q^2 \\ y' = 2pq \end{cases}$$

whence we have, for the general values of x , y , and z , in the equation proposed,

$$\begin{aligned} x &= 4p^3 + 20q^3 + 10pq^2 \\ y &= p^3 + 5q^3 + 8pq^2 \\ z &= p^3 - 5q^3 \end{aligned}$$

where p and q may be assumed any numbers at pleasure. If $p = 3$, and $q = 1$, we have $x = 85$, $y = 38$, and $z = 4$; which numbers answer the required conditions; for

$$86^3 - 5 \cdot 38^3 = 11 \cdot 4^3;$$

and by giving different values to p and q , a variety of other integral values may be found for x , y , and z .

Note.—It may happen that the first transformation will not reduce the equation to the form required, in which case we must again transform this anew, and, by continuing the operation, the reduction to the final form will be ultimately effected.

Ex. 2.—Required the values of x , y , and z , in the equation

$$x^3 - 12y^3 = 13z^3.$$

First, we have $x = ny - 13y'$, and substituting for x we have

$$\left(\frac{n^3 - 12}{13}\right)y'^3 - 2ny'y' + 13y'^3 = z^3;$$

and here $n = 5$, whence the equation becomes

$$\frac{y^3 - 10yy'y' + 13y'^3 = z^3}{(y - 5y')^2 - 12y'^2 = z^2}$$

Make now $y - 5y' = x'$, and it becomes

$$x'^2 - z^2 = 12y'^2$$

and the general values of x' and z in this equation, are

$$x' = 3p^2 + 4q^2, \quad z = 3p^2 - 4q, \quad \text{and } y' = 2pq.$$

Whence, by assuming $p = 2$, and $q = 1$, we have $x' = 16$, $z = 8$, and $y' = 4$; so that in the original equation, the values of x , y , and z , are as follow; viz.

$$\begin{cases} y = x' + 5y' = 36 \\ x = 5y - 12y' = 132 \\ z = z = 8 \end{cases} \text{ or, } \begin{cases} y = 9 \\ x = 33 \\ z = 2 \end{cases}$$

the latter values being formed by dividing the former by their greatest common divisor; and either of these sets of numbers answer the required conditions; for,

$$132^3 - 12 \cdot 36^3 = 13 \cdot 8^3, \text{ and } 33^3 - 12 \cdot 9^3 = 13 \cdot 2^3;$$

and various other values may be obtained by changing the values of p and q .

We will now give one example in which the required reduction does not take place in the first transformation.

Ex. 3.—Required the values of x , y , and z , in the equation

$$x^3 - 5y^3 = 19z^3.$$

Assume, as before, $x = ny - 19y'$: then the substitution of this value for x , gives

$$\left(\frac{n^3 - 5}{19}\right)y'^3 - 2ny'y' + 19y'^3 = z^3; \text{ in which } n = 10.$$

$$\text{Whence } \frac{5y^3 - 10yy'y' + 19y'^3 = z^3}{25y - 50y'y' + 95y'^2 = 5z^2}$$

$$\text{Making now, } \frac{5y - 10y'y' = x'}{x - 5y' = 5z}$$

and here, though we have not arrived at the form required, the last coefficient is reduced from 19 to 5; and thus every successive transformation will reduce the coefficients, till we ultimately arrive at that of unity; but without pursuing this reduction farther in the present case, we are led to the solution in an easier manner: for we see immediately, that x may be assumed $= 5$, $y' = 2$, and $z = 1$.

And from these we readily ascertain those of x , y , and z , in the proposed equation; for

$$\begin{cases} y = \frac{x' + ny'y'}{5} \text{ or } y = \frac{5 + 10 \cdot 2}{5} = 5 \\ x = ny - 19y'; \text{ or } x = 50 - 38 = 12 \\ z = 1 \end{cases} \text{ or } \begin{cases} y = 5 \\ x = 12 \\ z = 1 \end{cases}$$

which give $12^3 - 5 \cdot 5^3 = 19 \cdot 1^3$, as required

We shall now conclude this article with a synopsis of indeterminate forms; the demonstration and application of which the reader will find in Brouncker's "Elementary Investigation of the Properties of Numbers."

INDETERMINATE ANALYSIS.

Synopsis of Indeterminate Formule.

Form. 1. Equation $ax - by = \pm c$
 { General value of $x = m b \pm c q$
 of $y = m a \pm c p$

in which expressions m is indeterminate, and the values of p and q result from the solution of the equation $ap - bq = \pm 1$.

Form. 2. Equation $ax + by = c$
 { General value of $x = c q - m b$
 of $y = m a - c p$
 Number of solutions $= \frac{c q}{b} - \frac{c p}{a}$

the quantities p and q being ascertained as above, also m indeterminate.

Form. 3. Equation $ax + by + cz = d$
 { General value of $x = (d - cz) q - mb$
 of $y = ma - (d - cz) p$

the quantities p and q being found as above, also m indeterminate, and z any integer $< \frac{d}{c}$.

Form. 4. Equation $x^2 - ay^2 = z^2$
 { Gen. val. of $x = p^2 + a q^2$
 of $y = 2 p q$
 of $z = p^2 - a q^2$

in which expressions a is given, and p and q are indeterminates, that may be assumed at pleasure.

Form. 5. Equation $x^2 + ay^2 = z^2$
 { Gen. val. of $x = p^2 - a q^2$
 of $y = 2 p q$
 of $z = p^2 + a q^2$

a being given, and p and q indeterminates as above.

Form. 6. Equations $ax^2 + bxy + y^2 = z^2$
 { Gen. val. of $x = 2 p q + b q^2$
 of $y = p^2 - a q^2$
 of $z = p^2 + b p q + a q^2$

where p and q are indeterminates, and a and b given quantities.

Form. 7. Equation $ax^2 + bx = z^2$
 { Gen. val. of $x = \frac{b q^2}{p^2 - a q^2}$
 of $z = \frac{b p q}{p^2 - a q^2}$

where a and b are known quantities, and p and q indeterminates.

Form. 8. Equation $m^2 x^2 + bx + c = z^2$
 { Gen. val. of $x = \frac{p - c q}{b q - 2 m p q}$
 of $z = \frac{m p^2 + m c q - b p q^2}{b q^2 - 2 m p q^2}$

where m , b , and c are any given numbers, and p and q indeterminates.

Synopsis of Indeterminate Formule.

Form. 9. Equation $ax^2 + bx + m^2 = z^2$
 { Gen. val. of $x = \frac{b q^2 - 2 m p q}{p^2 - a q^2}$
 of $z = \frac{m p^2 + a m q^2 - b p q}{p^2 - a q^2}$

where m , a , and b are known; and p and q indeterminates.

Form. 10. Equation $x^2 - N y^2 = \pm 1$
 { Gen. val. of $x = \frac{(\rho + q \sqrt{N})^n + (\rho - q \sqrt{N})^n}{2}$
 of $y = \frac{(\rho + q \sqrt{N})^n - (\rho - q \sqrt{N})^n}{2 \sqrt{N}}$

where p and q arise from the equation $p^2 - N q^2 = \pm 1$, and m is indeterminate; except that it must be even or odd, as the case requires. See Prop. IX.

Form. 11. Equation $x^2 - N y^2 = \pm A$
 { Gen. val. of $x = p m \pm N q n$
 of $y = p n \pm q m$

the values of m and n being formed from the equation $m^2 - N n^2 = \pm A$, and p and q from the equation $p^2 - N q^2 = \pm 1$.

Form. 12. Equation $ax^3 + bx^2 + cx + f^2 = z^2$
 { Particular val. of $x = \frac{c^2 - 4 b f^2}{4 a f^2}$
 { Or, $x = \frac{(8 a f^2 - 4 b f^2 c + c^2) 8 f^2}{(4 b f^2 - c)^2}$

where all the quantities a , b , c , and f are given.

Form. 13. Equation $ax^3 + bx^2 + cx^2 + dx + f^2 = z^2$
 { Partic. val. of $x = \frac{(8 b f^2 - 4 c d f^2 + d^2) 8 f^2}{16 c f^2 - 64 a f^2 - 8 c d f^2 + d^2}$

where a , b , c , &c. are all known quantities.

Form. 14. Equation $m^2 x^3 + bx^3 + cx^3 + dx + e = z^2$
 { Partic. val. of $x = \frac{x = 16 c^2 m^4 - 64 c m^6 - 8 e b^2 m^2 + b^4}{(8 d m^3 - 4 c b m^3 + b^2) 8 m^2}$

where also m , b , c , &c. are all known quantities.

Form. 15. Equation $m^2 x^3 + bx^3 + cx^2 + dx + f^2 = z^2$
 { Particular val. of $x = \frac{d^2 \pm 8 m f^2 - 4 c f^2}{4 b f^2 \mp 4 m d f}$
 { Or, $x = \frac{4 m^2 d + 4 m b f}{b^2 \mp 8 m f - 4 m^2 c}$

In these expressions m , b , c , &c. are known quantities, and with regard to the ambiguous sign, it must be observed, that when it is taken $+$ in the numerator, it must be $-$ in the denominator, and the contrary.

Form. 16. Equation $ax^3 + bx^3 + cx + f^2 = z^2$
 { Particular val. of $x = \frac{(c^2 - 3 b f^2) 9 f^2}{27 a f^2 - c}$

a , b , c , &c. being known quantities.

Synopsis of Indeterminate Formule.

Form. 17. Equation $m^3 x^3 + b x^2 + c x + d = z^3$.

$$\left\{ \begin{array}{l} \text{Particular val. of } x = \frac{b^3 - 27 d m^6}{(3 c m^3 - b^2) 9 m^3} \\ \text{Or, } x = \frac{b^3 - 27 d m^6}{(3 c m^3 - b^2) 9 m^3} \\ \text{Or, } x = \frac{3 m f^3 - c}{b - 3 m^2 f} \end{array} \right.$$

$m, b, c,$ &c. being given quantities, as above.

Form. 18. Equation $m^3 x^3 + b x^2 + c x + f^3 = z^3$.

$$\left\{ \begin{array}{l} \text{Particular val. of } x = \frac{(c^3 - 3 b f^3) 9 f^3}{27 m^3 f^6 - c^3} \\ \text{Or, } x = \frac{b^3 - 27 f^3 m^6}{(3 c m^3 - b^2) 9 m^3} \\ \text{Or, } x = \frac{3 m f^3 - c}{b - 3 m^2 f} \end{array} \right.$$

where also $m, b, c,$ &c. are known quantities.

Form. 19. Equation $x^2 + a x y + b y^2 = z^2$.

$$\left\{ \begin{array}{l} \text{General val. of } x = t^2 - b t u^2 - a b u^2 \\ y = 3 t^2 u + 3 a t u^2 + (a^2 - b) u^3 \\ z = t^2 + a t u + u^2 \end{array} \right.$$

where t and u may be assumed at pleasure.

Form. 20. Equation $x^2 + b y^2 = z^2$.

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = t^2 - b t u^2 \\ y = 3 t^2 u - b u^2 \\ z = t^2 + u^2 \end{array} \right.$$

t and u being indeterminates, as above.

Form. 21. Equation $x^2 + b y^2 = z^2$.

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = t^2 - 6 b t^2 u^2 + b^2 u^4 \\ y = 4 t^2 u - 4 b t u^3 \\ z = t^2 + b u^2 \end{array} \right.$$

t and u being indeterminates, as above.

Form. 22. Equation $x^2 + b y^2 = z^2$.

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = t^2 - \beta t^{m-2} u^2 b + \delta t^{m-4} u^4 b^2 - \&c. \\ y = \alpha t^{m-1} u - \gamma t^{m-3} u^3 b + \epsilon t^{m-5} u^5 b^2 - \&c. \\ z = t^2 + b u^2 \end{array} \right.$$

where t and u are indeterminates, and $1, \alpha, \beta, \gamma, \delta,$ &c. the coefficients of $(t + u)^m$.

Form. 23. Equation $x^3 + c y^3 = z^3$.

$$\left\{ \begin{array}{l} \text{Gen. val. of } x = 4 t^3 - 4 c t u^2 \\ y = 8 t^2 u + c u^3 \\ z = t^3 + c u^3 \end{array} \right.$$

where t and u are indeterminates.

Form. 24. Equation $x^3 + a x^2 y + b x y^2 + c y^3 = z^3$.

$$\left\{ \begin{array}{l} \text{Partic. val. of } t = -\frac{u^3 + 2 a u c w + (a^2 - b) w^3}{2 a w} \\ \text{Gen. val. of } x = t^2 + 2 c u c w + a c w^2 \\ y = 2 t u - 2 b u c w - (a b - c) w^2 \end{array} \right.$$

where u and w are indeterminates, on which also depends the value of t .

INDETERMINATE Problem, is that in which there are more unknown quantities than there are equations; and therefore from the principles of algebra the number of solutions is unlimited, unless some other condition enter, such

as requiring integral values of the unknown quantities, by which means the problem frequently admits of only a definite number of answers; as may be seen in the preceding article. In geometry a problem is always said to be indeterminate, or unlimited, when there are not sufficient data to limit its construction.

INDEX, in *Anatomy*, the fore-finger.

INDEX, in *Arithmetic*, is the same with what is otherwise called the characteristic, or exponent of a logarithm.

The index is that which shews of how many places the absolute number belonging to the logarithm consists, and of what nature it is, whether an integer, or a fraction.

Thus, in this logarithm 2,521293, the number standing on the left hand of the point is called the index; and because it is 2, it shews you that the absolute number answering to it consists of three places; for it is always one more than the index, because the index of 1 is 0; of 10 is 1; and of 100 is 2, &c. And, therefore, in those final tables of Briggs's Logarithms, where the index is omitted, it must be always supplied before you can work by them. If the absolute number be a fraction, the index of the logarithm has a negative sign, and is marked thus, 2,521293: which shews the corresponding number to be a decimal fraction of three places; viz. 1,365.

Mr. Townly has a peculiar way of noting these indices, when they express fractions, now much in use, viz. by taking, instead of the true index, its arithmetical complement to 10; so that he would write the logarithm now mentioned thus: 7,562293.

How indices are to be added and subtracted, see under the article LOGARITHM.

INDEX, in *Music*, a character usually placed at the end of each line to indicate the first note of the next line. The following is the character W, which the Italians term a *mostra*, the English call it a *directa*.

INDEX of a Book, is that part annexed to a book, referring to the particular matters or passages therein contained.

INDEX of a Globe, is a little style fitted on to the north-pole, and turning round with it, pointing to certain divisions in the hour-circle.

It is sometimes also called *gnomon*. See *GLOBE*.

INDEX of Relation, in *Algebra*, the same with scale of relation. See *SCALE*.

INDEX, or *Indices*, is also the denomination of a congregation at Rome, whose business is to examine books, and to put such as they think fit to prohibit the reading and selling of, into an index. See *CONGREGATION*.

Indices, or *Expurgatory Indices*, denote the name by which the catalogues of prohibited books are called; among which, however, there is this difference, that some are condemned purely and absolutely, and others only *dumtaxat corrigantur*, till they be corrected.

Father Paul says, that Philip of Spain was the first who, by a law made in 1558, procured an index to be published of the books condemned by the inquisition of Spain. Pope Paul IV. took the hint, and ordered the congregation of the holy office at Rome to print a second in 1559. But Greffer, (De Jure Prohib. lib. i. cap. 19.) says, that the index of prohibited books was printed in Italy, by the papal authority, in 1548; and a larger one in 1552; and another larger in 1554. Pius IV. recommended the matter to the council of Trent; the fathers at Trent, after several debates not being able to agree, thought fit to refer the whole affair to the pope, who, with the advice of certain learned prelates,

published an index of the prohibited books, and certain rules, by his letters, in form of a brief. The same Pius IV. in a bull of March 24, 1564, says, that the index was presented to him by order of the synod, that it should not be published before it was approved by him. It was accordingly published by him, with a strict charge that it should be received by all, and the rules prefixed to it observed. Clement VIII. enlarged and confirmed it, together with the rules, and commanded it to be published in 1595. This was called by the name of the Roman index. By the fourth rule, the common reading of the Holy Scriptures is forbid in these words. "Since it is plain by experience, that if the sacred writings are permitted every where, and without difference to be read in the vulgar tongue, men, through their rashness, will receive more harm than good; let the bishop or inquisitor determine, with the advice of the parish priest or confessor, to whom to permit the reading of the bible, translated by Catholic authors in the vulgar tongue, according as they shall judge whether it be most likely that such reading of the scripture may do harm, or tend to the increase of faith and piety. Let them also have the same power as to all other writings. But if any, without such leave, shall presume to read or have them, without first shewing the bible to the ordinaries, he shall not receive the absolution of his sins. And as to all book-sellers, who shall sell the bibles translated into the vulgar tongue, without such leave, or by any other method shall publish them, let them forfeit the price of the books, and let the money be given to pious uses by the bishop; and let them be subject to other punishments; at the pleasure of the said bishop, according to the nature of the offence. As to regulars, they shall not read or buy them, without leave first obtained from their prelates." The tenth rule enjoins several restrictive regulations concerning the printing and publication of books. Hardouin's Concil. tom. x. p. 207, &c.

In pope Clement's catalogue is an extraordinary kind of decree, that all the books of Catholic authors, written since the year 1515, which was the year immediately preceding that in which Luther began to declaim against indulgences, should be corrected; not only by retrenching what is not conformable to the doctrine of Rome, but also by adding what may be judged proper by the correctors.

After this, the duke of Alva procured another to be printed at Antwerp in 1571, which was published by Francis Junius about the year 1586. There were two others published in 1584, and 1612, by the cardinals Quiroga and Sandoval, and several others by the inquisitors and masters of the sacred palace. The most considerable of all the indices is that of Anthony a Sotomayor, supreme president and inquisitor-general in the kingdom of Spain, which was made for all the states subject to the king of Spain, and comprehends all the others. This was published, with the advice of the supreme senate of the general inquisition, in 1640, and reprinted at Geneva in 1667. To this there were many rules prefixed; and to the Geneva edition was added the index of the decrees which were made by the master of the holy palace, by virtue of his office, or by the command of the holy congregation, or by the holy congregations for the indices and holy office, after the before-mentioned index of the council of Trent. The rules of the former indices are explained and confirmed by these; and the fifth rule, which enlarges the fourth of the index of Trent, prohibits not only all bibles in the vulgar tongue, comprehending all except those that are Hebrew, Greek, Latin, Chaldee, Syriac, Ethiopic, Persian, and Arabic; but all parts of them, either printed or manuscript, with all summaries and abridgments

in the vulgar language or tongue. Limborch's Hist. of the Inquisition by Chandler, book ii. chap. 16.

Of the operation of these indices, the authors of the Encyclopædia observe, that there has been hardly any good book of piety or morality in their language which has not been prohibited. Art. *Index*.

INDGEH, in Geography, a town of Asiatic Turkey, in Caramania; 12 miles S.W. of Kaisarieh.

INDGEH Su, a town of Asiatic Turkey, in Natolia; 40 miles S.W. of Angura.

INDIA, an extensive country of Asia, which was divided by Ptolemy and the ancient geographers into "India extra Gangem" and "India intra Gangem," or the peninsula beyond the Ganges and that on this side of the Ganges, to which the appellation of India, according to its original etymology, as the country of the people called "Hindoos" properly belongs. (See HINDOOSTAN.) India on this side of the Ganges was bounded, according to Ptolemy, on the W. by the Paropamisus, Arachofia, and Gedrosia; on the N. by mount Imaus; on the E. by the Ganges; and on the S. and partly on the W. by the Indian sea. The gulf into which the Indus discharged itself was called "Canthi-Colpus," and an island in this gulf was named "Barace." The western mouth of the Indus was denominated "Sagapa." Ptolemy enumerates seven mouths of this river under this and the following names; viz. "Olitium Sinthum, Oreum, Chariphi, Saparages, Sabalassa, and Lonibare." To the Ganges Ptolemy assigns five mouths, viz. those of "Polura, Ostim Magnum, O. Chambericum, O. Pseudo-Itomum, and Antibole." The part of India, which was situated towards the west, was called "Indo-Scythia." India beyond the Ganges had the Ganges on the W., on the N. certain parts of Scythia and Serica; on the E. the country of the Sina; and to the S. the Indian sea. This, however, is a vague name for wide and various, and till of late very much unknown, regions between Hindoostan and China. The territory thus denominated is rich and extensive, and includes the Birman empire, and the dominions of Pegu, Siam, Laos, Cambodia, Siampa, Cochinchina, Tonquin, and Malacca; which see respectively. See also ARRACAN, ASAM, AVA, and THIBET. For an account of "Hither India," or "India intra Ganges," see HINDOOSTAN and *East India Company*. For an elaborate account of the "Political History of India, from the introduction of Mr. Pitt's bill, A. D. 1784, to the present date," see Mr. Malcolm's "Sketch." Lond. 1811, 8vo.

INDIA, *East Company, Coins, Silk, &c.* See COMPANY, COIN, SILK, &c.

INDIA, SIGISMONDO D', in Biography, a musical composer, who was born at Palermo in Sicily, and flourished about the year 1610. In 1611 he published at Venice two sets of madrigals; and in 1627 a book of motetti, which did not go down the stream of oblivion unnoticed.

INDIAN, in a general sense, denotes any thing belonging to the Indies, East or West.

INDIAN Arrow root, in Botany. See MARANTA.

INDIAN Bay, in Geography, a bay that lies on the W. side of Bonavilla bay, in Newfoundland.

INDIAN Bread, in Botany. See CASSADA.

INDIAN Corn. See MAIZE.

INDIAN Corn-cars, Petrified, in Natural History. Many of the early writers on extraneous fossils mention ears of Indian corn among their reliquia. Mr. James Parkinson, in his Organic Remains, vol. i. p. 450, shews, that what Emanuel Swedenborg

Swedeborg figured as an ear of Indian corn, is the stem of an unknown plant, which, at pages 424 and 427, is said to belong to the series of vegetable remains inclosed in ironstone nodules. See plate 14, fig. 4. of W. Martin's *Pet. Durb.*

INDIAN Cove, in *Geography*, a harbour on the E. coast of Indian island, in Dusky bay.

INDIAN Creek, a creek on the island of Antigua, a little to the west of Standfast point.—Also, a river of Virginia, which runs into the Ohio, N. lat. 40° 25'. W. long. 80° 40'.—Also, a river of Virginia, which runs into the Chesapeake, N. lat. 37° 43'. W. long. 76° 27'.

INDIAN Creeks, in *Botany*. See *TROPICOLUM*.

INDIAN Corn Falls, in *Geography*, a cataract in the river St. Mary, about twenty miles from lake Superior. N. lat. 46° 22'. W. long. 84° 25'.

INDIAN Fig, in *Botany*. See *CACTUS*.

INDIAN Gem, in *Mineralogy*. See *GEM*.

INDIAN God-tree, in *Botany*. See *FICUS*.

INDIAN Head, in *Geography*, a cape on the E. coast of New Holland, so called by captain Cook from the number of natives who appeared near it as he passed in May 1770. S. lat. 25° 3'. E. long. 123° 56'.

INDIAN Island, a small island near the coast of North Carolina, at the mouth of Pamlico found. N. lat. 35° 23'. W. long. 76° 50'.—Also, an island on the S. part of Dusky bay, on the coast of New Zealand, about four miles in circumference, so called by captain Cook; about four miles from Pickeringill harbour.

INDIAN Ink. See *INK*.

INDIAN Leaf, *Malabathrum*, in *Botany*. See *TAMALAPATRA*.

INDIAN Mallow. See *SIDA*.

INDIAN Millet. See *HOLCUS*.

INDIAN Oak. See *TECTONA*.

INDIAN Ocean, in *Geography*. See *OCEAN*.

INDIAN Old Town, a town of America, in Hancock county, state of Maine, situated on an island in Penobscot river, just above the Great Falls, and about fifty miles below the Forks. Here are about 100 families of Roman Catholics, the remains of the Penobscot tribe, and the only Indians who reside in the district of Maine. They are in a thriving state, having obtained from the Provincial congress a tract of land, 12 miles wide, intersected in the middle by the river, and vested with a right of hunting and fishing as far as the mouth of Penobscot bay extends. They have a decent church, and a priest who conducts their religious service.

INDIAN Reed and Sbat, in *Botany*. See *CANNA*.

INDIAN River, in *Geography*, a river of Delaware, which runs into Rehoboth bay, N. lat. 38° 40'. W. long. 75° 16'.—Also, a small arm of the sea, between Chandlin and Pleasant river, in the district of Maine.—Also, a river on the E. coast of the peninsula of East Florida, rising near the sea-coast, and running from north to south, and forming a kind of inland passage along the coast. It is also called Rio Ays. N. lat. 27° 30'. W. long. 80° 40'.—Also, a town in Suffex county, Delaware, containing 1547 inhabitants.

INDIAN Sound, a gulf or bay on the S. coast of Patagonia, communicating with the Straits of Magellan by St. Jerome's channel.

INDIAN Town, a small town of North Carolina, 52 miles from Edenton.

INDIAN Town Point, a cape on the east coast of the island of Antigua. N. lat. 17° 15'. E. long. 61° 22'.

INDIAN Wood, called also *Jamaica* and *Campeachy Wood*, is taken out of the heart of a large tree growing plentifully

in the isles of Jamaica, Campeachy, &c. used in dyeing, its decoction being very red.

It has been observed, that putting some of this decoction into two bottles, and mixing a little powder of alum with the one, it will become of a very beautiful red, which will hold; the other in a day's time becoming yellow, though both bottles were stopp'd from the air alike; and that if a little of the same decoction be exposed to the air, it will become as black as ink in the same space of time. See *CAMPEACHY Wood*, *BRASIL*, and *LOGWOOD*.

INDIANA, in *Geography, a territory on the N.W. side of the Ohio, and lately formed a part of the N.W. territory. In January 1801, it was by act of congress erected into a temporary government, with powers and privileges similar to other territorial governments. It lies between the Great Miami river E., the Mississippi W., the Ohio S., and the Illinois N. It is divided into the three following counties:*

Countries.	Inhabitants.	Chief Towns.	Inhabitants.
Knox.....	2517	St. Vincennes.....	714
Randolph.....	1103	Kaskaskias.....	467
St. Clair.....	1255	Kakokia.....	719
Total	4875		

This territory has a fine soil, adapted to corn, wheat, rye, oats, cotton, hemp, tobacco, &c. The two western counties of Randolph and St. Clair have lately petitioned congress to be annexed to the Upper Louisiana, in the territorial government. On the N.W. bank of the Ohio, about twenty miles southward of the mouth of the Wabash, N. lat. 37° 36', is a remarkable cave, called the "Great Cave," which is one of the most surprising natural curiosities on the Ohio. The entrance is spacious and uniform; the dome is elliptical, and the uniformity continues to its termination in the hill. Morfe.

INDIANA, a territory in Virginia, lying between Ohio river and the Laurel mountain, containing about 3½ millions of acres; of a form nearly triangular, and extending in length from the Pennsylvania line to the waters of the Little Kenhaway.

INDIANA, a new county in the western parts of Pennsylvania, which, with Wellmoreland and Armstrong, constitute a district for the choice of three representatives.

INDIANE, a small harbour in the island of Cape Breton.

INDIANS, the name given to the aborigines of America. These people are scattered through the vast extent of the two prodigious continents, and divided into an infinite number of nations and tribes, differing from each other but little in their manners and customs. The Indians are tall and straight in their limbs: their bodies are strong, and adapted to endure much hardship. Their features are regular, but their countenances fierce; their hair long and lank, and the colour of their skins a reddish brown. Their only occupations are hunting and war; agriculture is left to the women, and for merchandise they have no taste. They are hospitable, generous, and good-tempered; but to the enemies of their country they are implacable: no length of time can allay their resentment, nor is any distance of place great enough to protect the object of their revenge. The Indians seem to have no just notion of a Supreme Being, though they maintain the existence of such a Being, eternal and incorruptible, who has power over all, to whom however they pay no worship; but they are exceedingly superstitious; and being desirous to look into futurity, they encourage and support a multitude of diviners, augurs, and magicians, upon whose

decisions and advice they rely in all matters that concern them, whether of health, war, or hunting. Liberty is the darling passion of the Indians; it is this which makes life supportable, and to this they are ready to sacrifice every thing. Some tribes acknowledge a head or king, but he is revered as a father rather than feared as a monarch. He has no guards, no prisons, no officers of justice: in most cases no other qualification is necessary for their chiefs, but age, experience, and ability in conducting their affairs. Every transaction is performed with much ceremony; and to fix the remembrance of them in their minds, they have belts of small shells or beads of different colours, which have all a different meaning, according to their colour or arrangement. These belts are carefully treasured up in each town, and serve as the public records of the nation; and to these they occasionally have recourse when any disputes happen between them and their neighbours.

When the ancients among the Indians have resolved upon a war, they do not declare what nation they mean to attack, nor the time when the attack shall be made, in order that the enemy may be off his guard, and unprepared for defence: but the principal captain summons the youths of the town to which he belongs, the war-kettle is set on the fire, the war-songs and dances begin; the hatchet is sent to all the villages of the same nation, and to all its allies; the fire catches, and the war-songs are heard in all parts. The prime qualities in an Indian war are vigilance and attention, to give and avoid surprize: likewise patience and strength to endure the intolerable fatigues and hardships which always attend it. The fate of their prisoners is the most severe of all: during the greatest part of their journey homewards they suffer no injury; but when they arrive at the territories of the conquering state, or at those of their allies, the people from every village meet them, and think that they show their attachment to their friends by their barbarous treatment of the prisoners. Many writers have asserted that the Indians, even at the maturest stage of their existence, are only furnished with hair on their heads, and that the other parts of the body are always free from it. This, however, is not the truth, for, naturally, their bodies resemble those of the Europeans; but regarding the beard, &c. as deformities, they pluck out each hair by its root, in order to increase their beauty. The men of every Indian nation differ in dress from each other, excepting those who trade with Europeans; these exchange their furs for blankets, shirts, and other apparel, which they wear as much for ornament as necessity. Those among the men who wish to appear gayer than the rest, pluck out the hair from their heads, except from a spot on the top of it, about the size of a crown piece, where it is permitted to grow to a considerable length: on this is fastened a plume of feathers of various colours, with silver or ivory quills. The manner of cutting and ornamenting this part of the head distinguishes different nations from each other. They paint their faces red and black, and their whole bodies when they go to war. Young Indians, who are desirous of excelling their companions in finery, slit the outward rim of both ears, at the same time that they take care not to separate them entirely, but leave the place thus cut still untouched at both extremities; around this spongy substance they twist brass wire, till the weight draws the amputated rim into a bow of five or six inches in diameter, and drags it almost down to the shoulder. It is also a common custom among them to bore their noses, and wear in them pendants of different sorts; sea shells are much worn by those of the interior, and are reckoned ornamental. Indians in general pay greater attention to their dress, and to the ornaments with which they

decorate their persons, than to the accommodation of their huts or tents. They construct the latter in the following method: being provided with poles of a proper length, they fasten two of them across near the ends with bands made of bark: having done this, they raise them up, and extend the bottom of each as wide as they purpose to make the area of the tent: they then erect others of an equal height, and fix them so as to support the two principal ones: over the top they spread the skins of beasts. These tents have neither chimnies nor windows; there is only an aperture left in the middle of the roof, through which the smoke is discharged. They have skins also for beds, generally those of the bear, which are placed in rows on the ground; and if the floor is not large enough to contain beds sufficient for the accommodation of the whole family, a frame is erected a few feet from the ground, in which the younger part of it sleep. As the habitations of the Indians are thus rude, their domestic utensils are few in number, and plain in their formation. The tools with which they fashion them are so awkward and defective, that it is not only impossible to form them with any degree of neatness, but the time required in the execution is so considerable, as to deter them from engaging in the manufacture of those which are not absolutely necessary. All the tribes are now possessed of knives, and steel to strike fire with: these are regarded as essential to the common uses of life, and the Indians usually purchase them with slaves. Indians, by a surprising sagacity, will cross a forest or plain of the greatest extent, and reach with the utmost exactness the place of their destination without any deviation from a direct line. Their memory is very tenacious, their belts of wampum preserve the substance of treaties which they have concluded with the neighbouring tribes for ages back, to which they will appeal with as much readiness and perspicuity as Europeans can to their written records. Every nation pays great respect to the dictates of age. The advice of a father is regarded: but the decisions of a grandfather create in the minds of the young an awe which they cannot withstand: his words are considered and obeyed as oracles. The Indians are fond of gaming, and often stake their arms, their apparel, and every thing of which they are possessed; they are strangers to all distinction of property, except in articles of domestic use, which every one considers as his own, and increases as circumstances admit. They are extremely liberal to each other, and supply the exigencies of those who belong to the same band with their superfluities. Of the value of money the Indians, excepting those who live near the European colonies, have no idea, but consider it as a source of innumerable evils. They are equally indifferent to the productions of art. They are ignorant of the sciences, and seem quite unacquainted with the first principles of astronomy, yet they contrive to divide the time in a rational and perspicuous manner. They count their years by winters, or, as they express themselves, by their snows; and they divide the years by the moons; and on the first appearance of each new moon they repeat some joyful sounds, stretching, at the same time, their hands towards it. Every month has with them a name expressive of its season: that which answers to our March or April, they call the *worm* month, because they observe that at this period the worms quit their retreats in the bark of trees, wood, &c. in which they have sheltered themselves during the winter; they have also the month or moon of flowers; the month of corn; the cold month; the snow month, &c. When the moon does not appear above the horizon, they say the moon is dead, and some call the three last days of each moon "naked days." They have no divisions of weeks, but days they count by sleeps; half days by pointing to the sun at noon, and

and quarters by the rising and setting of the sun; to express which, in their traditions they make use of hieroglyphics. Their sole knowledge in astronomy consists in being able to point out the polar star, by which they regulate their course when they travel by night. They reckon distances from one place to another by days' journeys, each being about 20 miles. They have no knowledge of arithmetic, and though they are able to count to any number, figures and letters appear to carry with them some hidden mystery, and much above their comprehension. Every separate body of Indians is divided into bands or tribes, and forms a little community within the nation to which it belongs. As the nation has some particular symbol by which it is distinguished from others, so each tribe has a badge from which it is denominated, as that of the eagle, the panther, the tiger, the buffalo, &c. Throughout every nation they particularize themselves in the same manner, and the meanest person among them will remember his lineal descent, and distinguish himself by his respective family. Every band has a chief, who is termed the Great Warrior, and who is elected for his warlike qualifications; besides this there is another who enjoys a pre-eminence as his hereditary right, and has the more immediate management of their civil affairs. When the chiefs are convened on any public business, they always conclude with a feast, at which festivity and cheerfulness know no limits. Dancing is a favourite exercise among the Indians, they never meet on any occasion but this makes a part of the entertainment; and when they are not engaged in war or hunting the youth of both sexes amuse themselves in this manner every evening. The Indians have several kinds of dances which they use on different occasions, as the pipe or calumet dance, the war dance, the marriage dance, and the dance of the sacrifice. The movements in every one of these are dissimilar, though it is impossible to give such a description of them as will convey to an European a just idea of the distinctions. Hunting is their principal occupation; they are trained to it from their youth, and it is an exercise which is esteemed no less honourable than necessary towards their subsistence. A dextrous hunter is held nearly in as high estimation as a distinguished warrior. Scarcely any device which the ingenuity of man has discovered for ensnaring or destroying those animals that supply them with food, or whose skins are valuable to Europeans, is unknown to them. Every hunter prepares himself by fasting during several days; the reason they give for this is, that fasting enables them to dream freely, and in their dreams they are informed where they shall find the greatest plenty of game; it is thought also to avert the displeasure of evil spirits, and induce them to be propitious. They seem to have some notion of a future state of existence, and suppose that their employments there will resemble those in which they are engaged here, without the labour and difficulty annexed to them in this period of existence. Among those who have priests, these priests are their physicians and their conjurers: they cure their wounds and diseases, interpret their dreams, give them charms which shall render them superior to external danger, and satisfy their curiosity with regard to future events. The Indian is subject to but very few diseases; the most fatal and destructive is the small-pox, which to them has been the most terrible of all pestilences: this is not, however, continual in their country, as it is in other nations; frequently there are intervals of many years in which it is never heard of; but when it prevails, towns and villages are thinned of their inhabitants. An Indian is said to meet death, when it approaches him in his hut, with the same resolution with which he has taken faced it in the field. If he is a chief, and has a fa-

mily, he makes a kind of funeral oration, which he concludes by giving to his children necessary advice for the regulation of their conduct. He then takes leave of his friends, and issues out orders for the preparation of a feast, which is designed to regale those of his tribe that come to pronounce his eulogium. After the last struggle the body is placed in the usual habiliments; the face is painted, and it is dressed in a fitting posture on a mat in the middle of the hut, with his weapons by his side. His relations being seated round, each harangues the deceased body, in turn, and, if he happen to have been a great warrior, recounts his heroic actions. After this, the body is carried to the burying place, where it is interred with other ceremonies. Such are the general characteristics of the Indians; the peculiarities of each tribe will be found in other parts of the dictionary. The amount of Indian population cannot be precisely ascertained. The newly discovered islands in the South sea, and part of the N. W. coast, are probably the most populous; as they have suffered less by invaders. The best informed writers have conjectured the number of aboriginal Indians in America to be under 23 millions. Since the discovery of America, the decrease, in consequence of labour and oppression, famine and pestilence, has been astonishing. A list of Indian tribes, in Imlay's History of Kentucky, makes the aggregate number less than 60,000 of those who inhabit the country, from the gulf of Mexico on both sides of the Mississippi to the gulf of St. Lawrence, and as far west as the country has been generally explored, that is, to the head water of the Mississippi, and from thence a good way up the Missouri, and between that river and Santa Fé. The population of the Indian nations in the northern parts of the United States is given differently from Mr. Imlay's statement by Mr. Purcell, who resided among them in 1780, as follows:

	Can. men.	Total.
Muscogees, commonly called Creeks	5860	17,280
Chactaws	4131	13,423
Chickasaws	575	2290
Cherokees	2800	8550
Catabaws	150	490
	<hr/> 13,516	<hr/> 42,033

The above red nations have somewhat increased since the general peace established among them in 1777. The whites incorporated among them are few in number, and lead a vagabond life, connecting themselves with one tribe after another. The increase of population is considerably checked by the use of spirituous liquors, and by a certain complaint introduced among them by the whites. In the northern district of North America, Mr. Hutchins, in 1778, estimated the Indians N. of the Ohio, and E. of the Mississippi, at 13,800, and those westward of lake Superior and the Mississippi, at 10,000.

INDICATION, in *Physic*, signifies the pointing out or discovering what is fit to be done, and what means applied in any case, from a knowledge of the nature of the disease, and the virtue of medicines.

Indications are of four kinds: *preservative*, or *prophylactic*, which direct how to cut off the cause of an approaching disease; *curative*, which shew how to remove a disease actually formed; *palliative*, which direct how to lessen its effects, or take off some of its symptoms, before it can be wholly removed; and *vital*, which relate to the strength of the body.

That

That part of phyfic which treats of indications is called *feinticia*.

INDICATIVE, in *Grammar*, the firft mood or manner of conjugating verbs, fhewing either the time prefent, paft, or future, and afferting what we think certain; and, therefore, fometimes called the *declarative mood*.

I love is the prefent tenfe; *I loved*, the paft; and *I will love* is the future of the indicative mood.

INDICATIVE COLUMN. See **COLUMN**.

INDICATOR, in *Anatomy*, inferior or abductor indicis, cubito-fus-ouguen; a mufcle of the fore-finger, fituated on the dorsal furface of the fore-arm. It is a flender mufcle, of an elongated figure, extended from the back of the ulna to the fore-finger. It arifes, by fhort aponeurotic fibres, from the pofterior furface of the ulna, beginning about the middle of the bone, and having its attachment extended towards the wrift; and in a flight degree from the interoffeous ligament. It is flender and pointed at its origin, grows gradually larger, and then diminifhes again and forms a fmall flattened tendon. From its origin at the middle of the ulna, it paffes obliquely to the carpal end of the radius, and is confined at the furface of that bone in a fibrous fheath common to it with the extenfor communis, to which it is here attached by means of the fynovial membrane which lines the fheath. Quitting the fheath, it runs along the back of the hand, on the radial fide of the tendon, which the fore-finger receives from the extenfor communis: thefe two approach each other, and are united at the articulation of the finger to the metacarpus. The common tendon paffes over the back of the firft joint of the fore-finger, over the firft phalanx, and then divides into three portions, which terminate like thofe of the extenfor digitorum communis: it corresponds to them alfo in every other particular. See **EXTENSOR**.

The pofterior furface of this mufcle is covered by the extenfor carpi ulnaris, the extenfor proprius articularis, and extenfor communis digitorum, and by the integuments. Its anterior furface is in contact with the ulna, interoffeous ligament, radius, carpus, interoffeous mufcle of the fecond interval, metacarpus, fynovial membranes of the digital articulations, and the phalanges. The radial edge is in contact for a confiderable fpace with the extenfor tertii internodii pollicis; the ulnar edge is attached to a ridge of the ulna. It will extend the three phalanges of the fore-finger, and move it towards the ulnar edge of the hand, as in pointing to an object. It will extend the wrift, and affift in the fupination of the radius.

INDICAVIT, in *Law*, a writ or prohibition that lies for a patron of a church, whofe clerk is fued in the fpiritual court by another clerk for tithes, which do amount to a fourth part of the profits of the advowfon; then the fuit belongs to the king's court, by the flat. Weft. 2. cap. 5. And the patron of the defendant being likely to be prejudiced in his church and advowfon, if the plaintiff recovers in the fpiritual court, hath this means to remove it to the king's court. Reg. Orig. 35. Old Nat. Br. 31.

INDICIS EXTENSOR, in *Anatomy*. See **INDICATOR**.

Semi-interoffeus. See **ABDUCTOR**.

INDICTION, fignifies the convoking of an ecclefiaftical afsembly; as a fynod, or council, or even a diet.

INDICTION is applied to the feveral feffions of the fame councils.

Hence it is, that at the end of the feffions of the council of Trent, the decree by which the council appoints the day of the future feffion, is called the *indiction* of that feffion.

INDICTION, in *Chronology*, a term ufed for a kind of epocha, or manner of counting time among the Romans; containing a cycle or revolution of fifteen years, which, when expired, begins anew, and goes round again without intermiffion.

This method of computation has no dependence on the heavenly motions. Petavius fays, there is nothing in chronology left known than the Roman indiction; he means, than its original and commencement. It is the general opinion, that it was instituted in the time of Conftantine, about the year 312; but this is a mere guefs. There were indictions in the time of the emperor Conftantius, as appears from the Theodofian Code. The learned hold, that indictions were originally no other than certain annual taxes, the tariffs whereof were publifhed every year; but why they were fo called, why confined to a cycle of fifteen years, when, and on what occafion, instituted, is not known.

We find three kinds of indictions mentioned in authors; the indiction of Conftantinople, beginning on the firft of September; the Imperial, or Cæfarean indiction, on the fourteenth of September; and the Roman or Papal indiction, which is that ufed in the pope's bulls, and which begins on the firft of January.

The popes have dated their acts by the year of the indiction, which was fixed to the firft of January, A. D. 313; ever fince Charlemagne made them fovereign; before which time they dated them by the years of the emperors.

At the time of the reformation of the calendar, the year 1582 was reckoned the tenth year of the indiction; fo that beginning to reckon hence, and dividing the number of years elapfed between that time and this by 15, the remainder, with the addition of 10, will be the year of indiction, corresponding to the year of our Lord 1811. The indiction may alfo be found by adding 3 to the year of our Lord, and dividing the fum by 15, the remainder is then the year of the indiction; if there be no remainder the indiction is 15. In either of thefe ways the year of indiction for 1811 is 14.

The word indiction comes from *indictio*, which fignifies *eflabliffment, order, or denunciation*. The time of the indiction, among the Romans, was that wherein the people were fummoned to pay a certain tribute; and it is for this reafon, that the imperial indiction began towards the end of September; becaufe the harveft being then got in, it was fuppofed the people could more eafily pay their tax.

INDICTIVE, INDICTIVUS, an epithet given to certain feaf-days appointed by the Roman magiftrates, *viz.* the couful, or prætor.

INDICTMENT, derived from the French *inditer, indicare*, or, according to M. Lambard, from *inducere, I charge, I inform againft*, in *Law*, a bill or declaration, of complaint, drawn up in form of law, for the benefit of the commonwealth: exhibited as an accusation of one for fome offence, criminal or penal, and preferred to a grand jury, and by their verdict found to be true, and pretended before a judge or officer, who has power to punifh or certify the fame offence.

INDICTMENT, in *Common Law*, fignifies as much as *accufatio* among the civilians; though in fome points it differs. See **ACCUSATION**.

Lambard fays, an indictment is an accusation at the fuit of the king, by the oaths of twelve men of the fame county where the offence was committed; returned to inquire of all offences in general in the county, determinable by the court into which they are returned, and their finding a bill

brought

INDICTMENT.

brought before them to be true. But when such accusation is found by a grand jury, without any bill brought before them, and afterward reduced to a formed indictment, it is called a presentment; and when it is found by jurors returned to enquire of that particular offence only, which is indicted, it is properly called an inquisition.

Although a bill of indictment may be preferred to a grand jury upon oath, they are not bound to find the bill, if they find cause to the contrary; and though a bill of indictment be brought to them without oath made, they may find the bill if they see cause. But it is not usual to prefer a bill unto them before oath be first made in court, that the evidence they are to give unto the grand inquest to prove the bill is true.

The grand jury (see JURY) are to find the whole of a bill, or to reject it; and not to find it specially in part, &c. If they are satisfied of the truth of the accusation, they then indorse upon the bill of indictment "a true bill," anciently *bilis vera*. But to find a bill, there must at least twelve of the jury agree. The indictment, when so found, is publicly delivered into court.

As indictments are purely for the good and quiet of the commonwealth, they are to be preferred for criminal, not civil matters. They are used in cases of high treason, and petit treason, felony, and trespasses of all kinds, and in all pleas of the crown; though they cannot be used for injuries of a private nature, that neither concern the king nor the public; and therefore all indictments ought to be brought for offences committed against the common law, or against statutes; and not for every slight misdemeanor. A person cannot be indicted of suspicion of felony, but of the very crime itself; and then if he be not in custody, the sheriff is commanded to attach his body by a *capias*, &c. A person indicted for felony may have counsel allowed to speak for him, as to matter of law only; but such as are indicted for treason may have a copy of their indictment before trial, in order to advise with counsel; and such indictments are to be found within three years after the offence committed, unless the treason be directly against the king's person. (7 and 8 W. III. cap. 3. which is extended to trials on impeachments by 28 Geo. II. cap. 30.) Persons indicted of treason must be by the oaths of two witnesses; but in other cases one witness is sufficient. The prisoner, in this case, shall also have a copy of the indictment, but not the names of the witnesses, five days at least before the trial, *i. e.* upon the true construction of the act 7 W. III. cap. 3. before his arraignment; he shall also have a copy of the panel of jurors two days before his trial; and he shall have the same compulative process to bring in his witnesses for him, as was usual to compel their appearance against him. By 7 Ann. cap. 21. every person indicted for high treason, or misprision of treason, shall not only have a copy of the indictment, but a list of all the witnesses to be produced, and of the jurors impanelled, with their professions and places of abode, delivered to him ten days before the trial, and in the presence of two witnesses. But this last act, so far as it affected indictments for the inferior species of high treason, respecting the coin and royal seals, is repealed by the statute 6 Geo. III. cap. 53. But no person indicted for felony is, or (as the law stands) can be, entitled to such copies, before the time of his trial.

Indictments must be certain in every point, and charge some particular offence; also goods stolen must be particularly set down, and the offence laid positively, and not by way of recital. There must also be expressed the Christian name, surname, and addition of the offender, with the day, year, and place in which the offence was committed, as also

the nature of the offence. (1 Hen. V. cap. 5.) In an indictment for murder, the length, depth, or other dimensions of the wound, must be expressed, that a judgment may be formed whether it was mortal; and in this case, the time of the death must be laid within a year and a day after the mortal stroke was given. (See APPEAL.) And in felony, the value of the things stolen is to be particularly mentioned, in order that it may appear whether the offender has been guilty of grand or petit larciny. A mistake in spelling the defendant's surname is not a sufficient cause for abating the indictment, provided it sounds like it. If a word of consequence be omitted in an indictment, it renders the whole naught; but the case is not the same where a word of form is omitted, or where there is an omission of a synonymous word, if the sense is not injured. In some crimes particular words of art must be used, which are so appropriated by the law to express the precise idea which it entertains of the offence, that no other words, however synonymous they may seem, are capable of doing it. Thus, in treason, the facts must be laid to be done "treasonably, and against his allegiance;" anciently, *proditore et contra ligantiam sue debittum*; else the indictment is void. In indictments for murder, it is necessary to say that the party indicted "murdered," not "killed" or "slew" the other; which, till the late statute, was expressed in Latin by the word "*murdravit*." In all indictments for felonies, the adverb "feloniously, felonically," must be used; and for burglaries also "*burglariter*," or in English, "burglariously;" and all these to ascertain the intent. In rapes the word "*rapuit*," or "ravished," is necessary, and must not be expressed by any periphrasis; in order to render the crime certain. So also in larcinies, the words "*felonice cepit et asportavit*," "feloniously took and carried away," are necessary to every indictment; for these only can express the very offence. In case one part of an indictment is inconsistent with another part of it, the indictment becomes void; though where the sense is plain, the court will dispense with a small inconsistency. Indictments are amendable the same term they are brought into court, but not afterwards; and in criminal prosecutions, the amendment must be only such as is permitted by the common law. Indictments for crimes committed, ought to be laid in the county where they were done; for otherwise, upon pleading the general issue not guilty, if it appears that the offence was committed in another county or place different from that in the indictment, the defendant will be acquitted. Yet if larceny be committed in any one county, and the goods carried into another, the offender may be indicted in either for the offence is complete in both. (1 Hal. P. C. 507.) Or, he may be indicted in England for larceny in Scotland, and carrying the goods with him into England, or *vice versa*; or for receiving in one part of the united kingdoms goods that have been stolen in another. (Stat. Geo. III. c. 31.) But for robbery, burglary, and the like, he can only be indicted where the fact was actually committed; for though the carrying away and keeping of the goods is a continuation of the original taking, and is therefore larceny in the second county, yet it is not a robbery or burglary in that jurisdiction. And if a person be indicted in one county for larceny of goods originally taken in another, and be thereof convicted or stands mute, he shall not be admitted to his clergy; provided the original taking be attended with such circumstances, as would have ousted him of his clergy by virtue of any statute made previous to the year 1691. (Stat. 25 Hen. VIII. 3 W. and M. c. 9.)

An offender is subject to indictment for a felony committed against a person unknown; yet he wholly must be proved to be the proprietor upon the trial, or else the property will

will be presumed to be in the prisoner, he having pleaded not guilty. An indictment being at the king's suit, the prosecutor is a good witness to prove the charge contained in it; and no damage can be given to the party aggrieved, except it be particularly grounded on some statute. Indictments before justices of the peace may be removed by certiorari into the king's bench.

A bill of indictment is said to be an accusation, because the jury, who inquire of the offence, do not receive it till the party that offered the bill, appearing, subscribes his name, and offers his oath for the truth of it.

It is always at the suit of the king, and differs from an accusation in this, that the pretenser is no way tied to the proof thereof upon any penalty if it be not proved, except there appears a conspiracy. But if any one prefer an indictment to the grand jury for any criminal offence, without probable cause, and the bill is not found, or the party is acquitted, action lies for a malicious prosecution. In order to which it is necessary that the plaintiff should obtain a copy of the record of his indictment and acquittal; but in prosecutions for felony, it is usual to deny a copy of the indictment, where there is any the least probable cause to found such prosecution upon. But an action for a malicious prosecution may be founded on such an indictment whereon no acquittal can be; as if it be rejected by the grand jury, or be *coram non iudice*, or be insufficiently drawn.

INDICTMENTS, *Demurrer to*. See DEMURRER.

INDICTOR, in *Law*, he that indicteth another for an offence: and *indictor* is the party who is indicted. 1 Ed. III. cap. 11. 21 Jac. I. cap. 8.

INDICUM. In the writings of the ancients we find this word very frequently used, as the name of a blue colour, or pigment used in dyeing, and imported to Rome, Greece, and other parts of the world, from the East Indies. The greater number of writers make this the same with our indigo, or anil feather; and some say it was the same with our woad; but the former opinion seems most probable.

This substance, which the Greeks call indicum, the Arabian writers, Avicenna, Serapion, and others, have called *nil*; though the same word is also sometimes used by them for the pigment made from woad. See INDICOFERA.

INDICUM *Folium*. See FOLIUM and TAMALAPATRA.

INDICUS CALMUS, in *Natural History*, is a fossil coralline body, supposed formerly to represent some species of reed, beset with flars on the surface.

INDICUS *Cocculus*. See COCCULUS.

INDICUS *Color*, a term used by several of the ancient writers to express black. The generality of the Greek and Roman physicians of old times have called the black lignum aloes, *agallobolum indicum*; and the only black kind of myrobalan they were acquainted with, was in the same manner called the indicum; not that these were supposed peculiarly the product of the Indies, in distinction from the paler lignum aloes, or the other myrobalan; but that they were of that colour which they called indicus color.

INDICUS *costus*. See COSTUS.

INDIES, EAST, in *Geography*, comprehends that vast tract of country, which is situated in the south of Tartary, between Persia and China, as well as the islands in the East Indian sea, such as Borneo, Sumatra, Ceylon, Java, the Maldives, Celebes, Moluccas, Philippines, &c. See INDIA and HINDOOSTAN, and each island separately.

INDIES, WEST, includes islands of the Atlantic, which extend from the west of Florida, in a curve, to the coast of Surinam, in South America, from W. long. 58 20' to

85° 30', and from N. lat. 10° to 27° 50'; Cuba being made the westerly boundary, and the Bahamas the most northerly; and fixing the easterly point at the island of Barbadoes, and the southerly at Trinidad. The name was given by Columbus, and has not been unfrequently applied to the whole of America. See each island separately described.

INDIGENOUS, of *indigena*, denotes a native of a country; or that which was originally born or produced in the country where it is found. In this sense, particular species of animals and plants are said to be indigenous in the country where they are native, in opposition to exotic.

INDIGESTION, in *Medicine*, in the acceptation in which we employ the term, implies not only the imperfect performance of the act of digestion, but also an impaired condition of the functions of the stomach and chylopoetic viscera in general.

In using the term *indigestion* in this extensive sense, we follow the example of Dr. Cullen, who has comprehended, under the head of *Dyspepsia* (from *δυσ*, ill, and *πρωσις*, to digest), a great variety of symptoms, which other nosologists have considered as distinct diseases, and described under various appellations, but which, he is of opinion, are all referrible to one common cause, an imbecility, or loss of tone in the stomach. (See Cullen, Nosol. Method. Gen. xiv. and Firsi. Lines, § 1190, and 1193.) Among the symptoms just alluded to, which stand as distinct genera in other nosological systems, are *Anorexia*, or *loss of appetite*; *Cardialgia*, or *heart-burn*; *Gastrodynia*, or *stomach colic*; *Flatulentia*, or *flatulence*; *Nausa*; *Vomitus*, *Seda*, &c. (See the Nosol. Systems of Sauvages, Vogel, and Linnæus.) To the same disordered condition of the digestive organs, when it is sympathetic of, or combined with other complaints, Dr. Cullen likewise referred many of those undefined affections, which have been confusedly classed together under the general title of *nervous diseases*, or under that of *chronic weakness*. From the great importance of the stomach in the animal economy, in which it is, as it were, the laboratory of health, and from its sympathetic relation to every other important organ in the body, it is obvious that every derangement to which it is exposed must occasion some corresponding derangement in other parts of the system, and that it must suffer, in its turn, whenever any distant organ is much indisposed; and hence, that indigestion will most frequently be accompanied with various adventitious symptoms, and that it will be of two kinds, idiopathic and sympathetic, according as the stomach itself, or some other organ, is the seat of the primary disorder. It is of the idiopathic indigestion, however, that we particularly treat at present.

The symptoms which characterize idiopathic *dyspepsia*, are an irregular, but commonly deficient appetite, with occasional squeamishness, sometimes actual vomiting;—a sense of load and distention of the stomach after meals, followed by eructations of air, or of solid or fluid matter, of various quantities, acid, pungent, odorous, or insipid;—heartburn, and pains in the region of the stomach. Some or all of these symptoms occur at different times or in different individuals, and are commonly combined with irregularity of the bowels, which are most frequently costive, but sometimes lax, or in each of these states by turns. The mouth and throat are usually dry, especially in the morning, and the tongue is at the same time furred, and of a white or yellow colour, and there is a disagreeable taste on the palate.

These are the direct indications of a deranged condition of the stomach itself, and the consequent irritation of indigested aliment. The sense of load is occasioned by the

remora of the food in its undigested state, and that of distention by the evolution of air, which is probably occasioned by the spontaneous decomposition or fermentation of the alimentary matter, and is relieved by eructation and the discharge of flatus. The irritation of the acid or acrid crudities upon the coats of the stomach, especially about the upper orifice, excites the sensation of heart-burn, and occasional spasmodic and inverted actions of the stomach and gullet, by which eructations are produced, as well as spasmodic contraction of the muscular parts of the stomach, which is accompanied by pain or gastrodynia: over-distention of the coats of the stomach, by the flatus, is likewise productive of pain.

But in addition to these morbid sensations and phenomena in the stomach itself, an infinite variety of symptoms occur, in different instances, indicating the sympathetic affection of the constitution at large, or of particular organs. These have commonly been called *nervous* symptoms, inasmuch as they have originated merely from a sympathy of parts, independently of any disordered state of the circulation, or of any morbid change in the structure of the suffering organs; and they are often more distressing than the primary symptoms belonging to the affection of the stomach. Among the symptoms to which we allude, are languor, sluggishness, and indisposition to exertion, either mental or corporeal, but especially the latter; drowsiness, particularly after meals or slight exercise; giddiness, noise in the ears, occasional dimness of sight, or a sense of objects floating before the eyes, with head-ache under various forms, most frequently affecting the forehead and temples, sometimes the crown and the occiput; severe flying pains; palpitations of the heart, or intermissions in its pulsation, with considerable variations in the state of the pulse; total restlessness, or unrefreshing sleep during the night, with frightful dreams, the *incubus*, or night-mare, &c.; temporary absence of mind, impaired memory, unusual timidity and despondency; and, in short, all the train of complaints which belong to *hypochondriasis* and *hysteria* in the constitutions in which they are liable respectively to occur. See these articles.

The experiments of modern physiologists have shewn that the process of digestion is principally effected by means of the fluids of the stomach, which possess a solvent power over the substances used as aliment; and that it is not a process of concoction, putrefaction, attrition, or fermentation, as was anciently supposed. (See DIGESTION.) It would seem, therefore, that the essential cause of idiopathic dyspepsia consists in a change in the quantity or quality of this gastric fluid, or solvent, originating from an impaired condition of the secretory function of the stomach. This, however, can perhaps only be ascribed to the deficiency of its tone and vigour as a muscular organ. Dr. Cullen justly remarks, that, as the peculiar nature of the digestive fluid, the changes which it may undergo, and the causes by which it may be changed, are very little known to us, we cannot found a practical doctrine upon any supposition respecting it; but as, at the same time, the imbecility of the stomach, either as the cause or the effect of the change in the digestive fluid, seems always to be present, and to have a great share in occasioning the symptoms of indigestion, we may still consider the imbecility of the stomach as the proximate and almost sole cause of *dyspepsia*. He observes, too, that this view of the subject is the more admissible, as it appears to be fully and clearly applicable to the explanation of the practice which experience has established as the most successful in this disease. First Lines, § 1166.

Causes of Indigestion.—Certain original constitution of the

body is obviously connected with a predisposition to this complaint: this is sometimes manifest only in a defective performance of the functions of the stomach itself; but in other cases it is evidently a part of the general want of tone and vigour in the body, and occurs in persons of lax fibre, and sanguine or sanguino-phlegmatic temperament. In persons of dark and fallow complexion, the stomach itself appears to be often originally weak, in a degree disproportionate to the general condition of the habit.

The exciting causes of indigestion, then, must be looked for among those circumstances which tend either to produce a loss of tone in the muscular fibres of the stomach, or which, in the debilitated state of that organ, tend to oppress its powers and to impede its functions. The causes which contribute to impair the vigour of the stomach are of two kinds; namely, those which operate directly upon that organ, and those which affect it indirectly, or through the medium of the general system.

The vigour of the stomach is impaired by the excessive use of stimulating condiments, and of spirituous liquors, as well as by the abuse of certain articles of the sedative or narcotic kind, such as tobacco, tea, coffee, opium, bitters; and by the too frequent and copious use of acid and ascendant articles of food, and of warm watery liquids. Frequent vomiting, whether arising spontaneously or excited by art, tends also greatly to debilitate the stomach; and over-distention of the organ by an excessive quantity of food or drink, or the use of food in itself difficult of digestion, or difficult from the idiosyncrasy of the individual, equally contribute to the same effect. The want of due mastication, and of the proper commixture of the saliva with the food, by which its tendency to putrefactive decomposition may be diminished, likewise materially enfeebles the digestive powers of the stomach, and adds to the oppression where it is already weakened. Whence the habit of frequent spitting, or rejection of the saliva, is justly enumerated among the causes of indigestion. Compression of the stomach after a full meal, as by particular postures, &c., or violent exercise or succussion of the body, under the same circumstances, have been found to have a material influence in preventing the process of digestion, and oppressing the powers of the stomach. Hence various occupations and trades, in which compression and succussion of the distended stomach are daily produced, occasion habitual *dyspepsia* in those who are predisposed to the disease.

Many of these occupations, however, debilitate the stomach likewise through the medium of the general system, or by deranging other organs and functions with which the stomach particularly sympathizes. The sedentary and inactive life, connected with many of them, debilitates the body in all its functions, and the stomach most particularly; intense study, or close application of mind to any business, when long continued; grief, anxiety, vexation of mind, and disorderly passions of any kind; Venus immodica; exposure to moist and cold air, when without exercise; and frequent intoxication, which belongs partly to this head, and partly to the former,—are all common remote causes of that imbecility of stomach which is connected with indigestion. Dr. Cullen remarks, that, though the disease, as proceeding from the last set of causes, may be considered as a symptomatic affection only; yet as the disorder of the stomach is generally the first, always the chief, and often the only effect which these causes produce or discover; so the affection of the stomach may be considered as the disease chiefly to be attended to in practice; and the more properly so, as in many cases the general debility is only to

be cured by restoring the tone of the stomach, and by remedies first applied to this organ.

On the other hand, however, it is not to be omitted, that the stomach, from its extensive sympathy, by which it is often a partaker of morbid irritation seated in other organs, occasionally displays symptoms of derangement so violent, and apparently so confined to itself, as to make the primary and proper source of the derangement be altogether overlooked. Many instances might be quoted of the successful treatment of seemingly idiopathic dyspepsia, by remedies which manifestly and chiefly operate upon other organs, and exert little or no immediate beneficial influence on the stomach. The viscera, more immediately concerned in the function of digestion, especially the liver, and the alimentary canal, are often the seat of the original irritation in such cases; the kidneys and the uterus occasionally produce similar effects.

Treatment of Indigestion.—In attempting to cure this state of the stomach, we may consider the following indications as the principal points to be pursued: *first*, to avoid, or remove, or, as far as may be, to regulate those things which have been enumerated above as the ordinary exciting causes of the disease; *secondly*, to palliate or remove those urgent symptoms, which especially contribute to aggravate and continue the disease; and *thirdly*, to restore the tone and vigour of the stomach, and of the system at large.

The propriety and necessity of the first indication is sufficiently evident, as the continued application, or frequent repetition of those causes, must necessarily tend to continue the disease, to defeat the efficacy of remedies, or to occasion the recurrence of the disorder in spite of the operation of these. Dr. Cullen justly remarks, that it is commonly owing to the neglect of this indication, that this disease is so frequently obdurate in its duration. It would be superfluous to enumerate the various modes of fulfilling this indication, which will be sufficiently obvious from the consideration of the several causes; but this circumstance evinces the importance of minutely investigating the origin of the disorder, previous to the administration of remedies, and of ascertaining whether the dyspepsia be constitutional or acquired, whether idiopathic or symptomatic, whether owing to any organic derangement of the stomach, such as tumour, ulcer, or scirrhoty, or whether arising merely from errors in diet, or other extrinsic agents. It must be observed, however, that the accomplishment of this first indication is often exceedingly difficult; for, in many cases, the circumstances of the patient will not admit of any material change; his avocations themselves, upon which his subsistence depends, comprehend, perhaps, the principal cause of the mischief. More frequently, the obstacles arise from the difficulty of inducing men to break in upon established habits, or to renounce the pursuit of pleasure; and especially, to persuade them that those practices, which they have often repeated, and seen others repeat, with seeming impunity, are in reality prejudicial.

Some allowance, indeed, is necessary to be made for the influence of habit, in all changes that relate to the animal economy, and especially where these habits have been carried to the extreme. For if the stomach have been long accustomed to excessive stimuli, whether from condiments or spirituous liquors, the total abstraction of these from the diet might occasion a direct debility, under which the powers of life might sink. Under such circumstances, therefore, some degree of the accustomed stimulus must be for some time indulged in, or some less prejudicial one substituted. But the apprehensions of danger, from great changes in the habits of life, which are generally entertained, are carried to an

extent which experience does not justify. Almost all the general rules which can be laid down, in respect to the wholesomeness of certain articles of diet, admit of exceptions from peculiarities of constitution in particular individuals. Some indications on this point, however, may be obtained by attending to the obvious prevailing state of the stomach, as evinced by the acid or nidorous eructations, &c. The acid state of the stomach implies the necessity of diminishing the proportion of vegetable food; while the nidorous condition may be benefited by augmenting that part of the diet, and lessening the quantity of animal food. It is of much importance that the whole quantity of food should be such as not to overload the stomach, or occasion considerable distension. There is a common precept, under which great errors are sometimes committed, in the way of overloading the stomach, or at least of exhausting its digestive powers, namely, that of eating little and often, so that long fasting may be avoided on the one hand, and too much repletion on the other. With the view of fulfilling this precept, an almost incessant supply of aliment is sometimes thrown into the stomach; so that the digestion of one portion is never completed, before another is combined with it in a crude state, thus aggravating the crudities which the disease itself produces, or preventing their more effectual assimilation.

In fulfilling the *second* indication, of removing urgent symptoms, one of the first objects pursued by some practitioners, is that of removing the crudities of the stomach produced by the disease, by means of emetics: Dr Cullen himself appears to be the advocate of this practice. (First Lines, par. 1204.) Nevertheless, as these crudities are commonly the effect of the disease, and not the cause, the expulsion of them from the stomach by vomiting can afford but a brief and temporary relief; and the same uneasiness will recur after the first or second meal. And, moreover, experience has shewn us, that frequent vomiting, however excited, tends to weaken the stomach, to diminish its powers of digestion, and to render it less able to retain what is thrown into it, and therefore ultimately to aggravate the symptoms which it was intended to relieve. "They are unhappy," says the same physician in another place, "who trust to this mode of relief, and have frequent recourse to it; for I am certain, from much experience, that frequent vomiting hurts the tone of the stomach, and often makes the symptoms of digestion recur more frequently and sooner than they otherwise would have done." (Cullen on Mater. Medica, vol. ii. p. 465. See also EMETICS.) We have stated under that article, the circumstances which have led to the erroneous supposition, that the indigestion and its concomitant symptoms originate in the presence of bile and other extraneous fluids in the stomach; and explained how the discharge of bilious and mucous matters from the stomach, under the operation of an emetic, may be the effect of the vomiting, although they might not previously have been lodged there. In short, there are few instances of *dyspepsia* in which the use of emetics can be deemed beneficial.

Of the other urgent symptoms, which require to be palliated, the principal are *acidity*, and its frequent concomitant, *heart-burn*,—pain in the stomach,—the ejection of a copious and clear fluid, or *water-brash* (as it is termed in Scotland),—and *constipation* of the bowels. It will not be necessary for us to dilate upon the method of treating these symptoms here, since they will be found amply discussed under their proper heads; as they are often so peculiarly distressing to the patients, as to be considered themselves the principal diseases, and to be the principal subject of complaint. We may briefly observe, that the presence of acid in the stomach

INDIGESTION.

in a morbid degree is known, not only by its rising occasionally into the mouth and throat by eructation, and by the heart-burn which accompanies it (see *CARDIALGIA*); but also by the occurrence of gnawing pains in the stomach, flatulency, irregular cravings for food, griping and looseness of the bowels, &c. The acidity already present in the stomach may be corrected, by neutralizing it by means of a chemical combination with some alkali or absorbent earth. The three alkalis, soda, potash, and ammonia, may be taken for this purpose respectively, either in the pure (or caustic) state, or mild, *i. e.* in the form of carbonates: on the whole, they seem to be more efficacious in the pure state. The soda-water, now manufactured in the shops, is an agreeable form of antacid; but the alkali may be taken with advantage in larger quantities than that beverage contains. Magnesia, chalk, and the tefaceous powders prepared from crabs-claws and oyster-shells, which are carbonates of lime, likewise combine with the gastric acid, and neutralize it: the magnesia (which is much more effectual in its pure state, or calcined, than in the form of carbonate) is often useful, inasmuch as it forms a neutral salt, which is in some degree laxative, with the acid of the stomach. It is not, however, sufficient to neutralize the present acidity, the disposition to generate it must be also obviated. This is to be effected partly by avoiding acceftent aliments of the vegetable class, and using animal food, such as is little capable of accefcency. But as vegetable food cannot be entirely discarded, the excess of its accefcency may be in some measure avoided, by chusing such vegetable matters as are the least disposed to the vinous fermentation, such as leavened bread, and well fermented liquors; and instead of using the fresh native acids, employing vinegar. But the disposition to acidity may be farther prevented by other means; namely, by those which invigorate the muscular fibres of the stomach, to be mentioned presently. It appears that the acidity occurs in a morbid quantity, either from a change in the digestive fluids, becoming less fit to moderate the natural progress to fermentation, or from their not being supplied in sufficient quantity; both of which probably arise from a weakened action of the stomach. For it is observed, in some instances, that sedative or depressing passions immediately occasion the appearance of acidity in the stomach, which did not appear before; and also that the use of stimulants, applied to the stomach, often corrects or obviates an acidity, that would otherwise have appeared.

Of that symptom of the dyspeptic state of the stomach, which is a common concomitant of indigestion, *pain*, or *stomach-colic*, *gaftrodynia*, we have already treated at length. (See the last term.) Having there stated the various circumstances under which it occurs, and especially in the two opposite states of repletion and inanition, as well as the method of cure, which succeed in these two conditions respectively, we deem it unnecessary to repeat the observations here.

In fulfilling the second indication, another symptom which requires particularly to be obviated is *costiveness*. There is so much connection between the several portions of the alimentary canal with respect to the peristaltic motion, that if accelerated or retarded in any one part, the other parts of it are commonly affected in the same manner. Thus as the brisker action of the stomach must accelerate the action of the intestines, so the slower action of the intestines must in some measure retard that of the stomach. It is therefore of consequence to the proper action of the stomach, that the peristaltic motion of the intestines, determining their contents downwards, be regularly continued, and that all costiveness, or interruption of that determination, be avoided. But an indiscriminate use of cathartic medicines is much to be deprecated. For it must be observed, that, as every considerable evacuation

of the intestines weakens their action, and tends therefore to induce costiveness when the evacuation is over; so those purgatives which produce a large evacuation are unfit for correcting the habit of costiveness. The milder cathartics, therefore, are the most suitable for this purpose, which do no more than sollicit the intestines to a more ready discharge of their present contents, without either hurrying their action, or increasing the excretions into their cavity; either of which might produce a purging. Dr. Cullen was of opinion, that medicines which particularly stimulate the large intestines, and act little on the higher parts of the intestinal canal, were peculiarly proper for this purpose, such as the aloeitic, and other resinous purgatives. These medicines certainly produce a very beneficial operation in numerous instances, probably by supplying the place, as it were, of the bile, which appears to be the natural tonic and laxative to the intestines, and which is often both deficient in quantity, and depraved in quality, in dyspeptic habits. The augmentation and correction of this fluid is often an important object in the treatment of indigestion, and the changes in the appearance, odour, and confidence of the stools, as well as the presence or absence of griping, tenesmus, heat and irritation in the seat, &c., are among the principal diagnostic symptoms in regard to the condition of the bile, which seems to be the chief cause of the variations of the alvine discharge. (See Abernethy's Observations on the Dis. of the Health, &c.) For the purposes of augmenting and correcting the biliary secretion, the milder preparations of mercury, which require to be varied according to circumstances, which have not yet been accurately described, appear to be the most effectual agents. It is probable that the long expected treatise of Dr. James Curry will contribute materially to elucidate this important subject; and we trust that we shall be able to avail ourselves of the assistance of that work, before we compose our article on the *chronic diseases of the LIVER*.

The peculiar modification of dyspepsia, called by the Scotch *water-brash*, the *Cardialgia sputatoria* of Linnæus, (Gen. Morborum, Class iv. Ord. 1.) and the *Pyrosis* of Cullen, (for which we have no appropriate English name,) is a sufficiently distinct disease to be discussed in a separate article. See PYROSIS. See also FLATULENCE, NAUSEA, and VOMITING.

The *third* indication, which is properly the curative one, is to restore the tone and vigour of the stomach, the loss of which is deemed the principal source of the disease. The means of accomplishing this indication may be referred to two heads; one of which includes those means which operate directly and chiefly on the stomach itself; and the other, those which, operating upon the whole system, communicate their tonic powers secondarily to the stomach.

The medicines which operate directly on the stomach, comprise all those articles which are denominated *tonics*, and many of those called *stimulants*, and *astringents*.—The bitter vegetable substances, or *bitters*, as they are emphatically called, and especially those which combine some aromatic quality with their bitterness, are most frequently prescribed for this purpose, and possess very considerable efficacy. Such are the roots of gentian, colomboa, and rhubarb; the bark of cinchona, cascarilla, &c.; the quassia wood; the flowers of chamomile; and many other vegetable productions. Experience, however, seems to have decided, that these bitters cannot be taken for a great length of time with impunity. Some have imagined that there is a certain quantity of a narcotic power resident in them, which, though insensible in its effects for a considerable time, ultimately occasions a deleterious influence on the constitution. This was particularly learned from the consequences of a long-continued use of the

INDIGESTION.

celebrated Portland Powder, for the cure of the gout : a very large number of those persons who took that medicine, which consisted of bitters and aromatics, having died of apoplexy, or some other severe disease, after having been apparently much benefited by its use. When these medicines are taken, therefore, with a view to restore the tone and vigour of the stomach, it is advisable not to employ them unremittently for a great length of time ; but to suspend the use of them occasionally for a considerable period, substituting some other corroborant medicines, if necessity require them. Among these the *mineral acids* are important adjuvants, especially the sulphuric (or vitriolic) and muriatic acid ; which have not only a direct tonic power upon the stomach, increase the appetite, and aid digestion, but also tend to prevent the process of fermentation in the food taken in. In this way, probably, their efficacy in preventing the formation of acidity in the stomach, and the heart-burn, &c. arising from such acidity, is to be explained. It is certain, that, in many instances, where the alkalies and absorbents have failed to obviate acidity and its consequences, connected with indigestion, the free use of one or other of the mineral acids has effectually remedied the disorder. *Aromatic* substances stimulate the stomach, and frequently therefore relieve accecity, flatulence, and cardialgia ; e. g. cinnamon, ginger, capicum, &c. but their stimulus is transitory, and if they are frequently repeated, and taken in large quantities, they may injure the tone of the stomach. *Chalybeate* medicines, or the various preparations of iron, are often employed as tonics, in the cure of indigestion ; and they may be administered in considerable quantities with safety. They have not, however, been found so efficacious in the cure of indigestion, as the remedies above-mentioned ; and they are principally taken in the form of *chalybeate waters*. But it is certain that these waters contain in general a very small proportion of steel ; and that other preparations of the steel are administered in much larger quantities without producing those salutary effects, which are often ascribed to the mineral waters ; it is, therefore, probable that the benefits, which are observed to accrue during the use of these waters, are generally the result of other circumstances connected with the drinking of them.

For, in fact, the most essential means of fulfilling the third indication are those which strengthen the system at large, and thus indirectly restore the vigour of the stomach ; and among these, *exercise* claims our first notice. We have shewn, in its proper place, the mode in which exercise operates, in promoting the full and perfect circulation of the fluids through all the organs of the body, and therefore in perfecting the performance of all the functions. (See EXERCISE.) But we may remark, with Dr. Cullen, that it in a particular manner strengthens the stomach by promoting perspiration, and exciting the action of the vessels on the surface of the body, the skin having a peculiar sympathy with the stomach. In this instance, however, as in every other operation of the animal economy, moderation must be the leading rule ; for, although the steady and free circulation through the cutaneous vessels conduces to a sympathetic support of the action of the stomach ; yet excessive perspiration, arising from over-action of these vessels, is followed by a languor and partial torpor, which is also communicated to the stomach ; inasmuch that sickness, and total loss of appetite are often the immediate results of violent exercise, attended with profuse perspiration. Regular exercise on horseback has been generally found the most effectual means of strengthening the stomach, and of curing indigestion.

Cold bathing is another important mode of restoring both general and local vigour ; but unless it be resorted to with

some discrimination, like other active agents upon the animal frame, it may be productive of much detriment. In order to obtain benefit from the external application of cold, a certain degree of vigour in the circulation, especially in the vessels of the skin, should be present. In the dyspeptic state, the temperature of the skin is liable to be defective, and the cutaneous circulation to be feeble ; and under such circumstances, so far from giving strength to the constitution, or to the stomach, the powers of life are depressed by the use of the cold bath, and the digestive organs sympathize in the torpor, produced in the skin. The tepid or warm bath is more beneficial when this condition of the system exists, and the baths of Buxton and Matlock may be resorted to with advantage ; the same principle, however, must be kept in view in the use of these ; which must not be entered with a chilly and shuddering surface ; nor the immersion be repeated, if a glow does not succeed. See COLDS, as a remedy.

In consequence of the great sympathy between the stomach and the skin, the proper regulation of the *clothing* is a matter of considerable importance to those who are liable to indigestion ; and as the temperature, though variable, is most frequently below the standard of health, so in general warmth is a necessary quality to be maintained. This is most particularly required in the extremities, in which the circulation is necessarily most languid, in consequence of the greater distance from the heart ; warmth and dryness of the feet, therefore, are peculiarly serviceable in the cure and prevention of dyspepsia ; and for those whose temperature is easily diminished by external cold, the general stimulus and flow-conducting power of woollen garments, worn next the skin during the winter months, may be considered as affording much security from the attacks of indigestion. But as profuse perspiration is generally accompanied by some degree of sympathetic debility in the stomach, these garments should not be used, during the hot seasons, by those whose skin is readily brought into a perspirable state.

A relaxation of the mind from the anxieties of business and the fatigues of study, and the pursuit of objects of amusement, contribute materially to the well-being of the animal economy, and especially to the proper performance of the digestive functions. This object is more particularly to be considered, when there is a tendency to hypochondriasis. And as we have already observed, it is probably from the amusements and regular exercise, which are generally enjoyed at watering places, as they are called, that more benefits accrue to the dyspeptic invalids, than from the virtues of the mineral springs, these places of resort may be recommended.

Before we conclude this topic, it may be proper to state, that several contemporary physicians and surgeons have observed, that a disordered condition of the digestive organs, however induced, becomes the cause of many secondary diseases, both general and local ; such as superficial ulcerations, pains, tumours, &c. ; which spontaneously cease, when the disorder of the digestive organs is removed. We may remark, however, that it is not every disorder of digestion which is followed by these consequences ; and that it is rather in the morbid condition of the *biliary* secretion, than of the stomach itself, that the disorder all tends to consist. Its symptoms are thus described by Mr. Abernethy. "This slighter disorder of the chylopoietic organs is, in general, manifested by a diminution of the appetite and digestion, flatulence, and an unnatural colour and factor of the excretions, which are generally deficient in quantity. The tongue is dry, whitish, or furred, particularly at the back part : this symptom is most apparent in the morning. The fur is greatest at the back part, and extends along the middle of the

the tongue to the tip, the edges remaining clean. As the disease advances, a tenderness is felt when the epigastric region is compressed, and the patient breathes more by the ribs, and less by the diaphragm, than in the healthy state. The urine is frequently turbid." (Abernethy on the Constitut. Origin of Local Dis.)

In whichever of the organs concerned in digestion this morbid condition may be principally seated, the others participate, and various effects follow. In the manner thus described by Mr. Abernethy. "It is generally admitted, that disorders of the chylipoietic viscera will affect the source of sensation, and consequently the whole body; but the variety of diseases, which may result from this cause, has not been duly weighed and reflected on. It may produce, in the nervous system, a diminution of the functions of the brain, or a state of excitation, causing delirium; partial nervous inactivity and insensibility, or the opposite state of irritation and pain. It may produce, in the muscular system, weakness, tremors, and palsy; or the contrary affections of spasm and convulsions. It may excite fever, by disturbing the actions of the sanguiferous system; and cause various local diseases, by the nervous irritation which it produces, and by the weakness which is consequent on nervous disorder or imperfect chylification. Or if local diseases occur in a constitution deranged in the manner which I have described, they will become peculiar in their nature and progress, and difficult of cure. Affections of all those parts which have a continuity of surface with the stomach, as the throat, mouth, lips, skin, eyes, nose, and ears, may be originally caused or aggravated by this complaint." Whenever, therefore, local diseases are connected with this slight derangement of the digestive organs, the first care will be to correct this derangement, as the most important step towards the cure of the former. For while the secretion of bile is either defective, or depraved in quality, (of which the appearances of the alvine discharge afford the best index,) the local or general symptoms of disorder, connected with this condition of the hepatic function, will not yield to remedies that would otherwise seem to be appropriate, and readily effect a cure.

INDIGETES, a name which the ancients gave to some of their gods.

There are various opinions about the origin and signification of this word; some pretending it was given to all the gods in general; and others only to the semi-gods, or great men deified. Others say it was given to such gods as were originally of the country, or rather such as were the gods of the country that bore this name; and others again hold, it was ascribed to such gods as were patrons and protectors of particular cities.

Lastly, others hold indigetes to be derived from *inde genitus*, or *in loco degens*, or from *inde* and *ago*, for *dego*, *I live*, *I inhabit*; which last opinion seems the most probable.

In effect it appears, 1. That these indigetes were also called *local gods*, *dii locali*, or *topical gods*, which is the same thing. 2. The indigetes were ordinarily men deified, who indeed were, in effect, local gods, being esteemed the protectors of those places where they were deified; so that the second and third opinion are very consistent. 3. Virgil joins *patrū* with indigetes, as being the same thing, *Georg. i. ver. 498*. *Dii patrū*, indigetes. 4. The gods to whom the Romans gave the name indigetes were, Faunus, Vesta, Æneas, Remulus, all the gods of Italy; and at Athens, Minerva, says Servius; and at Carthage, Dido. It is true, we meet with Jupiter *indiges*; but that Jupiter *indiges* is Æneas, not the great Jupiter; as we may see in Livy, lib. i.

cap. iii. in which last sense Servius assures us, *indiges* comes from the Latin in *dii ago*, *I am among the gods*.

Among these indigetes gods, there is none more celebrated, nor more extensively worshipped, than Hercules.

INDIGHIRKA, in *Geography*, a river of Russia, which rises in nearly 64 N. lat., in the Stanovoi-Krebet, and being reinforced by the Amekon and a multitude of smaller rivers, falls, in four great arms, into the Frozen ocean, N. lat. 73° E. long 144° 14'.

INDIGNATORIUS, in *Anatomy*, a muscle thus called, as being supposed to draw the eye from its inner corner outwards, which gives an appearance of scorn and anger.

But this is properly a compound motion of two muscles; for which, see *EYE*.

This muscle is called by others the *rectus exterior*, and *abducens*; and by Albinius, the *abductor*. It is one of his *quatuor recti oculi*.

INDIGO, or ANIL, *Botany*. See INDICOFFERA.

From this plant is extracted a dyer's drug, of a deep blue colour, brought hither from the West Indies and America. It is also made in the East Indies, particularly in the dominions of the Great Mogul, the kingdom of Golconda, &c.

The ancients were acquainted with the dye, which we call indigo, under the name of "Indicum." Pliny knew that it was a preparation of a vegetable substance, though he was not justly informed concerning the plant itself, and the process by which it was fitted for use. From its colour, and the country from which it was imported, it is denominated by some authors "Atramentum Indicum" and "Indicum nigrum." Even at the close of the 16th century it was not known in England what plant produced indigo. Gerard, in 1597, is wholly silent about it, and so is Johnston in 1642. Parkinson, however, in 1649, treats largely of it. He calls it "Indico or Indian woode," and gives a figure of the leaf from De Laet. He then describes it, first from Francis Ximenes in De Laet's description of America; and secondly, from Mr. William Finch, a London merchant, in Purchas's Pilgrims. Even in 1688 Mr. Ray says it was not agreed among botanists what plant it is from which indigo is made; but that the most probable opinion was, that it is a leguminose shrub, allied to Colutea. He describes it from Hernandez and Margraaf; and subjoins that of the "Ameri" from the Hortus Malabaricus. *Nil* or *Anil* is the American name. In Arabic it is *Nile*. The Portuguese have adopted their *Anil* or *Anilira* from the American. The other European nations generally call it *Indigo*. In Chinese it is *Tien luam*, which signifies sky-blue. Mr. Miller cultivated the dyer's indigo so long ago as the year 1731; and calls it *Guatemala indigo*, saying that with us it is an annual plant. Specimens of the *Indigofera tinctoria*, or dyer's indigo, from different parts of India, Madagascar, Java, Ceylon, &c. vary very much, if they are all really the same species. Linnæus says that it is almost an exotic in Ceylon, but frequent in Palacotta and Coromandel. According to Loureiro it is spontaneous in China and Cochinchina, and is cultivated all over those vast empires. Dr. Patrick Browne, besides the wild indigo already mentioned, has two others, which he calls the indigo, and the Guatimla indigo; the former yielding more of the dye than either of the others, is generally preferred, though subject to many more mischances.

It has been generally believed, that the indigo plant flourishes only in the climate of the torrid zone, and in those parts of the temperate zone which are near the tropics. But experiments lately made in Italy by Bruley, by order of government,

government, have proved that, in a fruitful soil and exposure, and with good feed, it may be cultivated in a fourtherly climate. Accordingly, he has obtained the indigo plant in the gardens of the Chateau de la Venerie, near Turin; and by submitting it to the process employed at St. Domingo, he has extracted an indigo which might bear comparison with the finest indigo of the colonies. His plantations were made towards the end of February. M. Icard de Bataligni, another colonist, cultivated the plant in 1805, in the department of Vaucluse, in France; and his results confirm the hopes formed with respect to the culture of indigo in Europe.

Labat has given a particular account of the culture of the plant, and the preparation of the indigo. The ground being thoroughly cleared from weeds (one of the principal points in the culture), and, we may add, drained, a number of flaves, ranged in a line, march across, making little trenches of the width of their hoes, and two or three inches deep, about a foot distance from one another every way: then, returning, they drop some seeds in each trench, and afterwards cover them with the earth taken out. The soil, it is observed by others, should be free and rich, and the climate warm; and the season of sowing should be rainy; as the earth must either already have imbibed water, or rain must speedily follow the sowing; otherwise the seed becomes heated, corrupts, and is lost, after all the labour it has occasioned. During the process of vegetation the ground must be carefully weeded, in order to prevent any mixture of herbs, which would injure the indigo in its manufacture. In moist weather, the plant comes up in three or four days; and in about two or three months after, it is fit for cutting: if suffered to stand till it runs into flower, the leaves become too dry and hard, and the indigo obtained from them proves less in quantity, and less beautiful: the due point of maturity is known, by the leaves beginning to grow less supple, or more brittle. In rainy seasons, the cutting may be repeated every six weeks: cutting in dry weather kills the plant, which, if that is avoided, continues to afford fresh crops for two years.

A large quantity of the herb is put into a vat or cistern of strong mason work, with so much water as is sufficient to cover it; and some wood laid above to prevent its rising up. The matter begins to ferment, sooner or later, according to the warmth of the weather, and the maturity of the plant, sometimes in six or eight hours, and sometimes not in less than twenty. The liquor grows hot, throws up a plentiful froth, thickens by degrees, and acquires a blue colour, inclining to violet. In proportion as the caloric increases, azote is disengaged, the herbaceous mucilage separates, the vegetable is decomposed, and the mixture absorbs oxygen. The fermenting fluid passes from a green to a violet tinge, and this by degrees changes to a blue colour. The great art of the manufacturer is to check the fermentation at a proper degree. If the fermentation is too feeble or too brief, the plant remains impregnated with much essential salt, which diminishes the quantity of indigo. If it be too long, the tender extremities of the plant undergo a putrefaction which destroys the colour. Some years ago, the following criterion was published at St. Domingo, for ascertaining invariably the correct fermentation of the indigo. It is only requisite to write on white paper with the matter to be examined. If this ink be of very high colour, it is a proof that the fermentation is not yet at its true point. The experiment is repeated every quarter of an hour, till it is perceived that the liquid has lost its colour. This was pronounced an infallible index to shew the true point of fermentation. Others, however,

judge of the proper stage of fermentation by means of a silver cup, into which they throw the liquid, shaking it till grains are formed; by their quality, and that of the fluid, they judge of the fermentation. When the feculent particles begin to precipitate to the bottom of the cup, it is then judged, that the herbs have attained the true degree of maceration for obtaining indigo. It has been observed, however, that this procedure often led into error; and, therefore, five or six minutes after the liquid has been put into the cup, it was perceived to form round its sides a cordon of fecula, or sediment, at first of a green colour, and then blue. When the maceration is not at the requisite point, this cordon, or girdle, detaches itself with difficulty from the sides of the cup, but finally precipitates, and concentrates at the bottom, always towards the centre, and the water above it becomes limpid, though of a yellowish tinge. When these signs are perceived, they indicate infallibly the success of the first operation. At this time, without touching the herb, the liquor impregnated with its tincture is let out, by cocks in the bottom, into another vat placed for that purpose, so as to be commanded by the first. The first vat is called the "fleeper;" the second and third are called the "beaters."

In the second vat, the liquor is strongly and incessantly beat and agitated, with a kind of buckets fixed to poles, till the colouring matter is united into a body. A good deal of nicety is requisite in hitting this point; if the beating is ceased too soon, a part of the tinging matter remains dissolved in the liquor; if continued a little too long, a part of that which had separated is dissolved afresh. The exact time for discontinuing the process is determined by taking up some of the liquor occasionally in a little cup, and observing whether the blue fecula is disposed to separate and subside.

The facility with which the grain precipitates to the bottom of the beater, is an unequivocal sign that the beating has arrived at the correct point.

The whole being now suffered to rest till the blue matter has settled, the clear water is let off, by cocks in the sides at different heights; and the blue part discharged by a cock in the bottom, into another vat. Here it is suffered to settle for some time longer, then farther drained in cloth-bags, or sacks, and exposed in shallow wooden boxes to the air, without exposing it to the sun, and carefully keeping it from the rain, till thoroughly dry.

Before it is perfectly dry, it is cut in small pieces of an inch square, which detach themselves readily from the box, when the indigo is entirely dry. Yet, however well drained and dried the indigo may be, it always experiences, in the first months of its fabrication, a diminution sufficiently evident to warrant a hastening of the sale. It is customary to pack the indigo in barrels, and thus to circulate it in commerce. Indigo is packed in sacks of coarse linen, and the sack is covered with an ox's hide, so hermetically sewed, that nothing can penetrate it. These packets are called "ceroons." They are much preferable to barrels, as they are more solid and more convenient for transportation. Two "ceroons" make the load of one animal.

The author above-mentioned, from whom the greatest part of the foregoing account is extracted, observes farther, that the goodness of the indigo depends greatly upon the age of the plant; that before it has grown fully ripe, the quantity it yields is less, but the colour proportionably more beautiful; that probably the secret of those whose indigo has been most esteemed, is no other than cutting the herb at the time when it yields the finest colour; that the superiority of some

some of the indigoes of the East Indies to those of America, is perhaps owing to the former being prepared more curiously from only the leaves of the plant; and that by beating the herb in the steeping-vat, which has been practised by some with a view to increase the quantity, great part of the substance of the leaves and bark is blended with the water along with the colouring matter, and the indigo extremely debased.

It is said that lime, or lime-water, is sometimes employed in the beating-vat, to promote the separation of the tinging particles from the water; and that the hardness or stinkiness of some sorts of indigo is owing to an over proportion of this addition.

Pomet says, that the Indians of the village of Sarqueffe, near Amadabat, use only the leaves of the indigo, and throw away the plant and branches; and from thence the most esteemed indigo is brought.

Indigo is commonly divided, from the colour which it exhibits upon breaking, into three kinds, copper-coloured, purple, and blue. It is said that the dyers use chiefly the first; and the calico-printers (for this drug gives a durable stain to linen as well as woollen) the last. On what particular circumstances these different appearances depend, we know not; nor is it certainly known whether the real quality of the indigo has any connection with them. The deepest and liveliest blue indigo, rubbed with the nail, appears like polished copper; and solutions of all the sorts, made in alkaline lixivium, assume alike a copper-coloured skin upon the surface.

Good indigo is moderately light, breaks of a shining surface, and burns almost wholly away upon a red-hot iron. It is quickly penetrated by water, and reduced into a kind of paste; a considerable part is at the same time diffused through the liquor, and very slowly subsides. This is probably what Labat and Hellot mean by its dissolving in water; for no part of the indigo really dissolves; it cannot indeed be expected that it should, from the process by which it is obtained.

Indigo requires an equal quantity or more of fixed alkaline salt, to render it totally soluble in water. On digesting the indigo, with a gentle heat, in the solution of the alkaline salt, a shining copper-coloured skin begins to appear, and gradually covers the whole surface; on agitating the matter, a large blue flower or froth arises, and the liquor underneath appears of a deep green. If woollen cloth, without any other preparation than moistening it with warm water, be dipped in this hot liquor, it comes out perfectly green, and changes almost instantly in the air to a fine blue. This is the common process of dyeing blue.

Mr. Hellot describes two indigo vats with urine; one of which is used hot, like the foregoing, and the other cold. The hot vat consists of equal parts of indigo, alum, and tartar, digested in urine till the liquor becomes green. The cold one is prepared, by digesting powdered indigo with vinegar for twenty-four hours, in the proportion of four pounds to about three quarts; then mixing the matter with about fifty gallons of urine, and stirring the whole together every night and morning, till the liquor turns green, and gathers a head like the common vat.

Indigo is fitted for printing on linen, by diluting it with water into the consistence of a syrup; then adding some powdered pearl-ashes, green vitriol, and lime newly flaked; with so much water, occasionally, as will reduce them into the consistence of thin paint; mixing the whole thoroughly together, and stirring the matter every now and then, till it gains a copper colour on the surface. The proportions used by the workmen are, two parts of indigo, one of pearl-ashes, three of vitriol, and two of lime. The same compo-

sition, diluted with a sufficient quantity of water (about six gallons to a pound of indigo), and boiled, gives a durable blue to tanned skins, whether dipped in hot or cold.

Indigo digested in a moderate heat with different volatile alkaline spirits, gave only yellowish and brownish red tinctures; with rectified spirit of wine, a reddish one; to lime-water, and to water acidulated with the vitriolic, nitrous, and marine acids, it gave no tincture at all.

The concentrated vitriolic acid unites with it into a smooth paste, especially if the indigo is previously well ground with powdered glass, sand, or other like substances. The indigo is thus rendered soluble in boiling water along with the acid, so as to pass through the pores of a filter; the solution, whilst hot, appears of a deep bright green colour, like that made by fixed alkalies, but fades as it grows cold, and changes at last to a brownish. These experiments, which were many times repeated with the same event, seem to overturn Mr. Hellot's ingenious theory, which deduces the green colour of solutions of indigo from the common property of blue juices being turned green by alkalies; and the blue colour which the cloth acquires soon after it is taken out of the vat, from a separation of the alkali. We here find, that a green solution of this concrete is obtainable by the strongest of the acids, and that with volatile alkalies it discovers no tendency to greenness.

For the method of preparing SAXON blue and SAXON green from indigo, see those articles.

Indigo is sometimes used among the painters for paper-hangings, and such gross uses, who grind and mix it with white to make a blue colour; for without that mixture it would paint blackish.

They also mix it with yellow to make a green colour. It is also used in dyeing, and by the laundresses, to give a bluish cast to their linen.

In the Hortus Indus Malabaricus is an account of the plant whence indigo is drawn; the decoction of whose root is said to be excellent against nephritic colics; its leaves, applied to the abdomen, good to promote urine; and the indigo itself is said to be of good use in drying of tumours.

Some physicians have recommended indigo in the quantity of a drachm, while others look upon it as a poison; and in Saxony the internal use of it is prohibited.

INDIGO, *Bastard*. See AMORPHIA.

INDIGO Mills. For the purpose of effecting the solution and union of indigo with the liquid used along with it, for the purposes of dyeing, mills of various constructions are in use. In this process trituration or friction is as much as possible avoided, and the pulverization is effected merely by bruising. For this two very sufficient reasons may be assigned; the first, in point of economy, and the second, to avoid chemical inconvenience. On whatever substance the indigo was triturated or rubbed, a certain proportion of the stuff would be mixed or incorporated along with the pulverized indigo, and that proportion of indigo which was absorbed by this stuff would be either totally lost, or brought into union with another substance which might prove useless, and probably injurious in the subsequent process of dyeing. If the former only was the case, the absorbed indigo would be totally lost; if the second took place, the whole process might be utterly spoiled by the combination. In the appropriate plate, *fig. 1.* represents the ground or horizontal plan of such an indigo mill as is generally used in small dye-works, and which is occasionally turned by a man's or boy's hand. This is tedious and laborious, for the operation must be continued for a very long time before the indigo is sufficiently mixed with the liquid to be fit for use, and only a small

small quantity can be put into the vessel at once. *Fig. 2.* is an elevated section of the same mill.

In this machine the pulverization or granulation of the indigo is effected by the pressure of a number of smooth cast-iron balls, like those used for the shot of great guns, which, being rolled among the indigo, press it into a paste by their weight, until it unites with the liquid by which it is to be held in solution.

In *fig. 1*, A represents the bottom and rim of the vessel which contains the indigo, and which is of a cylindrical form. B is an upright spindle, which, in this figure, does not appear. Upon the spindle B is fixed a wheel C C, with a convenient number of arms projecting round the vessel, like the radii of a circle; and below each of these arms are projecting pieces of iron, like the pins or teeth of a harrow, for moving the balls. When this wheel C is moved round its axis, the whole balls in the vessel A are set in motion, and, by rolling over the indigo, gradually press it, until it unites with the water or liquid with which it is surrounded. If the bottom of the cylinder be flat, a very small part of the surface of each ball can act upon the indigo; but by cutting circular hollow grooves, as represented in *fig. 2*, nearly the semi-diameter of the ball will press upon the stuff. The mill is moved by a handle D, *fig. 2*, which sets in motion the small bevel wheel E, and this wheel acting upon the horizontal wheel F, fixed upon the spindle B, sets it also in motion, and consequently the wheel C C is moved round its axis, and all the balls roll round upon the indigo. G is a cross shaft upon the top of the spindle B, loaded at each end with a heavy ball. There is generally another shaft placed at right angles to this, when they assist in regulating and equalizing the motion in the same manner as any other fly wheel. When the indigo is found to be sufficiently dissolved, and united with the water, the liquid thus formed is drawn off into any other vessel for use by means of a vent and spigot placed in any convenient part of the bottom of the vessel.

The great labour and time which it requires, and the small quantity of stuff which can be prepared at once by a machine of this kind, renders it ill adapted for the use of large works where much indigo is consumed, and where they have generally a horse-power water-wheel, or steam-engine, for raising water, cutting madder, and other purposes necessary in extensive works. *Fig. 3.* represents an elevated cross section of one of these machines, driven by any moving power, and capable of preparing a very great quantity of indigo at all times, as it requires no attendance, excepting to empty the vessel when the indigo is wanted, and add a fresh supply. H is a semi-circular vessel of cast-iron, placed upon a strong wooden frame O, and of any convenient length. I is a cover made in two pieces, with a circular aperture to admit the upright shaft K working upon the centre, or pivot P. At Q, the upright P is joined to a horizontal shaft of wood M, the other end of which is connected by the joint R, with a crank fixed on the end of a horizontal shaft N driven by the moving power. The circular motion of the shaft and crank N communicates an alternate, or reciprocating motion, by means of the horizontal connecting shaft M, to the upper end of the upright shaft K, which vibrating upon the centre joint P, sets in motion the iron cylinders L, L, in the body of the vessel, which press upon the indigo, and produce the same effect, but to a much greater extent, as the balls in the machine first described. The cylinders L, L, may be made of any diameter or length which is found convenient. The greater mass of iron that they contain, the quicker and more effectual will be their operation upon the stuff, provided there is

a sufficient power to drive them. The frame under the joint P extends the whole length of the semi-circular vessel H, which may be any length, according to the extent of the power and quantity of work required. As this machine requires no attention whatever, it is found very useful in large dye works, as, by means of it, they can constantly command a large supply of prepared indigo, which may be drawn off when wanted, for the longer it is under the preparing process, the better in every respect, and fresh indigo may be added as the supply gets low.

INDIGOFERA, in *Botany*, yields the blue dye called Indigo or Indicum, so eminently useful in dyeing various manufactures of a blue colour. This substance obtained the name of indigo from its native country, India.—*Linna.* Gen. 383. *Schreb.* 506. *Willd. Sp. Pl.* v. 3. 1220. *Mart. Mill. Dict.* v. 2. *Ait. Hort. Kew.* v. 3. 67. *Juss.* 359. *Lamarck Dict.* v. 3. 244. *Illustr. t.* 626. *Gertn.* t. 148. *Clafs and order, Diadelphis Decandria. Nat. Ord. Papilionaceae, Linn. Leguminosae, Juss.*

Gen. Ch. Cal. Perianth of one leaf, spreading, almost flat, five-toothed. *Cor.* papilionaceous; standard rounded, reflexed, emarginate, spreading; wings oblong, obtuse, spreading at the lower margin, of the shape of the standard; keel obtuse, spreading, deflexed, marked on each side by an hollow awl-shaped point. *Stam.* Filaments in two bundles, disposed into a cylinder, ascending at their tips; anthers somewhat roundish. *Pist.* Germen cylindrical; style short, ascending; stigma obtuse. *Peric.* Pod roundish, long. *Seeds* numerous, kidney-shaped.

Eff. Ch. Calyx spreading. Keel of the corolla having an awl-shaped spur on each side! Pod linear.

Obs. Till within the last century it was but imperfectly made out what plants produced the dye known to the Romans by the name of *Indicum*. Mr. Miller, however, cultivated the *Indigofera* so early as 1731; but he was acquainted with only five species of it; which same number Linnaeus imperfectly described. Professor Martyn enumerates thirty-five species, and Willdenow fifty-one; but since this genus is particularly known and esteemed for its utility in the arts, and that most of its species yield the blue dye, as well as many other plants of the same natural family, we shall merely give a general outline of the genus, without entering into a long systematic arrangement of the species.

The genus *Indigofera* is composed of shrubs and herbs, whose leaves are, in certain cases, simple, more generally ternate, but most frequently unequally pinnate. The leaflets in some species are jointed and awned at the base. Stipules distinct from the leaf-stalk. Peduncles axillary, generally many-flowered, in spikes or bunches. Many species are natives of the Cape of Good Hope; for instance, *I. filifolia*, *sericea*, *d-pressi*, *ovata*, *pyraloides*, *candicans*, *amena*, *incana*, *procumbens*, *sarmentosa*, *denudata*, *erecta*, *coriacea*, *filiformis*, *digitata*, *frutescens*, *stricta*, *angustifolia*, and *capillaris*.—The rest are either from the East or West Indies, Arabia Felix, New Holland, and the coast of Guinea.

It is said that Pliny was aware that *Indicum* was a preparation from a vegetable substance, though he was ill-informed both concerning the plant itself, and the process by which it is made fit for use. The following is a curious anecdote to shew that at the close of the 16th century it was unknown in England what plant produced Indigo, for in a book entitled "Remembrances for Master S. by Richard Hakluyt," written in 1582, Master S. is instructed "to know if Anle that colourth blew, be a natural commodity of Turkey, and if it be compounded of an herbe—to send the seed or root with the order of sowing, &c.—that it may become a natural commodity

commodity in the Realm, as woad is (*Isatis tinctoria*), that the high price of foreign woad may be brought down."

I. tinctoria, Dyer's Indigo, is a native of the East and West Indies, Madagascar, Ceylon, Java, &c. Its stem is suffruticose. Leaves pinnate, ovate. Bunches of flowers short. — Loureiro says it is cultivated all over the vast empires of China and Cochinchina. It is figured under the name of Ameri in the *Hortus Malabaricus*, v. 1. 101. t. 54.

INDIGERA. See **SOPHORA**.

INDIKOOD, in *Geography*, a town of Grand Bucharia; 60 miles W. of Balk. N. lat. 36° 38'. E. long. 64° 10'.

INDION, a town of Persia, in the province of Chorasan, near the Masjan; 210 miles N.N.E. of Herat.

INDIRECT MODES of Syllogisms, in *Logic*, are the five last modes, or moods, of the first figure, expressed by the barbarous words *baralipon, celantes, dabitis, sepsime, freffem*.

It is the conversion of the conclusion which renders the moods indirect: for instance, a syllogism in *darii*, and another in *dabitis*, would be perfectly alike, were it not for that conversion; the propositions having the same quantity, and the same quality, and the middle term being the subject in the major, and the attribute in the minor, in both. It remains, then, that, to make a distinction, that which is the subject of the conclusion in *darii*, be the attribute in the conclusion of *dabitis*; and that which is the attribute in the first, the subject in the last. See **SYLLOGISM**.

DA. Every thing that promotes salvation is advantageous:

RI. There are afflictions which promote salvation:

I. Therefore there are afflictions which are advantageous.

DA. Every thing that promotes salvation is advantageous:

BI. There are afflictions which promote salvation:

TIS. Therefore some things promoting salvation are afflictions.

INDIRECT Confirmation. See **CONFIRMATION**.

INDISCERNIBLES, in the *Philosophy of Leibnitz*. See **LEIBNITZIAN Philosophy**.

INDIVIDUAL, INDIVIDUUM, in *Logic*, a particular being of any species; or that which cannot be divided into two or more beings, equal or alike.

The usual division in logic is made into genera or genuses, those genera into species, and those species into individuals. See **GENUS, SPECIES, and DIVISION**.

The schoolmen make a four-fold distinction of individuals; *viz.*

INDIVIDUUM Vagum, that which, though it signifies but one thing, yet may be any of that kind; as when we say a man, a certain person, or one said to and so; though but one person is meant, yet that person, for aught that appears to the contrary, may be any body.

INDIVIDUUM Determinatum is, when the thing is named and determined; as Alexander, the river Nile, &c. this is also called *individuum signatum*.

INDIVIDUUM Demonstrativum is, when some demonstrative pronoun is used in the expression; as, *this man, that woman*.

INDIVIDUUM ex Hypothese, or by supposition, when an universal name or term is restrained, by the supposition, to a particular thing; as when we say, the son of such a one, and it be known that he had but one son.

INDIVISIBLES, in *Geometry*, those indefinitely small elements, or principles, into which any body or figure may be ultimately resolved.

A line is said to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces; and because each of these elements is supposed indivisible, if in any figure

a line be drawn through the elements perpendicularly, the number of points in that line will be the same as the number of the elements.

Whence it appears, that a parallelogram, prism, or cylinder, is resolvable into elements, as indivisible, all equal to each other, parallel, and like to the base; and a triangle into lines parallel to the base, but decreasing in arithmetical proportion; so also are the circles which constitute the parabolic conoid, and those which constitute the plane of a circle, or the surface of an isofceles cone.

A cylinder may be resolved into cylindrical curve surfaces, having all the same height, and continually decreasing inwards, as the circles of the base do, on which they insit. This way of considering magnitudes, is called the method of indivisibles, which is only the ancient method of exhaustions, a little disguised and contracted.

It is found of good use in shortening mathematical demonstrations; of which we may give an instance in that famous proposition of Archimedes, that a sphere is two-thirds of a cylinder circumscribing it.

Suppose a cylinder, an hemisphere, and an inverted cone (*Plate VIII. Geometry, fig. 102*. to have the same base and altitude, and to be cut by infinite planes all parallel to the base, of which dg is one; it is plain, the square of db will every where be equal to the square of ke (the radius of the sphere) the square $bce = ecb$ square; and, consequently, since the circles are to one another as the squares of the radii, all the circles of the hemisphere will be equal to all those of the cylinder, deducting thence all those of the cone; wherefore the cylinder, deducting thence all those of the cone; but it is known, that the cone is one-third of the cylinder, and consequently the sphere must be two-thirds of it.

Cavalleri was the first person who introduced this method of indivisibles into one of his works, entitled "Geometria Indivisibilium," printed in 1635; which he also made use of in another tract published in 1647.

INDIVISO.—*Pro* INDIVISO. See **PRO**.

INDIVISUM FOLIUM. See **LEAF**.

INDO-SCYTHIA, in *Ancient Geography*, a district of India, that lay on the western side of the river Indus, extending as far as the river Coas, or Cow river, and at present inhabited in part by those who are probably descendants of the Scythian Nomades, and called *Nemurdy*.

INDOCTORUM PARLIAMENTUM. See **PARLIAMENTUM**.

INDORE, in *Geography*, a town of Hindoostan, in the Malwa country, and residence of a Mahratta chief; 290 miles S.S.W. of Agra. N. lat. 22° 56'. E. long. 76° 11'.

INDORSEMENT, any thing written on the back of a deed or instrument. See **ENDORISING**.

A condition written on the back of an obligation is commonly called an indorsement: from *in*, and *dorsum*, *back*.

INDORSEMENT of a Bill of Exchange. See **ENDORSEMENT**.

INDOS, in *Geography*, a town of Hindoostan, in Bengal; 16 miles E. N. E. of Bissimpour. N. lat. 23° 10'. E. long. 87° 53'.

INDOUR, a town of Hindoostan, in Tellingana; 15 miles N.W. of Indelavoy.

INDRA, in *Mythology, is deemed, among the Pagan East Indians, the first of the demi-gods; and seems generally to rank in importance next to the three chief deities that form the Hindoo Trimurti. (See **TRIMURTI**.) The history of this first of their *di minores* might be extended through several volumes; and, indeed, including the fables*

connected with the motley history of this personage, many volumes thereon are extant among the Hindoos. He is said, in their theogony, to be the offspring of Kasyapa and Aditi (see KASYAPA), and has the whole firmament under his regency. In many particulars he corresponds with the Joves or Jupiters, for there were a great many among the Greeks and Romans; more especially, perhaps, with Jupiter Pluvius, for Indra is the god of showers. The Hindoos fancy the visible heavens to be under the guidance of eight genii, collectively called Marûts, or the Winds. (See MARÛT.) Of these, Indra is the principal, and he rules the eastern quarter. He may be deemed a personification of the firmament, ruling all atmospheric or meteoric phenomena. As god of thunder he is named Vajra Pani, or Lightning Sender; his disk-shaped weapon, *vajra*, represents lightning. He resides in the celestial city Umravati; his palace, Vajrayanta, is situated in the garden Nandana, which contains also the all-yielding trees Pariyataka, Kalpadruma, and three others similarly bountiful. He possesses also the all-prolific cow Kamdena, otherwise called Surabhi; and hence one of Indra's names means the *lord of wealth*. He has a consort named Indrani: he rides the elephant Iravat, with three proboscis, which are said to represent water-spouts, as the bow with which he is armed is the iris. Seated on mount Meru, or the north pole, attended by male and female dancers (Sînara and Upsâra), he regales the gods with nectar and heavenly music. He is painted with four arms, and fringed with eyes; hence one of his names is the *thousand-eyed* god. Another of his names is Puredera, or the *destroyer of towns*; he having, in revenge for supposed neglects, overwhelmed several cities; particularly Ujaini, or Oojein, the capital of Malwa.

INDRA Malava, the hereditary possession of the family of Sindia. The city has now lain submerged about 1900 years. (See OJOEIN.) Indra is also named Sîhatkrati, meaning he to whom is made a *hundred sacrifices*, for this "king of the immortals," another of his names, is very extensively propitiated in the numerous ceremonies of lustration and sacrifice that Brahmans, devoted to the service of the altar, are daily called upon to observe. Jealous, however, of the offerings made to other deities, he is represented as frequently interrupting, both by personal interposition and evil counsel, the sacrifice prepared or intended for other deities; in this character of an evil counsellor he is usually called Sakra, and although called and represented as *thousand-eyed*, he is sometimes painted with but one eye; the cause of which, with many other fables connected with the character and history of this important deity, is related in Moor's Hindoo Pantheon, whence most of the particulars of this article are taken.

Like most of the other Hindoo deities, Indra is represented as immoral and depraved, even to a proverbial degree; but we must refer to the work just mentioned for instances of his profligacy, excessively extravagant if received literally, but which, doubtless, are allegorical concealments of some astronomical or physical facts; for major Moor proves Indra to be a star or a constellation of the northern hemisphere, and that the wars which he sustains against giants, in which he is alternately conqueror and conquered, refer to some cycle or periodical revolution of the heavenly bodies. Metallic images of Indra are rarely seen: he is sculptured in Elephanta and other excavations in India, mounted on Iravat, and is often met with in paintings. Several engravings of him are given in the Hindoo Pantheon. Under the words severally referred to above, and the foreign names of persons and places that occur, farther particulars of the subjects of this article will be found; for Indra is so important a deity,

that his history, like his worship, mixes itself with that of most of his divine associates in the monstrous system of Hindoo idolatry.

INDRÂNI, is the name of the Sakti or consort (see SAKTI) of Indra, the regent of the firmament among the Hindoos. (See INDRA.) Her name is sometimes pronounced Aindrani. She is otherwise called Powlamaya, or Powlamya, and Saki, and is represented in the Hindoo Puranas, or mythological and theological romances, as a faithful and virtuous character, which is not always the case with their female divinities: she is also very handsome, and has resisted many temptations. She is called one of the seven divine mothers of the celestials. (See MATRI.) In the sixth volume of the Asiatic Researches, is a very curious and interesting account by sir Charles Malet, of the magnificent excavations at Ellora, accompanied by plates; one of them representing Indrani, of lovely form, seated on a lion, with a child in her lap, and a skull and crofs bones in her girdle: major Moor, however (Hindoo Pantheon, p. 271.), doubts if this elegant figure be really of Indrani, of whom he says he never law any sculptured representation. See ELORA; to our account of which may be added, that Mr. Daniel has engraved and published, from materials in the collection of sir Charles Malet, a series of views, both minute and perspective, of the interior and exterior of these wonderful excavations, that is altogether unrivalled by any work in Europe, as well for the accuracy of oriental scenery and costume, as for its general elegance and splendour.

INDRAPOUR, in Geography, a town on the W. coast of the island of Sumatra, and capital of a country, which has several other towns, where the Dutch have a factory for the purchase of pepper, 100 miles N.W. of Bencoolen. S. lat. 2°. E. long. 100 40'. This was once the seat of a monarchy of some consideration and extent. Its antiquity appears from an historical account given by the sultan of Bantam to Corneille le Brun, in which it is mentioned, that the son of the Arabian prince, who first converted the Javans to Mahometanism, about the year 1400, having got himself declared sovereign of Bantam, married the daughter of the raja of Indrapour, and had, as her portion, the territory of the Sillabares, a people of Banca-loulou. This was probably the first dismemberment which the Javan monarchs long availed themselves of; and since, the kingdom of Indrapour has dwindled into obscurity. From its ruins has sprung that of Anacoongey; extending on the sea-coast from Mandoota river to that of Oori; the present capital of which, if such towns deserve the appellation, is Moco Moco, Mariden's Sumatra, p. 284.

INDRAPOUR Point, a cape on the W. coast of Sumatra. S. lat. 2 10'. E. long. 100 34'.

INDRAT, a town of Hindooistan, in Dowlatabad; 23 miles N.W. of Beder.

INDRE, a river of France, which rises about four miles N. N. W. from Boufflac, in the department of the Creuse; and joins the Loire at Rigny, between Saumur and Tours.

INDRE, one of the departments of the central region of France, formerly Lower Berry, in N. lat. 46° 45', so called from the river which traverses it from S.E. to N.W.; bounded on the N. by the department of the Loir and Cher, on the E. by that of the Cher, on the S. by the departments of the Creuse and Upper Vienne, and on the W. by those of the Vienne and Indre and Loire, about 54 miles from N. to S., and 5 from E. to W. Its capital is Chateauroux. It contains 362 square leagues, and 207,911 inhabitants; it is divided into four districts, *viz.* Issoudun, containing 39,341 inhabitants; Chateauroux,

75,588; La Chatre, 45,171; and Le Blanc, 47,811. Its cantons are 23, and communes 275. Its contributions amount to 1,652,606 francs; and its expences to 219,394 fr. 59 cents. The western district of this department abounds in rocks, pools, and woods; but the other tracts, and in particular that on the right hand of the Indre, consist of cultivated fields, vineyards, &c. yielding grain, wine, and pastures; it has mines of iron, marble quarries, and mineral springs, &c.

INDRE and LOIRE, one of the nine departments of the western region of France, formerly Touraine, is N. lat. 47° 10', so called from the union of the two rivers: bounded on the N. by the department of the Sarthe, on the E. by the departments of the Loire and Cher and the Indre, on the S. and S.W. by the department of the Vienne, and on the W. and N.W. by the department of the Mayne and Loire; about 50 miles from N. to S., and 45 from E. to W. Its capital is Tours. It contains 325 square leagues, and 278,758 inhabitants. It is divided into three districts, *viz.* Tours, including 128,635 inhabitants; Loches, 57,094; and Chinon, 93,029. Its cantons are 24, and communes 311. Its annual contributions amount to 2,868,779 francs, and its expences to 246,653 francs. This department, on account of its fertility, has been styled the garden of France. The vallies and eminences near the borders of the large rivers are fertile, but at some distance are heaths and uncultivated tracts. The district lying between the Loire and the Cher is of a light and sandy, but productive soil. The peninsula formed by the Indre, the Loire, and the Vienne, is noted for its fertility. A tract, called Brenne, is moist, but tolerably fruitful. The principal products are rye, barley, millet, wine, fruits, and pastures. It has mines of iron, and mineral springs.

INDU, a name of the moon among Hindoo mythologues. This luminary is more commonly called Chandra, or Soma. (See SOMA.) It has been furnished that the name India and Hindoo, words unknown in the ancient language of the country, may have been derived from Indu; but Sir William Jones and Mr. Wilkins discountenance such an etymology. See Moor's Hindoo Infanticide, p. 171.

INDUCEMENT, in *Law*, is what is alleged as a motive or incitement to a thing; and it is used specially in several cases: *viz.* there is inducement to actions, to a traverse in pleading, a fact or offence committed, &c. Inducements to actions need not have so much certainty as in other cases: a general *indebitatus* is not sufficient, where it is the ground of the action; but where it is only the inducement to the action, as in consideration of forbearing a debt until such a day; (for that the parties are agreed upon the debt) this being but a collateral promise, is good without showing how due.

INDUCIARUM PETITIO. See PETITIO, and EMPAN-LANCE.

INDUCTION, in *Logic* and *Rhetoric*, a consequence drawn from several propositions, or principles, first laid down.

Thus the conclusion of a syllogism, is an induction made from the premises. See SYLLOGISM.

INDUCTION is also used for a kind of syllogism itself; being a medium between an enthymeme and a gradation, in regard it wants a proposition (which, however, is understood, as in the enthymeme; and abounds in assumptions (which yet are collateral, or of the same degree), which is the case in a gradation.

For instance; every terrestrial animal lives, every aerial animal lives, every aquatic animal lives, and every reptile animal also lives; therefore every animal lives.

Here, it may be observed, are various assumptions, from the more general species of the animal kind collected into one; which this proposition is supposed to precede; *e. gr.* that every animal is either terrestrial, aerial, aquatic, or reptile.

Suidas reckons three kinds of induction: that just mentioned, which concludes or infers some general proposition from an enumeration of all the particulars of a kind, he calls the *diabolic* induction.

The second proceeds by interrogation, and concludes probably, or with a verisimilitude; this is what the Greeks called *επιταξις*, and was that which Socrates ordinarily made use of, as Cicero, in his *Topics*, and Quintilian have observed; and, therefore, called the *Socratic* induction. This, however, is a cautious way of reasoning: for while the respondent is not aware of what is designed to be inferred, he is easily induced to make those concessions, which otherwise he would not. Besides, it is not so well suited to continued as to interlocutory discourses.

The third kind of induction is properly *rhetorical*; being a conclusion drawn from some example, or authority.

This is a very imperfect induction, all its force lying in a proposition which is concealed, and which will hardly bear being expressed. Thus, he that says, Codrus did bravely for his country, therefore I must die bravely for my country; proves nothing, unless this proposition be carried in mind, that I must do the same with Codrus. Again, Archimedes, and the other mathematicians, say, the sun is much bigger than the earth; therefore, it must be owned, the sun is much bigger than the earth. Where this proposition is understood, *viz.* whatever Archimedes, and the other mathematicians, say, is true.

Induction is one of the four forms of reasoning used by orators in confirmation; the other three are syllogism, enthymeme, and example, which last coincides with the third species of induction above enumerated.

INDUCTION, in the *English Laws*, is usually taken for the giving possession to an incumbent of his church, by leading him into it, and delivering to him the keys, by the chancellor, or bishop's deputy, and by his ringing one of the bells.

When a clerk is instituted into a benefice, he is to exhibit his mandate from the bishop to the archdeacon, or other person to whom it is directed, and hath a right thereby to be inducted into his living; and if he be refused induction, he hath a remedy both in the ecclesiastical court, and also an action of the case in common law, against the archdeacon. If the inductor, or person to be inducted, be kept out of the church, or house, by laymen, the writ *de vi laica* lies for the clerk, which is directed out of the chancery to the sheriff of the county, to remove the force, &c. If another clergyman, presented by the same patron, keep possession, a spoliation is grautable out of the spiritual court, whereby the tithes, &c. shall be sequestered, till the right be determined.

The archdeacon rarely inducts a clerk in person, but usually issues out a warrant to the clerks and lettered persons within the archdeaconry, empowering any of them to do it in his stead.

An induction made by the patron of the church is void; but bishops and archdeacons may induct a clerk to the benefices of which they are patrons, by prescription. No induction is necessary to a donative, where the patron, by donation in writing, puts the clerk in possession without presentation. 11 Hen. IV. cap. 7.

The usual form and manner of induction is, for the inductor to take the clerk by the hand, and then to lay it

on the key of the church, which must be then in the door, and to say, "By virtue of this instrument, I induct you in the real, actual, and corporal possession of the rectory or vicarage of _____, with all its fruits, profits, members, and appurtenances."—This done, he opens the door, and puts the clerk in possession of the church; and shuts the door upon him; who, after he hath tolled a bell (if there be any) to give the parishioners due notice and sufficient certainty of their new minister, comes out, and desires the inductor to indorse a certificate of his induction on the archdeacon's warrant, and that all present will signify it under their hands. If the church-key cannot be had, it is sufficient that the clerk lays hold of the ring of the door, the latch of the church, gate, &c. and, within two months after this, the clerk must read the thirty-nine articles, and all the service of the day, both at morning and evening prayers, in the parish church of his benefice, and in the time of common prayer, and declare his assent and consent; he must also then read the ordinary's certificate, in which is the declaration of his conformity, together with the same declaration, and of all this he must have two or three good witnesses, who must sign that they heard him do it, and be ready to attest it, *viva voce*, if required; and, within six months after induction, he must also take the oaths of allegiance, supremacy, and abjuration, at the quarter-sessions, or in some one of the courts at Westminster-hall.

Induction makes the parson complete incumbent, and fixes the freehold in him. When a clerk is thus presented, instituted, and inducted into a rectory, he is then, and not before, called in law, *persona imperfonata*, or parson imparfonce. 13 Eliz. c. 12. 13 and 14 C. II. c. 4. 1 Geo. stat. 2. c. 13. 9 Geo. II. c. 26. 23 Geo. II. c. 28.

INDULGENCE, in the *Romish Theology*, the remission of a punishment due to a sin, granted by the church, and supposed to save the sinner from purgatory.

The Romanists found their indulgences on the infinite treasure of the merits of Jesus Christ, the Holy Virgin, and all the saints; which they suppose the church has a right of distributing by virtue of the communion of saints. See SUPEREROGATION.

These indulgences were first invented in the eleventh century by popes Gregory VII. Victor, and Urban II. as a recompense for those who went in person upon the wild enterprise of conquering the Holy Land. See CROISADE.

They were afterwards granted to those who hired a soldier for that purpose, and in process of time were bestowed on such as gave money for accomplishing any pious works enjoined by the pope. In the beginning of the twelfth century, the bishops, whenever they wanted a supply of money for their private pleasures, or the exigencies of the church, resorted to the scandalous traffic of indulgences; and when the Roman pontiffs saw that immense treasures were thus accumulated by the inferior rulers of the church, they thought proper to limit the powers of the bishops in remitting the penalties imposed upon transgressors, and assumed it, almost entirely, as a profitable traffic to themselves. They began with granting a plenary remission of all the temporal pains and penalties which the church hath annexed to certain transgressions; and then proceeded to abolish even the punishments which are reserved in a future state for the workers of iniquity.

The Roman jubilee, first instituted by Boniface VIII. A.D. 1300, carries with it a plenary, or full indulgence, for all the crimes committed therein.

The pope also grants bulls of plenary indulgence to several churches, monasteries, and even to private persons; and it is

a frequent thing to have general indulgences for the time of the principal feasts of a year. Their casuists say that a plenary indulgence does not always prove effectual, for want of complying with the conditions whereon it was granted.

For the extirpation of heretics, it has been a common practice with the popes to grant indulgences. Thus Clement XII. "That we may stir up and encourage the faithful to extirpate this ungracious crew of forlorn wretches, (the Cevenons, when in arms against Lewis XIV.) we fully grant and indulge the full remission of all sins, whatever they may be (relying upon that power of binding and loosing, which our Lord conferred upon his chief apostle), to all those that shall lift themselves in this sacred militia, if they shall happen to fall in battle." See ABSOLUTION.

Julius II. had bestowed indulgences on all who contributed towards building the church of St. Peter at Rome, and pope Leo X. in order to carry on this magnificent structure, published indulgences, and a plenary remission on the same pretences. Finding the project take, he granted the right of promulgating these indulgences in Germany, together with a share in the profits arising from the sale of them, to Albert, elector of Mentz, and archbishop of Magdeburg, who employed Tetzl, a Dominican friar, as his chief agent for retailing them; and he farmed out those of other countries to the highest bidders, who, to make the best of their bargains, procured the ablet of their preachers to extol the value of the ware: "Happy times for sinners," says a modern writer, "their crimes were rated, and the remission of them set up by auction. The apostolic chamber taxed sins at a pretty reasonable rate; it cost but ninety lives and a few ducats, for crimes which people on this side the Alps punished with death."

These are specified in a book of rates called the Tax-Book of the Holy Apostolic Chancery, first printed at Rome in the year 1514, and ascribed by some to pope Innocent VIII. From a correct edition of this book, printed by L. Banck, professor at Norkopin, in Gothland, in 1651, it appears that the price of absolution for fornication, attended with the most heinous circumstances, was six grossi or groats; for a layman's murdering a layman, five groats; for laying violent hands on a priest, without shedding blood, nine groats; for committing incest, five groats; for a priest's keeping a concubine, seven groats; for forging the pope's hand-writing, seventeen or eighteen groats. See the Taxa S. Cancellarie Apostolicæ, a L. Banck. Francquera, 1651, p. 126, &c. It was this great abuse of indulgences, that contributed not a little to the first reformation of religion in Germany; wherein Martin Luther began first to declaim against the preachers of indulgences, and afterwards against indulgences themselves; but since that time, the popes have been more sparing in the exercise of this power; however, they afterwards carried on a great trade with them in the Indies, where they were purchased at two reals a-piece, and sometimes more. See REFORMATION.

INDULGENCE, or *Indulto*, signifies also a special favour, or privilege, conferred either on a community, or a particular person, by the pope's bulls; in virtue whereof the party is licensed to do or to obtain something contrary to the intention and disposition of the common laws.

There are two kinds of *indultos*: the one *active*, which consists in a power of nominating and presenting freely, and without reserve, to benefices that are otherwise limited, and restrained by the laws of the apostolical chancery; such are those ordinarily granted to secular princes, cardinals, bishops, &c.

Passive indultos consist in a power of receiving benefices, and

and expectative graces; of which kind are those of a parliament, of graduates, mandatories.

The indulto of kings is the power given them of presenting to consistorial benefices, either by treaty, by favour, or special privilege.

The indulto of cardinals is a licence for holding regular as well as secular benefices, and for disposing of benefices in *commendam*, or continuing them, &c.

Indulto of parliament is a right of privilege formerly granted to the chancellor, presidents, counsellors, and other officers in the parliaments of France, to obtain a benefice of the collator, upon the king's nomination directed to him. This was a kind of advowson, or patronage, belonging to the French king; the indulto being a mandate, or grace, by which he was permitted to name to any collator he pleased a counsellor, or other officer of parliament, on whom the collator should be obliged to bestow a benefice: so that the right of the indulto resided radically in the king, the officers being only the objects thereof.

INDULPHUS, in *Biography*, the seventy-seventh king of Scotland, began his reign in the year 959. The early years of his reign were peaceable and prosperous, but afterwards his kingdom was invaded several times by the Danes, who were enraged against him for making an alliance with the English. Their first descent was upon East Lothian, whence they were soon expelled, but crossed over to Fife. Here they were defeated, and driven out, and so well had Indulphus taken care to guard the coasts, that they could find no other opportunity of invading the country; till, having thrown the Scots off their guard, they made good their landing in Banffshire. Here Indulphus attacked them in their camp, and drove them towards their ships, but was killed in an ambuscade, into which he fell during the pursuit.

INDULTO, in *Commerce*, denotes a duty, tax, or custom paid to the king of Spain for all such commodities as are imported from the West Indies in the galleons.

INDURATING, a term applied to such things as give a harder or firmer consistence to others, either by the greater solidity of their particles, or by dissipating the thinner parts of any matter, so as to leave the remainder harder.

INDURATION of STRATA, in *Geology*, denotes the change which all the masses of the earth evidently have undergone since they were deposited in their present situation in a fluid or plastic state; under the article **HARDENING of Strata**, we have noticed some of the facts and theories on this subject, to which we beg to refer.

INDUS, or **SINDI**, or, according to the proper Sanscrit name *Sandhuo*, under which name it was not unknown to the Romans (*Indus incolis Sindus appellatur*, Pliny, l. vi.) a celebrated river of Asia, which is formed of about 10 principal streams, that descend from the mountains of Persia, Tartary, and Hindoostan, on the N.E. and N.W.; all which streams, uniting near Moultan in Hindoostan, form this famous river. The Aya Acbarree says, the Sindh, according to some, rises between Cashmere and Cashingar, whilst others place its source in Khatai, meaning probably Koter, the Chaze of Ptolemy, and not China. It is clear, however, that the people of Hindoostan consider the north-eastern branch as the true Sindh, though the ancients seemed to have reckoned otherwise; for Pliny says "in jugo Caucaei montis, quod vocatur Paropamisus, adversus Solis ortum effusus." The emperor Baber, indeed, applies the name of Sindh to one of its western branches, that springs near Bamian, but he appears to differ in this particular from the rest of his countrymen; for the name of Nilab, which was ap-

plied to the river that ran by the site of Attock (long before that city was founded), was applied also to the same river, in its course through Little Thibet; and Nilab is synonymous with Sindh. (See **NILAB**.) The Indus, under the name of Nilab, passes through the country of Little Thibet; and its head must be on the west of the great ridge of mountains called by the ancients Imaus, because on the east of it, the rivers all run in a direction opposite to that of the Indus. About 20 miles above Attock, the periodical rains, which fell on the northern mountains, having considerably swelled the river, its breadth was about $\frac{1}{2}$ of a mile; its course rapid and turbulent, and its water extremely cold, with a great quantity of black sand suspended in it. At Attock the Indus is joined by the Cabul, and very considerably increased by it, so that from Attock downwards to Moultan, or to the conflux of the Panjab water, where it has obtained the name of Attock, it is no longer fordable; below that point it is called Soor, or Shoor, until it divides itself into a number of branches near Tatta, where the principal branch takes the name of Makran. This river, however, when spoken of generally, is called Sindh; although particular parts of it are known by different names. The Indus, and its branches, admit of an uninterrupted navigation from Tatta, the capital of Sindy, to Moultan and Lahore, for vessels of near 200 tons. About 170 miles from the sea, by the course of the river, the Indus divides into two branches, of which the westernmost is by much the largest. This branch, after a course of about 50 miles to the S.W., divides into two more; the smallest of which runs in a W.S.W. course, to Larry-Bunder and Dacraway; and the largest, taking the name of Ritchel river, runs in a more southwardly course to the town or village of Ritchel, on the sea-coast. The other principal branch is that which bounds the eastern side of the Superior Delta; separating, as we have said, about 170 miles from the sea. It is smaller than the Ritchel river, but larger than that of Larry-Bunder, and according to circumstances and report, it opens into the mouth of the gulf of Cutch, nearly opposite to Jigat point; its course being somewhat to the eastward of south. Major Rennell infers from various circumstances, that the Delta of the Indus (see **DELTA**) is about 150 British miles in length along the sea-coast, and about 115 in depth, from the place of separation of the superior branches of the river, to the most prominent point of the sea-coast. The lower part of this Delta is intersected by rivers and creeks in almost every direction, like the **DELTA of the Ganges**, but without trees; the dry parts being covered with brushwood, and the remainder, being by much the greatest part, being noisome swamps, or muddy lakes. The upper part of the Delta is well cultivated, and yields abundance of rice. This Delta is set apart for the breeding of camels, answering this purpose by means of the tender parts of its brushwood, which serves them for fodder. The breadth of the Ritchel branch is estimated at one mile, just above the tide; and at Tatta, at only half a mile. It is certain that the Indus is very considerably less than the Ganges. The velocity of its current is estimated at four miles per hour in the dry season; but this is supposed by Rennell to be over-rated. The course of the Indus river is stated by major Rennell at (probably) $\frac{1}{2}$ that of the Thames being 1. This ingenious geographer mentions the moveable towns or villages that are situated on the banks of the river, noticed by Nearchus and the Aya Acbarree; some of which are the habitations of fishermen, and others of graziers; which are continually changing their positions like a camp. Few rivers abound more with fish than the Indus does; and among these are some very delicious sorts. The mouths of the

Indus are comprehended between N. lat. 23° 20' and 24° 40'.

INEADA, in Geography, a town of European Turkey, in Romania; 56 miles E.N.E. of Adrianople.

INEQUALITY of Natural Days. See EQUATION.

INEQUALITY, Optical. See OPTICAL.

INERT Vegetable Matter, in Agriculture, is a term lately given to that sort of vegetable matter which, by long and frequent exposure, has been so saturated and combined with the oxygen or pure air of the atmosphere, as to be rendered in a great degree insoluble. The surface of peat mosses, and the mould of such soils as have been much exposed to the action of pure air, by fallowing, are supposed to be rendered inert in this way by the author of the "Connection of Chemistry with Agriculture." See PLAT.

INERTIE Vis. See VIS INERTIE.

INESCUTCHEON, in Heraldry, a small escutcheon borne in a larger one, as part of some other coat. See ESCUTCHEON.

Güllim confines the name to an escutcheon borne single in the fess point or centre.

This is also sometimes called an *escutcheon of pretence*.

He who marries an heiress, bears her coat of arms on an *inescutcheon*, or *escutcheon of pretence*, in the middle of his own coat.

Modern heralds apply the name inescutcheon to those small escutcheons, several of which are borne in a large one.

INESERRHA, in Geography, a town of Africa, in Sennaar; 10 miles E. of Giessen.

IN ESSE is applied to things which are actually existing.

Authors make a difference between the thing *in esse*, and a thing *in posse*. A thing that is not, but may be, they say, is *in posse*, or *potentia*; but a thing apparent and visible, they say, is *in esse*, that is, it has a real being *eo instanti*; whereas the other is casual, and at best but a possibility.

INEVERAM, in Geography, a town of Hindoostan, in the circar of Rajamundry; 32 miles S.E. of Rajamundry.

INFALISTATIO, an ancient punishment of felons, by throwing them among the rocks and sands, customarily used in port-towns. It is the opinion of some writers, that *infalstatus* did imply some capital punishments; by exposing the malefactor upon the sands till the next tide carried him away; of which custom, it is said, there is an old tradition. However, the penalty seems to take its name from the Norman *falsse*, or *falsia*, which signified not the sands, but the rocks and cliffs adjoining, or impending on the sea-shore. "Committit feloniam ob quam fuit suspensus, utlagatus, vel alio modo morti damnatus, &c. vel apud Dover infalstatus, apud Southampton submersus, &c."

INFALIBLE, from *in*, taken privatively, and *fallo*, I deceive, that which cannot deceive or be deceived.

Upon this term stands one of the principal heads of controversy between the Reformed and the Catholics; the latter of whom maintain, that the church, assembled in general council, is infalible; which the former deny.

The Jesuits, in their disputes with the Jansenists, have expressly asserted that Jesus Christ hath given to all popes whenever they shall speak *à cathedra*, the same infalibility which he had, both in matters of right and fact.

The principal reasons alleged for the infalibility, are drawn from the promises of Christ, from the obscurity

of the scriptures, the insufficiency of private judgment, and the necessity there is of some infalible judge for the decision of controversies.

The infalibility of the pope is a doctrine of a late standing, and has not been entirely acquiesced in, even in their own communion, and altogether rejected by the Gallican church. See POPYRY.

INFAMOUS, derived from *in*, and *fama*, fame, report, in the ordinary use of the word, signifies something notoriously contrary to virtue, or honour.

Aulus Gellius uses the word *infames materias*, for what we ordinarily call *paradoxes*, i. e. discourses remote from the common opinion; propositions that appear opposite to truth, &c. as the elogy of Therites, the praise of a quar-tan ague, &c.

INFAMOUS, in Law, denotes a person or thing, which is of no repute, or esteem, in the world.

There are two kinds of infamy: some persons being infamous as having been noted by the laws, or stigmatized by public judgment.

Infamy, which extends to forgery, perjury, gross cheats, &c. disables a man to be a witness or juror: but a pardon of crimes restores a person's credit to make him a good evidence. Judgment of the pillory makes infamy by the common law, but by the civil and canon law, if the cause for which the person was convicted was not infamous, it infers no infamy.

Others are held infamous, by the exercise of some scandalous profession; as a catchpole, a merry-andrew, a hangman, an informer, &c.

Hertofore there were crowns of infamy given, by way of punishment, to criminals; they were made of wool.

INFANCY. See INFANT.

INFANT, in Law sensu, a person under the age of one-and-twenty years, whose acts are in many cases either void or voidable. (See AGE.) All gifts, grants, &c. of an infant, which do not take effect by delivery of his hand, are void; and if made to take effect by delivery of his own hand, are voidable by himself and his heirs; and those who shall have his estate.

Although an infant, under 21, can make no deed which is not afterwards voidable; yet in some cases he may bind himself apprentice by deed indented, or indentures for seven years (Stat. 5 Eliz. c. 4. 43 Eliz. c. 2. Cro. Car. 179); and he may by deed or will appoint a guardian to his children, if he has any. Stat. 12 Car. II. c. 24.

By the custom of London, an infant, unmarried, and above the age of fourteen, may bind himself apprentice to a freeman of London, by indenture, with proper covenants, which shall be binding.

An infant may bind himself to pay for necessaries, as meat, drink, apparel, physic, and learning, but not by bond with penalty; though a bill for necessaries, without a penalty for the very sum due, it is said, will bind him. Infants are not obliged to pay for clothes, unless it be averred for their own wearing; and that they were convenient and necessary for them to wear according to their degree and estate. An infant may buy, but cannot borrow money to buy necessaries: for the law will not trust him with necessaries, but at the peril of the lender, who must lay it out for him in necessaries, or see it thus laid out.

An infant has been adjudged of age the day before his birth-day; for this law will not make a fraction of a day; therefore where a person was born the third of September, and the second of September, twenty-one years after, he made his will, it was held good, and that he was then of age to devise his lands. And it is said such will shall

take effect, though the devisor dies by six at night of that day.

An infant eight years of age, or upwards, may commit homicide, and be hanged for it, if it appear, by any other act, that he had knowledge of good and evil; for *hæc malitia supplebit ætatem*: yet Coke on Littleton, sect. 405, says, "An infant shall not be punished till the age of fourteen;" which, according to him, is the age of discretion.

But this depends on the degree of judgment which he possesses. If an infant be *infra annos infantie*, viz. seven years old, he cannot be guilty of felony, whatever circumstances proving discretion may appear. See AGE, in *Law*, EXECUTOR, GUARDIAN, &c. See also RAPE.

An infant *en ventre sa mere*, or in the mother's womb, is capable of having a legacy, or a surrender of a copy-hold estate made to it. It may have a guardian assigned to it (lat. 12 Car. II. c. 24.); and is enabled to have an estate limited to his use, and to take afterwards by such limitation, as if it were then actually born (lat. 10 & 11 W. III. c. 16.); and in this point the civil law agrees with ours. Though infants cannot alien their estates, yet infant trustees or mortgagees are enabled to convey, under the direction of the court of chancery or exchequer, or other courts of equity, the estates they hold in trust or mortgage, to such person as the court shall appoint. By the custom of gavel-kind, an infant, at the age of fifteen, is reckoned at full age to sell his lands; and by custom, in some places, an infant seized of land in socage, may, at the same age, make a lease of years, that shall bind him after he comes of age.

An infant, who has an advowson, may present to the benefice when it becomes void. (Co. Litt. 172.) An infant is capable of inheriting, and may also purchase lands, but his purchase is incomplete; for, when he comes to age, he may either agree or disagree to it, without alleging any reason; and so may his heirs after him, if he dies without having completed his agreement. (Co. Litt. 2.) And in case any infant bargain and sell his land by deed, indented and enrolled, yet he may plead non-age.

If an infant grants leases for a term of years, he may, at his full age, either confirm the lease, or bring trespass against the lessee for the occupation. Also a lease granted to an infant, may be avoided by waiving the land before the rent-day expressed therein. However, infants are bound in all acts of necessity; as presentations to benefices, admissions and grants of copy-hold estates, assenting to legacies, and conditions annexed to lands, whether the estate comes by grant or descent. If an infant be the defendant in an action, the plaintiff shall have six years for commencing his action, after the defendant comes of age; and an infant, who is a plaintiff, has also six years after he comes of age, to sue by the statute of limitation.

INFANTS, Diseases of, in Medicine. When the extreme delicacy and tenderness of every part of the structure of the infant frame is considered, as well as the extraordinary revolution, which it suddenly undergoes, in passing from its vegetating state, as it were, in the uterus, to that of a breathing animal, it must be obvious that a thousand circumstances, which make no impression on the adult frame, will powerfully influence that of the infant; and that the utmost care will be required to shield it from numerous causes of disease, from the moment of its birth. To the neglect of these circumstances, or to their inability of attending to them, the great mortality that occurs among the children of the poor, in large cities, is perhaps chiefly to be ascribed. But this was formerly much augmented, among all ranks, by the absurd and unna-

tural interference of art, which was apparently dictated by a notion that the instincts and intimations of nature were to be opposed, as of the most baneful tendency. Fortunately the more rational system of following these intimations, as the best guides to health, has generally superseded that abuse; and it will only be requisite for us here to speak of some of the accidents attendant on birth, of the more frequent conative imperfections of structure, and of the diseases peculiarly belonging to the period of infancy and childhood.

Recovery of still-born or weakly infants.—Dr. Hamilton observes, that the occasional recovery of still-born children, under circumstances where experience alone could have encouraged any hopes, ought to teach practitioners the importance of employing, with patience and attention, the means conducive to that purpose. If there is no pulsation in the umbilical cord, the infant should be instantly separated from the mother, the cord being tied by a slip knot, and the body immersed in warm water. The lungs should be then dilated with air, by means of a bag of elastic gum; or a common syringe, (the pipe of which is to be inserted into one nostril, while the other and the mouth are carefully closed,) and again emptied by gentle pressure on the breast. In this way an alternate dilation and compression of the lungs should be continued for some time. Should the action of the heart be now perceived, the same means are to be continued, until the infant exhibit the usual marks of beginning respiration, when the artificial dilation of the lungs is to be only occasionally repeated, and all pressure on the breast is to be avoided. But if, notwithstanding these means, the pulsation of the heart be not restored, the infant should be taken out of the warm water, placed before the fire, carefully rubbed, and then wrapped in warm flannel. A glyster, consisting of a table-spoonful of spirits, and two or three table-spoonfuls of warm water should then be administered, and the temples, nostrils, and teguments of the face round the mouth, should be gently touched with a feather, dipped in vitriolic æther, or spirits of hartshorn. But, secondly, if the pulsation in the cord of a still-born child is distinct and soft, and the infant has the natural appearance, so long as the placenta remains attached to the uterus, the child ought not to be separated from the mother. The body should be carefully wrapped in warm flannel, the nostrils and fauces should be touched with a feather dipped in vitriolic æther, and a little spirits rubbed on the breast. If the after-birth become detached, (which is known by the lengthening of the cord,) the child must be immediately separated, and the above means employed. Should the process of breathing commence after these means have been used for a few minutes, nothing else is to be done than keeping the infant warm, with its face freely exposed to the air. But should this not take place, the lungs are to be defended and again compressed, as in the first case. See Prof. Hamilton's Hints on the Diseases of Infants, &c.

Although alive when born, the infant, in some instances, lives only a short time. If the lips be pale, and the pulsation in the heart very feeble or slow, it may be suspected that this originates from some cause which is not cognizable to the senses. On the supposition that it arises from a deficiency of vitality, stimulants have been applied to the surface, as a little brandy, or spirits of hartshorn, rubbed on the ribs and spine, &c.: and such means have occasionally proved efficacious, though in the majority of cases they fail. When the extremities are of a purple or bluish colour, and the breathing is impeded or unnatural, it is generally found that there is a defect in the heart or lungs, which is beyond the power of any remedy.

§ 1. *Connate Imperfections.*—Children are not always born in a state of perfection in respect to the structure of their bodies; for sometimes they have deficient, superfluous, or misplaced parts, natural passages closed, and various marks on the surface. Many of these imperfections admit of no remedy; while others may be easily rectified. The following are those which are most frequently met with.

Fissures in the lips not only constitute a remarkable deformity, but commonly prevent the child from sucking. They appear under various forms. Sometimes the fissure exists only in one lip, generally the upper one, and is occasioned merely by a division of the soft parts: in other cases, there is a considerable loss of substance between the divided parts: in some instances, again, there are two fissures in one lip, or both lips are affected: and in others, the fissure is not confined to the lips, but extends along the roof of the mouth. All these different species of the same deformity receive the general name of *hare-lip*; which see.

The *tongue* is naturally bound down to the lower part of the mouth by a membranous cord, to prevent it from too great a degree of motion. Sometimes, however, the cord fixes it too much, that the infant cannot suck, in which case it is commonly said to be *tongue-tied*. Women very often imagine that their children have this defect, when it does not really exist: and perhaps one instance of it does not occur in several hundreds of those that are born. The disease may be always discovered by putting a finger gently into the child's mouth; for if he be able to grasp it, as he would do the nipple in sucking, or if the tip of the tongue appear disengaged, the membrane does not require to be cut. The operation of dividing the *framum*, trifling as it may appear, requires some caution, in order to avoid wounding the sublingual veins, and cutting too deep; for in the first case, a fatal hæmorrhage may ensue; and in the second, if the tongue is loosened too much, the tip may be turned back, and close up the throat; an accident that must soon occasion death. It may be discovered by the threatening suffocation or convulsions, and by the introduction of the finger into the mouth, by which also the tongue may be pulled back, and the consequences avoided. This, however, is a very rare accident: it has been absurdly called "swallowing the point of the tongue." See Underwood on the Diseases of Children, vol. ii. p. 17. 5th edit.

The *natural passages*, especially the *anus*, *vagina*, and *urethra*, are sometimes *imperforate*, preventing altogether, or in great part, the usual excretions. In some cases, a collection of mucus alone proves the obstacle; but in others, membranous substances close up the passages, in which last instances, an operation will be requisite to open the parts, which must be performed by a skilful surgeon. In respect to the *vagina*, Dr. Underwood observes that he never found the external parts totally imperforate, there being always a small opening at the *meatus urinarius*: but the aperture of the *vagina* itself sometimes requires to be opened, either by the point of a lancet, or by the fingers only, which is generally easily effected, there being always a *raphe*, or line, where the natural opening should be. The *anus* is sometimes closed only by a thin membrane, so that the day after birth the meconium may be distinctly felt, and in a manner seen passing through it. A slight puncture with a lancet, and passing a bougie or the point of a finger into the bowel for two or three days afterwards, is sufficient to remove this impediment. But more commonly the imperforate anus is a melancholy case, allowing of no effectual remedy, as the gut often terminates in a cul-de-sac: so high as not to be reached. The imperforate penis is not quite so com-

mon a case; but is not unfrequently suspected, when the aperture of the passage is merely stopped up by a little mucus. Under such circumstances, washing the part with warm milk and water, or at most a little assistance with a small probe, or any such blunt-pointed instrument, will be sufficient to open the passage. When the urethra is perfectly open nearly to the extremity, as often happens, it is necessary only to make a small aperture with a lancet, or a fine trocar, and to keep the part open by the occasional introduction of a slender bougie.

Tumours about the back-bone of infants are always dangerous. If they be soft, partly transparent, and obviously connected with the spine, constituting the disease called *Spina bifida*, or *hydrocele*, they most generally prove fatal ultimately; although in some instances, the progress to that event has been very slow, the child having lived to the thirtieth year. Fortunately, however, it more commonly terminates within a few months after birth: where it is protruded, the individual is in a miserable state, being paralytic in his lower limbs, &c.

Retention of the Meconium.—The meconium is that black, viscid matter, which every infant discharges from the intestines for the first two or three days after birth; and many complaints have been ascribed to the undue retention of it, and consequently a great variety of purgative medicines have been recommended to be given, almost as soon as the child is born, with a view to expel it. But experience has taught that the natural evacuator of this matter is the first milk of the mother, which is slightly laxative in its properties: the infant, therefore, should be put to the breast as soon after birth as the situation of the mother will allow. The pernicious practice of giving infants purging medicines, Dr. Hamilton remarks, as soon as they are born, cannot be too much reprobated; for the retention of the meconium for some hours after birth certainly produces less inconvenience than is occasioned by the acrimony of the substances which the child is often forced to swallow. The most simple artificial means, he adds, for removing this matter, are Lisbon sugar dissolved in water, or a solution of manna. Where these fail, a teaspoonful of cold drawn castor oil is to be given.

Jaundice, or, as the nurses term it, the *yellow gum*, is among the diseases which take place within a few days after birth. It is preceded by drowsiness, and disinclination to suck, and is soon discovered by the universal yellowness of the skin. Sometimes the whites of the eyes appear yellow for a day or two before the other symptoms appear: the tinge of the skin is seldom deep, and the disease is more readily removable than the jaundice of adults; but cases are occasionally met with, where the colour of the skin is of a dark yellow, the infant moans constantly, and convulsions follow, which at last destroy life. In regard to the treatment of this disease, if the child seem to suffer no uneasiness, although its skin be quite yellow, and if his bowels be open, it will be unnecessary to administer any medicines. But if he be unable to suck, and have a disposition to constant sleep, active measures should be adopted. These consist principally in evacuating the viscid matter, which probably clogs up the biliary ducts. An emetic of ipecacuan, and brisk laxatives, as of rhubarb, or frequent doses of a solution of manna, will then be found necessary, and their effects may be much promoted by the warm bath. When violent colic pains or convulsions accompany the yellow gum, there is reason to fear that the liver is diseased, and little can be expected from any remedy.

The *thrush*, sore mouth, or *aphthæ*, is so common a disease in early infancy, that it has been imagined to be a salutary

effort of nature to expel some hurtful matter from the system, which might otherwise be productive of many complaints at a future period. This opinion, however, is merely a vulgar prejudice, founded neither on reason nor experience. *Aplthie* appear to be connected with a deranged condition of the alimentary canal, and seem to arise most frequently from the too early or too liberal use of spoon-meat, or improper food; but other causes occasionally produce it, such as exposure to cold, damp weather, &c. In the treatment of this complaint, Dr. Hamilton affirms, that the great object should be to promote its natural progress, and to counteract the effects of the acrimony of the saliva. The early use of stimulant applications, such as gargles of port-wine and borax; force off the spots before they have undergone the natural changes, and by their irritation keep up the disease. But the proper objects may be obtained by putting frequently into the infant's mouth a tea-spoonful of a liquor, prepared by mixing with the white of an unboiled egg, three table-spoonfuls of cold water, and a little refined sugar, by prohibiting all spoon-meat, and by frequently dousing the natural passages with prepared calamine or tully powder. When the spots become yellow, the borax may be allowed. It is to be mixed with eight or ten times its weight of powdered sugar or of honey, or it may be dissolved in fig-tea in the same proportion. If the spots grow livid, bark and port-wine should be used as a gargle, while the infant is supported by means of ten or twelve parts of warm cow's milk, mixed with one part of cherry wine. The same kind of nourishment is necessary in cases, where, from the extensive incrustation over the tongue and cheeks, the infant is incapable of sucking, which often happens for a day or two. See *APHTHÆ*.

§ 2. *Diseases of the Skin.*—Two diseases, of a febrile nature, connected with a morbid condition of the skin, have been described by writers on the disorders of infancy, which merit attention. They are almost unknown, however, except to the physicians of lying-in hospitals, as they have seldom occurred in the private houses of individuals. The first of these is erysipelas inflammation of the skin, called by Dr. Underwood *erysipelas infantile*, which ordinarily occurs within a few days after birth, and sometimes at a later period. It feizes the most robust, as well as delicate, children; making its attacks in a very sudden manner, and proceeding rapidly in its course. It most commonly appears first on the toes or fingers, which look swelled and blue, as if from cold; but in the more violent forms, it begins about the pubes, and extends upwards on the belly, and down the thighs and legs; or sometimes it commences in the neck, when it is equally dangerous. It appears, indeed, to be always most dangerous when it feizes or spreads to the body, and most mild when confined to the extremities. Suppuration and gangrene are occasionally the consequences; but even where neither of these events takes place, it may terminate fatally from effusion into some of the cavities, or from the inflammation extending to the contents of the abdomen, gluing the parts together, and throwing out upon their surface an exudation of coagulable lymph. On the whole, the treatment of this infantile *erysipelas* has too frequently proved unsuccessful. The use of saturnine lotions and poultices, on the first appearance of the inflammation, seemed to check its progress at first; but it was soon found to spread, and to terminate in a fatal suppuration or mortification. A more cordial plan of treatment has been attended with a somewhat greater degree of success; and the application of external stimulants, such as linen compresses wrung out of camphorated spirit, has in some cases checked the inflammation. The bowels should be kept open,

and the free admission of pure air enforced: indeed, it is probable that, in proportion to the effectual ventilation employed, the occurrence of the disease will be diminished, and its violence, when it does appear, mitigated.

Another affection of the skin, accompanied by fever, and occurring under similar circumstances, has been called by Dr. Underwood, who was one of the first to describe the disease, the *skin-bound disease*. This does not happen invariably, like the preceding complaint, within a short time after birth; for it has been known to attack infants above six months old. It is ushered in with violent fever, with coldness of the limbs, oppressed breathing, and almost constant moaning. The skin is of a yellowish-white colour, resembling soft wax in its appearance, and not only thickened and hardened, but evidently unyielding; the cellular membrane is fixed in such a manner that it will not slide over the subjacent muscles, not even on the back of the hands, where it is usually very loose and pliable. This stricture often extends over the whole body; but the skin is peculiarly rigid in the parts about the face, and on the extremities. The child is always cold, and whatever number of days it may survive, has constantly the appearance of being in a dying state. The stools are of a clayey colour and consistence; and the disease seems to be much connected with a disorder of the chylopoietic organs, especially of the liver. The free use of laxatives, together with the warm bath, and some cordial medicines, appears to have been occasionally successful; but in general, where the progress of the disease has not been arrested in the commencement, it has terminated fatally.

The most common affections of the skin, however, that occur in early infancy, are unaccompanied by fever, are productive only of slight inconvenience, without danger, and consist principally of certain rashes, or eruptions of papular or pustular spots. The most common of these is a papular eruption, which appears under a variety of forms, and has been called the *gum*, or technically *strophulus*. Dr. Willan has distributed these varieties of appearance under five heads: the most frequent of which is the *red gum* (or *red gown*, as it was formerly denominated, probably because the child's skin, thus variegated, somewhat resembles a piece of red printed linen), the *strophulus intermitens*. The *papule*, or pimples, in this affection, rise sensibly above the level of the cuticle, are of a vivid red colour, and commonly distinct from each other: their number and extent vary much in different cases. They appear most constantly on the cheeks, fore-arm, and back of the hand, but are sometimes diffused over the whole body. This eruption has not in general any tendency to become pustular, but usually terminates in scurf, or exfoliations of the cuticle. Its duration, however, is very uncertain: the papule and spots sometimes remain for a length of time without any alteration; sometimes disappear and come out again daily; but for the most part, one eruption of them succeeds another, at longer intervals, and with more regularity. The red gum occurs chiefly within the two first months of lactation: it is not always accompanied or preceded by any disorder of the constitution, but appears occasionally in the strongest and most healthy children. In many instances, it is connected with a weak irritable state of the alimentary canal, and consequent indigestion. For if it be, by any means, suddenly repelled from the surface, diarrhoea, vomiting, spasmodic affections of the bowels, and often general disturbance of the constitution, succeed; but as soon as it reappears, these internal complaints are wholly suspended. Dr. Armstrong and others have particularly noticed this reciprocation, which makes the *red gum* at times a disease of

some importance, though, in its usual form, it is not thought to be in any respect dangerous. On their remarks a necessary caution is founded, not to expose infants to a stream of very cold air, nor to plunge them unseasonably in a cold bath; the most violent and even fatal symptoms having often been the consequence of such imprudent conduct. Little need be said in regard to the treatment of the *red gum*: the common mild appearance of it, being consistent with a healthy state of all the functions of the body, requires no medicinal application. It is, however, advisable to keep the skin clear from *fordes*, and to promote equable perspiration. This may be done best by daily ablutions with tepid water, which prove useful in most cutaneous disorders, and will be found of considerable importance with respect to the general health of the infant.

The other varieties of *strophulus*, mentioned by Dr. Willan, are two, the *S. albidus*, or *white gum*, which differs from the former merely in the appearance of its papule, which consist of a number of minute, whitish specks, a little elevated, and sometimes, though not constantly, surrounded by a slight redness, occurring chiefly on the face, neck, and breast, and being more permanent than the papule of the *red gum*. 3. *S. confertus*, or *rank red gum*, sometimes also called the *tooth-reeb*, which usually takes place about the fourth or fifth month after birth, on the cheeks and sides of the nose, extending sometimes to the forehead and arms, but rarely to the trunk of the body, and accompanying the state of dentition; and in the seventh or eighth month assuming a somewhat different form, appearing in one or two large irregular patches, of a high red colour, on the arms, shoulder, or neck. 4. *S. voluticus*, which is characterized by small, circular patches, or clusters of papule, arising successively on different parts of the body, continuing red, with a little heat or itching, for about four days, when they turn brown, and begin to exfoliate; the successive patches, however, not ceasing to appear in less than three or four weeks. And, 5. *Strophulus candidus*, in which the papule are larger than in any of the foregoing species, have no inflammation round their base, and a very smooth and shining surface, whence they appear to be of a lighter colour than the adjoining cuticle; they are diffused, at a considerable distance from each other, over the loins, shoulders, and upper part of the arms. This eruption affects infants about a year old, and most commonly succeeds some of the acute diseases, to which they are liable, such as catarrhal fever, or inflammations of the bowels or lungs: the papule continue hard and elevated for about a week, and then gradually subside and disappear. See Willan on Cutan. Diseases, Order 1. Genus 1.

The *strophulus voluticus* being sometimes connected with a disorder of the stomach and bowels, it becomes requisite to administer a gentle emetic or some laxative medicines; after which the decoction of Peruvian bark will be found of advantage. No external application seems necessary. The *strophulus confertus*, when the child is otherwise healthy, is generally ascribed to a state of indigestion, or some feverish complaint in the mother or nurse: but the eruption is frequently seen when no such cause for it is evident. It may with more probability be considered as one of the numerous symptoms of irritation, arising from the inflamed and painful state of the gums in dentition; since it always occurs during that process, and disappears soon after the first teeth have cut through the gums. On this view the eruption requires no specific consideration in medical practice; it can only be alleviated by the general treatment proper for the state of teething, to be mentioned presently.

This species of *strophulus* appears under other modifications, which have been mistaken for measles. One very ob-

stinate and painful form of it is noticed by Dr. Willan, which takes place, though not often, on the lower extremities. The papule spread from the calves of the legs to the thighs, *nates*, loins, and round the body as high as the navel: being very numerous and close together, they produce a continuous redness over all the parts above-mentioned. The cuticle presently becomes shrivelled, cracks in various places, and finally separates from the skin in large pieces. During this process a new cuticle is formed, notwithstanding which the complaint recurs in a short time, and goes through the same course as before. In this manner, successive eruptions take place during the course of three or four months; and perhaps do not cease till the child is one year old, or somewhat more. Children necessarily suffer great uneasiness from the heat and irritation occasioned by so extensive an eruption; yet, while they are affected with it, they often remain free from any internal or febrile complaint.

This appearance, Dr. Willan remarks, should be distinguished from the *intertrigo* of infants, which exhibits an uniform red, smooth, shining surface, without papule; and which affects only the lower part of the *nates* and inside of the thighs, being produced by the stimulus of the urine, &c., with which the child's clothes are almost constantly wetted. Under the head of *intertrigo*, however, we must include all those varieties of *chafing* and *excoriation* which occur in those parts where the skin is folded, or in contact, and therefore liable to considerable attrition. (See *INTERTRIGO*.) From the delicate structure of the skin of infants, Dr. Hamilton observes, *excoriations* readily take place wherever one part of it is in contact with another, unless the most careful attention be paid to keep every part dry. The ears, neck, arm-pits, and groins are chiefly liable to be affected in this manner. When the excoriations are not allowed to continue for a considerable length of time, they seldom require any other treatment than being dusted, morning and evening, with prepared tully, or calamine, or with common ashes finely powdered, or a little hair-powder or starch. But when a discharge of matter is the consequence of neglected excoriations, a cure can only be obtained by much care and attention; for it is often very difficult to stop these runnings. Some practitioners have objected to such attempts, on the false supposition that the discharge is a salutary outlet for an overload of the system. Their opinions, admirably well calculated to favour the carelessness of nurses, are founded upon improper views of the operations of nature.

Many different remedies will be found beneficial in different cases of excoriation; such as washing the parts daily with brandy and water, lime-water, a weak solution of sugar of lead, or of white vitriol, and dressing them with any mild ointment, as spermaceti ointment, Turner's cerate, or ointments containing the oxyd of zinc, or a small portion of the ointment of nitrate of mercury. While these means are pursued, an open state of the bowels is to be promoted, by the occasional exhibition of any gentle laxative, as *manna* dissolved in water, &c. The use of mild mercurials, as alteratives, such as the *hydrargyrum cum creta*, &c. is likewise beneficial.

Some other slight eruptions, to which young children are liable, chiefly of the papular form, are mentioned by Dr. Underwood, and require no other treatment than an attention to the state of the bowels, or the use of some tesselaceous powders. See his Treatise on Dis. of Children, vol. i.

There is a very common eruption, says the writer just quoted, that calls for more attention, and to which medical writers have given the name of *crusta lactea*, (or *milk-blotches*, as Dr. Hamilton translates it,) "which has a very unpleasant appearance, but is, notwithstanding, equally innocent

with the former, and even prevents other complaints. I think I never saw an infant," he continues, "much loaded with it, but it has always been healthy, and cut its teeth remarkably well; indeed it falls to the lot of the finest children, and such as are well nourished; whereas some have imagined it owing only to the richness of the milk. And it is remarkable in this eruption, that howsoever thick and long-continued the scabs may be, the *crusta lactea* never excoriates, nor leaves any scar on the parts." It is not attended with any fever, or obvious derangement of the system. The crust appears first on the forehead, and often extends half way over the face in the form of large loose scabs. It is sometimes attended with severe itching. Practitioners in general affirm that medicines are not required, and are rather injurious than beneficial in this eruption; that mild laxatives, so as to keep the passage of the bowels free, may be employed, but that all active purgatives are to be avoided; and, lastly, that where there is excessive itching, some weak cooling allringent lotion, of the acetate of lead, or sulphate of zinc, should be applied to the parts. Dr. Underwood denies that the *crusta lactea* ever degenerates into scald-head, as some authors before him had mentioned. But Dr. Hamilton has pointed out a modification of *crusta lactea*, which frequently takes place during teething, and is a most obstinate and troublesome complaint. "This," he says, "is characterized by a redness of the skin round the edge of the incrustations; by an ichorous or clear-coloured exudation issuing from the surface of the scabs, which concretes, and which tends to carry the disease over every part of the face which it touches. There cannot be a doubt, indeed, that this form of *crusta lactea* is contagious, and nothing less than a variety of the scald-head, or *tinea capitis*, the *Porriigo* of Dr. Willan's nomenclature, in which this species is called *Porriigo larvacea*. The cure of this modification of the disease requires constant ablution with milk and water, thin gruel, &c., to remove the acrid fluid which exudes, and the application of some drying ointment. Some alterative preparation of mercury is likewise useful internally, such as the hydrargium creta, or the grey oxyd, followed by the vegetable and mineral tonics. See *Porrigo*."

Dr. Hamilton has stated the following practical conclusions respecting the eruptions of children in general. They may all be divided into two classes, he observes, the *first* of which are temporary, or of short duration; are commonly ushered in with symptoms of general indisposition, and are owing to some disorder of the stomach or bowels, or to some interruption of the usual excretions or secretions; the *second* are of an indefinite duration; break out gradually without any derangement of the ordinary health; and are probably, in most instances, the effects of some diseased condition of the lymphatic system, though, sometimes, they may be occasioned by a local affection of the skin itself. The treatment requisite in these two forms of eruption is thus stated. In the *first* class, where symptoms of indisposition, such as heat, restlessness, sickness, or oppression, are followed by an eruption, a brisk dose of calomel should be first ordered, together with the warm bath, and afterwards occasional purgatives, and a suitable regulation of the diet, are to be advised. But, in the *second* class, where the appearance of the eruption is unaccompanied by fever or marks of indisposition, some of the medicines called alteratives, and the daily use of warm bathing, particularly in sea-water, should be recommended. The medicines to which an alterative power is ascribed, he continues, are preparations of mercury, of antimony, of sulphur, and of neutral salts; and therefore calomel in very small doses, or antimonial wine, or the sulphuret of antimony, or Harrowgate or Cheltenham

waters, or some imitation of these, are the remedies to be chiefly depend upon. It is commonly necessary to order a protracted course of these medicines. In some cases, other topical applications (besides the warm bath) are necessary, to allay irritation, arising from excessive heat and itching of the skin. The most efficacious are liniment mixed with oil, a solution of potash, and the acetate of ammonia much diluted. The metallic solutions are too powerful to be employed, except upon very particular occasions. Issues have been often employed in these cases, but experience has proved that purging answers better. Very distressing effects have followed the application of a blister, where there was a tendency to chronic eruptions of the skin. Hamilton's Hints for the Treatment of the principal Diseases of Infancy and Childhood, p. 130.

§ 3. *Dentition*—It is generally admitted that the time of *teething* is an important period of the infant state, during which a number of disorders of a formidable character are liable to occur. Dr. Cadogan, indeed, and Dr. Armstrong seem to have entertained a somewhat different opinion upon this subject, and have ascribed the complaints, connected with the process of dentition, to some other morbid condition of the habit, such as too great fulness, or a corrupt state of the fluids; but this appears to be a difference only in terms, and implies an admission of the occurrence of the disease: alluded to. (See Armstrong on the Diseases most incident to Children, &c. p. 61.) It is certain that the natural process of dentition is productive of pain and indisposition in by far the greater number of instances: some infants, indeed, suffer less than others, but few enjoy perfect health while teething. We shall first describe the progress of the development of the teeth, and afterwards the ordinary affections which it excites in the constitution.

The *period of teething* is subject to considerable variety in different instances; but in the greater number of cases, the first pair of milk-teeth appear between the fifth and tenth month, and the last before the end of the second year. In some infants, however, the first pair or two are cut by the end of the third month; while, on the other hand, not a few attain the sixteenth or eighteenth month before a single pair appears. In general, those of the lower jaw are cut before the corresponding ones of the upper jaw; but sometimes the several pairs of the upper jaw are cut before those of the lower. The following is the order of succession in most instances: *viz.* first, the two middle fore-teeth of the lower jaw; then the corresponding pair in the upper; next follow the two adjoining teeth of the upper jaw; and, after these, the two next fore-teeth of the lower jaw; then come the two foremost grinders of the upper jaw, and after them the two anterior grinders of the lower jaw: the two eye-teeth make their appearance next; and some time after, the two opposite to them in the lower jaw; and finally, the posterior grinders. Of the first set of teeth there are twenty in all, but in some cases only sixteen: an interval of one, two, or more weeks is interposed between each successive pair; and there is commonly a longer interval between the first two pair than between the succeeding ones. Some children, however, cut their teeth cross, as it is called, or irregularly, the teeth appearing first in the upper jaw, and also at a distance, instead of being contiguous to each other; in some rare cases the grinders come out before the cutting teeth. This is accounted, and with some reason, an indication of difficult or painful dentition.

At birth the teeth are placed underneath the gums, and each tooth is inclosed in a fine membrane or capsule, which is supposed to be extremely sensible. This capsule, as well as the gum, must give way before the tooth can be protruded; and

and this is accompanied merely by the pressure of the enlarging tooth, which occasions the absorption of those parts. In favourable cases, the pressure of the teeth on the gums occasions pain, and an increased flow of the fluids furnished by the mouth. Hence the infant is fretful, restless during the night, drivels continually, and frequently thrusts his little hands, or whatever he can get hold of, into his mouth, to rub his gums; and he has occasionally sickness, gripes, and looseness. At last the corner of a tooth is perceived; but the uneasiness still continues for some days, when a second one is cut. During the interval between the cutting of the lower and upper teeth, he recovers his strength and usual good health; but is soon again subjected to the same uneasiness.

Were these the only complaints which attend teething, little danger might be apprehended; but sometimes many very formidable symptoms occur. In robust healthy constitutions, a violent fever frequently precedes the appearance of every tooth; the gums are swelled and inflamed, the eyes much affected, the belly bound, the skin hot; and there is every now and then continued screaming, with inability to suck, and the sleep is short and disturbed. Weakly infants, where teething is painful and difficult, are oppressed with sickness, loath all kinds of food, lose their colour, fret perpetually, have a constant looseness, and become much emaciated. Some, besides these symptoms, are subject to convulsions, which recur from time to time, till the tooth or teeth are above the gum. In others, cough, various eruptions on the skin, ulcerations in the gums, extending sometimes over the palate, oblitinate inflammation of the eyes, affections of the urinary organs, and sometimes most alarming determination to the head, are occasionally the effects of teething. All the symptoms are much aggravated, if several teeth be cut at once, or in immediate succession.

It is of great importance to be able to ascertain when any of the distressing symptoms, thus enumerated, arise from dentition. This is to be done by a careful examination of the state of the gums. Previous to the protrusion of any tooth, the seam, which may be distinctly observed on the edge of each gum, like a doubling of the skin, is done away, and the upper surface of the gum is rendered flat and broad, or is elevated in the form of a small swelling. The gum of the upper jaw is more apt to appear on the stretch than that of the lower. It is not easy to distinguish when the infant suffers pain from any part of the gum being pressed upon; otherwise that might assist in pointing out the advance of some particular tooth or teeth, because such a degree of fretfulness attends teething, that every attempt to feel the state of the mouth never fails to irritate the child.

An estimate of the danger attending dentition is to be formed chiefly from the nature of the symptoms. Experience proves that pany delicate infants often suffer less than the most healthy and robust. In this climate it has been found that summer is a more favourable season for teething than winter. Some infants cut their fore-teeth without any pain or difficulty, but are much distressed while cutting the grinders or eye-teeth; although, when the protrusion of the first two pair of fore-teeth is accompanied or preceded by great uneasiness, there is reason to fear that the individual will suffer during the whole period of teething: yet the converse of the proposition does not hold good; that is, where little derangement of health attends the first pair or two, it is not to be concluded that all the other teeth are to advance with the same facility. It is well known, that during teething every acute disease is more than usually dangerous; and it is also a well established fact, that infants, in a crowded

city, are more liable to pain and alarming symptoms at that time of life than those reared in the country.

The treatment of the ordinary complaints attending teething, should consist in moderating the pain, in regulating the state of the bowels, and in the continued employment of every means calculated to promote the general health of the infant. With these views, small quantities of anodyne balsam may be rubbed on the back-bone at bed-time, when the infant seems to be greatly pained. He ought to be fed with beef-tea twice a-day, if weakly, and if his bowels be loose; and should be kept as much as possible in the open air when the weather is favourable; the cold bath ought not to be laid aside in these cases, unless other concurrent disorders should render it necessary, as nothing is more conducive to promote general strength. Looseness, if excessive, must be moderated; and if the belly be bound should be artificially induced by gentle laxative medicines. When restles during the night, the child should be taken out of bed, and carried about in a cool airy room; and if not relieved in a short time, he ought to be put into a warm bath. Finally, he should be allowed something to rub his gums with, which will both gratify his wishes, and tend to promote the absorption of the parts inclosing the tooth. A piece of wax-candle, or of recent liquorice-root, is preferable to coral; though the latter substance is in no other respect injurious than that it may be, by awkwardness, forced into the nostril or eye.

The management, when alarming symptoms take place, must be varied according to circumstances; but in every case the indications to be fulfilled are, to cut asunder the parts which resist the protrusion of the tooth or teeth, and to palliate distressing or troublesome complaints. Some of these, which occur also under other circumstances, will be noticed immediately. See also DENTITION. Hamilton's Hints, &c. p. 73; *et seq.*

Canker of the mouth, cancrum oris, as it has been called, is most commonly connected with dentition; it is sometimes troublesome to remove, but commonly a trivial complaint. It sometimes makes its appearance in the first month, Dr. Underwood says; at others, about the time of teething; and frequently at the age of six or seven years, when children are shedding their first teeth, and the second are making their way through the gums. It consists of little foul sores covering the gums, and extending sometimes to the inside of the lips and cheeks. It is said to occur during teething most frequently where the gums have not been lanced. It is generally easily cured by keeping the body open, and by the use of some mild astringent application to the mouth. As much white vitriol, or rock alum, as will give a moderate roughness to a little honey, is usually sufficient for this purpose; or if it should not effect a cure when the complaint makes its appearance at the time of teething, it will generally go away as soon as the teeth are protruded. The worst species of this complaint, witnessed by Dr. Underwood, has occurred during the second period of dentition, when a child has been shedding a number of teeth together, leaving the decayed stumps behind, which have been neglected to be drawn out. The whole gums will then sometimes be spongy, or dissolve into foul spreading ulcers; and small apertures will be formed, communicating from one part to another, accompanied with an oozing of a fetid and sometimes purulent discharge. If the stumps of the decayed teeth are easily accessible, they ought to be extracted, and some astringent applications made to the parts, consisting of myrrh, Peruvian bark, alum, or crystals of tartar, made into a paste with honey of roses, or lotions made with the same ingredients, alluring tinctures, or mineral acids.

§ 4. *Bowel Complaints.*—Under this head we shall include

INFANTS.

the disorders of the whole of the alimentary canal, and of the organs connected with it, both by function and structure. These constitute, perhaps, the most important tribe of the diseases of children; inasmuch as they not only produce considerable distress by their direct effect in deranging the functions, but are likewise indirectly the source of numerous, fevers, and even fatal constitutional maladies, both chronic and acute. The disorders of the stomach, indeed, are seldom very formidable or troublesome in early life; but the derangements of the biliary secretion, of the intestinal canal, and of the mesenteric glands and absorbents, which are much connected with each other, are productive of much mischief during the whole period of infancy and childhood.

Sickness and Vomiting.—A slight degree of sickness is a very common occurrence in infants, as their stomach is so irritable, that it readily rejects any overload of food. But this spontaneous puking is attended with little violence to the stomach; the milk, or other aliment, seems to come up without any sensible action of the part, or any reaching effort of the child: and when the food is brought up immediately after sucking or feeding, and in an almost unchanged state, such sickness is observed to be not incompatible with a thriving state. Unless when the sickness is extremely violent, therefore, or long continued, it is seldom necessary to interfere. But when means are required to moderate or to allay it, we must endeavour to ascertain the cause of the vomiting, and apply them accordingly. The causes of sickness at the stomach in infants are either some altered condition of the nurse's milk, or the presence of some indigestible substance in the stomach. If the nurse have been under the influence of any violent emotion of the mind, or if she have begun to be out of order, or even to have the feelings preceding that event, it may be concluded that there is some morbid change in the milk. During the progress of teething, the increased quantity of saliva, together with its acrimony, proves occasionally the cause of sickness. In such cases the stomach may require the discharge of its contents by means of a gentle emetic: a little warm water or chamomile tea, or, at the most, some preparation of ipecacuan, will answer this purpose. Antimonials, in doses which excite vomiting, are frequently injurious to infants, and sometimes actually sink, with great rapidity, the living powers. When the vomiting is kept up by irritability of the stomach, which is sometimes the consequence of its actions having been disturbed by a cause already removed, slight cordials and aromatics may be given to strengthen the organ and abate its sensibility, and if these fail, some stimulant or anodyne may be applied externally.

It must be observed, however, that habitual vomiting from over-dilatation of the stomach, to which many infants are liable, may lay the foundation for future weakness of the digestive organs, and should therefore be guarded against by every precaution. For this reason, infants ought not to be allowed to suck too much at a time, and large quantities of spoon-meat should never be given in the early months.

Diarrhoea or Looseness.—The natural appearance of the stools of infants should be familiar to every practitioner. In general the colour is that of a bright orange, the consistence is pulpy and curdled, and the smell is not offensive. Any deviation in these respects marks some diseased state of the stomach or bowels. During infancy, from two to four evacuations, within the twenty-four hours, seem necessary and useful; and even where that number is exceeded, it is not to be regarded as injurious, unless the health be impaired, or the flesh be rendered flabby. The appearance of the stools, in cases of diarrhoea, is very various. When they are green, and at the same time emit a foul smell, which arises from the

prevalence of acidity in the first passages, there is generally griping and fretfulness, but the complaint is not dangerous. It generally yields to a laxative, or, in very young infants, to a medicine composed of a little magnesia and rhubarb, with a little distilled water of dill or penny-royal, with a few drops of ammoniacal spirit, or of the compound tincture of camphor. The nurse's food should be regulated in this case, and the infant ought to have no other food, in addition to the milk, than arrow-root.

Slimy stools are generally the effect of exposure to cold, though they occasionally arise from some irritation or accumulation in the bowels. In both cases they are apt to be slightly streaked with blood. If there be violent pain, or symptoms of fever, interfection is to be dreaded. A dose of cold-drawn castor oil, together with the warm-bath, or fomentation of the belly with flannels wrung out of hot water, are commonly all that are necessary, if the disease be attended to at the beginning. Where slimy stools are of the colour of clay, and emit a putrid smell, the infant soon becomes emaciated, and the disease often terminates fatally, though its progress be slow. Alteratives, with opiate frictions and occasional purgatives, afford the chief means of relief. If the infant be still at the breast, the milk should be changed, a practice which ought to be adopted in every instance where there is great tendency to looseness.

The most distressing cases of diarrhoea are those in which the stools are liquid, brown, black, or clay-coloured, and of an offensive smell. As the disorder proceeds, very unfavourable symptoms occur, such as emaciation and dryness of the skin, swelling or shrinking of the belly, with an altered appearance of the countenance; and there is a constant fretting or peevishness of temper. Swellings of the glands of the groin, and a little uneasiness of breathing, as if there were a slight tendency to cough, are also very unfavourable symptoms. In many of these cases the purging is the effect of a diseased state of some of the digestive organs, or of the mesenteric glands; but in others it arises from an irregular action of the former organs. In these disorders some practitioners begin the treatment by the use of emetics; but the advantages of these medicines are not very obvious, while the disadvantages resulting from their debilitating and irritating qualities in the stomach are sometimes unequivocal. On the whole, the continued use of alterative medicines, which maintained a steady but gentle action upon the alimentary canal and the adjoining viscera, seems to be the most successful treatment in these complaints; the physician, at the same time, correcting and modifying their operation according to circumstances, and palliating urgent symptoms. Part of the diet, in these cases, should consist of weak beef tea or chicken broth, with rice, or boiled cow's milk with baked flour, or arrow-root. The occasional use of injections of thin starch and laudanum, in the proportion of eight or ten drops of the latter to two table-spoonfuls of the former, may be employed to moderate the discharge when the strength is much reduced.

Of the severe and often fatal species of diarrhoea, just alluded to, there is one form which is known in Scotland by the name of the "*weaning brash*," and which has been well described by Dr Cheyne. (Essays on the Diseases of Children. Ess. ii.) It occurs after weaning a child too suddenly, especially at an unfavourable season, as the autumn. It commences, sometimes two or three days after weaning, but frequently not for three or four weeks, with a purging and griping, and green stools. This, being erroneously ascribed to teething, is perhaps neglected, and the symptoms increase, a retching and vomiting supervene, and are gradually followed by a loathing of every kind of food, emaciation.

emaciation and softness of the flesh, restlessness, thirst, and fever of a hectic character. But the most characteristic symptom of this disease is a constant pœvilinefs, the effect of unceasing griping pain, expressed by the wime of the child, but especially by the settled discontent of its features. In the progress of the disease, the evacuations from the belly shew very different actions of the intestines, and great changes in the biliary secretion; for they are sometimes of a natural colour, at other times slimy and ash-coloured, and sometimes lienteric. The disease seldom proves fatal before the sixth or seventh week; but sometimes an earlier termination is suddenly produced by incessant vomiting and purging, or by convulsions, from the extreme irritation in the bowels.

By dissection Dr. Cheyne ascertained the state of the viscera in children who had died of this disease. In every case the intestinal canal, from the stomach downward, abounded with singular contractions, and had in its course one or more intus-susceptions; the liver was exceedingly firm, larger than natural, and of a bright red colour; and the gall-bladder, which was enlarged, contained a dark-green bile. In some dissections the mesenteric glands were found swelled and inflamed; in others, however, they were scarcely enlarged, and had no appearance of inflammation. It is probable, therefore, that this disease is owing to an increased secretion of acrid bile, or rather to the morbid state of the liver which occasions this; and that the extremely irritable state of the whole abdominal viscera, marked by the spasmodic contractions and intus-susceptions, &c. is occasioned by the presence and passage of this acrid excretion.

As the exciting cause of this *weaning brash* is apparently too sudden an alteration of the diet of a child at an unfit season, it follows that children ought at all times, but more particularly in the autumn, to be weaned gradually, and well accustomed to the food on which they are afterwards to subsist before they are finally taken from the breast. At the beginning of the disease, or even later, when the attack is slight, Dr. Cheyne recommends a dose or two of rhubarb, to the extent of five or six grains, at the interval of two days between each dose; and that, in the mean time, the child should take half or a third part of a grain of ipecacuan powder, mixed with six or eight grains of prepared chalk, and a small portion of some aromatic powder, as cassia, every four or five hours. A starch glyster, with five or six drops of laudanum in it, may be administered at bed time with advantage, if there be much griping along with the purging. The success of these remedies, however, will depend upon a strict attention to diet. An animal diet produces less irritation than one which is solely composed of vegetable matter. Eggs, the finer kind of light ship-biscuit, or arrow-root, custard, the juice of lean meat, plain animal-jellies, broths freed from their oily part, and milk, are proper articles of nourishment. The breast milk might perhaps be restored with advantage. Vegetables of all sorts, particularly fruits, acids, and compositions of which sugar or butter form a part, and fermented liquors of every kind should be strictly prohibited. The feet should be kept warm by woollen stockings, and flannel worn next the skin; and the warm bath and fomentations may be frequently used to alleviate the continual spasms. Dr. Cheyne, however, taught by subsequent experience, recommends small doses of colamel as the most effectual remedy against the weaning brash, and other chronic forms of bilious diarrhœa. He generally gave half a grain of colamel, morning and evening, or a grain every night, for a week or ten days. After the third or fourth dose there is generally a

great change, he says, in the colour of the alvine discharge; it becomes of a dark mahogany colour, and is in general more offensive. When this change takes place it produces a favourable change in the disorder. Soon afterwards, the children become free from fever, more placid, and in a day or two more their appetite returns, with their former complexion, and every other demonstration of health. He never found, he adds, in the many cases in which he has given colamel, that it produced salivation, or any other unpleasant effect. Cheyne, *Essay* ii. On the Bowel Complaints more immediately connected with the Biliary Secretion.

Costiveness.—This opposite condition of the bowels, though seldom occurring in young infants, is productive, in children a little more advanced, of many distressing complaints. Some infants, indeed, seem to be habitually costive; and there is certainly a considerable variety, in respect to the state of the bowels, in different individuals. But what may be properly termed costiveness is never to be regarded as a natural deviation peculiar to any infant: it is always the effect of disease, or of the nurse's milk, or of the food. If one copious evacuation take place every twenty-four hours, and the infant be thriving, there is no occasion for interference; but if there be any greater torpor of the bowels than this, suitable remedies are to be employed. It is generally proper to treat the case at first as if it were the consequence of disease; and on this account a brisk laxative may be given every day, for four or five times successively. The best laxatives for infants are manna, calcined magnesia, colamel, and cold drawn castor-oil; and Dr. Hamilton recommends a laxative syrup, prepared with treacle and a strong infusion of senna.

Where these means fail, there is reason to attribute the costiveness to the nurse's milk. Sometimes that peculiar state of the milk may be altered by regulating the diet, and opening freely the bowels of the nurse. While proper means are tried for this purpose, the infant's bowels are to be kept clear by some mild laxative. But if it be found that the milk still possesses that injurious quality, the nurse should, if possible, be changed. Where this cannot be done, four or five drops of antimonial wine may be given to the infant every night at bed-time, and instead of the ordinary food, panada, made with small beer and treacle, should be substituted.

Temporary costiveness may be at any time removed by a suppository, made of a small piece of yellow soap, shaped like a very large Dutch writing-quill. This may be rendered more powerful, if necessary, by being dipped, previous to use, into some powdered sea-salt. Suppositories are more efficacious in infants, and much more easily managed than glysters, though these latter means are also sometimes useful. In cases of obstinate constipation, attended with symptoms of great oppression, aloës, suspended in treacle or syrup, is more powerful than any other laxative; from four to eight grains may be thus given for a dose. Many practitioners err, Dr. Hamilton affirms, by directing too small doses of laxative medicines for infants.

At a more advanced period of childhood, a morbid state of the alimentary canal, of which *costiveness* is a conspicuous symptom, frequently occurs, and is the source of several varieties of disease, both chronic and acute, which constitute perhaps the most frequent maladies of the puerile age. The first of these, to which we shall direct the attention of the reader, has been called, by Dr. Hamilton, senior, physician to the Royal Infirmary at Edinburgh, marasmus. See his *Observations on Purgative Medicines*, chap. iii. edit. 2d.

Marasmus includes a variety of symptoms which affect children of both sexes. The disease steals on gradually, and the following are the early symptoms by which it is characterized: a sluggishness, and lassitude on slight exertion, depravity and loss of appetite, a flabbiness and wasting of the muscular flesh, fulness of the features, and paleness or paly colour of the countenance, swelling of the upper lip, a constant itching of the nose, foetid breath, with a swelling of the belly, an irregular and generally costive state of the bowels, and a change in the colour and odour of the feces. When these symptoms have continued for some time other more urgent complaints ensue. There is an alternate paleness and flushing of the countenance, followed by heat and dryness of the skin, feeble and quick pulse, thirst, great fretfulness, increasing debility, and disturbed sleep, during which the little patients grind or gnash their teeth, and are subject to involuntary starting, and twitching of the different muscles, and, when awake, to a constant picking of the nostrils or lips, or even of the eyes, and to involuntary gesticulations, approaching to convulsions.

Every case of *marasmus* does not necessarily include all these symptoms; for they occur in different combinations. The disease appears most commonly among weak and infirm children, whether they are so from delicacy of constitution, or from incidental causes. It is particularly prevalent in large and populous cities, where children are deprived of ready access to exercise in pure air, and sicken and pine in the nursery; or when they are confined in crowded and airless school-rooms, whither they are sent, partly for the purposes of education, and partly, to use a common phrase, with the view of being kept out of harm's way. Children also, who are employed in manufactories, where their occupation and confinement are such as to weaken and enervate them, are liable to be attacked with this disease. Irregularity in diet and improper food also give rise to *marasmus*. It is accordingly observed to prevail most in the summer and autumn, the seasons which afford an opportunity of eating unripe fruit and vegetable articles from the garden.

Marasmus has generally been attributed to the presence of worms in the alimentary canal. But the *ascarides*, which are often passed in great numbers by children, are not accompanied, except incidentally, by the symptoms of *marasmus*; and the *taenia*, or tape-worm, is altogether unknown in infancy and childhood. The *lumbricus*, or round worm, must therefore be the generally supposed cause of the symptoms of *marasmus*. But the disease occurs, in numerous instances, and is cured, when no worms are seen; and, on the other hand, the presence of *lumbrici* in the bowels is by no means an uniform cause of bad health, and has been frequently noticed when *marasmus* did not occur. Various anthelmintic medicines, however, have been successively in vogue for the cure of the disease, upon the supposition of the existence of worms; but the utility of such of them as have been found to be most beneficial, Dr. Hamilton believes to have been in proportion to the purgative powers which they possessed. He says, "when I consider the languor and lassitude which precede this *marasmus*; when I recollect the constitutional or acquired debility of those who are more particularly exposed to be affected by it; instead of adopting the common opinion of its being occasioned by worms, I am more disposed to think, that a torpid state, or weakened action of the alimentary canal, is the immediate cause of the disease; whence proceed costiveness, distention of the bowels, and a peculiar irritation, the consequence of remora of the feces. I have accordingly been long in the habit of employing

purgative medicines for the cure of this *marasmus*; the object is to remove indurated and foetid feces, the accumulation perhaps of months; and as this object is accomplishing, the gradual return of appetite and vigour mark the progress of recovery." *Obs. on Purg. Med.* p. 51.

Since the practical conclusions are the same, it is not of material importance by what theoretical views they are supported; but we accord with the following observations of Dr. Hamilton, junior, (professor of midwifery at Edinburgh, whose excellent "Hints for the Treatment of the principal Diseases of Infants, &c." we have before quoted.) "There can be little doubt," he says, "that neither the mere accumulation of the stools, nor the torpor of the bowels, on which that appears to depend, can explain the various symptoms produced by this condition of the digestive organs. There is every reason to suppose that there is an altered action, not only in the stomach and intestines, but also in the liver and lacteals, perhaps in all the parts concerned in the digestion of the food. When this has continued for a certain time, the accumulation of acrid matter, which is the consequence, adds greatly to the irritation, and while all this is going on, the circulating juices become depraved." *Hints, &c.* p. 113.

In the treatment of *marasmus*, then, the leading objects are, to remove the accumulating mass of morbid and irritating feces from the bowels, to alter the morbid actions of the digestive organs, and to palliate the distressing symptoms which occur. The two first, which are the curative indications, are both fulfilled by a steady and persevering administration of purgative medicines.

In the incipient stage, while the disease is mild, the bowels are not altogether torpid and inactive, neither are they overloaded with accumulated feces. Mild purgatives, therefore, repeated at proper intervals, effect a cure. They preserve the bowels in proper action, carry off feces which had begun to be offensive and hurtful, and prevent farther accumulation. The disease yields in a few days to this treatment, and all that is farther required is some tonic medicine, which shall strengthen the stomach and bowels, together with a due regulation of diet, and occasionally a purgative at bed-time, the patient being likewise much in the open air. Preparations of iron are found the best tonics in these cases; and children readily take the wine of iron, or the filings covered with sugar. In selecting the purgatives, it is necessary to flatter the taste of our young patients. Powder of jalap is not altogether unpleasant; the mild neutral salts, dissolved in a suitable quantity of beef-tea, are also convenient purgatives; but calomel will prove, on several accounts, the most certain and useful remedy of this kind.

When the continued stage of *marasmus* has been allowed to arrive, manifest danger threatens the young sufferer, whose remaining flesh and strength are rapidly wasted by the supervening fever; while prostration and depravity of appetite withhold necessary nourishment, and at the same time the more inactive state of the bowels, and greater bulk of feculent matter, throw additional difficulties in the way of a cure. Under these circumstances, an active practice should be adopted, with the view of stimulating the intestines, and of putting the collected mass in motion without delay. These ends are best obtained by giving small doses of the purgative medicine, and by repeating these frequently, so that the latter doses may support the effects of the preceding ones. When the bowels are once opened, stronger purgatives, given at longer intervals, will accomplish the cure.

While the purgative medicines are thus exhibited, it is absolutely

absolutely necessary, in order to have full information of their effects, to inspect daily what is passed by stool. The smell and appearance of the feces are a criterion of the progress that is made in the cure, and direct the farther administration of the purgatives. This inspection is the more necessary, as we cannot expect the information we want from our little patients, and we shall often look for it in vain from the attendants, whose prejudices, and whose ignorance of our views, prevent them from seeing the propriety of the inquiry. During the prevalence of this disease, the feces are dark, fetid, and varying from a costive consistence to that of clay, and are often fluid; and such they appear upon the first exhibition of the purgative medicines. It may be observed, that the recovery of the sick keeps pace with the return of feces of a natural colour, form, and smell,—a change which the repetition of purgatives does not fail to produce.

While the purgatives are given in this manner, in the confirmed state of marasmus, in which the obliquity of the disease is sometimes great, and the danger attending it imminent, nourishing food, of light and digestible quality, and suited to the taste of the patient, and the moderate use of wine, are much required. For some time after the symptoms have disappeared, it is expedient to continue a mild stimulus to the bowels. As they have recently suffered, and have been weakened by over-dilatation, they are apt to favour subsequent accumulation of feces, the forerunner of a relapse, which is to be dreaded the more, as the patients have been weakened by the previous disease. And so far from being attended with any danger, this gentle sollicitation of the alvine discharge, (for it ought to be gentle,) is the greatest promoter of recovery. (Hamilton's Obs. on Purg.) At the close of the disease, strengthening medicines, such as chalybeates, and the infusions of bitter vegetables, may be employed with some advantage to complete the cure.

As *marasmus* proceeds from symptoms of slight indispotion, which are easily obviated by proper stimulus and evacuation of the bowels, through a series of others which become daily more and more obstinate and dangerous, the health of children should be watched with great assiduity. Proltration and depravity of appetite, a changing complexion, tumefaction of the abdomen, scanty and unnatural stools, and fetid breath, indicate approaching danger. When these, therefore, are observed, the assistance of medicine should be resorted to, by the prompt use of which much eventual distress, and even death itself, may be prevented. But other considerations call for this assiduity. *Marasmus* has a close connection with some other formidable diseases, and either precedes or seems to accompany them; of these we may notice more particularly two, *hydrocephalus* and *epilepsy*.

Of the *HYDROCEPHALUS internus*, the bane of infancy and of childhood, we have given an ample account under its proper head. The pathology of the disease has been the subject of much variety of opinion, and is still involved in some obscurity. Thus much, however, is known, that it often steals slowly on, with symptoms resembling those of incipient marasmus; and that where it has been believed to exist, from the presence of some of its most characteristic symptoms, a diligent exhibition of purgative medicines has succeeded in restoring health. Too much attention, therefore, cannot be paid, to prevent the confirmed state of marasmus. See *HYDROCEPHALUS*.

Epilepsy, which is a disease most distressing to the patient, and perplexing to the physician, also often appears in childhood. It is confirmed by the repetition of the fits, till their

frequency and the force of habit fix it, and make it a constitutional disease for life. Now it is generally understood, that the first attacks of epilepsy are not always idiopathic, but are frequently the effect of particular irritation of the body or mind. There are numerous instances, indeed, of irritation of the body inducing epilepsy; and, in children, when no other is evident, the loaded intestine, and the morbid change induced in its contents, in the course of the marasmus above described, may be suspected of giving the irritation in question. In fact, worms in the intestines (or *marasmus*, for we may thus interpret the language of medical writers) have been mentioned among the causes of epilepsy. Surely, therefore, this consideration suggests another cogent reason for watching the rise and progress of marasmus: and it will induce us, on the first attack of epilepsy in children, arising from an uncertain cause, to set on foot a decided and active course of purgative medicines; and not to incur the risk of allowing the disease to strike root, while we are idly employed in the exhibition of inert and useless vermifuge medicines; or are groping in the dark in quest of other causes of the disease, or of uncertain remedies for their removal.

Colic pains are not uncommon in infants at the breast; for the denecy of the bowels renders them liable to be affected by the most apparently trifling causes. Hence exposure to cold, inattention to changing the clothes when they become wet, too great a quantity of spoon-meat, some fault in the milk, too large doses of magnesia, and a collection of acid slime, or of air in the stomach and bowels, may severally be productive of this complaint. If an infant be fretful by fits, or at intervals, if its upper lip look bluish or livid, if it writhe or contort its body, and draw up its limbs towards the stomach, and more especially if it occasionally pass wind, which seems to afford relief, there is good reason to suppose it affected with *colic*. The lesser degrees of this complaint are of temporary duration, and so well understood, that a medical practitioner is seldom consulted on the subject. But the more violent degrees assume an appearance, which seldom fails to occasion much anxiety and alarm. Excessive and long continued shrieking, great fever, indicated by the heat of the skin and flushing of the face, oppressed breathing during the intervals of the screaming, and the evidence of pain being occasioned by the slightest pressure on the belly, are the ordinary symptoms in such cases.

With respect to one of the causes of colic above-mentioned, the exhibition of too much magnesia, it may be observed, that many women, from the best motives, but the most improper views, torment their infants with the frequent administration of this drug: because it has little taste, they naturally imagine that it can do no injury. But its operation depends on its undergoing a change, by combination with acids, in the stomach and bowels, which gives it the same properties as the laxative salts; and it is obvious, if too large a dose of these occasions colic pains in grown persons, the magnesia must, when given in too great quantity, or when there is much predominant acid in the first passages, produce the same effects in infants. Too much sugar, put into the meat of children, tends to generate much acid; whence it gives occasion to these pains, as well as to the green colour and sour smell of the stools, the green colour being occasioned by the mixture of an acid with the bile.

In slight degrees of colic, a few drops of Dalby's carminative, mixed with sugar and water, and a dose of cold drawn castor-oil, if the bowels be confined, are all that are necessary. The too common practice of giving spirits and
water

water to infants cannot be reprobated in terms sufficiently strong. Professor Hamilton asserts, from his personal knowledge, that many infants are essentially destroyed in Edinburgh by this most unnatural practice; and we have too much evidence that the same practice is constantly resorted to by nurses on this side the Tweed. The best mode of preventing slight degrees of colic, is to take care that the infant do not suck too much at a time; to prevent the discharge of any air that may be swallowed while suckling, by gently tossing the child now and then before his next cibé shall be taken; to prepare the cavity of the stomach to the powers of digestion; and to regulate the diet of the nurse, as it is now well known, that after certain articles of food, (such as particular kinds of malt-liquor and of vegetables,) a great deal more air than usual is separated during digestion from the milk.

In the more violent degrees of colic, the treatment must be varied according to the circumstances of the individual case. If it seem to arise from the accumulation of flime, or from some fault in the milk, saltable doses of cold drawn castor-oil, or magnesia and rhubarb, together with the warm-bath, or fomentations of the belly, are to be employed. But if the bowels be quite open, and the complaint have been evidently excited by exposure to cold, or some external circumstances; along with the warm-bath or fomentations, opiates, in the form of anodyne balsam, rubbed on the belly, may be safely prescribed. Preparations of opium should almost never be given internally to infants, as they may do, and have done, irreparable mischief. Dr. Hamilton recommends the tincture of *hyoscyamus* as a substitute. When constipation attends colic, the most active means of opening the bowels are to be resorted to. For this purpose even large doses of calomel, followed by cold drawn castor-oil and laxative glysters, are sometimes insufficient, and more powerful purgatives must be devised.

Introsusception, or intus-susception, is a very dangerous disease, which resembles colic so much, that it sometimes requires great practical discernment to draw the line of distinction between the two diseases. This disorder consists of the passage or inversion of one portion of the intestines into another, together with a stricture and consequent inflammation in the intro-suscepted portion. Sometimes these are such as to close the canal; but in other cases, the passage through the gut, though narrowed, remains free. *Introsusception* is occasioned by violent irritation and spasmodic action of a part of the gut, and this may be excited by worms, by morbid feces, or undigested aliment, by drastic purgatives, &c.; whence it is sometimes the consequence of colic.

If, along with the ordinary symptoms of very violent colic, the pulse be unusually slow, or if there be urgent calls to void the stools, and nothing but slime, or slime tinged with blood be passed, there is much reason to dread the existence of this disease.

When *introsusception* is discovered at the beginning, it often yields to the use of leeches, warm fomentations, and a medicine calculated to excite both vomiting and purging. But if its nature be overlooked or misunderstood, even for a few hours, the fatal event can hardly be prevented. A discharge of blood from the bowels, but more often stupor and occasional convulsions, precede death. Hamilton's "Hints." See also the surgical article *INTRO-, OR INTUS-SUSCEPTION*.

Prolapsus ani, or falling down of the gut, that is, a partial eversion of the rectum, or straight gut, through the fundament, is a common effect of bowel-complaints in weakly children; and seems to consist of a relaxation of the gut, which is forced downwards by any irritation that excites constant or frequent efforts to expel feces, followed by some

degree of spasmodic stricture in the *sphincter* muscle, which prevents it from returning. It is generally of temporary duration only, and is easily replaced by slight pressure. Nurses commonly apply a piece of woollen cloth or a napkin for this purpose; but, Dr. Hamilton says, a better plan is to lay the child upon his face, to separate his thighs, and then to press together both his buttocks. If these means fail, it becomes necessary to introduce the fore-finger, previously greased, into the gut, to remove the stricture from the sphincter. This is a more safe and speedy method than the application of astringent substances to the protruded parts, which might irritate or inflame them. With the view of preventing the frequent recurrence of this most unpleasant, though not dangerous complaint, all irritations of the bowels ought to be guarded against; the water should be dipped twice a day into a tubful of cold water, in which a red-hot iron had been frequently quenched, and the child ought to be made to sit regularly on a firm hard seat. In some instances the relaxation of the part becomes so great, that the gut descends every time the child goes to stool. In this case, astringent lotions, applied by means of a compress of soft tow, have been resorted to with success; or suppositories of various substances have been introduced into the bowel after going to stool, giving a mechanical support to the parts.

Worms in the intestines, although commonly supposed to be the cause of all the varieties of *marasmus*, are much less frequent causes of disease in children, as we have above stated, than other morbid charges in the digestive organs. None of the three varieties of intestinal worms, however, are peculiar to children; and the *tania*, or *tape-worm*, is seldom, if ever, found in infants. Of the *ascarides*, or small thread-worms, as they have been called, a full account has already been given; and a description of the *lumbrieus*, or round-worm, will be found under its proper head. For the symptoms of worms, as they are commonly related, see the foregoing history of *Marasmus*.

§ 5. *Febriæ Dysæstæ*.—Infants and children are liable to most of the fevers which affect adults, both contagious and non-contagious; although within the first eight or ten months they are not so susceptible of the influence of contagion, as they afterward become. A sucking child will sometimes escape the infection of scarlet-fever, measles, and even the small-pox, which seizes the rest of a young family. Each of the diseases just mentioned, as well as the whooping-cough, chicken-pox, and catarrhal fevers, which are among the disorders, which children seldom escape, are sufficiently important for separate consideration respectively. (See FEVER, *Scarlatina*, MEASLES, SMALL-POX, PERTUSSIS, VARICELLA, and CROUP; also COW-POCK.) Our attention, in this place, will be chiefly confined to a form of fever, which is in some measure peculiar to infants, and is now generally known by the name of "infantile remittent fever."

The *infantile remittent fever*, or *febris infantum remittens*, as it was first denominated by Dr. Butcher, might perhaps have been included without impropriety under the foregoing section, among the disorders originating in the bowels; for it is now pretty generally understood, that this fever is connected with a morbid state of the excretions in that canal. As the *marasmus*, above described, has been commonly attributed to the presence of worms in the intestines; so this fever has been ascribed to the same cause, and has been called the *worm-fever*; partly, it would seem, from the occasional discharge of worms during the course of the fever, and partly from the sameness of the symptoms of irritation in the bowels, from whatever cause it may arise. This fever was called *Hæctica febris infantum* by Sydenham, and *Hæctica infantilis* by Sauvages, from the slow and moderate progress which it com-

INFANTS.

monly makes; and for the same reason, Hoffman gave it the appellation of *Febria lenta infantum*.

The fever in question is most commonly preceded for some days, and occasionally for weeks, by symptoms of indigestion, much resembling the early symptoms of *marasmus*. The child is observed not to look well, and his colour often changes. He is indolent, spiritless, and fretful; frequently picks his nose, lips, and fingers, even sometimes till he draws blood: his breath is offensive, and he is affected with a short dry cough. If he can speak, he complains of pain in his head, or belly, or both; and when still older, he says also that he is faint and weak. He has a desire for drink more than for food; is much troubled with wind; and his belly is sometimes larger than natural. In his sleep, he flirts, moans, and makes a grating noise with his teeth. His urine puts on a milky appearance almost as soon as made, and, in a few minutes, deposits a sediment of the same colour, leaving the body of the urine with very little colour. His bowels are generally in the extreme, being either colic or loose.

After these symptoms have continued for a longer or shorter time, the fever makes its appearance, sometimes preceded by a distinct cold fit, at other times, however, gradually in its approach, that the commencement is not observed. It always assumes more or less of the remittent form, when it is distinctly seen, and the exacerbations are long, and the remissions short, in proportion to the violence of the fever. During the exacerbation all the symptoms are increased; there is great heat of skin, and the patient is drowsy, and sleeps, but not soundly; for he flirts, moans, talks incoherently, and even screams in his sleeps. The wind is particularly troublesome, makes a rumbling noise in the bowels, and is exploded copiously both upwards and downwards, with manifest relief. The cough is more frequent, and the breathing is quickened and oppressed. The patient is often sick, and sometimes retches, and even vomits phlegmy stuff of various colours. The pulse beats from a hundred and forty to a hundred and sixty pulsations in the minute. In the remissions, all the symptoms abate. The patient is wakeful, is attentive to things around him, often inclines to be playful, and is in general averse to lying in bed. What sleep he has is usually composed. The pulse beats from a hundred and twenty to a hundred and thirty strokes in a minute.

These exacerbations and remissions often occur with a considerable degree of regularity; the exacerbation generally beginning in the evening, and the remission taking place in the morning; but in the more acute form of the disease, there are one or two shorter exacerbations during the day. In the latter case, both in the exacerbations and remissions the skin is commonly dry: when sweats happen, they are partial, affecting only the head, breast, or palms. The belly and palms are always warmer than any other part of the body. Where there is only the nocturnal exacerbation, it is usually terminated by a profuse sweat; and through the day, the skin is temperate, but feels dry and harsh. The patient has no appetite, and scarcely any thirst; so that in many cases, it is with great difficulty that he can be made to take either food or drink. The state of the bowels is uncertain; but the stools are always unnatural, either as to their colour, consistence, contents, or smell; most commonly they are morbid in all these respects; for they are either whiter or darker than natural; they are always more offensive; are seldom without a great deal of slime, and sometimes consist of nothing but slime: sometimes they froth and ferment like yeast.

The patients frequently pass worms in the course of this fever, even when they were never known to void any before. These worms are not only thrown off by vomiting and stool, but are sometimes observed to work themselves out of the body both ways, seemingly unassisted by any exertions on the part of the patient's organs. But in many cases of this fever, no worms are ever seen.

When the fever is on the decline, the exacerbations grow milder and shorter, and at length disappear one after another; the appetite returns by degrees; the sleep becomes calm and refreshing, attended with a general moisture of the skin, and the stools approach more and more to the natural state, till they become as in health. The duration of this fever, in its more acute form, is from eight or ten days to a fortnight or three weeks; in the more slow and mild form, it will last for two or three months or more.

That the cause of this remittent fever of children lies in the alimentary canal, and is of the same nature with that from which *marasmus*, and several other infantile diseases originate, has not been doubted since it was so well pointed out by Dr. Butter. It is proved, in the first place, by the similarity of the symptoms with which it is preceded and ushered in, and, secondly, by the nature of the alvine discharges during its continuance, but more especially by the success of the practice, which is founded upon this principle, and consists in carrying off the accumulation of morbid excretions from the bowels, and augmenting their strength. The same cause operating in different constitutions, will produce a different series of symptoms; and it is probably from the peculiar irritability of habit in some children, that this fever is produced, by the same morbid secretion and accumulation in the *primæ viæ*, which give rise to *marasmus*, and other chronic maladies in others. "It may be accelerated by cold, fatigue, or the like," says Dr. Butter, (speaking of the remittent fever,) "but the principal causes are crude accumulations in the first passages, which, with a very irritable predisposition, draw the intestinal canal into spasm, &c." whence the irritation is communicated to the rest of the body, and general fever induced.

Cure of the infantile remittent fever.—The two principal indications of cure are, to allay the febrile irritation, and to remove the great irritating cause; the former of which, although in a great measure palliative only, is an object of considerable importance. It is extremely desirable, therefore, that from the first occurrence of the febrile symptoms, the child should be kept still, and quiet, in a chamber which is of a cool temperature; that all solid food and stimulating drink should be cautiously abstained from; and the sole support of the patient be diluting and nourishing liquors, such as small broth, gruel, and barley-water.

The second, or proper curative indication, is fulfilled by such medicines as keep up a constant gentle action upon the bowels, and contribute at once to dislodge the morbid accumulation, and to correct the morbid condition, of the alvine excretions. This purpose may be effected either by the neutral salts, or by small doses of mercurial laxatives, especially in combination with absorbents. Dr. Butter gives the preference to the former; and commonly employs the *polychrest salt*, which promotes both urine and stools. For a child of five years old (and proportionally for a younger or older subject) he dissolves a drachm of this salt in a quarter of a pint of water, sweetening it with two drachms of sugar. Of this mixture two spoonfuls are administered every four hours, or at such intervals, when the child is awake, that the whole may be finished in twenty-four hours. This medicine is to be repeated daily, so as to promote one, two, three,

three, or four stools, according to the circumstances of the case, the larger number in the more acute forms of the disease. When the fever is attended with a looseness, Dr. Butler interdicts the use of the neutral salts, and prescribes the extract of hemlock (*Conium*, Linn.); the quantity of five grains to be taken in the course of 24 hours, suspended in water with a little sugar. It relieves every symptom of the fever, he says, and at the same time gradually carries off the looseness. Under similar circumstances, we have seen essential service from small doses of some mercurial, combined with absorbents, as the *Hydrargyrum cum Creta*, of the London Pharmacopœia; or a grain of calomel united, by rubbing, with a little soda and terebaceous powder. While the *conium* is given as above-mentioned, as much rhubarb may be administered as will keep the body gently open, where the fever is not very acute.

When there is great restlessness and vociferation, the belly should be fomented with flannel cloths, wrung out of a decoction of chamomile, and applied agreeably warm, for twenty minutes or half an hour at a time, as occasion may require; and this operation should be repeated as often as the symptoms return. As the disease declines, the child may be allowed to return gradually to his usual diet and way of life; but some care will be requisite, that he may not have his free liberty as to eating, drinking, and exercise, until he has recovered his full flesh and strength; and the medicines above recommended must be continued till the fever is quite gone.

Catarrhal fever is not a very frequent disease during infancy, and when it does occur, seldom requires any other treatment, than an emetic at the beginning, an open state of the bowels, and the warm bath every night while it continues. When it extends to the degree of pulmonary inflammation, blistering the chest is often an effectual remedy, or, in strong children, the application of leeches to the chest may be resorted to. The principle of treatment, indeed, is the same in these complaints, whether they occur in the early or later periods of life; except that the infantile constitution is more easily acted upon by remedies, and therefore that a laxative and a blister will often accomplish a degree of alleviation of fever, which more active measures will be required to produce in adults. See CATARRH and PERIPNEUMONY.

Among the fevers incident to children, the *acute hydrocephalus*, or water in the head, should be described; but we have already given the history of that important disease in its place. (See HYDROCEPHALUS.) It remains for us to say a few words on the subject of convulsions.

§ 6. *Convulsive Diseases*.—The subject of convulsions, in general, has been treated under its proper head, (see CONVULSIONS,) as well as the most severe modifications of convulsive disease, the epilepsy and St. Vitus's dance. (See EPILEPSY and CHOREA.) It will, therefore, be sufficient to state here some circumstances relative to the convulsions of infants in particular. And first it must be observed, that, in consequence of the peculiar susceptibility of impression in the nervous system of infants, many circumstances excite convulsions at that early age, which have no such effect at a subsequent period of life. Accordingly it is well known, that in general the younger the infant is, the more readily do fits occur, and that some families are more liable than others to the disease, apparently from a weak state of the nervous or vascular system being communicated from the parents. The obvious exciting causes are dentition, mechanical injuries, acute diseases, impurities of the air, passions of the mind, indigestible or poisonous substances in the stomach or bowels, over-dilatation of those organs, irritations in them from acrid matter or worms, the state of the system previous

to the appearance of small-pox, measles, &c. All these act by disturbing the nervous system, and altering or deranging the actions of the vessels.

In some cases convulsions come on suddenly; the infant, from being in the most perfect health, turns in a moment livid, his eyes and features are contorted, and his limbs and whole frame are thrown into violent agitations. These symptoms are succeeded by a suspension of the vital powers, as in faintings, which may or may not prove fatal. Sometimes the attack is gradual, and the first symptoms are not easily discerned by the attendants; the infant shows some degree of uneasiness; he changes colour, his lips quiver, his eyes are turned upwards, and he unexpectedly, as it were, stretches himself out, or his hands become clenched. The lesser degrees of these are called by the nurses *inward fits*. Convulsions commonly precede the fatal termination of most of the diseases of infancy, which explains the reason of their appearing in the bills of mortality to be of such frequent occurrence. Accordingly, where they take place after any considerable indispotion, they are to be regarded as the harbingers of death. But even where the infant had been in perfect health previous to the attack, the event is always to be considered as extremely uncertain, for a single fit may kill. In ordinary cases, the danger is to be estimated by the degree of violence of the fit, and by the cause which had produced it. Thus if the cause be some irritation, which is naturally of temporary duration, or which can be easily removed, a favourable event may be looked for; but if it be not obvious, it may be suspected to be some state of the brain, which admits of no remedy. In many instances, where it was impossible to discover the cause of the fits during life, an accumulation of water within the ventricles of the brain has been found after death.

There is no medicine possessed of any specific power in suppressing convulsions, although cochineal, mistletoe, musk, and other substances, have been at different times extolled for supposed virtues of this nature. One of the most effectual means of alleviating the fits, is to immerse the child, during their attack, in a tubful of water, heated to 60° of Fahrenheit's thermometer, or to a warmth that the hand can easily bear. In very young infants opiates are not always safe, and cannot be trusted in the hands of nurses or inexperienced persons; but in children upwards of eighteen months, where the warm bath does not speedily succeed in abating the convulsions, from one or two to four or five drops of the tincture of opium might be administered, according to the severity of the fits; or a proportionate quantity of the camphorated tincture of opium, or of the extract of poppies diffused in a little water. Professor Hamilton has recommended a substitute for opium, which may be given to younger children; namely, the tincture of *hyoscyamus*: "twenty drops, evening and morning, have been repeatedly given to infants within six months of age." He remarks that, when the convulsions have been the effect of whooping-cough, great benefit has been derived from this medicine. Camphor, in the form of glyster, has seemed serviceable in some few cases, the same author states, but chiefly in children beyond the second year. He adds, "when a child seems to be suddenly deprived of life by one or two fits, if he appeared previously in good health, he ought on no account to be considered as irrecoverably lost; but the common means for restoring suspended animation should be carefully employed, as long as his colour is not entirely changed." Hints, &c.

Some other diseases, which occur in infancy and childhood, might here have been described; especially the glandular affections, both internal and external; the various disorders

of the scalp, as the scald-head, ring-worm of the scalp, &c.; the rickets, and so forth. But some of these are not peculiar to the age of childhood, and others are sufficiently important to be discussed more at length. See *TAKES mesenterica*, or mesenteric consumption; *SCROFULA*, *POURRIU*, *RICKETS*.

The prevention of diseases in children depends principally on the regulation of the diet and sleeping, exercise in the open air, and cleanliness. On the subject of the two or three last points we have little to say, as the value of a proper attention to them is now generally understood. In regard to diet, it may be sufficient to state, that, after weaning, preparations of milk, of eggs, of vegetable and animal jellies, should precede solid animal food; that, during childhood, a proper proportion of animal and vegetable matter should be used; and that all condiments, except salt, are unnecessary, and all spirituous fermented liquors pernicious. In respect to clothing, it is important to observe, that the attempts to rear children in a hardy manner, by allowing their legs to be bare, and other parts of the body to be much exposed (a practice sanctioned by some great names) have proved most unsuccessful; for by these means not only has the growth been, in many instances, stunted and perverted, but the constitution has been much injured, and, in some cases, life absolutely destroyed, in consequence of inflammations of the lungs and bowels, or various serofulous affections, thus excited. It would appear, indeed, that serofulous and consumptive diseases owe their origin principally to the cold and humidity of our climate, and the deleterious influence of these causes upon the constitution in childhood was strikingly illustrated in the attempt lately made by the Sierr. Leone Company to form an establishment for the education of African children in this country. Mr. John Pearson, who superintended this institution, states that they all died of consumption: they almost uniformly became serofulous; they bore the first winter tolerably well, but drooped during the second, and the third generally proved fatal to them; inasmuch that it became necessary to abandon the plan. Now we cannot but deem the situation of a child, who is to be hardened by thin clothing, as analogous to that of these African children, and to believe that, by such delusive attempts to give strength, the perfect and healthy evolution of the system is prevented, and the foundation laid for serofula, consumption, and other chronic diseases.

INFANTS, Running Eyes of. See *OPTHALMIA*.

INFANTS at Bethlehem, Slaughter of, by Herod, a fact mentioned in the gospel of St. Matthew, chap. ii. 16.; but disputed on account of the silence of Josephus, who has written the history of the Jews, and particularly the reign of Herod. The fact is not in itself improbable nor incredible, if we consider the cruelty of Herod's disposition and other savage acts of which he was guilty (see *HEROD*), and more especially if we recollect, that the slaughter, mentioned by St. Matthew, was perpetrated upon the occasion of tidings brought to Jerusalem, of the birth of one who was "king of the Jews." Josephus, who has given an account of a terrible execution made in Herod's court, and at Jerusalem, about the same time, upon the occasion of some predictions, that God was about to take away the kingdom from Herod, might omit the murder of the infants at Bethlehem from a fear of being charged with a design to load Herod unreasonably, or a fear of rendering his history disagreeable by too particular a detail of cruel actions. The silence of Josephus, it is said, is no more an objection against St. Matthew, than the silence of other writers with regard to facts mentioned by Josephus is an objection against him. Josephus, however, if he was a firm Jew, as most writers

have supposed, had a particular reason for passing over this event at Bethlehem, because he could not have mentioned it, without giving great advantage to the Christian cause. If he had written that Herod, at the latter end of his reign, had put to death all the young children at Bethlehem, on occasion of a report spread at Jerusalem, that the "king of the Jews" had been newly born there, he would very much have gratified the Christians; since it was well known, when he wrote, that about thirty years after the death of Herod, Jesus, being then about thirty years of age, had been styled the "king of the Jews," and had been publicly crucified at Jerusalem with that title; and it was widely believed by all his followers, that he was the great person spoken of under that character, and was now advanced to dominion and power. If Josephus did not wish to serve the Christians and their cause, he would therefore be silent with regard to this fact. But it has been alleged, that the Greek and Roman historians are silent with respect to this event; but this may easily be accounted for, if we consider, that the Roman empire was at this time so extensive, that the affairs of many dependent provinces have been lost in the crowd. Nevertheless, St. Matthew's account is confirmed by the testimony of ancient Christian authors. Justin Martyr, Irenæus, Origen, and other Christian writers have mentioned the fact. Moreover, there is also a noted passage in Macrobius, a heathen author, who flourished in the latter end of the fourth century, who, among other jests of Augustus, has this: "When he (Augustus) had heard that among the children within two years of age, which Herod king of the Jews commanded to be slain in Syria, his own son had been killed, he said, 'it is better to be Herod's dog than his son.'" Macrobius, Sat. l. ii. c. 4. This passage, if we deduce no other inference from it, shews, that Herod's slaughter of the infants in Judea was a thing well known in Macrobius's time, and was not contested by the heathens. See *Lardner's Works*, vol. i. chap. 2.

INFANTA, in *Geography*, a river of Africa, which runs into the Indian sea, S. lat. 32.

INFANTE and *INFANTA*, are titles of honour given to the children of some princes; particularly those of the houses of Spain and Portugal.

It is usually said, that the appellation of *infanta* was introduced into Spain on occasion of the marriage of Eleanor of England with king Ferdinand of Castile: and that their son Sancho was the first that bore it. But this is contradicted by Pelagius, bishop of Oviedo, who lived in the year 1100, and who informs us, that the titles *infante* and *infanta* were used in Spain ever since the reign of king Evremond II.

INFANTICIDA, in *Mythology*, the name of a deity to whom, according to Lyciphron, children were sacrificed by the Greeks. It is not likely that this was originally the name of any separate deity; but from the lamentable frequency of this almost incredible offering, this horrible distinction was appropriately applied to, most probably, Hecate, or some other form of the goddess Diana, of multifarious names and characters. The subject of *infanticide* has lately undergone more than usual discussion, and the prevalence of the practice, both heretofore and existing, proved of greater extent than could have been imagined. See the following article.

INFANTICIDE, or child murder, is an enormity that our reason and feelings would lead us to reckon as a crime of very rare occurrence. That it should exist at all, is, at the first view, surprising,—that it should prevail to any extent is difficult of belief,—that parents should be its perpetrators is in a high degree painful to imagine; but that mothers should

should be the executioners of their own offspring, nay, their habitual and systematic executioners, is such an agonizing contemplation, such an outrage on humanity, as every amiable feeling of our nature sickens and revolts at. But that this lamentable custom is, notwithstanding, extensively prevalent, has lately been developed so demonstratively, that, however comfortable it may be to our wounded sensibility to indulge the hope of error, it is, unhappily, the wantonness of scepticism to doubt. To try, however, as it would seem, the stretch of our credulity, we are imprudently called upon to believe this unparalleled enormity of a race, heretofore supposed to be the most humane in existence; viz. of the Hindoos; but of that race, which is among the most tender in other respects, we are constrained to believe that by them this sad deed has been systematically and universally perpetrated!

A few years ago it was discovered by Mr. Duncan, then resident at Benares, that a sect of Hindoos in that neighbourhood, called Ráj-kúmar, was in the habit of destroying all their female infants. A notice of this extraordinary fact was soon after published in the fourth volume of the Asiatic Researches, by Sir John Shore (now Lord Teignmouth), then governor-general of India. Mr. Duncan succeeded in persuading this devoted tribe to relinquish their barbarous habit; and so effectually, that no instance has since been discovered of an infringement of the written obligation that the chiefs and other individuals of that tribe then voluntarily entered into. As well as the Ráj-kúmar, other sects of Hindoos, in the vicinity of Benares, were found to have been in similar habits, though to a less extent, and they executed a similar deed of renunciation.

The same gentleman, the Hon. Mr. Duncan, now governor of Bombay, in the year 1800, being at Surat, heard incidentally that on the western side of India also, and especially in the contiguous countries of Guzerat, Kutch, and Sind, infanticide was extensively practised; due enquiry amply confirmed the fact. Availing himself of the recently improved connection between the British government and that of the Gaikwar, or sovereign of Guzerat, Mr. Duncan, through the able and zealous co-operation and agency of colonel Walker of the Bombay establishment, our political resident and military commander in Guzerat, again succeeded in the entire and effectual abolition of the custom; all the chiefs of the tribes in which it had obtained binding themselves and their families, and adherents, to a permanent renunciation and discontinuance of it; rendering themselves, in default of a due observance of the agreement, obnoxious to penal inflictions on the part of the British and Gaikwar governments.

Among the military tribe of Jarejah, infanticide was found most common; so common, indeed, that a Jarejah female was very rarely seen or heard of. The men of this tribe procured wives from others who reared their daughters. The number of infants, thus sacrificed, amounted, by one computation, to 30,000 annually, in the peninsula of Guzerat alone; but this colonel Walker deemed an exaggeration. Another estimate, erring probably on the other hand, reckoned 2000 as nearer the annual amount. It appeared to be the universal practice to destroy the infant immediately on his birth: this was done generally by the midwife, or some female attendant; sometimes, however, by the mother! The father never interfered, and the name or subject of a daughter was never mentioned in his presence. Sometimes the infants were smothered in various ways, or suffered to expire from want of nurture: different methods of destruction are related, and it seems to have been a matter of indifference how, provided the inhuman deed were done.

In the contiguous countries of Kutch and Sind, infanticide also prevails: but it has not been ascertained to what extent. It is recognized and avowed by the persons possessing the powers of government, who assert the antiquity of the usage, and forbid any interference on our part with a view to its abolition: our endeavours to effect that salutary end have in those quarters entirely failed.

It is, however, a comforting fact to reflect on, that solely through British interposition this custom has been put an entire stop to throughout the vast extent of our influence in India. None of the former governments, whether Hindoo or Mahometan, of the countries comprehended within that term, appear ever to have made any effort toward working for desirable a reform, although the religious tenets of both pointedly prohibit the practice.

These particulars we have gathered from a recent publication by major Moor, on "Hindoo Infanticide;" wherein he has given at length all the correspondence and negotiations that led to its discovery and suppression in India; with notices of a similar custom, which, and the exposure of children, he proves to have prevailed both in ancient and modern times among many nations in almost every part of the world. He adduces many speculations on its existence, origin, and effects; extending, indeed, to a lengthened discussion on a subject that, as much as any on record, evinces the almost incredible inconsistency and weakness, and wickedness of man. See INFANTICIDA.

INFANTOS, in Geography, a town of Spain, in New Castile; 20 miles W. of Alcazar.

INFANTRY, the body of foot soldiers, in an army, or other corps. See FOOT.

The infantry stand contradistinguished from the cavalry or horse, which see.

Europe is unquestionably indebted to the Swifs for a total change in the military system, particularly so with regard to foot soldiers.

Dr. Robertson, in the first volume of his history of Charles V. p. 105, observes, that the system of employing the Swifs in the Italian wars, was the occasion of introducing a total innovation in the military custom. The arms and discipline of the Swifs were different from those of other European nations. During their long and violent struggles in defence of their liberties against the house of Austria, whose armies, like those of other considerable princes, consisted chiefly of heavy-armed cavalry, the Swifs found that their poverty, and the small number of gentlemen residing in their country, at that time barren and ill cultivated, put it out of their power to bring into the field any body of horse capable of facing the enemy. Necessity compelled them to place all their confidence in infantry; and in order to render it capable of withstanding the shock of cavalry, they gave the soldiers breast-plates and helmets, as defensive armour, together with long spears, halberds, and heavy swords, as weapons of offence. They formed them into large battalions, ranged in deep and close array, so that they could present on every side a formidable front to the enemy. (See Machiavel's Art of War, b. ii. chap. ii. p. 451.) The men at arms could make no impression on the solid strength of such a body. It repulsed the Austrians in all their attempts to conquer Switzerland. It broke the Burgundian Gendarmerie, which was scarcely inferior to that of France, either in number or reputation; and when first called to act in Italy, it bore down, by its irresistible force, every enemy that attempted to oppose it. These repeated proofs of the decisive effects of infantry, exhibited on such conspicuous occasions, restored that service to reputation, and gradually re-established the opinion which had

been long exploded, of its superior importance in the operations of war. But the glory the Swiss had acquired, having inspired them with such high ideas of their own prowess and consequence, as frequently rendered them mutinous and insolent, the princes who employed them became weary of depending on the caprice of foreign mercenaries, and began to turn their attention towards the improvement of their national infantry.

The German powers having the command of men, whom nature has endowed with that steady courage and persevering strength which form them to be soldiers, soon modelled their troops in such a manner, that they vied with the Swiss both in discipline and valour.

The French monarchs, though more slowly, and with greater difficulty, accustoming the impetuous spirit of their people to subordination and discipline; and were at such pains to render their national infantry respectable, that as early as the reign of Louis XII. several gentlemen of high rank had so far abandoned their ancient ideas, as to condescend to enter into their service.

The Spaniards, whose situation made it difficult to employ any other than their national troops in the southern parts of Italy, which was the chief scene of their operations in that country, not only adopted the Swiss discipline, but improved upon it, by mingling a proper number of soldiers, armed with heavy muskets, in their battalions; and thus formed that famous body of infantry, which, during a century and a half, was the admiration and terror of all Europe. The Italian states gradually diminished the number of their cavalry, and in imitation of their more powerful neighbours, brought the strength of their armies to consist in foot soldiers. From this period, the nations of Europe have carried on war with forces more adapted to every species of service, more capable of acting in every country, and better fitted both for conquests, and for preserving them.

INFANTRY, Exercise. See EXERCISE.

INFANTRY, Foreign. The foreign infantry in the service of Great Britain, according to the returns delivered in on the 1st of November 1800, consists of Loyal French Emigrants, Calrics, Mortemart, Roll and Dillon; Menrou ditto; four ditto Dutch, each having a company of artillery attached, and one Dutch rifle with a company of pioneers; Lowenstein's corps, which was not completed, and one corps of foreign invalids. Staff to a foreign hospital. There are besides 16 unattached foreign officers who receive full pay, 166 ditto on half pay, 504 aged and wounded ditto, 46 foreign officers widows, 44 children of foreign officers who have died in the king's service. There is also a small corps of estafettes, which is attached to the waggon train, and consists wholly of foreigners.

INFANTRY, Heavy armed, among the ancients, were such as wore a complete suit of armour, and engaged with broad shields and long spears. They were the flower and strength of the Grecian armies, and had the highest rank of military honour.

INFANTRY, Light armed, amongst the ancients, were distinguished for skirmishes, and for fighting at a distance. Their weapons were arrows, darts or slings.

INFANTRY, Light, have only been in use since the year 1656. They have no camp equipage to carry, and their arms and accoutrements are much lighter than the common infantry, or battalion men. Wherever there is light cavalry, there should be light infantry to act in conjunction.

INFARCTION, in *Medicine*, *infarctus*, $\epsilon\mu\phi\alpha\alpha\epsilon\tau\iota\varsigma$; of the Greeks, is synonymous with *obstruction*, and *congestion*, and denotes that state of any organ of the body, which is tumid, with the blood-vessels loaded, and is more especially applied

to the tumours produced by a chronic inflammation of the parts.

INFARCTION of the Liver. See HEPATITIS, and LIVER, *Chronic Diseases of.*

INFARCTION of the Spleen. See SPLENITIS and SPLEEN.

INFARCTION of the Mesentery. See MARASMUS, and TABES *Mesenterica.*

INFATUATE, to prepossess any one in favour of some person or thing that does not deserve it, so far as that he cannot easily be disabused.

The word *infatuare* comes from the Latin *fatuus*, *fool*, of *fari*, to speak out; which is borrowed from the Greek $\phi\alpha\sigma\iota\varsigma$, whence $\phi\alpha\sigma\iota\varsigma$, which signifies the fame with *wates* in Latin, or *propriet* in English: and the reason is, because their prophets or priests used to be seized with a kind of madness or folly when they began to make their predictions, or deliver oracles.

The Romans called those persons infatuated, *infatuati*, who fancied they had seen visions, or imagined the God Faunus, whom they called *Fatuus*, had appeared to them.

INFECTIO, in *Medicine*, a word used in two acceptations: first as denoting the effluvia or infectious matter, exhaled from the person of one diseased, and capable of communicating the disease to others who inhale it; in which sense it is synonymous with *contagion*: and secondly, as signifying the act of communication of such morbid effluvia, by which the disease is transferred. The word comes from the Latin verb *inficere*, which properly signifies to dye of some other colour, or to cause something to be imbedded. See **CONTAGION**.

INFECODATION of Tithes, in *Law*. See TITHES.

INFERIE, in *Antiquity*, sacrifices offered to the dii manes, or the souls of deceased heroes and illustrious persons; or even of any relation or person whose memory was held in veneration.

INFERIOR, stands opposed to superior.

INFERIOR Courts of Record, in *English Law-writers*, is used as a general name for corporation-courts, courts-leet, and sheriffs-torns. See **COURTS**.

Most courts are subordinate to some other; but for distinction sake the term inferior-court is by Sir Matthew Hale, and others, applied in the manner here mentioned.

INFERIOR Maxilla, Ocean, Planet. See the substantives.

INFERIOR Penis, in *Anatomy*, a name given by Spigelius to one of the muscles of the penis, generally called the accelerator by the moderns; and by Vesalius, and others of his time, *primus penis*.

INFERIOR Obliquus, Serratus, Subscapularis. See the several articles.

INFERIORIS labii depressor, labii elevator. See **DEPRESSOR**, and **ELEVATOR**.

INFERNAL GLASS, in *Chemistry*, is a name given to the bolt-head, when its stem is continued downward into the body of the glass vessel, and left open only by a very small orifice.

INFERNAL Salt, a name given by Hoffman, and some other of the chemical writers, to nitre; they have also called it *terberus chemicus*.

INFERNAL Stone. See **LAPIS Infernalis**, **CAUSTIC**, and **CRYSTALS of Silver**.

INFERNALS, in *Artillery*, floating mines constructed in the bodies of ships or boats. The first inventor of them, or at least the first who put them in practice, was Frederick Jambelli, an Italian engineer, at the siege of Antwerp by the Spaniards under Alexander, prince of Parma, in the year 1585. A very particular and interesting relation of their wonderful effects is given by Strada, in his "History of the

Belgic War." The great destruction made by these caused several others to be tried; but none of them succeeded. At Dunkirk and St. Maloes they were tried by the English; at Havre de Grace by the English and Dutch, under king William; and one was conducted by the French to be used against Algiers, in 1688, but it was not employed. St. Remi, in his Memoirs of Artillery, has given a section and view of the infernal used at St. Maloes. See a description and figure of it in Grose's Military Antiquities, v. 1. p. 410.

INFERTILITY. See FERTILITY.

INFIBULATION, in *Antiquity*. It was a custom among the Romans, to infibulate their linging boys, in order to preserve their voices; for this operation, which prevented their retracting the prepuce over the glans, and is the very reverse to circumcision, kept them from injuring their voices by premature and preposterous venery: serving as a kind of padlock, if not to their inclinations, at least to their abilities. It appears by some passages in Martial, that a less decent use was made of infibulation among the luxurious Romans: for some ladies of distinction, it seems, took this method of confining their paramours to their own embraces. Juvenal also hints at some such practice. Celsus, a chaste author, says, infibulation was sometimes practised for the sake of health; and nothing destroys it more than the silly practice this operation seems intended to prevent. This practice is not perhaps likely to be revived; if, however, any one who has suffered in his constitution by preposterous venery, should be able to get children, and should be inclined to prevent the same misfortune in them, by infibulation; the method of doing it is thus:

The skin which is above the glans is to be extended, and marked on both sides with ink, where it is perforated, and then suffered to retract itself. If the marks recur upon the glans, too much of the skin has been taken up, and we must make the marks farther; if the glans remain free from them, they shew the proper place for affixing a fibula: then pass a needle and thread through the skin where the marks are, and tie the threads together; taking care to move it every day, until the parts about the perforations are cicatrised: this being effected take out the thread, and put in the fibula; which the tighter it is the better. Celsus, lib. vii. cap. 25.

Authors have not determined what the fibula of the ancient fargeons was, though no doubt they were for different purposes. In the present case, the fibula seems to mean a ring of metal, not unlike what the country people put through the noses of swine.

INFIDEL, a term applied to such persons as are not baptized, and that do not believe the truths of the Christian religion. See DEIST.

INFIERNO, in *Geography*, one of the smaller Canary islands, between Lancerotta and St. Clara.

INFUESTO, a town of Spain, in the province of Asturias; 20 miles E. of Oviedo.

INFILTRATION, in *Geology*, is one of the processes of nature, by which stony hardnefs seems to have been given or increased in mineral substances or strata, in certain situations, effected by the infiltration or soakage of water laden with stony particles, through porous substances, and then depositing their lapidiferous contents: Mr. Kirwan, in his "Geological Essays," pages 45, 128, 131, and 412, has considered this mode of indurating the terrestrial strata, and quoted a number of curious mineral changes and appearances ascribed to this agent.

INFINITE, that which has neither beginning nor end: in which sense God alone is infinite.

INFINITE is also used to signify that which has had a beginning, but will have no end: as angels, and human souls.

This makes what the schoolmen call *infinitum a parte post*; as, on the contrary, by *infinitum a parte ante*, they mean that which has an end, but had no beginning. See INDEFINITE and FINITE.

INFINITE, in *Mathematics*, is applied to quantities which are either greater or smaller, than any assignable ones. In which sense it differs not much from what we otherwise call *indefinite* or *indeterminate*. Thus, an

INFINITE, or Infinitely great line, in *Geometry*, denotes only an indefinite or indeterminate line; to which no certain bounds or limits are prescribed.

INFINITE Quantities. Though the idea of magnitude infinitely great, or such as exceeds any assignable quantity, does include a negation of limits; yet all such magnitudes are not equal among themselves; but besides infinite length and infinite area, there are no less than three several sorts of infinite solidity; all of which are quantities *sui generis*; and those of each species are in given proportions.

Infinitely length, or a line infinitely long, is to be considered, either as beginning at a point, and so infinitely extended one way; or else both ways from the same point: in which case the one, which is a beginning of infinity, is one-half of the whole, which is the sum of the beginning and ceasing infinity, or infinity *a parte ante*, and *a parte post*, which is analogous to eternity in time or duration; in which there is always as much to follow, as is past any point or moment of time.

Nor does the addition or subtraction of time, length or space of time, alter the case, either as to infinity or eternity; since neither the one nor the other can be any part of the whole.

As to infinite surface or area, any right line infinitely extended both ways on any infinite plane, divides that plane into equal parts, the one to the right, and the other to the left of the said line; but if from any point in such a plane, two right lines be infinitely extended, so as to make an angle; the infinite area, intercepted between these infinite right lines, is to the whole infinite plane, as the arc of a circle drawn on the point of concurrence of those lines as a centre, intercepted between the said lines, is to the circumference of the circle; or as the degrees of the angle to the 360 degrees of a circle.

For an example—Two infinite right lines meeting at a right angle on an infinite plane, do include a quarter part of the whole infinite area of such a plane: if two parallel infinite lines be supposed drawn on such an infinite plane, the area intercepted between them will be likewise infinite; but at the same time it will be infinitely less than the space intercepted between two infinite lines, that are inclined, though with never so small an angle, because in the one case the given finite distance of the parallel lines diminishes the infinity in one degree of dimension; whereas in a factor, there is infinity in both dimensions; and consequently the quantities are one infinitely greater than the other, and there is no proportion between them.

From the same consideration arise three several species of infinite space or solidity; for a paralleloiped, or a cylinder infinitely long, is greater than any finite magnitude, how great soever; all such solids supposed to be formed on a given basis, are in proportion to one another as those bases. But if two of those three dimensions are wanting, as in the space intercepted between two parallel planes infinitely extended, and at a finite distance; or with infinite length and

breadth, it have a finite thickness; all such solids shall be as the given finite distances one to another.

But these quantities, though infinitely greater than the other, are yet infinitely less than any of those wherein all the three dimensions are infinite—Such are the spaces intercepted between two inclined planes infinitely extended: the space intercepted by the surface of a cone, or the sides of a pyramid, likewise infinitely continued, &c. all which, notwithstanding the proportion of one to another, and to the π π , or vast abyss of infinite space (wherein is the locus of all things that are, or can be) or to the solid of infinite length, breadth, and thickness (taken all manner of ways) are easily assignable.—For the space between two planes is to the whole, as the angle of those planes to the 360 degrees of the circle. As for cones and pyramids, they are as the spherical surface intercepted by them, is to the surface of the sphere; and therefore cones are as the versed sines of half their angles to the diameter of the circle; these three sorts of infinite quantity are analogous to a line, surface, and solid; and like them, cannot be compared or have any proportion one to another.

INFINITES, *Arithmetic of*. See ARITHMETIC.

INFINITES, *Characters in Arithmetic of*. See CHARACTER.

INFINITE *Decimals*. See REPETEND.

INFINITE *Distress*, in Law. See DISTRESS.

INFINITE *Proposition*, in Logic. See PROPOSITION.

INFINITE *Series*. See SERIES.

INFINITELY *small quantity*, called also an *infinitesimal*, is that which is to very minute, as to be incomparable to any finite quantity; or it is that which is less than any assignable quantity.

An infinite quantity cannot be either augmented or lessened, by adding or taking from it any finite quantity; neither can a finite quantity be either augmented or lessened, by adding to, or taking from it an infinitely small quantity.

If there be four proportionals, and the first be infinitely greater than the second; the third will be infinitely greater than the fourth.

If a finite quantity be divided by an infinitely small one, the quotient will be an infinitely great one; and if a finite quantity be multiplied by an infinitely small one, the product will be an infinitely small one; if by an infinitely great one, the product will be a finite quantity.

If an infinitely small quantity be multiplied into an infinitely great one, the product will be a finite quantity.

In the method of infinitesimals, or of infinitely small quantities, the element by which any quantity increases or decreases, is supposed to be infinitely small, and is generally expressed by two or more terms; some of which are infinitely less than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity. The terms that are neglected in this manner, as infinitely less than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation of the generating motion, during the infinitely small time in which the element is generated; so that the remaining terms express the element that would have been produced in that time, if the generating motion had continued uniform, as is farther explained under FLUXION.

Therefore those differences are accurately in the same ratio to each other as the generating motions or fluxions. And hence, though infinitesimal parts of the elements are neglected, the conclusions are accurately true, without even an infinitely small error, and agree precisely with those that

are deduced by the methods of fluxions. In order to render the application of this method easy, some analogous principles are admitted, as that the infinitely small elements of a curve are right lines, or that a circle is a polygon of an infinite number of sides, which being produced, give the tangents of a curve, and by their inclination to each other measure the curvature. This is as if we should suppose that when the base flows uniformly, the ordinate flows with a motion which is uniform for every infinitely small part of time; and increases, or decreases, by infinitely small differences at the end of every such time.

But however convenient this principle may be, it must be applied with caution and art, on various occasions. It is usual, therefore, in many cases, to resolve the element of the curve into two or more infinitely small right lines; and sometimes it is necessary (if we would avoid error) to resolve it into an infinite number of such right lines, which are infinitesimals of the second order. In general it is a *postulatum* in this method, that we may descend to infinitesimals of any order whatever, as we find it necessary; by which means any error that might arise in the application of it may be discovered and corrected by a proper use of this method itself.

It is also to be observed, that when the value of a quantity that is required in a philosophical problem becomes, in certain particular cases, infinitely great or infinitely little, the solution would not be always just, though such magnitudes were admitted. As when it is required, to find by what centripetal force a curve would be described about a fixed point that is either in a curve, or is so situated that a tangent may be drawn from it to the curve. The value of the force is found infinite at the centre of the forces in the former case, and at the point of contact in the latter; yet it is obvious, that an infinite force could not deflect the line described by a body that should proceed from either of these points into a curve; because the direction of its motion in either case passes through the centre of the forces, and no force, how great soever, that tends towards the centre, could cause it to change that direction. But it is to be observed, that the geometrical magnitude by which the force is measured, is no more imaginary in this than in other cases, where it becomes infinite; and philosophical problems have limitations that enter not always into the general solution given by geometry.

But although by proper care errors may be avoided in the method of infinitesimals, yet it must be owned that to such who have been accustomed to a more strict and rigid kind of demonstration in the elementary parts of geometry, it may not seem to be consistent with perfect accuracy, that, in determining the first differences, any part of the element of the variable quantity should be rejected, merely because it is infinitely less than the rest; and that the same part should be afterwards employed for determining the second and higher differences, and resolving some of the most important problems. Nor can we suppose that their scruples will be removed, but rather confirmed, when they come to consider what has been advanced by some of the most celebrated writers on this method, who have expressed their sentiments concerning infinitely small quantities in the precise terms; while some of them deny their reality, and consider them only as incomparably less than infinite quantities, in the same manner as a grain of sand is incomparably less than the whole earth; and others represent them in all their orders, as no less real than finite quantities. And although it appears, from what has been said in this article, that a satisfactory account may be given for the brief way of reasoning that is used in the method of infinitesimals; while nothing is neglected without accounting for it; and then the harmony

between

between the method of fluxions, and that of infinitesimals thus appears more perfect.

And however late and convenient this method may be, yet some will always scruple to admit infinitely little quantities and infinite orders of infinitesimals, into a science that boasts of the most evident and accurate principles, as well as of the most rigid demonstrations. It is therefore proper, that this extensive and useful doctrine should be established on unexceptionable principles. See the articles FLUXION and LIMIT. See also Mr. Maclaurin's Treat. of FLUXIONS, in the Introduction, p. 39, 40, &c. and book i. art. 495 to 502.

INFINITELY *Infinite Fractions*, or all the powers of all the fractions whose numerator is one, are together equal to an unit. See the demonstration hereof given by Dr. Wood, in Hook. Phil. Coll. N. 3. p. 45, seq.

Hence, it is deduced, 1. That there are not only infinite progressions, or progressions *in infinitum*; but also infinitely farther than one kind of infinity. 2. That the infinitely infinite progressions are notwithstanding computable, and to be brought into one sum; and that not one finite, but so small as to be less than any assignable number. 3. That of infinite quantities, some are equal, others unequal. 4. That one infinite quantity may be equal to two, three, or more other quantities, whether infinite or finite.

INFINITIVE, in *Grammar*, the name of one of the moods, which serve for the conjugating of verbs.

The infinitive does not denote any precise time, nor does it determinate the number, or persons, but expresses things in a loose indefinite manner; as, *to teach*, &c.

Hence the Latin and modern grammarians have called verbs under this mode, from their indefinite nature, infinitives. Sanctus has given them the name of imperfonals; and the Greeks that of ἀποφυσιστικῶν from the same reason of their not discovering either person or number.

Infinitives, says Mr. Harris, not only lay aside the character of attributives, but they also assume that of substantives, and are distinguished with their several attributes: e. g. "Dulce & decorum est pro patria mori; scire tuum nihil est, &c."

Hence the infinitive has been sometimes called ὀνομαζόμενον, a verbal noun; sometimes ὀνομαζόμενον ἑνεστικόν, the verb's noun. The reason of the appellation is evident in Greek, by its taking the prepositive articles before it in all cases; thus τὸ γράσειν, τὸ γράσεις, τὸ γράσειν. The same construction is not unknown in English. Thus Spencer,

"For not to have been dipped in Lethe's lake
Could save the son of Thetis from to die;" i. e.

εἶπε τὴν θάλασσαν.

The Stoics held the infinitive as the genuine ἰδέα, or verb, a name which they denied to all other modes; because the true verbal character was conceived to be contained simple and unmixed in the infinitive only: thus, *to walk*, means simply that energy, and nothing more; the other modes, besides expressing this energy, superadd certain affections which respect persons and circumstances. The infinitive, says Priscian, "significat ipsam rem, quam continet verbum." The infinitive, in the application of it, naturally coalesces with all those verbs, that denote any tendency, desire, or volition of the soul, but not readily with others. See Harris's *Hermes*, p. 163, &c.

In most languages, both ancient and modern, the infinitive is distinguished by a termination peculiar to it; as τέρπειν in the Greek, *scribere* in the Latin, *crire* in the French, *scrivere* in the Italian, &c. but the English is defective in this point; so that to denote the infinitive, we are obliged to

have recourse to the article *to*: excepting sometimes when two or more infinitives follow each other.

The practice of using a number of infinitives successively, is a great but a common fault in language; as *he offered to go to teach to write English*.—Indeed, where the infinitives have no dependence on each other, they may be used elegantly enough; as *to mourn, to sigh, to sink, to swoon, to die*.

INFINITO, in the *Italian Music*, is used for such canons or fugues, as may be begun again and again: whence they are also called *perpetual fugues*. See FUGUE.

INFINITY, the quality which denominates a thing infinite. The idea signified by the name infinity is best examined by considering to what things infinity is by the mind attributed, and how the idea itself is framed: finite and infinite are looked upon as the modes of quantity, and are attributed primarily to things that have parts, and are capable of increase or diminution, by the addition or subtraction of any the least part. Such are the ideas of space, duration, and number. When we apply this idea to the Supreme Being, we do it primarily in respect of his duration and ubiquity: and more figuratively, when to his wisdom, power, goodness, and other attributes, which are properly inextinguishable and incomprehensible: for when we call them infinite, we have no other idea of this infinity but what carries with it some reflection on the number, or the extent of the acts or objects of God's power and wisdom, which can never be supposed to great, or so many, that these attributes will not always surmount and exceed, though we multiply them in our thoughts with the infinity of endless number. We do not pretend to say, how these attributes are in God, who is infinitely beyond the reach of our narrow capacities: but this is our way of conceiving them, and these are our ideas of their infinity.

We come by the idea of infinity thus: every one that has any idea of any stated length or space, as a foot, yard, &c. finds that he can repeat that idea, and join it to another, to a third, and so on, without ever coming to an end of his additions. From this power of enlarging his idea of space, he takes the idea of infinite space, or immensity. By the same power of repeating the idea of any length or duration we have in our minds, with all the endless addition of number, we also come by the idea of eternity.

If our idea of infinity be got by repeating without end our own ideas, it may be asked, why do we not attribute it to other ideas, as well as those of space and duration; since they may be as easily, and as often repeated in our minds, as the other? yet nobody ever thinks of infinite sweetness, or whiteness, though he can repeat the idea of sweet or white, as frequently as those of yard or day? To this it is answered, that those ideas which have parts, and are capable of increase by the addition of any parts, afford us by their repetition an idea of infinity; because with the endless repetition there is connected an enlargement, of which there is no end: but it is not so in other ideas; for if to the most perfect idea I have of white, I add another of equal whiteness, it enlarges not my idea at all. Those ideas, which consist not of parts, cannot be augmented to what proportion men please, or be stretched beyond what they have received by their senses; but space, duration, and number, being capable of increase by repetition, leave in the mind an idea of an endless room for more; and so those ideas alone lead the mind towards the thought of infinity.

We are carefully to distinguish between the idea of the infinity of space, and the idea of the space infinite. The first is nothing but a supposed endless progression of the mind over any repeated idea of space; but to have actually in the mind the idea of space infinite,—is to suppose the

mind already passed over all those repeated ideas of space, which an endless repetition can never totally represent to it; which carries in it a plain contradiction. See **SPACE**.

This will be plainer, if we consider infinity in numbers: the infinity of numbers, to the end of whose addition every one perceives there is no approach, easily appears to any one that reflects on it: but how clear forever this idea of the infinity of numbers be, there is nothing yet more evident than the absurdity of the idea of an actual infinite number. See **Locke's Essay**, vol. i. chap. xvii.

INFINITY of Actions, in *Law*; the lord of the soil may have a special action against him who shall dig soil in the king's highway: but one subject may not have his action against another for common nuisances; for if he might, then every man might have it, and so the actions would be infinite. *See* 1 **Co. Inst.** 56. 9 **Rep.** 113.

INFIRMARY, a place where the sick and weak belonging to any society, or community, are disposed, either for nursing or cure. See **HOSPITAL**.

INFLAMMABILITY, is that property of bodies which disposes them to kindle, or catch fire. See **FLAME**, **HEAT**, and **PHLOGISTON**.

INFLAMMABILITY of Oils. See **OIL**.

INFLAMMABLE AIR. See **HYDROGEN**.

INFLAMMABLE Springs. About the middle of the last century, a spring or well at Broseley in Shropshire, was much noticed on account of the inflammable exhalations or gasses which it emitted, so that when a cover was adapted to it, that contracted the stream of air, and a candle was applied, it continued to burn with a lambent blue flame for a long time: but the coal-works in the neighbourhood have long since drained this well. During the driving of Stoke fough, to drain the lead mines near Eyam in Derbyshire, such a quantity of liquid bitumen or rock oil was liberated from the small cavities in the limestone, and from gorges of limestone in the shale above it, that it frequently swam on the water in the fough, in sufficient quantities to take fire and burn for a time, after the application of a lighted candle: this was called by Mr. Bry, in his "Tour" (p. 176.) a burning spring, but improperly, seeing that the bitumen was only let free by the tools of the workmen, and was not spontaneously discharged from the rock, a condition which seems essential to a spring of any kind. See an account of this fough, in Mr. Farey's Report on Derbyshire, vol. i. p. 330.

INFLAMMATION is concerned, either as a cause, symptom, consequence, or complication of the greater number of diseases, to which the human body is liable, and hence it has always been considered by the most enlightened pathologists as a subject which, in point of importance, is inferior to none in the whole circle of medical science. It interests the physician, the surgeon, the accoucheur, and, in short, every individual, who is in the habit of being entrusted with the treatment of any kind of disorder, or accidental injury. A knowledge of the nature and laws of inflammation, and just ideas respecting the means of checking and curing this affection, may be said to constitute a key, or introduction, to the comprehension of diseases in general; for some may be alleged to consist of it, and very few are entirely unattended with it in one stage or another. It is for such reasons, that systematic authors mostly treat of it at the very beginning of their works.

The term inflammation, which is derived from the Latin word *inflammatio*, probably owes its origin to an ancient opinion, that there was fire in the part affected, and, if we advert to the considerable sensation of heat, which the patient experiences in the seat of the complaint, the use of such an expression seems almost natural. The Greeks appear to

have employed terms of similar import, as *φλεγμονή*, or *φλογωσις*, from *φλογή*, I burn.

Inflammation is divisible into several species. The distinctions chiefly insisted upon by surgical writers, are the *acute* and *chronic*. When inflammation is unattended with any particular disease, it is sometimes called *simple* or *healthy*, of which there can only be one kind. But the *morbid* inflammations, or such as are influenced by the presence of a diseased action, are as numerous and various as diseases themselves, each disease, in fact, having its own specific kind of inflammation; as, for instance, the small-pox pustule, the cow-pox vesicle, the carbuncle, erysipelas, scrofula, the venereal disease, &c.

When common inflammation is spoken of, the acute healthy species is usually implied, or that which is so well known by the name of *phlegmon*. It is attended with four remarkable symptoms in the part affected, namely, pain, redness, swelling and heat: "notæ vero inflammationis sunt quatuor; rubor et tumor, cum calore et dolore." Celsus, lib. iii. cap. 10.

The pain which accompanies the various sorts of inflammation, differs very materially both in its degree and kind. In many instances, indeed, it might be more proper to say, that there is an alteration in the natural sensations and sensibility of the part, than that there is pain, which latter term leads one to understand a degree of agony. Numerous chronic inflammations produce very trivial uneasiness in the part, the patient feeling, perhaps in the seat of the disease, merely a sensation of weight and heaviness. It is likewise remarked by Richerand, that the pruritus, which precedes and attends certain cutaneous eruptions, so far from being painful, occasions rather an agreeable sensation. It is only when the sensibility is carried beyond a particular pitch that it amounts to pain. In phlegmonous inflammation the pain is of a throbbing description, and the suffering is joined with an annoying sense of weight. In erysipelas the pain is of a burning kind. In anthrax it is accompanied by a feeling of stiffness. The severity of the pain is generally in proportion to the vehemence of the inflammation, the sensibility of the parts, and the resistance which their structure makes to the tumefaction.

It is a curious fact, of which the practice of surgery affords many proofs, that parts which, in their natural healthy state, are not remarkable for their great sensibility, are frequently affected when inflamed with an exquisite degree of tenderness and pain. The gums, in the sound state, are not very sensible; they may be divided with a lancet, without any great deal of pain being occasioned: and the pressure of hard substances against them in maturation is not productive of injury. When inflamed, however, in consequence of decayed teeth, a cold, or any other cause, they are affected with extreme sensibility, swell in a considerable degree, and cannot be touched, or pressed, in the slightest manner, without much suffering being excited. The ligaments are naturally almost devoid of sensation; but, in several diseases of the joints, they are even much more painful, than some other inflamed parts, which, when sound, possess a vast deal of sensibility.

A preceding remark, therefore, that the pain is in proportion to the natural sensibility of the parts affected, is not to be received without exceptions. With respect to the immediate way, in which pain is excited in cases of inflammation, it seems most rational to impute the degree of suffering to the augmented sensibility of the nerves, and the unnatural condition in which they are placed. In chronic inflammation, the changes which the parts undergo are slow, and the nerves seem to have time to adapt themselves to the alteration;

INFLAMMATION.

tion; but in acute inflammation, the mutations are quick, and the pain is, for the most part, considerable.

The swelling appears to be occasioned by several circumstances, yet principally by the increased determination of blood to the vessels of the part, and by an effusion of coagulating lymph in the interstices of the cellular substance. The dilatation of the blood-vessels, and the interruption of absorption, probably have also a share in producing the effect.

The considerable injection of the small vessels with red blood, and their great increase of diameter, afford some explanation of the manner in which the preternatural redness arises. It has been a prevailing sentiment, that the redness of common inflammation is partly owing, not merely to a dilatation, but at the same time to an actual increase in the number of the blood-vessels of the inflamed part. New vessels are supposed to be generated. This doctrine, however, is far from resting upon unquestionable evidence. When coagulating lymph is extravasated upon the surface of a wound, an inflamed membrane, &c. it is beyond a doubt often rendered vascular, or, in other words, becomes furnished with new vessels. But, in the extravasated lymph of a phlegmonous tumour, we have no evidence to prove that there is any generation of new vessels. If the vessels have the appearance of being more numerous, it is because their diameters are enlarged, and many, which previously contained only a colourless fluid, are now filled with visibly red blood. Were the extravasated lymph of a phlegmonous swelling to be rendered organized and vascular, the tumefaction and redness would probably be more permanent, and not admit (at least so easily as they often do) of resolution. When adhesions form between two inflamed surfaces, the organized substance, forming the connection, lives after the subsidence of the inflammation, and is a permanent effect. (Dict. of Pract. Surgery.) According to Mr. Burns, the supposition easily admits of refutation; for heat, and many other causes of inflammation, operate so quickly, that there can be no time for the formation of any new vessels; and yet the redness is as great, and the inflammation as perfect, in a minute, as in an hour, or a day, after the application of the exciting cause. (Dissert. on Inflammation). Now that we are noticing the redness of inflamed parts, it may be as well to mention the circumstance of red blood itself being sometimes extravasated, in consequence of inflammation. The occurrence generally indicates, that the inflammatory mischief has been rapid and violent. The most striking instances, which just now present themselves to our mind, are, first, that state of an inflamed eye, termed *chemosis*, for an account of which we refer to OPTHALMY; and, secondly, the spots, produced by effused blood, on the inner coat of the stomach, when this viscus has been inflamed, in consequence of poison. There is still another circumstance, which has been mentioned by the celebrated Mr. John Hunter, as conducive to the red appearance of inflamed parts, *viz.* the blood, after it has become venous, retaining a certain degree of the bright scarlet colour, which it possessed in the arteries. We cannot offer any opinion concerning the truth of the latter suggestion; as coming from Mr. Hunter, it cannot fail to deserve attention.

The experiments which Mr. Hunter made with the thermometer, tend to evince, that the real augmentation of the heat of an inflamed part is inconsiderable, although it seems to be very great, when a judgment is derived from the patient's feelings. If we recollect, that the sensibility of the nerves is augmented, we can no longer be surprized, that they should convey to the sensorium false impressions. With regard to the manner, in which the increased tempera-

ture of inflamed parts is produced, this subject is explicable on the principles, which apply to the production of animal heat in general. We shall merely observe, that there is always a greater determination of blood to a part which is in a state of inflammation, than to the same part when it is not inflamed. The blood flows through it with augmented velocity, and we always find, that the heat of the whole body, as well as of any portion of it, is always in a ratio to the accelerated state of the circulation. When a person runs, he hurries the current of the entire mass of blood, and his whole body is thrown into a heated state. In fevers, the circulation is quickened, and there is likewise general heat. But in inflammation unattended with febrile disorder, the blood flows only through the inflamed part with increased impetuosity, and, of course, the augmentation of heat is local and circumscribed.

Phlegmon, or what may be called common inflammation, has been regarded by many writers as an affection of the cellular membrane. Its frequent occurrence in every situation, both internal and external, has been accounted for by the way, in which the cellular substance pervades the texture of almost every part of the body. Phlegmon is represented as being attended with more swelling than any other species of inflammation. The bright red colour in the centre of the tumour gradually extends towards the circumference, and is insensibly lost on the surrounding skin. The swelling, on the other hand, is distinctly circumscribed. The heat has been compared with that arising from the steam of boiling water. The throbbing, to which we have already adverted, manifestly depends upon the pulsation of the arteries, and is synchronous with the pulse of the whole system. The throbbing particularly affects the patient himself, and the surgeon may plainly perceive it when he touches the part, all the small vessels of which are dilated, and beat in a preternatural degree. In a common whitlow, this vehement throbbing is not confined to the finger, but extends to the large arteries, a considerable way up the arm.

The active mind of the late Mr. John Hunter led him to pay much attention to the interesting subject before us, and from him we have many fertile and original observations. The principles and laws of inflammation were better explained by this philosophical observer, than by any of his professional predecessors. He has noticed the well established circumstance, attending phlegmonous and other inflammations, wherefore situated, namely, their being always most violent on the side next to the external surface of the body. Thus, when inflammation invades the socket of a tooth, it chiefly takes place towards the cheek, and not on the inside of the alveolar process. He points out, that the situation, position, structure, functions, and dilance of the part affected from the source of the circulation, cause considerable variety in the progress and termination of all inflammation. He maintains, that parts, naturally enjoying a vigorous circulation of blood then can bear inflammation better than others in the opposite condition. From this observation, however, he excepts vital parts, which, though they may be exceedingly vascular, do not undergo inflammation favourably, because the natural operations of universal health depend so much upon the foundations of such organs. Mr. Hunter also endeavours to shew, that the depending position of a part seems to have a bad effect on inflammation, probably by retarding the return of the blood. It is one of the same author's principles, that new-formed parts, as many tumours and excrescences, callus, scars, &c. possess less vitality than is the share of

INFLAMMATION.

other parts, which constitute a portion of the original fabric of the body; hence, when inflamed, they are exceedingly apt to be destroyed by ulceration, or mortification.

When an inflammation is of trivial extent, and not ferriously painful, the effects of the complaint are altogether local. In the contrary case, the whole circulation partakes in the excitement, and the inflammatory fever occurs.

The blood, taken from a patient labouring under inflammation, is well known by all medical practitioners to exhibit peculiar appearances. The blood, when it has escaped out of the living vessels, spontaneously separates into two distinct parts, the serum and the crassamentum. The last is a compound substance, consisting chiefly of coagulating lymph and red globules, the most heavy ingredients in the blood. Now, it is to be observed, that blood, taken away from persons affected with inflammation, is longer in coagulating, and coagulates more firmly, than when drawn from people in other circumstances. Hence the red globules, which are very heavy, not being so soon entangled in the lymph, descend by their gravity more deeply from its surface, which, being in this manner more or less divested of the red colouring matter, is, from its appearance, termed the *buffy coat*, or *inflammatory crust*. The firmer and more compact coagulation of the lymph compresses out an unusual quantity of serum from it, and the surface of the *fecy* blood, as it is frequently called, is often formed into a hollow, the edges being drawn inwards. These changes in the blood are, in some cases, a more infallible proof of the existence of inflammation than the pulse itself. At the same time, it is probably only a criterion of some unusual operation going on in the system; for the blood, taken away from pregnant women, is always found to exhibit the above appearances, a circumstance which should always be recollected. In peritoneal inflammation, the patient sometimes seems to be in the most feeble state, and the pulse, abstractedly considered, would rather induce the practitioner to employ tonics and stimulants, than evacuations; but should the continuance, or exacerbation of the disorder, or any other reason, lead the surgeon to use the lancet, then the *buffy coat*, the *concave surface* of the blood, and the *large quantity of serum*, clear away all doubt concerning the existence of inflammation. But every practitioner ought to bear in his mind, that, besides pregnant women, there are a few anomalous constitutions met with, where the blood, taken away by the lancet, always exhibits the foregoing peculiarities, though inflammation may not prevail.

We see three very remarkable effects follow the prevalence of inflammation; *viz.* adhesions of parts of the body to each other; the formation of pus, or suppuration; and ulceration, a process in which the lymphatics are more concerned than the blood-vessels. Hence Mr. Hunter termed the different stages of inflammation the *adhesive*, the *suppurative*, and the *ulcerative*.

All parts of the body are not equally liable to each of the preceding consequences. It was remarked by Mr. Hunter, that in the cellular membrane, and in the circumscribed cavities, the adhesive stage takes place more readily than the others; suppuration may be said to follow next in order of frequency; and, lastly, ulceration. Whenever mucous membranes are affected, the suppurative inflammation comes on more readily, than either the adhesive or the ulcerative. Here adhesions, which originate from the slightest degree of inflammation in other situations and structures, can only be produced by the most violent kind. Indeed, ulceration is much more frequently met with upon mucous surfaces than adhesions. The cellular membrane

appears to be much more susceptible of the adhesive inflammation than the adipose, and much more readily passes into the suppurative. Thus, we see the cellular substance, connecting the muscles together, and the adipose membrane to the muscles, inflaming and suppurating, and the matter separating the muscles from their lateral connections, and even the fat from the muscles, while the adipose substance and the skin are only highly inflamed. Yet, it must be allowed, that in situations where fat abounds, we very frequently meet with abscesses. This is so much the case, that Mr. Bromfield accounted the fat a more common nidus for collections of matter, than the cellular substance itself. Thus abscesses about the anus, mamme, &c. are remarkably frequent. When we speak of the fat inflaming and suppurating, we should rather say, that the membranous cavities containing this secretion are so affected; for, fat itself has no vessels, principle of life, nor action of its own, and, consequently, cannot be supposed to be capable of undergoing inflammation and suppuration.

Parts of the body, which lie deeply from the surface, but more particularly such as are known by the name of vital, are readily affected with the adhesive inflammation. That they are not so much disposed to suppurate as the superficial parts are, is strikingly illustrated in cases of extraneous bodies, which, if deeply lodged, only produce the adhesive inflammation. By this process a cyst is formed, in which the foreign body lies, without much inconvenience to the patient, and may even change its situation, without ferriously disturbing the parts through which it passes. But no sooner does it approach the skin, than abscesses immediately arise.

Much might be said concerning the difference of the pulse in the various cases of inflammation. Thus, when any part of the surface of the body is affected with a certain degree of phlegmonous inflammation, the pulse is generally full, frequent, and strong. When the peritoneum and bowels are inflamed, it is very quick and small, &c. We shall not, however, enlarge upon this topic, as the state of the pulse, in the several cases, will be noticed in the many articles of this work appropriated to the consideration of inflammatory diseases.

According to Mr. Hunter, the susceptibility of the body for inflammation is of two kinds; the one *original*, constituting a part of the animal economy, and beyond the reach of human investigation; the other *acquired* from the influence of climate, habits of life, and state of the mind over the constitution. The first kind of susceptibility, being innate, cannot be diminished by art; the second may be lessened by the mere avoidance of the particular causes upon which it depends. These latter might be named *predisposing*.

With regard to the *remote*, *exciting*, or *occasional* causes of inflammation, they are infinite in number; but very easy of comprehension, because most of them are referable to two general classes. The first includes all such as operate by their stimulant or chemical qualities, as, for instance, heat, cantharides, sulphuric acid, aqua ammonia puræ, &c. The second embraces such as act mechanically, as bruises, wounds, fractures, &c.

The principle on which cold becomes an exciting cause of inflammation, is yet contested among surgical writers, and may still be considered as not decidedly known.

Feveris would sometimes appear to be the exciting cause of inflammation. The local affection, thus originating, is often called *critical*, and is supposed by many to be the means, by which a stop is put to the constitutional indispo-

INFLAMMATION.

sion. Strong injunctions are, therefore, given not to repress an inflammation of this kind, lest the method should be productive of some worse and even fatal disorder. We have always considered this mode of reasoning unsatisfactory, and should have little apprehension of any real evils, which might arise from the attempt to diminish an inflammation, that appears as a consequence of a fever.

The following observations respecting the proximate cause of inflammation, are taken from Mr. S. Cooper's Dictionary of Practical Surgery.

Numerous opinions have been entertained upon this subject; but almost every theory has been built upon the supposition of there being some kind of obstruction in the inflamed part.

While the circulation of the blood was unknown, and the hypothetical notions of the power of the liver, in preparing and sending forth this fluid continued to prevail, it is not astonishing, that the theories of physic should be exceedingly imperfect. So fully persuaded were physicians of the existence and influence of different humours and spirits, and so little did they know of the regular and constant motion of the blood, that they believed in the possibility of depositions and congections of the blood, the bile, or lymph; and acknowledged these as the cause of inflammation. Their anatomists taught them, and their professors of physic supported the opinion, that the liver was the centre of the vascular system, from which the blood went forth by day to the extremities, and returned again by night. If then any peccant matter irritated the liver, the blood was sent out more forcibly; and if, at the same time, any part of the body were weakened, or otherwise disposed to receive a greater quantity of fluid than the rest, then a swelling was produced by the flow of humours to this place. Fluxions, or flows of humour to a place, might happen either from weakness of the part which allowed the humours to enter more abundantly, or from the place attracting the humours, in consequence of the application of heat or other agents.

The peculiar nature of the swelling thus occasioned was supposed, by the ancients, to depend upon the kind of humour. Blood produced the true phlegmon, bile, erysipelas, &c.

The ancient physicians also entertained an idea, that the blood and humours might slowly stagnate in a part, from a want of expulsive power, and this affection was termed a *congestion*, while the expression *fluxion* or *defluxion* was used to denote any swelling arising from the sudden flow of humours from a distant part. The first was formed gradually without much pain, or the feeling of pulsation, and ran its course slowly; the second appeared suddenly, and was very painful, had a pulsatory feel, and was rapid in its progress. The ancients, who supposed that the blood had very little motion, and that its course could be easily directed or changed, recommended bleeding from some part which was remote from a recent inflammation, by which they imagined that the current of blood was altered, and a *resolvent* made. A *resolvent* was also made by raising a tumour in some other part, by means of ligatures, cupping-glasses, &c. or by giving nature an opportunity of discharging the humours from distant parts, by applying leeches or blisters. Hence Scarpa's was applied to the feet in diseases of the superior parts.

When blood was drawn from the vicinity of the fluxion, or congestion, the mode was called *derivation*, which only differed from *resolvent* in the distance to which the humour was drawn being less.

We shall not enter further into an account of the practice

of the ancients in the treatment of inflammation; but shall refer the reader to what Mr. Burns has written on the subject. Our present object is only to trace the leading doctrines which have at different times prevailed, respecting the proximate cause of inflammation.

From the theories of *fluxion* and *congestion*, which were quite incompatible with the laws of the circulation of the blood, we turn our attention to the doctrine of *obstruction*.

Boerhaave inculcated, (Aph 375 et seq.) that inflammation was caused by an obstruction to the free circulation of the blood in the minute vessels, and this obstruction, he supposed, might be caused by heat, diarrhoea, too copious flow of urine and sweat, or whatever could dissipate the thinner parts of the blood and produce a thickens or viscosity of that fluid. When the lentor did not exil before the production of inflammation, he imagined, that the larger globules of the blood got into the small vessels, and thus plugged them up. When, for instance, the perspiration was stopped, the fluid, being retained, dilated the vessels, and allowed some of these milchivous globules to enter, and produce a more permanent obstruction. This circumstance was termed an *error loci*, and was one of the chief causes assigned for inflammation. The obstruction, whether caused by *viscosity* or an *error loci*, was imagined to occasion a resistance to the circulation in the part affected; hence increased it in the other vessels, proving an irritation to the heart, and augmenting the force or attraction of the blood in that part of the vessel which was behind the obstruction. This caused heat and pain, while the accumulation of the blood produced redness; which three symptoms are the essence of the disease. Besides *obstruction*, Boerhaave also brought into the account an *acrimonious state of the fluids*, which rendered resolution out of the question, and gangrene likely to follow. Aph. 388.

The viscosity of the blood cannot be admitted as the proximate cause of inflammation; because we have no proof that this state ever exilts; or, granting that it did, it would not explain the phenomena. Were a viscosity to occur, it would exil in the whole mass of blood, would affect every part of the body alike, and could not be supposed to produce only a local disorder. How also could such a lentor be produced by causes which bring on inflammation suddenly, without there being time for changes of the fluids to take place?

With regard to the doctrine of *error loci*, or of red globules going into vessels, which did not formerly transmit them, the fact must be admitted, at the same time, that the conclusion is denied. When the eye becomes inflamed, the tunica conjunctiva is seen with its vessels full of red blood, which in health is not the case; but this redness never appears until the inflammation has commenced; and must, therefore, be considered as an effect, not a cause. Nor can this *error loci* occasion any obstruction in these vessels; for if they be divided, the blood flows freely, which shews, that they are large enough to allow an easy circulation.

Boerhaave's theory of obstruction was too circumscribed, and too mechanical; it reduced all inflammations to one species. The only distinctions which could have arisen, must have proceeded from the nature of the obstruction itself. This doctrine could never account for the action of many specific diseases and morbid poisons.

As for the supposition of the co-operation of an *acrimony of the fluids*, the proportion of the saline matter of the blood has never been proved to be greater in this, than in any other state of the body. Even were a general disorder of this kind to be admitted, no rational explanation of the proximate cause of local inflammation could be deduced from it.

INFLAMMATION.

Dr. Cullen attributed the proximate cause of inflammation to a "spasm of the extreme arteries supporting an increased action in the course of them." This theory only differs from that of Boerhaave in the cause which is assigned for the obstruction. Some causes of inequality in the distribution of the blood, may throw an unusual quantity of it upon particular vessels, to which it must necessarily prove a stimulus. But, farther, it is probable that, to relieve the congestion, the *vis medicatrix naturæ* increases still more the action of the vessels; and which, as in all other febrile diseases, it affects, by the formation of a spasm on their extremities. "A spasm of the extreme arteries, supporting an increased action in the course of them, may, therefore, be considered as the proximate cause of inflammation; at least, in all cases not arising from direct stimuli applied; and even in this case, the stimuli may be supposed to produce a spasm of the extreme vessels."

The inconsistencies in Cullen's theory are very glaring. The congestion or accumulation of blood, which is only an effect or consequence of inflammation, is set down as the cause of the spasm of the vessels, to which spasmodic contractions Cullen, strangely enough, assigns the name of proximate cause. The spasmodic contraction of the extremities of the vessels, instead of propelling the accumulated quantity of blood, would render the passage of the blood from the arterial into the venous system still more difficult. Spasmodic constriction of the small vessels is so far from being a satisfactory explanation of the proximate cause of inflammation, that even tying a large vessel does not of itself bring on the affection. Phlegmon is also attended with an effusion into the cellular substance from the extremities of the arteries; a circumstance not easily explained upon the principle of obstructed circulation. See Burns on Inflammation.

We shall now notice the celebrated, and very original opinions promulgated on this subject by the famous John Hunter. According to him inflammation is to be considered only as a disturbed state of parts, which requires a new, but salutary mode of action, to restore them to that state, wherein a natural mode of action alone is necessary. From such a view of the subject, therefore, inflammation, in itself, is not to be considered as a disease, but as a salutary operation, consequent either to some violence, or some disease. Elsewhere, the author remarks, the act of inflammation is to be considered as an increased action of the vessels, which, at first, consists simply in an increase or distention beyond their natural size. This increase seems to depend upon a diminution of the muscular power of the vessels, at the same time that the elastic power of the artery must be dilated in the same proportion. This is, therefore, something more than simply a common relaxation; we must suppose it an action in the parts to produce an increase of size, to answer particular purposes, and this Mr. Hunter would call an act of dilatation. The whole is to be considered as a necessary operation of nature. Owing to this dilatation, there is a greater quantity of blood circulating in the part, which is according to the common rules of the animal economy; for, whenever a part has more to do than simply to support itself, the blood is there collected in larger quantity. The swelling is produced by an extravasation of coagulable lymph, with some serum; but this lymph differs from the common lymph, in consequence of passing through inflamed vessels. It is this lymph which becomes the uniting medium of inflamed parts; vessels shoot into it, and it has even the power of becoming vascular itself. The pain proceeds from spasm. The redness is produced either by the arteries being more dilated than the veins, or because the blood is not changed

in the veins. When, after an injury, a part cannot be restored to health by inflammation alone, or by adhesion, then suppuration, as a preparatory step to the formation of granulations, and the consequent restoration of the part, takes place. The vessels are nearly in the same state as in inflammation; but they are more quiescent, and have acquired a new mode of action. See Hunter on the Blood, Inflammation, &c.

An increased action of the vessels is now almost universally regarded as the proximate cause of inflammation. This opinion derives strong support from a review of the several exciting causes of the affection, which, being in general of an irritating nature, must, when applied to living or sensible parts, occasion a preternatural exertion of their vessels. The method of cure tends also to confirm the common sentiment concerning the proximate cause of inflammation. See Dictionary of Practical Surgery.

Treatment of Inflammation.—According to the preceding views of the subject, the first and principal object to be aimed at in the treatment of inflammation, is to diminish that immoderate action of the arteries, which exists in so conspicuous a degree. There are several means conducive to this end; but that which demands primary attention, and, indeed, which seems to be indicated by common sense, is to remove, if possible, whatever constitutes the remote or exciting cause of the inflammation. Thus, supposing the eye were to inflame in consequence of a small insect lodging under the eyelids, how obvious would be the propriety of immediately taking away the source of irritation? If the irritation of a thorn or splinter should excite inflammation, who would not of his own accord endeavour to extract the extraneous substance? When the affection is excited by extravasated urine, by pressure, friction, stimulating applications, &c. the surgeon often has it in his power to render most essential service, by removing at once what excites and keeps up the complaint. Frequently, the exciting cause is transient in its operation, and yet, the inflammation cannot be prevented from running a certain course. Thus, many kinds of external violence are inflicted in a moment; but inflammation must follow, and go through its operations, though the duration of the circumstance which gave rise to the process has ceased. The living solids demonstrate, in these instances, a kind of reaction. Since, therefore, the removal of the stimulus which excites inflammation will not always put an immediate stop to the complaint, however it may tend to alleviate it, we are generally called upon to moderate, by other means, the increased vascular action.

There are few persons so entirely ignorant of the subject before us, as not to know that bleeding is one of the most powerful means of counteracting inflammation. This well known fact, which has obtained the assent of the most celebrated physicians and surgeons in every age and country, can hardly fail to be quite congenial with such ideas and expectations as are naturally impressed upon the mind by a description of the disorder. Indeed, one principal effect of the increased action of the vessels, is the transmissibility of a larger quantity of blood through the inflamed part. The propriety of endeavouring, therefore, in most cases, to diminish this determination of blood to the seat of the inflammation, cannot be doubted. The chief mode of accomplishing this object is by general and topical bleeding. This evacuation is called *general*, when the blood is taken from a large vessel, at a distance from the inflamed part; *local* or *topical*, when the blood is evacuated by leeches, scarifications, or cupping, from the vessels which are near, or belong to the inflamed part. General bleeding is not so invariably proper as topical.

INFLAMMATION.

cal. Inflammation is a local affection, and therefore must particularly require local curative means. Objections have been urged against topical bleeding, except when the skin, over and near the inflamed part, is itself free from the inflammation. However, most surgeons in this country think otherwise; they put leeches on the inflamed skin, and even scarify the dilated vessels of the conjunctiva, in cases of ophthalmia, as we think, with decided good effect. It is also an incontrovertible truth that bleeding is generally more effectual, the nearer the evacuation is made to the seat of the inflammation. But it is not always in our power to take away a sufficient quantity of blood in this manner. Many inflammations must be immediately checked, or the patient is destroyed. Therefore, when inflammation affects a part of such consequence in the animal economy that it cannot undergo much disturbance, without life itself being endangered, the surgeon is not to be satisfied with local measures. Thus, when the brain, the lungs, the stomach, the bowels, &c. are inflamed, the inflammation, unless suddenly arrested, will inevitably end in death. Also, when the inflamed parts are endowed with inferior powers of recovery, it is often necessary to have recourse to general as well as topical bleeding; as in inflammation of a joint. When inflammation is situated in an organ, where suppuration would certainly destroy its uses, it is likewise advisable to moderate the local affection, even at the expence of the whole system. Ophthalmia is a case of this kind. Moreover, it ought to be well understood that every considerable and extensive phlegmonous inflammation, wherefoever situated, ought always to be resisted by general bleeding.

There is no utility in bleeding, when the inflammation and fever are trivial, and the cause of the disorder can be entirely removed. Such evacuation must often be hurtful and dangerous, when the patient is much debilitated by previous indisposition, extreme age, or any other circumstance. The symptomatic fever, attendant on inflammation, can seldom be of itself a just ground for bleeding, as it constantly increases and subsides with the local affection. We are, therefore, to be principally guided by the state of the inflammation. Bled with a view of diminishing this, but never for the sole purpose of lessening the fever.

It is a principle very generally acknowledged by surgeons, that the efficacy of bleeding is greater the sooner it is practiced, the nearer it is done to the part affected, and the more suddenly the blood is discharged. Hence, when an organ, like the brain, is inflamed, and it is an object of infinite moment to put an immediate check to the inflammation, the surgeon should take away in the first instance sixteen or twenty ounces of blood, if possible, from the temporal arteries; but if that quantity cannot be thus procured, the deficient proportion ought to be taken from the arm.

Another plan, calculated to check and diminish inflammation, and which is necessary in almost all cases, is to give the patient mild aperient medicines, such as Epsom salt, Glauber's salt, magnesia sulphas, &c. Strong drastic purgatives, through their irritation on the constitution, are seldom allowable, and almost always prove hurtful. Gentle purging is even more invariably proper, in all cases where inflammation already exists, or is to be apprehended, than bleeding; for this latter evacuation is productive of more lasting weakness, and therefore, in slight cases, and weak habits, is generally dispensed with. Purgings probably counteracts inflammation, first by increasing the secretion of the bowels, so as to lessen the quantity of the circulating fluids; and secondly, by specifically diminishing every operation going on in the body, and among others, inflammatory action.

In many instances, the effect of the aperient medicines is

to be promoted with clysters. Indeed, there are some examples, where the latter are safer than purgatives given by the mouth: when the peritonum and bowels are inflamed, the prudent surgeon is often afraid to prescribe any very active opening medicines. Perhaps he ventures to exhibit half an ounce of the oleum ricini, which frequently does not take effect, although the dose be repeated, until assisted with a clyster.

Antimonial medicines have acquired considerable reputation in numerous cases of inflammation, and, as far as we can judge, they are really of eminent service. Nauseating doses of antimonium tartarizatum prove advantageous in several ways; they relieve that oppressive dryness of the skin, which accompanies the fever attendant on severe local inflammation; they promote all the excretions; and they diminish the increased action of the inflamed part. The latter effect is produced, because, whenever an inclination to sickness prevails, the sympathy of the whole constitution with the stomach is so intimate, that the system is immediately thrown into a temporary state of debility, every considerable operation in the machine becoming lowered, and, among others, the process of inflammation. When the inflammation is dangerous, and there is urgent reason for putting an immediate check to it, the employment of antimonials ought never to be neglected. Thus, when the brain or its membranes are affected with inflammation, it is usual to exhibit small doses of antimony.

Opium is not prescribed in cases of common inflammation, unless the severity of the pain render this medicine indispensably necessary; for it is generally considered as a powerful stimulant, and therefore hurtful in regard to the local complaint. Instances, however, certainly do present themselves, in which opium is proper. Procuring the patient ease and sleep, during the violence of many severe inflammations, is an object of the highest importance; and, it may be questioned whether the inflammation itself would not be aggravated more by leaving the patient to all his pain and restlessness, than by making an attempt to diminish his sufferings, and lull him to sleep by opiates. One thing seems certain, that if opium is to be given in cases where pain and inflammation exist, it should be prescribed in an adequate dose. Thus, after any great operation, such as an amputation, the removal of a breast, &c. the surgeon should give from twenty-five to forty drops of the tinctura opii; small doses of opium, in such cases, always have the effect of seriously increasing the restlessness, fever, &c. instead of affording ease, and procuring sleep.

The patient's regimen and diet are to be low; no spirits nor fermented liquors are allowable; and when the inflammation is at all extensive, or such as to be of consequence, the patient should abstain from eating meat, and live on thin broths, barley-water, tea, &c. The practitioner would in vain make depletions in order to stop an inflammation, while his patient was living upon gross, hot, stimulating dishes. On the contrary, when the regimen and diet are such as they ought to be, the patient will do with less evacuations, and his health will not be so much injured by the requisite treatment. He should be advised to drink plentifully of diluent cooling beverages, like lemonade and acidulated barley-water. Oranges, strawberries, saline draughts, &c. may be permitted, as being exceedingly grateful to patients, who are feverish and thirsty, from being affected with any serious degree of inflammation. The patient's chamber should be kept cool, nor ought he to be covered with too much bedding. The antiphlogistic regimen, moreover, requires perfect repose both of body and mind.

With

With regard to the topical applications, these are generally either cold astringent lotions, or else warm relaxing emollients. Heat is well known to promote and increase all animal actions, and must therefore tend to keep up and augment the process of inflammation. Hence arises the indication to diminish the heat of the part affected, by making use of cold topical applications, and maintaining a continual evaporation from the inflamed surface. The common plan is to dip linen in the saturnine lotion, and after folding it once or twice, lay it all over the part affected, taking care afterwards to keep it constantly wet with the application. In some instances cold water will answer every purpose; in others the aqua ammoniac acetate, or lotions of the sulphate of zinc, alum, &c. may be employed. Poultices made with linseed-meal and water, or with bread and milk, are the ordinary emollient applications when such are considered proper. Those of the first kind are frequently preferable to the latter, which are apt to turn sour and acquire an irritating quality, a circumstance of high importance where the cuticle is detached, ulceration is present, or the part is exquisitely sensible. When poultices are used, fomentations are also frequently proper, as having in all febrile cases a great effect in lessening the pain. Likewise, when suppuration is unavoidable, they accelerate the cure by promoting the formation of matter, and hastening its approach to the surface of the body. The common method is to dip flannels in a decoction of chamomile flowers, or white poppy heads, wring them, and apply them very warm to the inflamed part.

In discriminating the cases which require cold applications from others to which warm ones are most serviceable, the practitioner should always bear in mind, that when suppuration is inevitable, it is invariably most advantageous to discontinue cold astringents without delay. In general, where the chance of the inflammation being resolved is great, cold applications are best; but sometimes the choice of the topical remedies must be partly regulated by the patient's feelings. There are some patients who seem to derive most ease from cold applications: there are others who appear to experience most comfort from cold ones. The latter remedies ought perhaps rather to have the preference, when the prospect of preventing suppuration is fair and rational, and when at the same time they afford as much ease as poultices.

In technical language, inflammation is said to have different terminations. When the redness, swelling, heat, and pain, all gradually subside, without any formation of matter, the case ends in what is termed *resolution*, which is the most favourable event that can happen.

In some instances, a change takes place in the action of the vessels of the inflamed part, and they assume the power of secreting pus, or matter. Thus an abscess is formed, and the case (surgically speaking) terminates in *suppuration*.

In certain examples, ulceration is a direct consequence of inflammation, but in general an abscess precedes the sore.

The last termination of inflammation, to be noticed here, is in *mortification*, which is the worst, but happily the least frequent result of common cases. See GANGRENE, SUPPURATION, &c.

For an account of particular kinds of inflammation, see Erysipelas, Anthrax, Carbuncle, Furunculus, Scrofula, Lues Venerea, &c.

The inflammations of various parts of the body are also treated of under distinct heads. For inflammation of the eye, see Ophthalmia; for that of the parts about the

anus, see Fistula in Ano; for that of the dura mater, see Injuries of the Head; for that of the testicle, see Hernia Humoralis; for that of the fingers, see Whitlow, &c. &c.

INFLAMMATION of the Bladder. See CYSTITIS.
 INFLAMMATION of the Bowels. See ENTERITIS.
 INFLAMMATION of the Brain. See PHRENETIS.
 INFLAMMATION of the Diaphragm. See PARAPHRENETIS.
 INFLAMMATION of the Ear. See OTALGIA.
 INFLAMMATION of the Eye. See OPHTHALMIA.
 INFLAMMATION of the Heart. See CARDITIS.
 INFLAMMATION of the Kidneys. See NEPHRITIS.

 INFLAMMATION of the Throat. See CYNANCHE.
 INFLAMMATION of the Tonsils. See CYNANCHE Tonsillarum.
 INFLAMMATION of the Womb. See HYSTERITIS.

INFLAMMATION, Spontaneous, of earthy matters, in Mining. It is a curious and important fact, that several pyritic and bituminous thin strata which are found accompanying the coal-seams in some situations, will, on being thrown out or exposed to the air in the works, heat and take fire. This seems particularly the case in the thick coal-seam about Dudley in Staffordshire, as mentioned by Mr. Keir in Shaw's History of Staffordshire. In different parts of Derbyshire there are also thin strata of duns, taws, &c. which thus intumesce and take fire in the coal-works, as at Heanor, Derby-hall and other pits, which are particularized by Mr. Farey in his Report on this county, vol. i. p. 348.

INFLAMMATORY DISEASES, in Medicine, are all those diseases in which any part or organ of the body is affected with inflammation, as above described; but these terms, in the general acceptation, imply more particularly those acute and severe inflammations which excite a degree of febrile commotion in the system. In addition to those just enumerated, with references, the gout, acute rheumatism, erysipelas, &c. may be included under the class of inflammatory diseases, and, together with them, constitute, in fact, a distinct Order, in the system of our best nosologist, Dr. Cullen, under the title of *Phlegmasia*; namely, the second order, of the first class, *Pyrexia, or Febrile diseases*. See his Nosol. Method.

We judge of the presence of an internal inflammatory disease by the occurrence of the following congeries of symptoms; namely, when, together with a state of fever, there is a fixed pain in any internal part, attended with some interruption in the exercise of its functions. It is to be observed, that the concurrence of all these symptoms is necessary to prove the existence of active inflammation in any organ, and that the occurrence of any one or two of them may originate from other causes than inflammation. Thus pain may arise from a spasmodic contraction of the muscular fibres of the part, and it may be moveable, and pass from one part to another; fever may arise with or without pain; and the functions of an organ may be impeded without either pain or fever. In none of these cases are we to conclude that active inflammation is going on. We may illustrate this with respect to inflammation of the lungs, or *peripneumony*. This disease is known to be present, when, together with general fever (*i. e.* a frequent pulse, hot skin, thirst,

thirst, &c.), there is a fixed *point* in some part of the chest, cough, and difficulty of breathing. (Cullen, Nosol. Meth. Class i. Ord. ii. Gen. 11.) Now fever occurs from many other causes, and without these other symptoms; in which case no pulmonary inflammation is judged to be present. Pain may be felt in the chest when there is neither cough nor fever, nor difficult respiration, as in the case of rheumatism in the intercostal muscles, the diaphragm, or perhaps the mediastinum, or in the case of partial or general spasm in these muscles. It may be also felt, with difficulty of breathing, but without fever, as in the case of spasm of the diaphragm, in hydrothorax, or in *angina pectoris*; or it may concur with fever when there may be no cough, as sometimes happens when the liver is inflamed on the surface contiguous to the diaphragm. Again, there may be an impeded function (*i. e.* in this case *difficulty of respiration*) without fever or pain, as in many cases of asthma and chronic dyspnea, connected with a spasmodic contraction of the bronchial passages, or a considerable secretion of mucus into the cells and bronchial tubes. But where there is inflammation in the lungs, there is necessarily, in the first place, a symptomatic fever; in the next, from the congestion and over-distention of the vessels of the inflamed organ, there is a fixed *point*, and also a difficulty of admission of air into the compressed cells, *i. e.* *difficult breathing*; and the irritation upon the nerves of the bronchiæ, by this congestion, as well as by the mucus secreted, necessarily excites cough.

These concurring phenomena, then, of pain and impeded function in any organ, with general fever, are the diagnostic symptoms of all internal inflammatory diseases. But there are still other phenomena which indicate the degree of violence of the inflammation which is going on. These are principally the other conditions of the pulse, besides its frequency, and the appearance of the blood drawn from the veins. Where an acute inflammation subsists, the pulsation of the heart and arteries is generally very vigorous; so that the pulse at the wrist strikes against the finger with a considerable force, and with a sharpness of stroke which elevates the finger, compressing the artery, even when firmly held on it. The terms hard, strong, and sharp, have been used to denote this vigorous pulsation of the artery. The degree of hardness, strength, or sharpness of the pulse, however, varies greatly, not only according to the violence of the disease, but to the vigour of the patient's natural constitution; and it differs also according to the peculiar structure of the organ inflamed; all of which circumstances must be taken into the consideration of the physician before he decide upon the practical treatment which he shall adopt. Even in the most severe inflammation, which a very delicate habit is capable of undergoing, the pulse may be less full and strong than in a slight febrile affection in a robust habit; but there is generally a degree of sharpness in the stroke of the pulse, even in a feeble habit under the excitement of acute inflammation, which the *tail*, acquired by a little experience, enables the physician to estimate. Besides, in such cases, the degree of pain and of impeded function, and the state of the pulse, mutually illustrate each other. If the pain has remained fixed and severe for many hours, and the function of the suffering organ is greatly deranged, although the pulse may betray but a moderate degree of sharpness or hardness in a habit not originally strong, the proper evacuations for the cure of inflammation must be considered as indicated. This is particularly necessary, as we have just hinted, in respect to certain organs. When there is an acute inflammation in the lungs or liver, and especially when the enveloping membranes are affected, the pulse is perhaps invariably characterized by hardness and strength. (See HEPATITIS and PLEURISY.)

But when the *stomach* is inflamed, the pulse is often without any considerable hardness, and generally small, but very frequent. In this case, therefore, the existence of acute inflammation might be overlooked, if we judged principally from the pulse; and it is necessary to compare the state of the pulse with the degree of fixed burning pain in the stomach, and the sudden increase of that pain, as well as the vomiting which is excited by any thing whatever that is taken into the stomach, in order to ascertain the nature of the disease. See GASTRITIS.

The other circumstances, which has been mentioned as aiding us in distinguishing the degree of violence of any internal inflammation, is the appearance of the blood drawn from the veins. When the lancet is used in inflammatory diseases, the blood, which is drawn, after standing some time in any vessel until coagulation has taken place, exhibits, on the surface of the *coagulum*, a thick gelatinous substance, without any admixture of red blood; this has been variously termed the *buffy coat*, or simply the *buff*, the *inflammatory crust*, &c.; and has been considered as a proof of the existence of inflammation, and as a test, in a great measure, of the severity of the disease. It is certain, that this buffy crust is commonly found in pleurisy, peripneumony, hepatitis, acute rheumatism, &c., and is not seen where blood flows from a person in ordinary health. It seems to arise from a difference in the mode of coagulation, so that the red particles subside and leave the upper portion of the coagulating lymph untinged; and not to consist of a morbid humour in the blood, as the humoral pathologists believed. But experience has taught us, that the buffy state of the blood is not a criterion, by which the necessity or propriety of blood-letting can be determined in diseases. For, not to mention the absurdity of relying upon a test, which requires the practice to be adopted, to some extent or other, before its propriety can be ascertained, (a doctrine which has often led to the folly of taking away a little blood, "to see how it looked,") observation has proved, that the blood is actually often in the condition to shew the buffy coat, where no inflammatory action is going on, and where, although a certain degree of inflammatory action may be present, yet it will not be removed by blood-letting; but if the blood-letting be repeated, the patient may be destroyed before the buffy coat on the blood will disappear. Thus the buffy coat is almost invariably seen on blood drawn from women in a state of pregnancy; it is likewise seen on that, which is taken from persons labouring under hectic fever, from pulmonary contusion; nay, it has been observed on the blood drawn from patients affected with the typhus fever, and with scurvy (see FOURCROY, *Commiss. Chimiques*; also BLOOD, *morbid alterations of*); in all which cases we should occasion infinite mischief, were we to conceive that this appearance indicated the necessity of repeating the use of the lancet. But, farther, it is a fact, which has not hitherto been satisfactorily explained, that in a violent attack of unequivocal inflammation, as of pleurisy, if, during one bleeding, the blood be received in two or three different vessels, the coagulum in one or two of the vessels shall present the buffy coat, while none will appear on that in the others; and in like manner, if blood-letting be repeated two or three times, the blood of the first drawing shall exhibit no buffy crust, while that of the subsequent drawing shall shew it in large quantity. This variety has been principally attributed to the velocity with which the blood flows from the vein; thus it would appear, that the blood which trickles slowly down the arm, seldom shews so much buff, as that which flows in a full and copious stream. In a word, then, the appearances of the blood drawn in the cure of diseases, is to be considered as a very imperfect guide

in directing the farther use of the lancet, and is only to be deemed a secondary adjuvant in determining the proper mode of practice, in conjunction with a careful investigation of the violence of the symptoms of the disease, its duration, and tendency, and of the age, strength, and constitution of the patient.

In attempting to form an accurate *diagnosis*, in regard to inflammatory diseases, two difficulties present themselves: the first of these is the difficulty of distinguishing the inflammation of one organ from that of another, which is contiguous to it, or in its vicinity. For instance, the leading symptoms of inflammation of the lungs, in very many cases, are present in hepatitis, or inflammation of the liver, on the one hand, and in carditis, and pericarditis, or inflammation of the heart, and of the pericardium, on the other. The distinction, which is commonly supposed to exist between the inflammation of the heart and its membranous bag, and inflammation of the lungs, consists in the occurrence of palpitation, syncope, and an irregular pulse, in the former disease, in addition to the symptoms of the latter: but Dr. Cullen admits that these three symptoms are occasionally absent in *pericarditis*, and accords with the observation of Vogel, that "the symptoms of *carditis* are nearly the same as those of *peripneumony*, but more severe;" i. e. fever, with pain in the left side of the chest, difficulty of breathing, and cough. (See Cullen, *Nosol. Meth. Clafs i. Ord. ii. Gen. 13 and 11.*) In like manner, these four diagnostic symptoms of *peripneumony* and pleurisy are commonly present in inflammation of the liver, especially when the convex side of that viscus, which lies in contact with the diaphragm, is the seat of the inflammation: for in addition to fever, and pain in the side, a difficulty of breathing is occasioned by the suffering, which any attempt to depress the diaphragm in the act of inspiration, excited by compressing the inflamed liver; and a cough, which, however, is commonly dry, or unaccompanied by expectoration, but not always, and which is excited probably by the vicinity of the seat of irritation to the lungs. As the hepatitis proceeds, the other symptoms belonging to it, especially the bilious tinge of the skin and eyes, point out clearly the seat of the inflammation.

It is satisfactory, however, to know that, in such cases of extreme similarity of symptoms, no practical evil can arise from the inability to decide as to the seat of the disease: for, in the first place, the inflammation actually spreads, in some instances, to the contiguous organs, so that the symptoms indicative of the disorder in both must necessarily co-exist; and, in the second place, the inflammation requires the same practical measures to be adopted for its removal, in whatever viscus it may be seated; namely, evacuations proportioned to its violence, and to the vigour of the patient.

The second difficulty, in distinguishing inflammatory diseases, to which we have alluded, arises from the occasional severity and fixed seat of the pain, which is attendant on cramps or spasmodic diseases, more especially in the stomach and the bowels. Hence it is often extremely difficult to pronounce, whether an acute pain in the belly, for instance, is occasioned by the *colic*, or by *enteritis* (inflammation of the bowels), for constipation accompanies both; and although a mere spasmodic pain is very commonly present, without any acceleration of the pulse, or febrile heat; yet when such pain is extremely acute, and has continued for some length of time, the constitution begins to suffer from excessive irritation, and the pulsations of the heart and arteries are quickened; and if it still continues, actual inflammation in the part is liable to ensue, so that what was colic in the commencement, becomes finally enteritis. It is important to discriminate accurately in the outset between these two states

of pain; because that, which is spasmodic, may be removed by large doses of opium, and other antispasmodics; whereas the inflammatory pain would be augmented, and the disease itself rendered more dangerous, by the exhibition of such medicines. In making this discrimination, the practitioner is principally guided by the hardness and force, or the softness and weakness of the pulse;—by the rigidity of fibre and robust habit, or the contrary condition of the patient;—by the unsparing intensity and seat of the pain, or its occasional remissions and slight change of place;—and by a knowledge of the nature of former attacks, of a similar kind, where such have occurred.

The experienced and accurate observer of the phenomena of diseases, therefore, will seldom be at a loss in selecting the proper mode of treatment in such cases; and it is fortunate here also, that the evacuation of blood-letting, which is absolutely necessary to subdue a violent inflammatory affection of the bowels, often succeeds in removing a fixed and severe spasm in the same organs. And as a spasmodic affection, of considerable duration, is liable to terminate in inflammation and its fatal consequences, the depletion of the blood-vessels is indicated, under such circumstances, both as a preventive and as a cure, where the age, strength, and constitution of the patient do not render the safety of such a depletion very equivocal.

In regard to the treatment of inflammatory diseases, we have already in part anticipated the discussion. The great decisive remedy for such diseases is found, in diminishing the quantity of the circulating blood. This operation of blood-letting is supposed to produce its beneficial effects upon the disease, by removing the "stimulus of distention" from the blood-vessels; for it is an ascertained property of the living solid, to contract more forcibly after a great extension of its fibres. It cannot operate by letting out the *morbid matter* or *humour* from the circulating fluids, as the older pathologists imagined; for if we suppose the whole mass of fluids to be impregnated with a morbid humour, how can we, by abstracting a part, purify the condition of the remainder? The fact, however, is fully established, and cannot be invalidated by any error in the hypothesis, which may be framed for the purpose of explaining it. The depletion of the vessels may be effected by opening the smaller branches of the arteries, where they are superficial, and easily subjected to pressure, as in the temples;—or by opening the external veins by the lancet; or by a more limited and topical discharge by means of leeches, and cupping. The circumstances, under which one or other of these modes of depletion is to be preferred, vary materially according to the seat and degree of inflammation, and will be mentioned under the head of each disease. While this mode of reducing inflammatory action is resorted to, it is generally necessary, also, to employ other concurring means; such as purging, exciting a diaphoresis or gentle perspiration, procuring a discharge from the skin in the vicinity of the inflamed organ, by blisters, &c.; and, at the same time, to employ all the negative means of diminishing excitement, which constitute the antiphlogistic regimen; such as avoiding heat, noise, exertion of body or mind, and shunning all solid animal food, condiments, spirituous, viscid, or other fermented liquors, which increase the action of the vascular system.

INFLATION, formed from *in*, and *flatus*; or *fla*, *I blow*; *blowing up*, the act of stretching or filling any flaccid or distensible body, with a flatulent or windy substance.

INFLECTION, called also *diffraction*, and *deflection*, in *Optics*, is a property of light, by reason of which, when it comes within a certain distance of any body, it will either be

INFLECTION.

bent from it, or towards it; which is a kind of imperfect refraction or refraction. See DIREFRACTION.

This property was first taken notice of by Dr. Hooke; who shows that it differs both from *reflexion* and *refraction*; and seems to depend on the unequal density of the constituent parts of the ray, whereby the light is dispersed from the place of condensation, and rarified or gradually diverged into a quadrant: and this deflection, he says, is made towards the superficies of the opaque body perpendicularly. Some writers ascribe the first discovery of it to Grimaldi, the Jesuit. He first published an account of it, in his treatise "De Lumine, Coloribus, et Iride," printed in 1666; nor did any other person lay claim to the discovery, except Dr. Hooke, who communicated his observations on this subject to the Royal Society, in 1672. It appears, however, that Dr. Hooke had not heard of the discoveries of Grimaldi; for he speaks of his own as a discovery of a new property of light, not mentioned by any optical writer before him.

Sir Isaac Newton discovered also, by plain experiment, this inflection of the rays of light; and M. de la Hire assures us he found, that the beams of the stars being observed, in a deep valley, to pass near the brow of a hill, are always more refracted than if there were no such hill, or the observations were made on the top thereof; as if the rays of light were bent down into a curve, by passing near the surface of the mountain.

Sir Isaac Newton, in his *Optics*, makes several experiments and observations on the inflection of the rays of light; which see under *LIGHT*, and *RAYS*.

Although Sir I. Newton particularly examined the phenomena, relating to this subject, under a considerable variety of circumstances, his observations were not quite correct; nor was his hypothetical explanation very plausible. Subsequent experiments and observations seem to reduce the phenomena of inflection to a single principle, viz. to the attraction of bodies towards light; which attraction becomes conspicuous when the rays of light pass within a certain distance of their surfaces. Besides their being bent, the rays of light are likewise separated into colours by the vicinity of bodies, and this produces the singular phenomenon of the coloured fringes that accompany the inflection. Various experiments have been made relative to the inflection of light by Maraldi, Grimaldi, Delisle, Mairan, Du Tour, Muschenbroek, and others, as well as Newton; an account of which experiments the reader may see in Priestley's *History of Vision, Light, and Colours*, part vi. § 6.

M. de la Hire observed, that when we look at a candle, or any luminous body, with our eyes nearly shut, rays of light are extended from it, in several directions, to a considerable distance, like the tails of comets. The true occasion of this phenomenon, which has exercised the sagacity of Des Cartes, Rohault, and others, seems to be, that the light passing among the eye-lashes, in this situation of the eye, is inflected by its near approach to them, and therefore enters the eye in a great variety of directions.

INFLECTION, in *Grammar*, the variation of nouns and verbs, in their several cases, tenses, and declensions.

Inflection is a general name, under which are comprehended both conjugation and declension.

INFLECTION, *Point of*, of a curve, in *Geometry*, is a point or place where the curve begins to bend, or turn a contrary way.

If a curve line, as A F K (*Plate X. Analysis, fig. 2.*) be partly concave, and partly convex towards a right line, as A B, or towards a fixed point, the point F, which divides the concave from the convex part, and consequently is at the

beginning of the one and end of the other, is called the *point of inflection*, as long as the curve, being continued beyond F, keeps its course the same: when it returns back again towards that part or side from whence it took its origin, it is called the *point of retrogression*.

To conceive this, it is to be considered, that any quantity, which goes on continually increasing or decreasing, cannot change from a positive to a negative expression, or from a negative to a positive one, without first becoming equal to an infinite, or nothing. It becomes equal to nothing, if it continually decrease; and equal to an infinite if it continually increase.

Now, if through the point F be drawn the ordinate E F, and the tangent F L, and from any point, as M, on the same side of A F, be drawn the ordinate M P, and the tangent M T; then in curves which have a point of inflection, the absciss A P continually increases, and the part A T of the diameter, intercepted between the vertex of the diameter, and the tangent M T, increases also, till the point P fall into E; after which it again begins to diminish: whence the line A T must become a maximum A L, when the point P falls into the point E.

In those curves which have a point of retrogression, the part A T increases continually, and the absciss increases, till the point T falls into L; after which it again diminishes: whence A P must become a maximum, when the point T falls into L.

If A E = x, E F = y, then will A L = $\frac{y \dot{x}}{y}$ - x (see **TANGENT**), whose fluxion, which is $\frac{y^2 \dot{x} \dot{x} - \dot{y} \dot{x} y}{y^2} - \dot{x} = \frac{y^2 \dot{x} \dot{x} - \dot{y} \dot{x} y - \dot{y}^2 \dot{x}}{y^2}$, supposing \dot{x} constant,

being divided by \dot{y} , the fluxion of A L must become nothing; i. e. $\frac{-\dot{y} \dot{y}}{y^2} = 0$: so that multiplying by y^2 , and

dividing by $-\dot{y}$, $\dot{y} = 0$; which is a general form for finding F, the point of inflection, or retrogression, in those curves whose ordinates are parallel to one another. For the nature of the curve A F K being given, put the equation of the curve into fluxions; from which, or from other properties of the curve, find the value of \dot{x} or \dot{y} , and put this \dot{x} or \dot{y} and its value into fluxions, making both \dot{x} and $\dot{y} = 0$: then by expunging the rest of the fluxional quantities, we shall determine the value of x, i. e. A E or y, i. e. E F, at the point of inflection sought.

To distinguish the points of inflection from those of retrogression, which arise indifferently according to the above method, it will be sufficient to attend to the progress of the curve, by taking any ordinate very near the point; which will always serve to remove any doubt on that head.

Ex. 1.—To find the point of inflection B in the curve A B Y (*fig. 3.*) whose equation (putting the absciss A C = x, ordinate C B = y, and the perpendicular A E = a) is $a^2 x^2 = a^2 y + x^2 y$. From the fluxion of this equation, viz. $2 a x \dot{x} = a^2 \dot{y} + x^2 \dot{y}$. From the fluxion of this equation, viz. $2 a x \dot{x} = a^2 \dot{y} + 2 x \dot{x} \dot{y} + x^2 \ddot{y}$, we deduce $\dot{y} = \frac{2 a x \dot{x} - 2 x \dot{x} \dot{y}}{a^2 + x^2}$

i. e. by substituting for \dot{y} its value $\frac{a x^2}{a^2 + x^2}$, $\dot{y} = \frac{2 a^1 x \dot{x}}{(a^2 + x^2)^2}$; and the fluxion of this equation, making both \dot{x} and $\dot{y} = 0$,

is $0 = \frac{2 a^1 \dot{x}^2 (a^2 + x^2)^3 - (3 a^1 x \dot{x} + 4 x^2 \dot{x}) 2 a^1 x \dot{x}}{(a^2 + x^2)^4}$
which,

INFLECTION.

which multiplied by $(a^2 + x^2)^2$ and divided by $2 a^2 x^2$, gives $0 = (a^2 + x^2) - 4 a^2 x^2 - 4 x^4$; therefore, $4 x^4 + 4 a^2 x^2 = (a^2 + x^2)^2$; which equation divided by $x^2 + a^2$ makes $4 x^2 = a^2 + x^2$; therefore $3 x^2 = a^2$, and $x = a \sqrt{\frac{2}{3}}$; and if this value be substituted for it in the given equation of the curve, we shall have y , or the ordinate at the point of inflection $= \frac{a x^2}{a^2 + x^2} = \frac{\frac{1}{3} a^3}{\frac{4}{3} a^2} = \frac{1}{4} a$. I. et

A C be equal to $\frac{1}{2}$ A E, and with the radius e E, describe the arc E C; then will C be the point from which the ordinate to the point of inflection must be drawn: for $e C = \frac{1}{2} a$; and $C e^2 - e A^2 = A C$, i. e. $\frac{3}{4} a - \frac{1}{4} a^2 = \frac{1}{2} a^2 = A C^2 = x^2$; or $x = a \sqrt{\frac{2}{3}}$.

Another method of finding the point of inflection, or retrogression, is as follows. From the nature of curvature it is evident, that while a curve is concave towards its axis, the fluxion of the ordinate decreases, or is in a decreasing ratio, with regard to the fluxion of the absciss; and on the contrary, this fluxion increases, or is in an increasing ratio to the fluxion of the absciss, when the curve is convex towards the axis; and hence it follows, that these two fluxions are in a constant ratio at the point of inflection, or retrogression,

where the curve is neither concave nor convex; that is, $\frac{\dot{x}}{y}$, or $\frac{\dot{y}}{x}$, is a constant quantity. But constant quantities have

no fluxion, or their fluxion is equal to 0; whence we derive this general rule.

Put the given equation of the curve into fluxions; from which equation of the fluxions, find either $\frac{\dot{x}}{y}$, or $\frac{\dot{y}}{x}$, and take again the fluxion of this fraction, and make it equal to 0, and from this last equation find also the value of the same expression $\frac{\dot{x}}{y}$, or $\frac{\dot{y}}{x}$; and by equating these two, and the given equation of the curve, x and y will be determined, being the absciss or ordinate answering to the point of inflection. Or, otherwise, putting the fluxion of $\frac{\dot{x}}{y} = 0$, that is

$$\frac{\ddot{x} y - \dot{x} \dot{y}}{y^2} = 0; \text{ or } \ddot{x} y - \dot{x} \dot{y} = 0, \text{ whence } \ddot{x} y = \dot{x} \dot{y},$$

or, $\dot{x} : y :: \ddot{x} : \dot{y}$, that is, the second fluxions have the same ratio as the first fluxions; and therefore if \dot{x} be constant, or $\ddot{x} = 0$, then shall $\dot{y} = 0$, which gives the following rule, viz.

Take both the first and second fluxions of the given equation of the curve; in which make $\dot{x} = 0$, and $\dot{y} = 0$, and the resulting equations will determine the values of x and y , or the absciss and ordinate answering to the required point.

This repeating again the preceding example, in which the given equation is $a x^2 = a y + x^2 y$; and of which the point of inflection is required.

By the first rule, the fluxion of $a x^2 = a^2 y + x^2 y$, is $2 a x \dot{x} = a^2 \dot{y} + 2 x y \dot{x} + x^2 \dot{y}$; whence $\frac{\dot{x}}{y} =$

$$\frac{a^2 + x^2}{2 a x - 2 a y}$$

And now making again the fluxion of this quantity = 0, we have

$$2 x \dot{x} (a x - x y) = (a^2 + x^2) (a \dot{x} - y \dot{x} - x \dot{y}); \text{ whence } \frac{\dot{x}}{y} = \frac{a^2 + x^2}{a^2 - x^2} \times \frac{x}{a - y}$$

And now equating these two expressions, we have

$$\frac{a^2 + x^2}{a^2 - x^2} \times \frac{x}{a - y} = \frac{a^2 + x^2}{2 x} \times \frac{1}{a - y}$$

which being reduced, gives $2 x^2 = a^2 - x^2$, or $3 x^2 = a^2$, and $x = a \sqrt{\frac{2}{3}}$, the same result as before; and this value of x substituted in the original equation of the curve, becomes

$$y = \frac{a x^2}{a^2 + x^2} = \frac{\frac{1}{3} a^3}{\frac{4}{3} a^2} = \frac{1}{4} a, \text{ the ordinate at the point of inflection.}$$

The second method differs from the first rather in enunciation than in principle, the application of it is therefore omitted.

Ex. 2.—Again, let it be proposed to find the point of inflection in a curve whose equation is $b y^2 = a x^3 - x^4$.

The fluxion of this expression gives

$$b^2 \dot{y} = 2 a x \dot{x} - 3 x^2 \dot{x}; \text{ or } \frac{\dot{y}}{x} = \frac{2 a x - 3 x^2}{b^2}$$

Taking again the fluxion of this expression, and making it equal to 0, we have

$$2 a b^2 \dot{x} - 6 b^2 x \dot{x} = 0, \text{ or } 2 a b^2 = 6 b^2 x,$$

because \dot{y} does not enter; whence $x = \frac{1}{3} a$, which is the absciss answering to the point of inflection sought.

Ex. 3.—Let it be proposed to find the point of inflection, or retrogression, in the cubic parabola, with the equation $y = a + \sqrt{(a^2 - 2 a^2 x + a x^3)}$.

By taking the fluxion, we have

$$\dot{y} = \frac{(-2 a^2 + 2 a x) \dot{x}}{3 (a^2 - 2 a^2 x + a x^3)^{\frac{1}{2}}}, \text{ or } \frac{\dot{y}}{x} = \frac{\frac{2}{3} (a x - 2 a^2)}{(a^2 - 2 a^2 x + a x^3)^{\frac{1}{2}}}$$

Taking again the fluxion of this expression, and making it equal to 0, according to the above rule, we have $a \dot{x}$

$$(a^2 - 2 a^2 x + a x^3)^{\frac{1}{2}} = \frac{2(-2 a^2 \dot{x} + 2 a x \dot{x}) \times (2 a x - 2 a^2)}{3 (a^2 - 2 a^2 x + a x^3)^{\frac{1}{2}}}$$

because \dot{y} is not found in the second fluxion, which expression being reduced, gives $x = a$; and this value substituted for x , gives also $y = a$; hence the point required is, that answering to the conditions of the absciss and ordinate, which is a point of retrogression, as will appear from considering the nature of the curve.

Ex. 4.—Let it be proposed to investigate the point of contrary flexure in the curve commonly called the *witch*; of which the equation is $y x = a - a x$.

Taking the fluxion of this expression, we have

$$2 y \dot{y} x + y^2 \dot{x} = -a^2 \dot{x}; \text{ or } \frac{\dot{y}}{x} = \frac{-(a^2 + y^2)}{2 y x}$$

Now, again, making the fluxion of this expression = 0, we have

$$-4 y^2 \dot{y} x + (2 x y \dot{y} + 2 y \dot{x}) (a^2 + y^2) = 0, \text{ or } 2 x (a + y) \dot{y} - 4 y \dot{x} x + 2 y \dot{x} (a^2 + y^2) = 0;$$

whence

$$\frac{\dot{y}}{x} = \frac{-2 y (a^2 + y^2)}{2 x (a^2 + y^2) - 4 y^2 x}$$

And now equating this value of $\frac{\dot{y}}{x}$ with the foregoing, there

INFLECTION.

there is obtained

$$\frac{2y(a^2 + y^2)}{2x(a^2 + y^2) - 4yx} = \frac{a^2 + y^2}{2yx}$$

or, $4y^2x = 2x(a^2 + y^2) - 4y^2x$, or $4y^2 = a^2 + y^2$;

whence $y = a\sqrt{3}$; which being substituted in the original equation, gives $x = \frac{3}{2}a$; which are therefore the values of x and y answering to the required point of inflection.

At present we have only considered those curves that have parallel ordinates, and which are referred to one common axis; but it is necessary to employ a different method when the curves are referred to a common focus; it will therefore be proper now to attend to this latter case, observing only, with regard to the former, that in order to know whether any curve be concave or convex towards any point assigned in the axis, find the value of y at that point; then if this value be positive, that curve will be convex towards the axis, and if it be negative, it will be concave. The rule for determining the points of contrary flexure and retrogression of curves, which supposes the second fluxion of the ordinate to be nothing or infinite, *i. e.* $\dot{y} = 0$ or ∞ , is liable to several exceptions, as it shewn very fully and clearly by Maclaurin in his Treatise of Fluxions, book i. chap. 9 book ii. chap. 5. art. 856 and 867.

The ordinate y passes through a point of contrary flexure when, the curve being continued on both sides of the ordinate, is a maximum or minimum. But this does not always happen when $\dot{y} = 0$, or ∞ . Maclaurin observes, in general, that if \dot{y} , \ddot{y} , $\ddot{\dot{y}}$, &c. vanish, the number of these fluxions being odd, and the fluxions of the next order to them having a real and finite value, then y passes through a point of contrary flexure; but if the number of these fluxions that vanish be even, it cannot be said to pass through such a point; unless it should be allowed that a double infinitely small flexure can be formed at one point.

The curve being supposed to be continued from the ordinate y , on both sides, if y be infinite, the extremity of the ordinate is not therefore always a point of contrary flexure, as y is not always, in this case, a maximum or minimum; and the curve may have its concavity turned the same way on both sides of the ordinate. But these cases may be distinguished by comparing the signs of \dot{y} on the different sides of the ordinate; for when these signs are different, the extremity of y meeting the curve is a point of contrary flexure.

The suppositions of $\dot{y} = 0$, or ∞ , and of $\ddot{y} = 0$, or ∞ , serve to direct us where we are to search for the maxima and minima, and for points of contrary flexure; but we are not always sure of finding them. For though an ordinate or fluxion that is positive, never becomes negative at once, but by increasing and decreasing gradually, yet after it has decreased till it vanish, it may thereafter increase, continuing still positive; or after increasing till it becomes infinite, it may thereafter decrease without changing its sign.

Of the points of inflection and retrogression of curves referred to a common focus.

Let ADE (figs. 4. and 5.) represent a curve referred to the focus Q, from whence the ordinates QD, QD proceed; and let Qd be indefinitely near to QD. Draw QT perpendicular to QD, and Q't perpendicular to Qd. Draw D't a tangent to the point D, and d't a tangent in the point d. Let Q't (produced if necessary) meet D't in the point o. Now it is plain, that as the ordinates increase, if the curve be concave towards the focus Q (fig. 4.),

Q't will be greater than Q'T; but if the curve be convex towards the focus Q (fig. 5.) Q't will be less than Q'T; and therefore, as the curve changes from being concave to convex, or *vice versa*, that is, in the point of inflection, or retrogression, the line or quantity $o't$, from being positive, ought to become negative, or the contrary; and therefore must pass through nothing or infinity.

Therefore make QD = y , DM = x ; and with the centre Q, let the indefinitely small arcs D'M, T'H, be described: then the two triangles d'MD, d'Q'T will be similar, as also d'Q'o, T'H'o, and therefore it will be

$$dM : MD :: dQ (or DQ) : Q'T, \text{ or } x : y :: \dot{x}y = Q'T.$$

But the two sectors DQM, TQH are also similar; whence

$$DQ : DM :: QT : TH, \text{ or } y : x :: y\dot{x} : \dot{y} = TH;$$

and because of the similar triangles d'Q'o, and T'H'o, it will be d'Q (or DQ) : Q'o (or Q'T) :: TH : H'o; that is, $y : y\dot{x} :: \dot{y} : \dot{y}\dot{x}$ = H'o. But H't (fig. 3.) represents the fluxion of Q'T, that is, $H't = \dot{x}^2 - y\dot{x}\dot{y}$

by taking \dot{x} as constant. Therefore $to = tH + H'o = \dot{x}^2 - y\dot{x}\dot{y} + \dot{x}^2$, which must be equal to 0, or to ∞ , infinity; and consequently multiplying by y^2 , and dividing by \dot{x} , it will be $\dot{y}^2 - y\dot{y} + \dot{x}^2 = 0$, or ∞ .

In fig. 4. $o't$ becomes negative, and therefore $ot = -\dot{x}\dot{y} + y\dot{x}\dot{y} - \dot{x}^2$, and multiplying and dividing this expression as above, we have again

$$\dot{y}^2 - y\dot{y} + \dot{x}^2 = 0, \text{ or } \infty,$$

which therefore is the general formula for finding the point of inflection or retrogression in curves that are referred to a focus.

Let us now make an application of this formula to an example, by proposing to find the point of contrary flexure in the curve, which is generated as follows:

AED being a circle described from the centre B, let AFK be such a curve, that, drawing any radius BFE, the square of FE may be always equal to the rectangle of the corresponding arc AE, into a right line b . See fig. 6.

Let the arc AE = a , BA = BE = a , BF = y , and FG = x , drawing BE' indefinitely near to BE, and with the centre B, and radius BF describe the small arc FG; then by the nature of the curve, it will be $b\hat{z} = a^2 - 2ay + y^2$; and taking the fluxions we have $b\dot{\hat{z}} = -2a\dot{y} + 2y\dot{y}$,

$$\text{whence } \dot{\hat{z}} = \frac{2y\dot{y} - 2a\dot{y}}{b} = B'E'.$$

But because of the similar sectors BE'E', and BFG, it will be as BE : BF ::

$$E'E' : FG; \text{ that is, } a : y :: \frac{2y\dot{y} - 2a\dot{y}}{b} : \dot{x}; \text{ whence}$$

$$\dot{x} = \frac{2y\dot{y} - 2a\dot{y}}{ab};$$

and now taking the fluxions again and making x constant, we have $4y\dot{y}^2 + 2y^2\dot{y} - 2a\dot{y}^2 - 2a\dot{y}y = 0$; therefore $y\dot{y} = \frac{a^2 - 2ay^2}{y - a}$.

Now the general formula above is $\dot{x}^2 + \dot{y}^2 - y\dot{y} = 0$, and therefore substituting for these quantities their respective values, the expression becomes

$$4y^4$$

$$\frac{4y^4y^2 - 8ay^3y^2 + 4a^2y^2y^2 + a^2b^2y^2}{ab^2} = \frac{4y^6 - 8ay^5 + 4a^2y^4 + a^2b^2y^2}{ab^2}$$

$$\frac{ay^2 - 2y^2}{y-a} = 0, \text{ and these again reduced to a common denominator will be}$$

$$\frac{4y^6 - 12ay^5 + 12a^2y^4 - 4a^3y^3 + 3a^2b^2y - 2a^3b^2}{a^2b^2(y-a)}$$

= 0, or ∞; the roots of which equations will give those values of y, or of B F, that answer to so many different points of contrary flexure. In general the number of roots in the finite equation always indicate the number of points of inflection or retrogression belonging to the curve which is the subject of investigation; and consequently, in those curves that have but one such point, it is determined by a simple equation.

Curves may also have another kind of retrogression different from that we have been considering; which is, when the curve returns backwards towards its origin, turning its cavity the same way that it did before its retrogression, as in the following case.

Let the curve be B A C (fig. 7.), with a contrary flexure at A, and let it be evolved by a thread beginning at any point D, different from the point of contrary flexure A: the evolution of the portion D C generates the curve D G, and that of the portion A B generates the curve E F; in such manner that the evolution of the whole curve B A C will form the entire curve F E D G, which has two retrogressions, one at D of the usual form, because the two branches D E, D G, turn their convexity; the other at E of the second sort, because the branches E D, E F, are concave towards the same parts. Let now M N, N n m, be any two radii, indefinitely near, of the evolution D A; and N H, and n H, two perpendiculars to the fame; the two indefinitely small factors N m M, H N n, will be similar, and therefore H N : N M :: N n : M m. But in the point of contrary flexure A, the radius H N ought to be either infinite, or nothing; and the radius N m, which becomes A E, continues finite. Therefore, in the case of contrary flexure A, that is, the point of retrogression E, of the second sort, the ratio of N n, M m, or the ratio of the fluxion of the radius M N, to the element of the curve, ought to be either infinitely great, or infinitely

small. But the formula of the radius M N is $\frac{(x^2 + y^2)^{\frac{3}{2}}}{-x \dot{y}}$, considering \dot{x} as constant; the fluxion of which is

$$-\frac{3x\dot{y}\dot{y}^2\sqrt{(x^2+y^2)} + x^2\dot{y}^2(x^2+y^2)^{\frac{3}{2}}}{x^2\dot{y}^2}$$

and $M m = \sqrt{(x^2 + y^2)}$; therefore $\frac{N}{M} \frac{n}{m} = \frac{x^2\dot{y} + y^2\dot{y} - 3\dot{x}\dot{y}^2}{x^2\dot{y}^2} = 0, \text{ or } \infty;$

which is the formula for points of retrogression of the second order.

For other methods of finding the points of inflection and retrogression of curves, the reader is referred to Simpson's and Maclaurin's Fluxions; Donna Agnesi's Analytical Infinites; and to the *Traité Elementaire de Calcul Differential*, par La Croix.

INFLORESCENCE, in *Botanical Phrasology*, *inflorescentia* of Linnaeus, is used to express the particular manner in which flowers are disposed upon a plant, and which preceding writers denominated the *modus florendi*, or "manner of flowering." The several kinds of inflorescence come under the heads of *Verticillus*, *Racemus*, *Spica*, *Corymbus*,

Fasciculus, *Capitulum*, *Umbella*, *Cyma*, *Panicula* and *Thyrsum*, which the reader will find in their proper places. A slight correction of the definition which stands under our article **CAPITULUM** is necessary, the *Static Armeria* or *Thrift*, and *Gomphrena globosa* or *Globe amaranthus*, being better examples of that kind of inflorescence than any compound flower.

For the reasons again taking generic characters from the inflorescence, see **CYME** and **GENUS**.

INFLUENCE, a quality supposed to flow from the bodies of the stars, either with their heat or light, to which astrologers vainly attribute all the events which happen on the earth.

Alchemists, also, who to this ascribe the philosopher's stone, tell us that every thing in nature is produced by the influences of the stars, which, in their passage through the atmosphere, imbibe many of its moist parts, the grossest whereof they deposit in the sands and earths where they fall; that these, filtrating through the pores of the earth, descend even to the centre, whence they are driven, by the central fire, back again to the surface; and in their ascent, by a natural kind of sublimation, as they find earths duly disposed, they form natural bodies, as metals, minerals and vegetables, &c. Thus it is pretended, that chemistry, consisting of an artificial imitation of these natural operations, and in applying active principles to passive principles, can form natural bodies, make gold, &c. See **TRANSMUTATION**, and **PHILOSOPHER'S STONE**.

INFLUENT, a term used where a liquor or juice, by the contrivance of nature, and the laws of circulation, falls into a current or receptacle.

Thus with respect to the common receptacle, the chyle is its influent juice; and so is the bile to the gall-bladder; the venal blood to the heart in its diastole; and the like.

INFLUENZA, in *Medicine*, a term generally employed to denote an *epidemic catarrh*, which has at different times spread more rapidly and extensively than any other epidemic disorder. For it has seldom occurred in any one country of Europe without appearing successively in every other part of it; it has sometimes apparently traversed the whole of the old world; and, in some instances, it has been even transferred to America, and has spread itself over that continent likewise. The French give it the name of *La Grippe*.

In truth, this extensive prevalence of the disease constitutes its most remarkable peculiarity: for in all the instances of its occurrence, from the fourteenth century down to the present day, its phenomena have not only been pretty uniformly the same, but have differed little, except in severity, from those of the common febrile catarrh. (See **CATARRH**.) This will appear from the following description of the disease, when epidemic in 1782, which is taken from a comprehensive view of it, compiled by the late Dr. Gray, of the British Museum, from a number of accounts given by physicians, in various parts of Great Britain, from their own personal observation (see *Medical Communications*, vol. i. art. 1. Lond. 1784); and from a similar account published by the College of Physicians. *Med. Transactions*, vol. iii. art. 8.

Very little authentic information was procured respecting the history of this epidemic, before the time of its appearance in London: all that was stated, on good authority, was, that it prevailed at Moscow in the months of December 1781, and January 1782, and at Petersburg in February 1782; and it was traced to Tobolski, to which place it was supposed to have been brought from China. In confirmation of this opinion it was observed, that several accounts from different parts of the East Indies made mention of a disorder, similar in its symptoms, which prevailed in those parts in the

months

INFLUENZA.

months of October and November 1781. At all events, its course was in the beginning westward; for it was in Denmark in the latter end of April 1782, or the beginning of May; and many people were said to have died of it at Copenhagen before the 11th of May. It appeared at Newcastle-upon-Tyne about the end of April, and in the second week in May it was certainly in London; some persons indeed thought that it had reached the metropolis sooner. According to the accounts received from various parts of England, it did not begin to appear in most of them until after its prevalence in London, namely, until the latter end of May, or the beginning of June. In Scotland and Ireland it seems to have been rather later, and in the fourth of Europe later still; for it prevailed in France in the months of June and July; in Italy, in July and August; and in Portugal and Spain, in August and September. The fourth week in May was the period of its most general prevalence in London: from that time it began to decline, and in the space of two or three weeks ceased to exist as a general disorder; but it did not altogether leave the city till the month of September.

No attempt was made to ascertain with accuracy the proportional number of persons attacked by this influenza: the number was every where very great; the proportion of the inhabitants affected in some places being estimated at three-fourths, in other places at four-fifths of the whole; and in London it was ascertained, from a pretty competent view of the matter, that the number of those attacked by it was much greater than that of those who escaped it. Both sexes appeared to be equally liable to it; but persons of the middle age were more subject to its attacks than old people, and these more than children; while infants were considerably less pre-disposed to it than either, though not entirely exempt from it. When old persons were attacked, they generally had the disease very violently.

This epidemic appeared with a considerable variety of symptoms; but the most general form of it was certainly that of catarrh; and the great debility or depression of strength which accompanied its attack, and the rapidity with which its symptoms came on, (which in some instances was truly wonderful,) seem to have been the most remarkable characters of it. Persons, apparently in perfect health, were seized instantaneously, as it were, with a violent cold, to which succeeded head-ache, running at the nose, &c.; while others were as suddenly seized with giddiness, stricture on the chest, sickness at the stomach, and cold sweats, which were speedily followed by the pectoral symptoms. The most common course of the symptoms, however, was the following:

The disease generally began with fits of chilliness and heat alternately succeeding each other; sometimes with a slight shivering, followed by more or less of fever; anxiety of the præcordia; pain in the back and limbs; stitches and cramps in the muscles subservient to respiration; a very great discharge of their lymph from the eyes and nose; a sensation in the eyes as if they were about to start out of the head; sneezing, hoarseness, and frequently an incessant cough, forcing up large quantities of mucus, and sometimes attended with a soreness of the breast. In many instances the appetite and sense of taste were lost or much impaired, with some degree of nausea; and a few vomited. Most of the patients laboured under great lassitude and restlessness. The sleep was generally much broken; and many could hardly sleep at all. The pulse was frequent, but seldom hard or tense. Languor, debility, and dejection of spirits were general, and very great in all; far beyond what might have been expected from the degree of all the other symptoms.

But the symptom which universally prevailed, and which appeared to be almost a pathognomonic of the disease, was a distressing pain and sense of constriction in the forehead, temples, and sometimes in the whole face, accompanied with a sense of soreness about the cheek-bones under the muscles. This, now and then, was felt previously to the catarrh, and not unfrequently was followed by very little or no catarrhus affection.

The distemper was by no means so uniform as to present the same identical appearances in every subject whom it attacked; nor yet so various, but that the resemblance could easily be discovered; diversified perhaps by the peculiar habit and constitution of the sufferer, or by some other circumstances not easily explained. In some, a part only of the mucous membrane was affected, in others the whole. In the latter, a soreness of the throat was common, with frequent excretion. Upon inspecting the *fauces* of these, a redness might be observed; but in few instances any considerable swelling, and in none any ulceration. In some there was a great propensity to perspiration; it could be readily excited in most, and often appeared where no means had been employed for that purpose; but in a few the skin was dry throughout the whole complaint. Daily exacerbations and remissions of the cough and fever were obvious in many instances; in some, they either did not take place, or if they did, were very obscure. The state of the belly was very different in different patients; in some it was regular, in others disposed to costiveness; which, however, was easily removed: and several had a spontaneous purging at various periods of the disease, sometimes with pain, but oftener without. Nothing in general could be collected from the urine that deserves notice.

These were the most general and frequent appearances of the influenza of 1782. But it must be observed, that not only in London, but in all parts of the island from whence accounts were received, it now and then degenerated into pleurisy or peripneumony; yet these affections still manifested themselves as particular modifications of the epidemic, being either preceded or accompanied by some of its characteristic symptoms. Some, thus attacked, had in the beginning either that distinguishing pain in the face and forehead, or catarrh, or both; and in all there was that debility of body and depression of mind, which are not essential to inflammation; the presence of which here, however, was obvious and indispensible.

The rarer occurrences were in some few an unusual disposition to sleep; in others, strangury independent of blisters, and in some instances attended with bloody urine for three or four days; hæmorrhages from the nose, with relief to the catarrhal affections; and one instance of a clear discharge from the ears, as copious as others had it from the nose.

Extensive as the range of this epidemic was, its influence was neither very fatally exerted, nor long continued. Very few died of it; and of those to whom it proved fatal, the greater part were old, asthmatic, or had been debilitated by some previous indisposition. The continuance of the distemper in any one place was not above six weeks: where it appeared in May, it vanished before the end of June; and where it did not break out before June, it remained until the middle, or towards the decline of July. Its duration with each individual whom it attacked was as various as the degree of violence with which the attack was made. It seldom held any one above a fortnight; in some its duration was not above a day or two; but it usually lasted about a week, or longer. In some parts of the country relapses were common a second, third, or even fourth time; this was also the case in London, but to a less extent. The cough was some-

INFLUENZA.

times troublesome for a considerable time after the febrile state of the disorder had ceased; and a great weakness often remained after the disease.

The influenza, as above described, may be taken as an example of the epidemic at all times of its appearance; but it has sometimes assumed a more violent and inflammatory type, been more frequently accompanied with symptoms of pleurisy and peripneumony, and therefore more frequently fatal, and also laid the foundation for more numerous cases of pulmonary consumption, than in the instance of 1782. Such was the fact, in regard to the influenza of 1762 in particular; which, indeed, appeared to be far more fatal, both at the time of its raging, and in its consequences, as several persons continued languishing under the remains of it for one or two years, and never recovered.

The causes of the influenza have been the subject of much difference of opinion; and all that has been said in respect to them rather tends to prove the difficulty of obtaining a sufficient number of unquestionable facts to found a clear opinion upon, than to set the subject at rest. Three different views of the matter have been taken by different physicians: 1. Some attributed the disease solely to the state of the weather; *i. e.* they believed it to be a common catarrh, occasioned by changes in the sensible qualities of the atmosphere, such as cold, moisture, &c.: 2. Others ascribed it to a particular and specific morbid principle, totally different from and independent of the sensible qualities of the atmosphere, but resident in and conveyed by the air: 3. While the greatest number concurred in the opinion, that the influenza was contagious, in the ordinary acceptance of the word, *i. e.* was propagated only by the contact, or at least by the sufficiently near approach, of an infected person. The first opinion, however, that it originated in the sensible variations of the air, seems to be untenable: for not only was there no peculiarity of the atmospheric temperature, moisture, &c., which was common to the different periods when the influenza prevailed, or was obviously different from that of other seasons, when it had not appeared; but the sensible state of the air preceding and accompanying the same epidemic was different in different places. Thus, though in most parts of England it had been uncommonly cold and wet, yet in the other parts of the world, as in Germany, where the disorder was equally general, it had been very dry. Again, it was observed in several places, that great alterations happened in the weather during its prevalence, without any sensible change in the symptoms of the disorder.

The second opinion, that the cause of the disease, though not connected with the sensible qualities of the atmosphere, was yet resident in it, and thus conveyed from place to place, was supported upon the following grounds: 1st. That those who were most exposed to the air were generally the first persons attacked: 2dly. That many had the disorder without having had any communication with a diseased person: 3dly. That several escaped though surrounded by persons ill of the disease: 4thly. That some *whhole families* were seized at once: and, 5thly. That some persons had the disorder a week or a fortnight before it began to be taken notice of as a general one. Without pretending to decide upon so difficult and intricate a question, we may state the following objections to these arguments.

The first argument, that those who were most exposed to the air were generally the first persons attacked, (which, by the way, was altogether denied by many observers,) is surely by no means in favour of the opinion, that the cause of the disorder resided in the atmosphere; for if it had resided there, what should have prevented those who staid at home

from being infected? since the air which they breathed must necessarily have been the same as that breathed by those who went out. But if, on the other hand, a communication with some infected person was necessary to produce the distemper, it is very clear that those who went out of doors, and mixed with the world, were more likely to get it than those who did not stir from home.

Before the second argument, namely, that many were attacked without having had any communication with a diseased person, can be allowed to have any weight, it must be clearly proved, not only that the persons themselves had not had such communication, but also, that no person, who had been near them, had previously been where the disorder existed; for it is pretty clearly established, with respect to other active contagions, such as the small-pox, &c. that a person, who has already suffered the disease, may nevertheless convey the contagion from one place to another.

From the third argument, that many escaped though surrounded by persons affected with the disease, no inference of any consequence to the present question can be drawn; it being certainly not less difficult to account for their escape when surrounded by diseased persons, than when surrounded by the same air, which had (according to the hypothesis) caused the disease in those persons.

With respect to the fourth argument, that some *whhole families* were seized at once, without having been exposed to infection, it may be remarked that, when we consider what has been said in answer to the second argument, it will be very difficult to prove that they were not exposed to it; and equally difficult to give any reasons why, if the exciting cause of the disorder resided in the air, any whole family should have been affected by that cause, rather than an equal number of persons in divers families; but if we suppose the disease to have been propagated by personal intercourse, it is very easy to conceive in what manner it may have been communicated to some whole families at the same time. And, in answer to the last argument, that some persons had the disorder a week or a fortnight before any others were known to have it, it may be sufficient to remark, that, admitting these cases to have been really influenza, the supposition, that the cause of it existed in the air, will not render it more easy to explain why those persons only should at that time have been affected by this cause.

These considerations tend to favour the third opinion above-mentioned, that the disease was propagated by contagion, in the common acceptance of the term, that is, by personal communication with the diseased; but they are very far from being decisive of the question. Indeed, the question of contagion, as connected with any particular epidemic, in which there is no palpable matter produced, by which the disease can be communicated, is always difficult, and has been agitated even with regard to the plague itself. (See CONTAGION and EPIDEMIC.) But it has been satisfactorily demonstrated, that the contagion of all malignant and eruptive fevers cannot be conveyed through the air to any distance (even many feet) from its source. If the contagion of the influenza, therefore, could be suspended and conveyed through the atmospheric air, so as to spread the disease far and wide, it would form an exception to the general properties of known contagions. Several facts, recorded during the epidemic of 1782, militate strongly against such a supposition. It was remarked, for example, that the disease was prevalent in one place a week or two before it appeared in another, only a few miles distant from the first. Thus it shewed itself at Edinburgh on the 20th of May, and soon raged very much, and was prevalent at Glasgow in the first week in June; yet it did not appear at Musselburgh, a village

village about five miles south-east of Edinburgh, until the 9th or 10th of June. Again, it was prevalent at Dartmouth much sooner than at Exeter, and yet it appeared at Exeter much sooner than at Tinnmouth, although the last mentioned place is situated between Dartmouth and Exeter.

The opinion, that it was propagated by personal intercourse, was also favoured by its progress in numerous instances. Thus it was frequently observed, that some one individual in a family was first attacked, and that then several more, and sometimes the whole of the same family, were very soon afterwards seized with it, in some instances all at once, but in others successively. Very early in June, three families, consisting of seventeen persons, came on the same day to the hotel in the Adelphi buildings; they were all in perfect health when they arrived; and they were all affected the next day with the symptoms of the illness then reigning in London. In some cases, it seemed to be propagated, like contagious diseases in general, by fomites, that is, by articles of clothing or furniture impregnated with the morbid effluvia. One physician, Dr. Meale of Strabane, in Ireland, says, "I have no shadow of doubt that the disorder was contagious; and am certain, I myself received the infection from a small trunk of wearing apparel, which came from Dublin, where it then raged. I may add, that this was the first introduction of it into this town." The disease appeared to be carried on board two ships of war, on their arrival at Gravesend from the West Indies, by three custom-house officers, who were put on board: in a few hours after, the crews of both ships, till then in good health, were seized with symptoms of the influenza; hardly a man in either ship escaped, and some had it very feverishly. In some instances it was observed, that the epidemic did not shew itself in certain places, until some one or more arrived at those places, either actually labouring under the disease, or coming immediately from other places, whose inhabitants had been affected by it for some days. In general the disease appeared earlier in towns, than it did in the surrounding villages, and in villages earlier than in the detached houses in the neighbourhood.

On the whole, the progress of the disorder is perhaps more easily explained, upon the supposition that it was propagated by personal communication, than by any other. In objection to this hypothesis, however, it is credibly affirmed, that the crews of several ships were seized with the influenza many miles distant from land, and came into various parts of England labouring under it; and the same thing is said to have happened to ships in the East Indies, and other parts. But great caution is requisite in admitting such statements as facts, from which any satisfactory inferences can be deduced.

A similar epidemic catarrh, or influenza, is recorded as having visited Europe, and even other parts of the globe, two or three times in the fourteenth century, and at several subsequent periods; namely, in the year 1510, 1575, and 1580, the last of which is said to have originated, like several of those which succeeded, in Asia; and again in 1591, in 1658, in 1675, in 1709, in the latter end of 1732, and in the beginning of 1733, in 1743, in 1748, in 1762, in 1767, in 1775, in 1782, and in 1803. Those who are desirous of investigating the records of these epidemics, will find references to the works in which they are contained, arranged in chronological order, in Dr. Cullen's *Synopsis Nosologie Method.* under the head of *Catarrhus*, Gen. xl. and species 2. C. à contagio.

Cure of the Influenza.—Since the effects of this disease

were different in different individuals, no general method of cure could rationally be followed. Many, indeed, were so slightly indisposed, as to require but little or no medicine. Nothing more was wanted for their cure, than to abstain for two or three days from animal food and fermented liquors, and to use some diluting tepid drink. A lenient purgative, given at the beginning of the disease, was useful in moderating the fever; and nature sometimes seemed to point out the repetition of it afterwards, when there were pains in the stomach and bowels, and a tendency to a diarrhœa. The same was observed in the epidemics of 1732 and 1762. Nothing likewise was observed so successfully to mitigate the cough, as to open the bowels with a gentle purgative, and afterwards to give a slight opiate at night. It was observed by numerous practitioners, that emetics, exhibited upon the first attack, were evidently of use in relieving the head and breast, and also in producing a speedy and free perspiration. All attempts to force much sweating appeared to do harm, especially by means of the stimulating diaphoretics, such as contrayerva, ammonia, wine whey, &c. In fact, in most of the mild and simpler forms of the disease, an early perspiration generally came on spontaneously, which seldom failed to relieve the symptoms materially, and it was only necessary to give tepid aqueous liquors, the neutral salts, or antimonials in small doses, to keep up a regular and gentle moisture upon the skin.

But in the more severe forms of the disorder, other remedies became necessary, according to the severity of the symptoms. Whenever symptoms of pleurisy or peripneumony appeared, the propriety of blood-letting was commonly admitted, notwithstanding the languor and depression connected with the disease. There was, however, considerable difference of opinion upon the subject of blood-letting. Several learned and experienced physicians, if called at the beginning of the disease to a person strong and plethoric, and labouring under great heat and inquietude, even in cases where no direct symptoms of pneumonic inflammation appeared, ordered bleeding without hesitation; and under such circumstances, they several times observed, that the languor, oppression, and feverish anxiety, were abated by the loss of a few ounces of blood; that both the head and the breast were relieved; and that the disease proceeded to its termination with fewer difficulties both to the patients and to themselves, and without any subsequent inconvenience. Yet others were of opinion that the blood-letting, although indicated by the symptoms, and also by the appearance of the blood drawn, not only failed to procure that relief, which might have been expected from it under ordinary catarrhal or pneumonic symptoms, but in some cases even proved prejudicial. Blisters were applied to various parts with good effects: when there was pain in the breast or side, the application of them to the part affected was found very beneficial; and it was frequently thought proper to keep them open for some time. In some cases, it was remarked, that a second blister, applied a few days after the first, produced great relief, when the first had failed to do so. On account of the great debility, which seldom failed to accompany or follow the disorder, bark and cordials were often deemed necessary, especially towards the close of the disease; but they would probably be deemed less necessary by the practitioners of the present day; for when a diseased condition is removed, the constitution commonly recovers its strength with rapidity, when care is taken the food be light and nutritious, and there is a free access to pure air. See *Medical Transact.* vol. iii. art. 8.—*Medical Communications*, vol. i. art. 1.—*Hill. de la Soc. Royale*

Royale de Med. de Paris, pour 1776.—Edin. Med. Essays, vol. ii. art. 2.—Rutty, Hist. of Weather.

INFORMED.

INFORMEMENT. } See {

IN FORMA PAUPERIS, in *Law*. See *FORMA*

Pauperis.

INFORMATION, for the king, is much the same with what is called declaration for a common person: it is not always done directly by the king or his attorney, or the clerk of the crown-office; but sometimes by another, who sues as well for the king as himself, on a bench of some penal law or statute, wherein a penalty is given, one part to the use of the king, and another to the use of the informer. And it differs from an indictment, which is found by the oaths of twelve men; and is only the allegation of the officer who exhibits it. The latter sort of informations, which are partly at the suit of the king, and partly at that of a subject, is a species of *qui tam* actions, so called because they are brought by a person *qui tam pro domino rege, &c. quam pro seipso in hac parte sequitur*, and carried on by a criminal instead of a civil process. By 31 Eliz. c. 5, no prosecution of this kind can be brought by any common informer, after one year is expired since the commission of the offence; nor out of the country where the offence was committed; nor on behalf of the crown after the lapse of two years longer; nor, where the forfeiture is originally given to the king alone, can such prosecution be had after the expiration of two years from the commission of the offence. It is also enacted by 18 Eliz. c. 5, that if any person, informing under pretence of any penal law, makes any composition without leave of the court, or takes any money or promise from the defendant to excuse him, he shall forfeit ten pounds, and two hours on the pillory, and be for ever disabled to sue on any penal or penal statute. And by the same statute, if a person exhibits his information only for vexation, the defendant may bring information against the informer. See **COMPOSITION** of *Informations*.

Informations that are exhibited in the name of the king alone are of two kinds; those which are truly and properly his own suits, and filed *ex officio* by his own immediate officer, the attorney-general; and those, in which, though the king is the nominal prosecutor, yet it is at the relation of some private person or common informer; and they are filed by the king's coroner and attorney in the court of king's bench, usually called the master of the crown-office, who, for this purpose, is the standing officer of the public. The objects of the king's own prosecutions, filed *ex officio* by his own attorney-general, are properly such enormous misdemeanors as particularly tend to disturb or endanger his government, or to molest or affront him in the regular discharge of his royal functions. The objects of the other species of information are any gross and notorious misdemeanors, riots, batteries, libels, and other immoralities of an atrocious kind. And when an information is filed in either of these ways, it must be tried by a petit jury of the county where the offence arises; after which, if the defendant be found guilty, he must be referred to the court for his punishment. These informations, which are as ancient as the law itself (1 Show. 118.), of every kind, are confined by the constitutional law to mere misdemeanors only, without extending to any capital offence. The oppressive use of information by the court of Star-chamber, &c. in the times preceding the Revolution, occasioned a struggle soon after the accession of king William, to procure a declaration of their illegality by the judgment of the court of king's bench. But Sir John Holt, who then presided there, and all the judges,

were clearly of opinion, that this proceeding was founded on the common law, and could not then be impeached. However, in a few years afterwards, it was enacted by 4 & 5 W. & M. c. 18, that the clerk of the crown shall not file any information without express direction from the court of king's bench; and that every prosecutor, permitted to promote such information, shall give security by a recognizance of twenty pounds (a sum now too small), to prosecute the same with effect; and to pay costs to the defendant, in case of his acquittal, unless the judge, who tries the information, shall certify there was reasonable cause for filing it; and, at all events, to pay costs, unless the information shall be tried within a year after issue joined. But there is a proviso in this act, that it shall not extend to any other informations than those which are exhibited by the master of the crown office; and, consequently, informations at the king's own suit, filed by his attorney-general, are no way restrained thereby.

There is one species of informations, still further regulated by 9 Ann. c. 20, *viz.* those in the nature of a writ of *quo warranto*, which is a remedy given to the crown against such as had usurped or intruded into any office or franchise. The modern information tends to the same purpose as the ancient writ, being generally made use of to try the civil rights of such franchises; though it is commenced in the same manner as other informations are, by leave of the court, or at the will of the attorney-general; being properly a criminal prosecution, in order to fine the defendant for his usurpation, as well as to oust him from his office; yet usually considered at present as merely a civil proceeding.

An information on behalf of the crown, filed in the exchequer by the king's attorney-general, is a method of suit for recovering money or other chattels, or for obtaining satisfaction for damages in any personal wrong committed in the lands or possessions of the crown. (Moor, 375.) The most usual informations are those of *intrusion and debt*; the former being for any trespass committed on the lands of the crown (Cro. Jac. 212. 1 Leon. 48. Savil. 49.), as by entering thereon without title, holding over after a lease is determined, taking the profits, cutting down timber, or the like; and the latter, upon any contract for monies due to the king, or for any forfeiture due to the crown upon the breach of a penal statute. There is also an information *in rem*, usually filed in the exchequer, where any goods are supposed to become the property of the crown, if no man appears to claim them, or to dispute the title of the king. There is also another information, filed *ex officio* by the attorney-general, in the court of chancery, at the relation of some informant, called the relator, for the proper establishment of charities, of which the king has the general superintendance. Blackl. Com. b. iii. and iv.

INFORMATUS NON SUM, or *Non sum informatus*, a formal answer made of course by an attorney, who is commanded by the court to say any thing he thinks good in behalf of his client: who having nothing material to urge, makes answer, he is not informed: on which judgment passes for the other party.

INFORMER, INFORMATOR, a person that informs against, or prosecutes in any of the king's courts, those that offend against any law or penal statute. See **INFORMATION**.

INFORMIS, UNFORMED, that which has not the form or perfection it should have.

INFORMES Stellæ, in Astronomy, are such stars as have not yet been reduced into any constellation: otherwise called *sporades*.

Of this kind there was a great number left by the ancient astronomers; but Hevelius, and some others of the moderns, have provided for the greater part of them, by making new constellations.

INFORTUNUM, HOMICIDE BY. See **HOMICIDE.**

INFRA, Lat. below. See **HYPO.**

INFRACTION, formed from *in* and the supine of *frango, I break*, a rupture or violation of a treaty, law, ordinance, or the like.

INFRALAPSARIJ, in Ecclesiastical History, the name of a sect of Predestinarians, who maintain, that God has created a certain number of men only to be damned, without allowing them the means necessary to save themselves, if they would; and they are thus called, because they hold that God's decrees were formed *infra lapsor*, after his knowledge of the fall, and in consequence thereof; in contradistinction to the Supralapsarians.

INFRAASCAPULARIS, in Anatomy, a name of the infraspinatus muscle. See the following article.

INFRA SPINATUS, is a muscle of the shoulder, called by the French *sous-epineux*, and *sous-scapulo-trochiterien*. It is placed at the back of the shoulder, covering that division of the dorsum of the scapula which is below the spine, and extends from the basis of the scapula to the great tubercle of the humerus. It is thick, broad, and triangular.

Its posterior surface is covered above and on the outside by the deltoid; and below and within by the trapezius, and below by the latissimus dorsi: in the rest of this surface it is covered by the skin. A thin aponeurosis, common to this muscle and the teres minor, immediately invests its posterior surface. This aponeurosis is continuous above with those of the trapezius and deltoid, it is attached on the inside to the basis of the scapula; is continuous below, with a septum placed between the two teres muscles and the infraspinatus; and is fixed on the outside to the posterior edge of the inferior margin of the scapula.

Its anterior surface covers the scapula below the spine, to the posterior three-fourths of which it is attached. It is separated from the anterior fourth of this lower division of the scapula by the superior and external scapular vessels, by the scapular nerve, and by cellular substance. Beyond the scapula this surface of the muscle covers the shoulder joint, to the orbicular ligament of which it is strongly connected. The inner edge is fixed to the basis of the scapula, from the spine almost to the inferior angle. Its upper edge is attached to the lower surface of the spine of the scapula, and to the aponeurosis of the deltoid: the outer portion of this margin is parallel to the inferior edge of the supraspinatus. The lower border is oblique from below upwards, and from within outwards. This is united to the teres major by an aponeurotic septum, which is soon divided into two layers: one of these passes between the two teres muscles, the other between the teres minor and infraspinatus. The lower border of the latter is then united to the teres minor through about half its length; for the rest of their extent they are separated by a cellular line. In many subjects the fibres of these two muscles are so confounded at this part, that they cannot be separated.

The superior and inferior edges are united at a truncated angle, which is large and thick, and attached to the middle of the great tubercle of the humerus.

The infraspinatus muscle is composed of tendinous and muscular parts. It is attached to the humerus by a broad and thick tendon, which expands into an aponeurotic plane continued into the substance of the muscle beyond its middle, and nearer to the posterior than to the anterior surface of the muscle. The muscular fibres arise from the dorsum

of the scapula, from the under surface of its spine, from the aponeurosis of the deltoid, and from the aponeurotic septum, which separates this from the two teres muscles. They join the common tendon, which they accompany nearly to the humerus, pursuing, however, very different directions. The superior fibres proceed nearly horizontally from within outwards: all the others are oblique from within outwards, and from below upwards, and their obliquity increases as they are placed lower down. Those fibres, which arise from the aponeurosis of the deltoid, and from the lower surface of the spine of the scapula, descend slightly, and terminate on the posterior surface of the tendon, on which they are extended almost to its attachment to the humerus.

The motions which this muscle can produce in the humerus, differ according to the position of that bone. When the arm is hanging by the side, the humerus will be moved on its axis, so as to be turned from before outwards and backwards. If the humerus has been previously elevated, the infraspinatus will carry it backwards. When the arm is fixed, this muscle will draw the scapula, and through it the trunk also, forwards. The strength and breadth of its tendon enable it to support the head of the humerus, and to prevent it from being thrown out of the glenoid cavity, when the arm is moved suddenly forwards.

INFULA, a name anciently given to one of the pontifical ornaments worn on the head. Festus tells us that the infula were filaments or fringes of wool, covering that part of the head where the hair grows as far as the temples, whence, on each side, hung down two strings called *vitta*, for binding it, wherewith the ancients used to adorn their priests, their victims, and even their temples. The infula was the same thing to priests that the diadem was to kings; *viz.* the badge of their dignity and authority. The difference in shape between the diadem and the infula consisted in this, that the diadem was flat and broad, and the infula was rounded and twisted.

INFUMA, or **DIKJESCHOT,** in *Geography*, a town of Africa, in the kingdom of Anté, where the English built a fort in 1691.

INFUNDIBULA of Birds. See *Anatomy of Birds.*

INFUNDIBULIFORM FLOWERS, in *Botany*, are such as resemble the figure of a funnel; being broad and ample at top, and contracted into a neck at bottom; such as that of the bear's ear, or auricula.

INFUNDIBULUM, a Latin word signifying a *funnel*; whence divers parts in the human body, having a resemblance thereto in shape, are called by the same name.

Hence also certain parts of plants are called *infundibuliformes*.

The word *infundibulum* is also used by the metallurgic writers to signify a vessel of a conic shape, used to pour a melted metal out of the crucible into.

INFUNDIBULUM, in Anatomy, a small process in the brain. See **BRAIN.**

INFUSION, in Pharmacy, an operation whereby the virtues of plants, roots, and the like are drawn out by letting them steep in some convenient fluid menstruum without boiling them therein; since boiling is found to dissipate the finer parts of many bitter and aromatic substances, without carefully extracting their medicinal principles.

Infusion is used in bodies of a lax texture, whose parts are so light as not to admit of a greater motion without hazard of flying away in vapour.

Its chief use is to communicate the virtues of bodies to liquors,

INFUSION.

liquors, either in order to regulate their force, or correct their ill qualities.

Some infusions are made in common water, others in wine, vinegar, milk, spirit of wine, &c. Boiling water is sometimes effused upon any substance; and allowed to stand upon it for some time. Water is also occasionally effused cold in the same manner; and in this case the specific form of cold infusion is used.

The same operation is applicable to those substances which contain any parts volatile in the heat of 212; to the separation of more readily soluble constituent parts from those which are less so, and to the preparation of slighter impregnations than boiling for a length of time produces. The boiling temperature of the water is so soon lost in this mode of application, that even with the most delicate substances it does no injury, and it assists in loosening the texture of the vegetable, and effecting the solution much sooner than cold water alone does. Infusions are usually matters of extemporaneous prescription, and cannot generally be kept ready prepared in the shops without spoiling. Their number has been extended to most of the articles in common use, and the strength of each is accommodated to the most usual standards of practice. We shall recite some of the principal.

The *Liter infusion* is prepared by cutting the tops of the lesser centuary and chamomile flowers of each half an ounce, and the yellow rind of lemon and orange peel, of each two drams, in small pieces, and infusing them in a quart of boiling water. A tea-cupful of this infusion may be taken twice or thrice a day for indigestion, weakness of the stomach, or want of appetite.

Infusion of the Bark is made by infusing an ounce of the powder in a pint of boiling water, with the addition of four or five table-spoonfuls of brandy, for two or three days. In disorders which require the bark, a tea-cupful of this may be taken two or three times a day.

Infusion of Calumbæ, infusum Calumbæ, is prepared by slicing a dram of Calumbæ root, and macerating it for two hours in half a pint of boiling water in a covered vessel, and straining it. See COLUMBO.

Infusion of Camomile, infusum anthemidis, is made by macerating for ten minutes, in a covered vessel, two drams of camomile flowers in a pint of boiling water, and straining.

Infusion of Carduus is made by infusing an ounce of the dried leaves of carduus benedictus in a pint of common water for six hours, without heat, and then filtering the liquor through paper. This infusion, which may be flavoured at pleasure with cinnamon, or other aromatics, may be beneficially used in weaknesses of the stomach, where the common bitters do not agree.

Infusion of Cascarella is prepared by macerating for two hours, in a covered vessel, half an ounce of Cascarella bark bruised in half a pint of boiling water, and straining. See CASCARILLA.

Infusion of Catechu is obtained by taking 2½ drams of extract of catechu, and half a dram of bruised cinnamon bark, macerating them for an hour, in a covered vessel, in half a pint of boiling water, and straining. See CATECHU.

Infusion of Cinchona, infusum cinchonæ, is obtained by macerating for two hours, in a covered vessel, half an ounce of lance-leaved Cinchona bark in half a pint of boiling water, and straining.

Infusion of Cloves, infusum caryophyllorum, is obtained by macerating for two hours, in a covered vessel, a dram of cloves bruised in half a pint of boiling water, and straining.

Infusion of Cusparia is procured by macerating for two hours, in a covered vessel, two drams of bruised Cusparia bark in half a pint of boiling water, and straining.

Infusion of Fox-glove, infusum digitalis, is obtained by macerating for four hours, in a covered vessel, a dram of purple fox-glove leaves, dried and powdered, in half a pint of boiling water, and straining; then adding half a fluid-ounce of spirit of cinnamon. See DIGITALIS.

Infusion, Compound, of Gentian, infusum amaram simplex, P. L. 1745, is procured by macerating in a covered vessel, gentian root sliced and orange-peel dried, of each a dram, two drams of fresh lemon-peel, in twelve ounces of boiling water, and straining.

Infusion, Compound, of Horse-radish, infusum armoraciz compositum, is procured by macerating for two hours, in a covered vessel, fresh horie-radish root sliced, and mustard seeds bruised, of each an ounce, in a pint of boiling water, and straining; then adding a fluid-ounce of compound spirit of horse-radish. An infusion for the palsy may be made by infusing horse-radish root shaved, mustard seed bruised, of each four ounces; and one ounce of the outer rind of orange-peel in two quarts of boiling water, in a close vessel for twenty-four hours. A tea-cupful of this warm stimulating medicine may be taken three or four times a day, in paralytic complaints. It excites the action of the solids, proves diuretic, and, with warmth, promotes perspiration. If two or three ounces of the dried leaves of marsh-mallows be used instead of the mustard, we shall have the antiscorbatic infusion.

Infusion of Linseed, infusum lini, is prepared by infusing two spoonfuls of linseed, or an ounce of linseed bruised, and half an ounce of liquorice root sliced, in two pints of boiling water by the fire for four hours, and then straining off the liquor. The pectoral infusion is made by adding to these ingredients an ounce of the leaves of colt's-foot. These enollent liquors may be taken in difficulty of making water, and in coughs and other complaints of the breast.

Infusion of Quassia is obtained by macerating for two hours, in a covered vessel, a scruple of quassia-wood sliced, in half a pint of boiling water, and straining. See QUASSIA.

Infusion of Rhubarb, infusum rhei, is procured by macerating for two hours, in a covered vessel, a dram of sliced rhubarb-root in half a pint of boiling water, and straining. See RHUBARB.

Infusion of Roses, infusum rosæ, tinctura rosarum, P. L. 1718, tinctura rosarum rubrarum, P. L. 1720, is made by infusing half an ounce of the petals of red roses, dried, in 2½ pints of boiling water; afterwards pouring in three fluid-drams of dilute sulphuric acid, and 1½ ounce of double refined sugar. Pour the water upon the petals of the rose in a covered glass vessel; then add the acid, and macerate for half an hour. Lastly, strain the infusion, and add the sugar to it. A tea-cupful of this astringent infusion may be taken every three or four hours, in an excessive flow of the meneses, vomiting of blood, and other hæmorrhages. It will likewise serve as a very good gargle.

Infusion of Senna, infusum Sennæ, is prepared by macerating for an hour, in a covered vessel, 1½ ounce of Senna leaves, a dram of sliced ginger-root, in a pint of boiling water, and straining the liquor. An infusion of Senna, named "infusum Sennæ tartarizatum," may be had by adding extemporaneously to each pint of the infusion two drams of superatrate of potash, in such proportions as circumstances may require.

Infusion of Senna and Tamarinds, is prepared by infusing for four or five hours one ounce of tamarinds and senna, and crystals of tartar, of each two drams, in a pint of boiling water; straining the liquor, and adding to it an ounce or two of the aromatic tincture. Persons who are easily purged, may leave out either the tamarinds or the crystals of tartar. A tea-cupful of this agreeable cooling-purge may be taken every half hour till it operates.

Infusion of Simarouba is made by macerating for two hours, in a covered vessel, half a dram of Simarouba bark, bruised, in half a pint of boiling water, and straining. See SIMAROUBA.

Infusion, Spanish, is made by infusing an ounce of Spanish juice cut into small pieces, and three drams of salt of tartar in a quart of boiling water for a night; and adding to the strained liquor an ounce and a half of the syrup of poppies. In recent colds, coughs, and obstructions of the breath, a tea-cupful of this infusion may be taken with advantage three or four times a day. See LIQUORIC.

Infusion of Tobacco, *infusum tabaci*, is made by macerating for an hour, in a covered vessel, a dram of tobacco leaves in a pint of boiling water, and straining. This infusion is intended to be used as a clyster, to which purpose it is often directed.

INFUSION is also used to signify the action of conveying liquor into the body by the veins. See INJECTION.

Some physicians have found out a new method of purging, by infusing a cathartic into the veins, which operates pretty much after the manner of a clyster.

ING, in *Agriculture*, a provincial term, employed to signify a common pasture or meadow which lies low or wet, and which is chiefly employed as lay lands.

INGA, in *Botany*. See MIMOSA.

INGANNO, *Ital.* a trick, a disappointment, a disappointed cadence, or cloze, is, when, after preparing for a regular termination, some unexpected chord or modulation occurs to lengthen the movement and postpone the cadence. See CADENCE.

INGARD POINT, in *Geography*, a cape of Ireland, on the fourth coast of the county of Wexford, within which lies the small dry harbour of Feathard, which is only fit for small vessels.

INGARYD, a town of Sweden, in the province of Smaland; five miles S. of Jonkioping.

INGATESTONE, a small town in the hundred of Chelmsford and county of Essex, England, is situated 23 miles from London, on the high road to Colchester. It consists principally of one street, and contained, according to the late return to parliament, 120 houses and 645 inhabitants. In the church, which has a high embattled brick tower, are several elaborate monuments of the Petre family, whose burial place adjoins the chancel on the north side. A considerable market was formerly held here, but having greatly declined, it has been for several years wholly discontinued; but a very large fair for Scotch and Welch cattle is still held on the first of December, annually. An almshouse, for seven women and three men, was founded, in the year 1557, by sir William Petre, and endowed by him to the amount of 90*l.* 13*s.* 4*d.* per annum.

Near the town is Ingatstone-hall, a venerable, but irregular structure, which was the family residence of the lords Petre, previous to the building of a new mansion at West Thorndon. *Beauties of England and Wales*, vol. v.

INGATORP, a town of Sweden, in the province of Smaland; 40 miles N. of Wexio.

INGELFINGEN, a town of Germany, in the princi-

pality of Hohlenoe, on the Kocher; eight miles N. E. of Ohrenburg.

INGELHEIM, OBER, a town of France, in the department of Mont Tonnerre, situated on the Selz; 12 miles W. of Mentz. N. lat. 49° 56'. E. long. 8° 1'.

INGELHEIM, NIDER, a town of France, in the department of Mont Tonnerre, one mile from Ingelheim Ober.

INGELLY, a town of Hindooistan, in Bengal, at the mouth of the Hoogly; 60 miles S. of Calcutta.

INGELMUNSTER, a town of France, with a castle, in the department of the Lys, and chief place of a canton, in the district of Courtray; five miles N. of Courtray. The town contains 4873, and the canton 14,284 inhabitants, on a territory of 52½ kilometres in four communes.

INGELSBURG, a town of Saxony, in the Vogtland; nine miles S. S. E. of Oelsnitz.

INGELSTAD, a town of Sweden, in the province of Smaland; 10 miles S. E. of Wexio.

INGEMINATED FLOWERS, are those where one flower stands on, or naturally grows out of another; called also prolificiferous flowers.

INGEN, in *Geography*, a small island in the North sea, near the coast of Lapland. N. lat. 70° 56'.

INGENDRING. See ENGENDERING.

INGENERATE, in *Natural History*, is a term used to express the kind of petrifications produced by intromission, or the introduction of the mineral particles into the internal texture of the original organized. Martia's "Outlines," p. 67.

INGENHOUS, JOHN, in *Biography*, an eminent physician and chemist, was born at Breda in the year 1730. Little is known of his early life; but in 1767 he came to England with a view of obtaining information on the Suttonian method of inoculation for the small-pox, and in the following year he went, on the recommendation of the late sir John Pringle, to Vienna, to inoculate the archduchess Theresa-Elizabeth, only daughter of Joseph II., and the archdukes Ferdinand and Maximilian, brothers of the emperor. For these services he obtained rewards and honours: he was made body-physician and counsellor of state to their imperial majesties, with a pension of 600*l.* per annum. In the following spring he went to Italy; and inoculated the grand duke of Tuscany: after this he returned to England, to which he was much attached, where he spent his time in scientific pursuits. He published a very valuable work, entitled "Experiments on Vegetables, discovering their great power of purifying the common air in sunshine, but injuring it in the shade and night." This work was first published in 1779, and has been frequently referred to by Dr. Priestley and others, who have carried their observations much farther. It was translated into the French and German languages, and highly esteemed by all the experimental philosophers of that period. He ascertained, that not only from the green matter found on stagnant waters, but likewise from the leaves of vegetables, from the green branches and shoots, even from the entire vegetable, when placed under water and exposed to the solar light, oxygen gas, in a state generally of great purity, is evolved; and as the result of his numerous experiments he adopted the conclusion, that oxygen is elaborated in the leaves and other organs of vegetables, by a vital action excited and sustained by the solar light. The doctor, through the whole of his life, was fond of exhibiting among his friends, particularly young persons, experiments of this kind, which required scarcely any apparatus, excepting a bell glass and a phial or two, and with the oxygen gas which he obtained from cabbage leaves or other vegetables, he would exhibit the combustion of zinc wire, which is a

striking and very brilliant experiment. Dr. Ingenhousz was author of many papers inserted in the Transactions of the Royal Society, of which body he was an active and useful member. Of these papers we may notice the following: Experiments on the torpedo.—Methods of measuring the diminution of bulk taking place on the mixture of nitrous with common air.—Experiments on the electro-phorus.—New Methods of suspending magnetic needles.—Considerations on the influence of the vegetable kingdom on the animal creation. He died in the year 1799, highly esteemed for the simplicity of his manners, and for the discoveries which he had made in the several departments of experimental philosophy. Monthly and Gentleman's Magazine. Murray's Chemistry.

INGENITE, INBORN, signifies any disease or habit which comes into the world with a person, nearly the same with hereditary.

INGENUITAS REGNI, anciently signified the freeholders and commonalty of the kingdom: the title was also sometimes given to the barons and lords of the king's council.

INGENUOUS, INGENUUS, among the Romans, a title applicable to a person born free, or of free parents.

Hisdore says, they are called *ingenui, qui libertatem habent in genere non in factis*; those who are born free, not those who acquire their freedom.

A person was accounted ingenuous, if only the mother were free, and the father a slave.

These could give their votes, and enjoy offices, from which the *liberti*, or freedmen, &c. were debarred.

INGENUUS is sometimes also used to signify a native of a country in contradistinction to a foreigner.

INGERAM, in *Geography*, a small island in the straits of Malacca, near the coast of Selangore. N. lat. 3° 15'. E. long. 101° 26'.—Also, a town of Hindoostan, in the circar of Rajamundry; 30 miles S.E. of Rajamundry.

INGETORP, a town of Sweden, in the province of Schonen; 10 miles E. of Ytad.

INGINEER, or ENGINEER. See **ENGINEER**.

INGKALU, in *Geography*, a small island in the North sea, near the coast of Lapland. N. lat. 70° 50'.

INGLEBOROUGH, a mountain of England, in the N.W. part of the county of York, said to be 20 miles in circumference. The height is stated by Housman to be 3987 feet; but by the barometrical measurement of Mr. Ewart 2377.12, and by trigonometrical measurement 2380.7 feet above the level of the sea.

INGLOTT, WILLIAM, in *Biography*, an organist of the cathedral church of Norwich, who seems, by an inscription on his monument in that church honourable to his memory, to have been a man of no common abilities. We have never heard or seen any of his productions; but in all probability, Dr. Croft had; who, a hundred years after his decease, had his monument repaired. Ingloft died in 1621.

INGLUVIES. See **CHAW**.

INGOLSTADT, in *Geography*, a town of Bavaria, situated on the Danube, and surrounded with a morass. It has an university, founded in the year 1472, which embraced the Reformation in 1743; 37 miles N. of Munich. N. lat. 48° 43'. E. long. 11° 21'.

INGOT, a mass or lump of gold or silver, from the mines, melted down, and cast in a sort of mould, but not coined or wrought.

The word seems formed from the French *lingot*, which signifies the same.

INGOT is also a name given to the moulds or cavities, wherein they cast melted metals, or regulus of semimetals.

INGOULT, NICHOLAS LOUIS, in *Biography*, a French Jesuit, was born at Gisors, devoted himself to an ecclesiastical life, and became a very eloquent preacher. He published the eighth volume of the Memoirs of the Missions of the Society of Jesus in the Levant. He was author also of sermons which were highly applauded. He died in 1753.

INGOUELLE, in *Geography*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the district of Le Havre. The place contains 5509, and the canton 10,347 inhabitants, on a territory of 40 kilometres, in six communes.

INGRAFTING, or ENGRAFTING. See **ENGRAFTING**.

INGRAILED. See **ENGRAILED**.

INGRAM, ROBERT, in *Biography*, was born in Yorkshire, and educated at Beverley school, from whence he was sent to Corpus Christi college, Cambridge, of which he became fellow, and took there his degrees in arts. His first preferment was the perpetual curacy of Bridhurst, in Kent, after which he obtained successively the small vicarage of Orilton, in Nottinghamshire, and the vicarages of Wormington and Boxted, in Essex. He died in 1804, leaving behind him a high character for simplicity of manners, great integrity, and genuine benevolence. He had a high sense of the dignity and importance of the clerical functions, and for 50 years of his life was indefatigable in his attention to professional duties. He was author of "A view of the great events of the seventh plague, or period, when the mystery of God shall be finished." "Accounts of the ten tribes of Israel being in America, originally published by Manasseh Ben Israel, &c." "A complete and uniform explanation of the prophecy of the seven vials of wrath, or seven last plagues contained in the Revelations of St. John, &c."

INGRASSIAS, JOHN PHILIP, was a native of Sicily. He studied medicine at Padua, where he took the degree of doctor in medicine in the year 1537, with singular reputation; inasmuch that he soon received several invitations to professorships from different schools in Italy. He accepted the chair of medicine and anatomy at Naples, which he occupied for a number of years, lecturing to the most crowded audiences drawn by his fame from all parts of the country. He possessed peculiar qualifications for the office, having united a consummate knowledge of the writings of the ancient physicians with great practical skill and a sound judgment, which led him to estimate justly the merits and defects of those fathers of the art. A singular testimony of his talents and unremitting attention to the improvement of his pupils was given by the latter, who caused his portrait to be placed in the schools of Naples with the following inscription: "Philippo Ingrassie Siculo, qui veram medicinam artem et anatomiam publice enarrando, Neapoli restituit, Discipuli memorie causa, P. P." At length he quitted his situation at Naples in order to return to his native island, where he settled at Palermo. Here also he received many marks of public distinction. The rights of citizenship were conferred upon him; and in 1563, Philip II. king of Spain, appointed him first physician for Sicily and the adjacent isles. By virtue of the powers attached to this office he restored order in the medical constitution of the country, by preventing all persons, unqualified by their education and abilities, from practising there. His zeal for the credit of his profession rendered him rigid and severe in his examination of candidates: and he exercised his art himself in the most honourable manner. When the plague raged at Palermo in 1575, he adopted such excellent regulations, in quality

quality of deputy of health and first consultant, that he put a stop to the calamity, and restored the city to health, and was hailed by all the citizens, the Sicilian Hippocrates. The magistrates were so grateful for his services, that they voted him a reward of two hundred and fifty gold crowns a month: but he disinterestedly declined to accept any more than what served for the maintenance and decoration of the chapel of St. Barbe, which he had built in the cloister of the Dominican convent of Palermo. He died greatly regretted in 1580, at the age of 70 years.

Ingraffias cultivated anatomy with great assiduity, and is esteemed one of the improvers of that art, especially in regard to the structure of the cranium, and the organ of hearing. He discovered the small bone of the ear, called the *flaper*, which has been claimed as the discovery of others, but is admitted even by Fallopius to have been his. He described minutely the cavity of the *tympanum*, the *fenestra rotunda* and *ovalis*, the *cochlea*, semicircular canals, mastoid cells, &c.; and Eloy thinks, from a view of his plates, that he was acquainted with the muscle of the *malleus*, the discovery of which is ascribed to Eustachius. He is said also to have discovered the femal vesicles. He was author of the following works: 1. "Jatropologia; Liber quo multa adversus Barbaros Medicos disputantur," Venice, 1544, 1558, 8vo.—2. "Scholia in Jatropologiam," Naples, 1549, 8vo.—3. "De Tumoribus præter naturam," *ibid.* 1553, folio, vol. i. This is properly a commentary on some of the books of Avicenna.—4. "Ragionamento fatto sopra l'infiermita epidemica dell' anno 1558," Palermo, 1560, 4to., together with "Trattato di due mostri nati in Palermo in diversi tempi."—5. "Constitutiones et Capitula, necnon Jurisdictiones Regii Proto-Medicatus officii, cum Pandectis ejusdem reformatis," Palermo, 1564, 1657, 4to.—6. "Quæstio de purgatione per medicamentum, atque obiter etiam de sanguinis missione, an sexta die possit fieri," Venice, 1568, 4to.—7. "Galeni Ars Medica," *ibid.* 1573, folio.—8. "De frigide potu post medicamentum purgans Epitola," *ibid.* 1575, 4to., reprinted at Milan, 1586.—9. "Informatione del pestifero e contagioso morbo, il quale affligge e habbe afflito la città di Palermo, e molte altre città e terre del regno di Sicilia, nell' anno 1575 e 1576," Palermo, 1576, 4to. This work was translated into Latin by Joachim Camerarius, and published under the title of "Methodicus curandi pestiferum contagium," at Nürimberg, 1583.—10. "In Galeni Librum de ossibus doctissima et expertissima Commentaria," apollunous publication, printed at Messina, in 1603, under the inspection of his nephew, Nicholas Ingraffias. This, which may be deemed the principal work of Ingraffias, contains the text of Galen, in Greek and Latin, with a very diffuse and learned commentary, in which there is much minute and accurate description, particularly of the parts belonging to the organ of hearing. The figures are those of Vesalius. The author defends Galen as far as he is able, but not against the truth of modern discovery. See ELOY. Dict. Hist. Gen. Biog. Haller Bibl. Anatom.

INGRAVING, or ENGRAVING. See ENGRAVING.

INGRE, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the district of Orleans; four miles N. W. of Orleans. The place contains 2905, and the canton 10,810 inhabitants, in a territory of 16 kilometres, in 10 communes.

INGREDIENTS, all the simples which go into the composition of any medicine, ointment, fauce, or the like.

INGRESS, in *Astronomy*, the sun's entering the first scruple of one of the four cardinal signs, especially Aries.

INGRESS, *Egressi*, and *Regressi*, in *Law*, are words in

leases of land, signifying a free entry into, a going out of and returning from some part of the premises leased to another; as to get in a crop of corn, &c. after the term expired.

INGRESSU, a writ of entry, whereby a person seeks entry into lands or tenements. It lies in various cases, and has various forms. It is also called *precipe quod reddat*.

INGRIA, or INGERMANLAND, in *Geography*, that part of Russia, which was wrested by Peter the Great from the Swedes, and confirmed to Russia at the peace of Nyfadt in 1721. It is now called the "Government of St. Peterburg;" which see.

INGRIN, or GRAIN, a town of Africa, in the country of the Foulahs; 30 miles S. W. of Cayor.

INGROSSATOR *Magni Rotuli*, is the same as clerk of the pipe.

INGROSSER, or ENGRESSER, in *Common Law*, is one who buys up corn growing, or any provisions by wholesale, before the market, to sell again. See FORESTALLING.

It also signifies a clerk, who writes records, or instruments of law, on skins of parchment. See ENGRESSING.

INGROSSING of a *Fin.*, is the making the indentures by the chirographer, for delivery of them to the party to whom the fine is levied.

INGROWITZ, in *Geography*, a town of Moravia, in the circle of Brunn; 30 miles N. N. W. of Brunn. N. lat. 49 36'. E. long. 16 2'.

INGSKAR, a small island in the gulf of Bothnia. N. lat. 61 15'. E. long. 17 24'.

INGUE-LOUKA, a town of Chinese Tartary. N. lat. 42 16'. E. long. 124 44'.

INGUEN, in *Anatomy*, the technical term for the groin.

INGUIMBERTI, DOMINIC-JOSEPH-MARY D', in *Biography*, a learned French prelate, was born at Charpentras in 1683. He devoted himself from a very early age to the ecclesiastical profession, became a member of the Dominicans, and afterwards joined the Cistercians, in order that he might submit to what he conceived the more perfect rules of monastic discipline. In this last order his merits raised him to the highest offices of honour and confidence. Being deputed to Rome on the business of his monastery, he so highly recommended himself to the esteem of pope Clement XII. that in the year 1733, he was raised to the rank of bishop of Charpentras, and other ecclesiastical preferment. He died in the year 1757, and is known in the republic of letters by several original works, and translations of others. As a bishop he obtained universal respect, and employed his wealth in serving the public and in relieving the poor. He built a large and noble hospital, and he collected the most extensive and valuable library in Provence, which he gave for the use of the public.

INGUINAL GLANDS, in *Surgery*. See GLANDS.

INGUINAL Hernia, a rupture, or protrusion of the bowels at the abdominal ring; a bubonocoele. See HERNIA.

INGUINAL Ligament, this, which has been also called from its discoverer ligamentum Fallopii, is an aponeurotic, or ligamentary band, fastened by one end to the anterior and superior part of the os ilium, and by the other to the spine of the os pubis. The middle portion of it is very narrow, but it expands considerably towards both its extremities. It is closely joined to the muscles of the abdomen, and to the aponeurotic fascia of the thigh, but seems to be often wanting.

INGUINALIS, in *Anatomy*, an epithet sometimes applied to the external iliac artery and vein.

INGUL,

INGUL, in *Geography*, a river of Ruffia, which runs into the Bug, near Matvieka.

INGULETZ, a river of Ruffia, which runs into the Duiper; 12 miles N.E. of Cherfon.

INGULPHUS, in *Biography*, a monastic historian, was the son of a courtier of Edward the Confessor, and was born at London about 1030. He pursued his maturer studies at Westminster and Oxford, and distinguished himself as a great adept in the Peripatetic philosophy. Scarcely had he attained the age of manhood when he was appointed secretary to duke William, by whose permission he visited the Holy Land and Constantinople in 1064, and upon his return, he entered into the order of the Benedictines at the abbey of Fontenelle, in Normandy, of which he became prior. When his patron, William, obtained the crown of England, Ingulphus was created abbot of the rich monastery of Croyland, which being in a dilapidated state, he rebuilt, and for which he obtained many privileges. He died in 1109, leaving behind him as evidences of his great learning, a work on the life and miracles of St. Guthlac, and a history of the monastery of Croyland. The last gives the author rank with the English historians. It was published at London, by sir Henry Saville, among the quinqué scriptores, in 1506, being almost five hundred years after the death of the author. It has been several times reprinted: the best edition is that of Oxford, in 1684.

INGULSK, in *Geography*, a town of Ruffia, in the government of Ekaterinoflav, on the Ingul; 28 miles S. of Elizavet.

INGURTY, a town of Hindooflan, in the province of Goleonda; 22 miles S.E. of Warangole.

INGWEILER, a town of France, in the department of the Lower Rhine, on the Motter; 21 miles N.N.W. of Strasbourg.

INHÄLER, in *Surgery*, a machine lately invented by Mr. Mudge, and so contrived, that the air drawn through a tube in respiration, passes first through hot water, and thus comes to the lungs loaded with warm vapour. The same air, when expelled in expiration, passes back through the tube, and thence through a valve, which by proper management it may be distributed over the surface of the body and thus act as a vapour-bath. The author's directions for the process are as follow:

In the evening, a little before bed-time, the patient, if of adult age, is to take three drams, or as many tea-spoonfuls of elixir pargoricum in a glass of water; if the subject is younger, e.g. under five years old, one tea-spoonful; or within that and ten years, two. About three quarters of an hour after he should go to bed, and being covered warm, the inhaler, filled three parts with water nearly boiling, and wrapped up in a napkin, but so that the valve in the cover is not obstructed by it, is to be placed at the arm-pit, and the bed-cloaths being drawn up, and over it close to the throat, the tube is to be applied to the mouth, and the patient should inspire and expire through it about twenty minutes or half an hour. This, he assures us, is an infallible and immediate cure for the cough consequent on catching cold. Mudge's radical and expeditious Cure for a recent Catarrhus Cough, 1778.

INHÄLOW, in *Geography*, one of the smaller Orkney islands, between Pomona and Rousa.

INHAMBANE, or **INNANBAM**, a kingdom of Africa, in the country of Mocaranga, bounded N. by Sobia, E. and S.E. by the Indian sea, S.W. by the river Manica, and N.W. by an unknown country.

INHAME, in *Botany*. See **DIOSCOREA**.

INHAMOIT, in *Geography*, a town and district of

Africa, in the country of Mocaranga, situated about S. lat. 17° 30'. E. long. 31° 20'.

INHAMPURA, a river of Africa, in the kingdom of Jubahanc, which runs into the Indian sea, S. lat. 24° 30'.

INHANBANO, a river of Africa, which runs into the Indian sea, S. lat. 23° 15'.

INHANGOMA, an island of Africa, in the river Zambeze. S. lat. 17° 45'. E. long. 32° 20'.

INHANZARA, a town of Nubia, in Sennaar; 30 miles from Giffen.

INHAQUEA, a town of Africa, in the kingdom of Sofala, possessed by the Portuguese, near the sea-coast; 20 miles S.W. of Sofala.

INHARMONICAL RELATION, in *Music*. See **RELATION**, *inharmonical*.

INHARMONICAL, is said of an interval or chord that is impracticable in harmony, and, consequently, in melody. Notes out of tune are inharmonical.

INHARMONIOUS, or unnatural relations, according to Mr. John Holden (Essay, p. 331.) are such intervals as result from the sums of notes or intervals not contiguous in the scale, as a minor third to a major seventh, &c.

INHASATO, in *Geography*, a small island in the Indian sea, near the coast of Africa. S. lat. 20° 35'.

INHERENCE, in *Philosophy*, is applied to the juncture or connection of an accident with its substance.

Thus quantity has a necessary inherence in a natural body.

INHERENT, in *Natural History*, is a term used by Mr. William Martin (Outlines, p. 180.) to express that class of organic remains or reliquia, which stick in the surface of the matrix or seat. The extraneous fossils of veins are frequently found in this state.

INHERITABLE BLOOD, in *Law*. See **BLOOD**.

INHERITANCE, **HEREDITAS**, a property in lands and tenements to a man and his heirs. See **ESTATE**, in *Law*.

Inheritance is not only understood where a man hath inheritance of lands and tenements by descent or heritage; but every fee-simple or fee-tail, that a man hath by his purchase, may be said to be an inheritance, because his heirs may inherit it after him. (See **FREE-SIMPLE** and **FREE-TAIL**.) The inheritances mentioned in our law are either corporeal or incorporeal; the corporeal relate to houses, lands, &c. that may be touched or handled; and the incorporeal are rights issuing out of, annexed to, or exercised with corporeal inheritances; as advowsons, tithes, annuities, offices, commons, franchises, &c. (See **HEREDITAMENTS**.) There is likewise another inheritance denominated several, that is, where two or more hold lands severally; as when two persons hold to them and the heirs of their two bodies, in which case these two have joint-estate during their lives, but their heirs have several inheritances. Goods and chattels cannot be turned into an inheritance. For the rules of inheritance, see **DISENT**, *collateral*.

INHIBITION, a writ to inhibit or forbid a judge from farther proceeding in a cause depending before him.

Sometimes prohibition and inhibition are put together, as of the same import; but inhibition is most commonly a writ issuing out of a higher court-christian to a lower; and prohibition out of the king's court to an inferior court.

INHIBITION, in *Scots Law*, is a personal prohibition, which passes by letters under the signet, prohibiting the party inhibited to contract any debt, or do any deed, by which any part of his lands may be aliened or carried off in prejudice of the creditor inhibiting. It must be executed against the debtor, personally, or at his dwelling-house, as summons, and afterwards published and registered in the same manner with interdictions. Inhibition may proceed either

upon a liquid obligation, or even as an action commenced by a creditor for making good a claim not yet satisfied by the judge; which last is called "inhibition upon a depending action." Although inhibitions, by their uniform style, disable the debtor from selling his moveable as well as his heritable estate, their effect has been long limited to heritage, from the interruption that such an embargo upon moveables must have given to commerce; so that debts, contracted after inhibition, may be the foundation of diligence against the debtor's person and moveable estate. An inhibition secures the inhibitor against the alienation, not only of lands that belonged to his debtor, when he was inhibited, but of those which he shall afterwards acquire; but no inhibition can extend to such after-purchases as lie in a jurisdiction where the inhibition was not registered; for it could not have extended to those though they had been made prior to the inhibition. An inhibition is simply prohibitory; so that the debt on which it proceeds, continues personal after the diligence. The heir of the person inhibited is not restrained from alienation by the diligence used against his ancestor, for the prohibition is personal, affecting only the debtor against whom the diligence is used. Inhibitions do not of themselves make void the posterior debts or deeds of the person prohibited. When payment is made by the debtor to the inhibitor, the inhibition is said to be "purged."

INHOC, or **INHOKE**, in our *Old Writers*, is used for any corner or part of a common field ploughed up and sowed with oats, &c. and sometimes fenced in with a dry hedge in that year wherein the rest of the same field lies fallow and common. It is called in the North of England an *intock*, and in Oxfordshire a *hitchin*. And no such *inhoke* is now made without the joint consent of all the commoners, who in most places have their share by lot in the benefit of it, except in some manors where the lord has a special privilege in so doing. Kennet's Paroch. Antiq. 297, &c. and his *Glossary*.

The word is Saxon, compounded of *in*, *within*, and *hole*, a *corner*.

INHUMATION. See **BURIAL** and **INTERMENT**.

INHUMATION, in *Chemistry*, a method of digesting substances together, by burying the vessel in which they are put in horse-dung, or in dry sandy earth exposed to the sun. See **DIGESTION**.

INIA, in *Geography*, a river of Russia, which runs into the Oby, 50 miles N.E. of Kolivan.—Also, a river of Russia, which runs into the Lena, N. lat. 55° 20'. E. long. 116° 14'.

INJAMBI, or **TIETE**, a river of Brazil, which runs into the Parana, 180 miles N.W. of St. Paul, on the borders of Paraguay.

INIARA, a town of Russia, in the government of Penza; 48 miles W. of Penza.

INJECTION, in *Anatomy*, is the art of filling the blood-vessels or other hollow organs of the dead body with various substances, for the purpose of investigating their structure, situation, &c. or for displaying any facts connected with these subjects by subsequent artificial preparation. See **PREPARATIONS**, *Anatomical*.

INJECTION, in *Pharmacy*, any liquid medicine made to be injected or thrown into the body, or any of its parts, by a syringe, clyster-pipe, or other instrument.

INJECTION, or *Injections*, in *Surgery*, the throwing in some liquor or medicine into a vein opened by incision. This practice, and that of transfusion, or the conveying the arterial blood of one man, or other animal, into another, were once greatly practised, but are now laid aside.

The method of injecting is this: a vein is to be opened in

the arm with a lancet as in bleeding, and a small pipe of a syringe being introduced at the orifice, the liquor intended to be mixed with the blood, and contained in that purpose in the body of the syringe is to be forcibly injected, or thrown into the vein upwards, or toward the heart; which done, the orifice is to be secured with compresses and bandages as in bleeding.

Whether this practice of injecting proper medicines into the blood may not be found of use in apoplexies, quinies, hydrophobia, &c. is worthy to be tried by repeated experiments. The method of injecting liquors into the blood of living animals, is said to be the invention of sir Christopher Wren. His method was by making ligatures on the veins, and opening them on the side of the ligature towards the heart; then putting into them small syringes or quills fastened to bladders in the manner of clyster-pipes, containing the matter to be injected. Mr. Boyle soon made the experiment upon dogs, with infusions of opium and crocus metallorum; all which he circumstantially described, in his *Usefulness of Experimental Philosophy*, part ii. c. 2. Phil. Trans. N. 7. p. 128.

The ingenious Dr. Hales made a variety of experiments of this kind on different animals. See his *Statical Essays*, vol. ii. p. 116.

Many disorders of particular parts are no way curable, unless the parts affected are injected with a proper liquor by means of a syringe and proper tube. The method of performing this is too obvious to need any directions; but these general cautions are necessary in regard to it, that the syringe or tube be applied tenderly and carefully to the parts, especially in very sensible or nervous parts, to avoid giving the patient any pain; and that the liquor to be injected be neither too hot nor too cold.

In ulcerations and inflammations of the uvula, tonsils, and fauces, injections are generally useful: but care must be taken to press down the tongue with a spatula, or with the flat end of a spoon, and having introduced the syringe two or three fingers breadth into the mouth, the injection is to be carefully and gently thrown in at several times. In gonorrhœas, injections are often necessary to allay the heat and soreness of the urethra, and to wash out the matter. The safest and best injections on this occasion are warm milk and barley-water, sweetened with sugar, honey, or syrup of marshmallows; and towards the end a little saccharum saturni dissolved in plantane water.

INJELIEE, in *Geography*, a province of Bengal, on the right side of the Hoogly, near its mouth.

INIO, a small island in the Baltic, near the coast of Finland, with a town. N. lat. 60° 26'. E. long. 21° 14'.

INIS, a word in the Irish language signifying *island*; and therefore used as a prefix to the names of many islands on the coast of Ireland, some of which are noticed in succeeding articles, but a much greater number passed by as too insignificant.

INISBEG, in *Geography*, the name of several small islands on the coast of Ireland, the name signifying *Little Island*. One of these is in a small bay of the county of Cork, near the town of Skibbereen; another is on the west coast of Kerry, near the Great Blasket island; and a third is on the north coast of the county of Donegal, about 6 miles N.E. of Bloody Farland Point.

INISBOFFIN, or **ENNISBOFFIN** *i. e.* the island of the *White Cow*, an island near the west coast of Ireland, containing 1200 acres. It is about a mile and a half from the main land of the county of Galway, and is a parish in the diocese of Tuam. There was formerly an abbey here. There is an island of the same name on the coast of Donegal,

ral, about four or five miles E. by N. of Bloody Farland Point; and a third in Lough Ree, an expansion of the river Shannon, in which was an abbey that the Danes plundered and destroyed in 1089. Beaufort, Carlisle.

INISCALTRA, or **INISCALTHRA**, an island situated in the river Shannon, belonging to the county of Galway, about two miles S. from mount Shannon, and eight N. by W. from Killaloe. In this mountain island are a fine anchor-tower, above seventy feet high, and the remains of seven small churches.

INISCATTERY, or **INISCATHRIE**, an island belonging to the county of Clare, province of Munster, Ireland. This rich and beautiful little island is situated at the entrance of the river Shannon, between the counties of Kerry and Clare, two miles S. by W. from Kiltruff, and nearly opposite to the castle of Caunigfoile, which was besieged and taken by Sir W. St. Leger in 1580. According to Mr. Archdall, a monastery was founded in Iniscattery, of which St. Senan was the first abbot. There were eleven churches for the monks, and no women were permitted to land on the island before the coming of the Danes into Ireland. In process of time it became a priory of regular canons. The monument of St. Senan is still to be seen here, with the remains of eleven small churches and several cells: in the stone that encloses the top of the altar window of the great church is the head of the saint with his mitre, boldly executed, and but little defaced. An ancient round tower of 120 feet in height, and in complete repair, graces the scene. This island is remarkable for the resort of pilgrims on certain festivals. Archdall, Carlisle.

INISDRISUL, or **INISDRISCOL**, an island belonging to the county of Cork, province of Munster, Ireland, situated in *Roaring Water Bay*, a little north of Cape Clear island.

INISDUFF, or **INISDUBH**, a small island off the coast of Donegal, in the province of Ulster, Ireland, about six miles N.E. from Bloody Farland Point. Carlisle.

INISFREE, the name of two islands off the west coast of the county of Donegal, province of Ulster, Ireland; one of which is in the cluster of the North Arran isles, a little south of Rutland; the other, which gives name to a small harbour, lies between Rutland and Bloody Farland Point. Mackenzie, Beaufort.

INISGLORA, a small uninhabited island off the west coast of Mayo, in the province of Connaught, Ireland.

INISGOLA, an island in Clew bay, county of Mayo, province of Connaught, Ireland, on the east side of which is good anchorage for large vessels. Mackenzie.

INISHARK ISLAND, an island near the west coast of Ireland and county of Galway. N. lat. 53° 34'. W. long. 10° 14'.

INISHEGIL, or, according to Mackenzie, *Inisbegil*, an island off the coast of Mayo, Ireland, between Achill island and the main land.

INISHERKAN, an island near the fourth coast of Ireland, belonging to the county of Cork, on the west side of Baltimore harbour. N. lat. 51° 24'. W. long. 9° 19'.

INISHONAN, or **INISHANNON**, a post-town of Ireland, in the county of Cork, and province of Munster. It is on the Bandon river, ten miles from Cork, three from Eandon, and 133 S.W. from Dublin.

INISHOVEN a large peninsula and barony of the county of Donegal, Ireland, which stretches N.E. from Londonderry, bounding Lough Foyle. It is a dreary mountainous region, but great exertions have been made to meliorate its natural rudeness. It indeed returns a greater

rent than any other part of the county. The mountains feed a number of cattle, and the flats produce tolerable crops. They have manure of the best quality in abundance, such as limestone, shells, and sea-ware, which act powerfully upon the barrenness of the soil. Robertson.

INISHOVEN Head, a cape in Ireland, forming the eastern extremity of the peninsula, a little north of the entrance into Lough Foyle. N. lat. 55° 15'. E. long. 6° 48'.

INISKEA, the name of two small islands off the west coast of Ireland, between which there is good anchorage. They are about two miles from the peninsula of the Mullet, in the county of Mayo; between 54° 7' and 54° 10' N. lat. and 10° W. long.

INISLIRE, an island in Newport or Clew bay, county of Mayo, Ireland, which gives name to one of the best stations for vessels in that extensive bay. Mackenzie.

INISMURRY, **INISMURRA**, or *Inis-muidhr*, an island which lies off the coast of Sligo, Ireland, about three miles distant from the main land. It contains 130 acres, two wells of excellent water, and some bog of remarkably good turf. The inhabitants are few, and live by fishing. There are the remains of some chapels within a stone wall ten feet high, and from five to seven and eight feet thick, without cement. Mr. Archdall says it is impossible to determine whether it is round or oval; and that more rude, inelegant workmanship was never seen. There are a few cells under ground, which receive their light, some through a hole at the top, others through a loop-hole in the side; they are dark and horrible dungeons. Gen. Vallancey infers from part of these ruins, that in Pagan times, the island was dedicated to the worship of Boodha, and says that a monument in this island is an exact representation of the Mabody of the Gentoos found in the island of Elephanta, near Bombay, by captain Pyke. Many devotees still flock to this island to do penance in the cells, and many are brought from great distances to be buried in the churches. There is a ledge of rocks running from this island, which require the attention of all who enter the bay of Sligo. Vallancey's Prospectus of a Dictionary; Carlisle.

INISTIOGE, a small post-town of Ireland, in the county of Kilkenny, and province of Leinster. It is situated on the river Nore, which is navigable to it, and over which it has a bridge with ten arches. Inistioge is one of those places which before the Union sent two members to the house of commons of Ireland. It is 63 miles S.W. from Dublin.

INISTUISKAR, an island off the west coast of the county of Kerry, Ireland, about four miles from Caunfa head, and north of the Blasquets. N. lat. 52° 8'. W. long. 10° 25'.

INSTURC, an island situated about seven miles from the west coast of Mayo, Ireland, not far from the Killeries. N. lat. 53° 42'. W. long. 10°.

INITIALIA, a name anciently given to the mysteries of Ceres. See CERESIA.

INITIALIS *et pausa generalis*, the beginning of a musical composition, and the cad. See TEMPO, PROLATION, and PAUSE.

INITIANS PRINCIPUM. See PRINCIPUM.

INITIATE, *Tenant by Curtesy*, in *Law*. See TENANT.

INITIATED, a term properly used in speaking of the religion of the ancient heathens; where it signifies being admitted to the participation of the sacred mysteries.

The word comes from the Latin *initiare*, of *initiare*, *initiare*; which properly signifies to begin sacrificing, or to receive or admit a person to the beginning of the mysteries, or of ceremonies of less importance.

The ancients never discovered the deeper mysteries of their religion, nor even permitted some of their temples to be opened to none but those who had been initiated. See MYSTERY.

INJUNCTION, in *Law*, a writ generally grounded upon an interlocutory order or decree out of the court of chancery or exchequer, sometimes to give possession to the plaintiff, for want of the defendant's appearance; sometimes to the king's ordinary court, and sometimes to the court-christian, to stop proceedings in a cause, upon suggestion made, that the rigour of the law, if it take place, is against equity and conscience in that case, that the complainant is not able to make his defence in these courts for want of witnesses, &c. or that they act erroneously denying him some just advantage. The writ of injunction is directed not only to the party himself, but to all and singular his counsellors, attorneys, and solicitors; and if any attorney, after having been served with an injunction, proceeds afterward contrary to it, the court of chancery will commit the attorney to the fleet for contempt. But if an injunction be granted by the court of chancery in a criminal matter, the court of king's bench may break it, and protect any that proceed in contempt of it.

INJURY, **INJURIA**, in a general sense, signifies any thing contrary to justice and equity; that is, any wrong or damage done to a man's person, reputation, or goods.

The word is derived from the Latin preposition *in*, which here has a negative power; and *jus, law, right: injuria, sicutur omne quod non jure fit*. The ancients made a goddess of injury, and called her Ate. Homer makes her the daughter of Jupiter, and says she did mischief to every body, even to her father; that she was very nimble and tenderfooted, and walked altogether on men's heads without ever touching the ground.

Civilians define injury a private offence, committed designedly, and with an evil intention to any man's prejudice, with regard to his person or his property. All civil injuries are of two kinds; the one without force or violence, as slander or breach of contract; the other joined with force and violence, as batteries and false imprisonment. The author of the Rhetorics to Herennius says, "Injuria est quæ aut pulsatione, aut convitio, aut turpitudine, corpus, aures, aut vitam alicujus violavit."

By the Roman law, the action for an injury was annual: that is, no reparation could be required after the expiration of a year. By the law of the twelve tables, where the injury was the breaking of a limb, the injured person might demand talionem, that is, that he might break the same limb of the criminal.

For the breaking of a bone there were also considerable pecuniary punishments assigned: for other injuries only twenty asses were decreed, which the poverty of those times thought a sufficient penalty; but the prætors afterwards finding this too slender a satisfaction, in lieu thereof, appointed the injured person to set a rate on the injury, which they afterwards increased or lessened as they thought good.

Some of our lawyers make a distinction between a *damage* and an injury; and indeed there are many acts which may be done to the prejudice of a third person, which may be properly said to be *damnum sine injuria*.

As the absolute rights of individuals are those of personal security, personal liberty, and private property, the wrongs or injuries affecting them must consequently be of a corresponding nature. Injuries that affect the personal security of individuals are injuries against their lives, their limbs, their bodies, their health, or their reputation. For the first class of injuries, see HOMICIDE, MANSLAUGHTER,

and MURDER. The two next species of injuries, affecting the limbs or bodies of individuals, may be committed by threats, assault, battery, wounding, mayhem, which are respectively. For the four last injuries now enumerated, an indictment may be brought as well as an action; and frequently both are accordingly prosecuted, the one at the suit of the crown for the crime against the public; the other at the suit of the party injured, to make him a reparation in damages. Injuries affecting a man's health, or those by which any unwholesome practices of another cause a man to sustain any apparent danger in his victuals or constitution; as selling him bad provisions, as wine (1 Roll. Abr. 90.); by the exercise of a noisome trade, which fills the air in the neighbourhood (9 Rep. 52. Hutt. 135.); or by the neglect or unskillful management of his physician, surgeon, or apothecary. (Lord Raym. 214.) For these injuries, unaccompanied by force, there is a remedy in damages, by a special action of *trespass upon the case*. Injuries affecting a man's reputation, or good name, are, first, by malicious, scandalous, and slanderous words, tending to his damage and derogation. (See WORDS and SCANDALUM MAGISTRUM; and ACTION upon the case.) A second way of affecting a man's reputation is by printed or written libels, pictures, signs, and the like; which set him in an odious or ridiculous light, and thereby diminish his reputation. (2 Shaw. 314. 11 Mod. 99.) See LIBEL. A third way of destroying or injuring a man's reputation is by preferring malicious indictments or prosecutions against him; which, under the mask of justice and public spirit, are sometimes made the engines of private spite or enmity. For this, however, the law has given a very adequate remedy in damages, either by an action of conspiracy (Finch. L. 305.), which cannot be brought but against two at the least; or, which is the more useful way, by a special action on the case for a false and malicious prosecution. (F. N. B. 116.) The violation of the right of personal liberty is effected by the injury of false imprisonment, for which the law has not only decreed a punishment, as a heinous public crime, but has also given a private reparation to the party; as well by removing the actual confinement for the present, as, after it is over, by subjecting the wrong doer to a civil action, on account of the damage sustained by the loss of time and liberty. (See IMPRISONMENT, and FALSE Imprisonment.) The injuries that affect the rights of personal property, affect it either as it is in possession or in action. (See PROPERTY.) The former kind of property is liable to two species of injuries, viz. the amotion or deprivation of that possession, and the abuse or damage of the chattels, while the possession continues in the legal owner. The deprivation of possession comprehends the unjust and unlawful taking away, and the unjust detention, though the original taking might be lawful. The remedy which the law has provided for the wrongful taking of goods, is the restitution of them, with damages for the loss sustained by such unjust invasion, which is effected by action of "replevin," which see. Other remedies for other unlawful taking of a man's goods consist only in recovering a satisfaction in damages, by an action of *trespass vi et armis*, or action of *trover* and *conversion*, which see respectively. For unjust detention of another's goods, when the original taking was unlawful, the remedy for the recovery of possession is by action of *detinue*; or action of *trover*, which see. The remedies given by the law to redress damages, which the things detained may have suffered, are action of *trespass vi et armis*, where the act is in itself immediately injurious to another's property, and accompanied with some degree of force; and special *action on the case*, where the act itself is indifferent, and the injury only conse-

quential, and therefore arising without any breach of the peace. As to injuries that regard things in *action* only, they pertain to such rights as are founded on, and arise from contracts, which may be either *express* or *implied*. The former are *debts, covenants, and promises*; see each term: the latter are such as reason and justice dictate, and which the law presumes that every man has contracted to perform. Thus it is that every person is bound, and hath virtually agreed to pay such particular sums of money as are charged upon him by the sentence, or assented by the interpretation of the law. A debt is thus contracted, and the defendant is bound to pay it. The same reasoning will apply to all penal statutes, that is, such acts of parliament by which a forfeiture is inflicted for transgressing the provisions therein enacted. The party offending must pay the forfeiture incurred to such persons as the law requires. Another class of contracts includes those which arise from natural reason, or the just construction of law. (See ASSUMPSIT.) The last class of contracts, implied by reason and construction of law, arises upon this supposition, that every one who undertakes any office or employment, trust or duty, contracts with those who employ or trust him, to perform it with integrity, diligence, and skill; and if for want of these qualities any injury accrues to individuals, they have their remedy in damages by a special action on the case.

Besides the special action on the case, there is also a peculiar remedy, entitled an action of *deceit*, (F. N. B. 95.) to give damages in some particular cases of fraud, and principally where one man does any thing in the name of another, by which he is deceived or injured.

As to those injuries that affect men with regard to their *relative* rights, they may be done to persons under the four following relations: husband and wife, parent and child, guardian and ward, master and servant; and they comprehend in the relation of a husband, *abduction, adultery, and beating* or otherwise abusing the wife. In the relation of a parent, the injury is *abduction*, which is remedied by a writ of *rescission*, or action of *trespass vi et armis, de filio vel filia, raptio vel abductio*. (F. N. B. 90.) See the other terms above specified.

Having briefly recited the principal injuries that may be offered to *personal* property, with their several remedies by suit or action, we shall next direct our attention to those injuries which affect that species of property which the laws of England have denominated *real*. Real injuries, or injuries affecting real rights, are principally the following six; *ouster, trespass, nuisance, waste, subinfeudation, and disturbance*; which see respectively. Blackst. Com. b. iii.

INJURIES of the Head. Some subjects, connected with this highly interesting part of *urgery*, have already been treated of in the preceding volumes of this Cyclopaedia. See COMPRESSION; CONCUSSION; and EXTRAVASATION. Here it is incumbent upon us to consider certain other cases, which are the consequence of external violence applied to the head, as wounds and contusions of the scalp; inflammation of the dura mater, and suppuration under the cranium; fractures of the skull, &c.

Injuries of the Scalp.—Injuries done to the scalp by external violence are generally of a more serious nature than a similar degree of mischief done to any other part of the common integuments. Surgical authors have endeavoured to account for this fact by ascribing to the prodigious quantity of nervous filaments distributed to the scalp, the many different parts which compose it, its structure, connections, &c. We are not, however, to suppose every injury of the external coverings of the head dangerous. A mere cut with a sharp instrument usually heals as favourably in this situation as in any other, and often more so, perhaps, in conse-

quence of the great vascularity of the skin of the head, and the very steady manner in which the edges of the wound admit of being kept in contact, supported as they are upon the fixed surface of the cranium. But punctures, lacerated wounds, and contusions of the scalp, as every experienced surgeon well knows, are cafes frequently followed by such symptoms as may terminate fatally.

We shall pass over incised wounds of the scalp, since they are attended with no peculiarity, and only require the same treatment as ordinary cuts upon any part of the surface of the body.

Lacerated wounds of the scalp are divided by Mr. Pott into two kinds; *viz.* those in which the scalp, though torn, or unequally divided, still keeps its natural situation, and is not stripped nor separated from the cranium to any considerable distance beyond the breadth of the wound; and those, in which it is considerably detached from the parts it ought to cover.

The first of these, if simple, and not combined with the symptoms, or appearances of any other mischief, do not require any particular or different treatment from what the same kind of wounds require on all other parts; but the latter, or those in which the scalp is separated and detached from the parts it ought to cover, are not only, by the different methods in which they may be treated, frequently capable of being cured with a considerable deal more or less ease and expedition, but are also sometimes a matter of great consequence to the health and well-being of the patient.

Not many years ago surgeons were accustomed to treat this last sort of case in a most objectionable way. Too hastily convinced of the impossibility of the separated and torn pieces of the scalp ever becoming united again, practitioners used, without hesitation, to cut them away, so as to occasion a large fore, requiring a long time to heal, and leaving considerable deformity. Far different is the practice of the most approved modern surgeons, with whom it is an invariable maxim, that the preservation of the scalp ought always to be attempted. The reasons for this line of conduct are plain and obvious. The detached portions of the scalp were formerly cut off, because it was supposed that they were in such a state as precluded all chance of their union. But the fact is, it can never be foreseen with certainty whether the detached torn edges of a lacerated wound will slough or not. Now, as no harm can arise from trying whether they will live and unite; as considerable benefit will result from the success of such an attempt; and, as the excision of the part is painful, and productive of no solid advantage, even when sloughing is unavoidable, the method is supported neither by reason nor experience. Whatever may be the course of the case, the proceeding is only calculated to cause unnecessary pain, lengthen the time required for the cure, and render deformity, which is uncertain, quite inevitable. The head having been shaven round the wound, the torn piece of the scalp is to be first freed from all dirt and extraneous substances, and then restored as quickly and as perfectly as possible to its natural situation. Strips of adhesive plaster fully suffice for bringing the parts together without the assistance of sutures, which, unless absolutely necessary, ought never to be used. It has always appeared to us a very beneficial plan to maintain the pieces of the scalp closely applied to the cranium by means of small lint-compresses, bound on with adhesive plaster. Thus, no cavity will be left for the lodgment of matter, and the parts will have the fairest opportunity of uniting. Sometimes the loosened scalp will unite with the parts from which it was torn and separated, and there will be no other fore than what

what arises from the impossibility of bringing the lips of the wound into smooth and immediate contact, the fear of which force must be small in proportion. Sometimes such perfect reunion is not to be obtained; in which case matter will be formed and collected in those places where the parts do not coalesce; but this will not hinder the preservation of the coverings of the head, the cure being only a little retarded by a few small abscesses, and the matter admitting of being let out by one or two small openings.

Occasionally, the whole separated piece will unite perfectly, especially in young and healthy persons. In certain instances the union will take place in some parts, and not in others; and, consequently, matter will be formed, and require to be discharged, perhaps, at several different points. In other particular cases, circumstances, and habits, there will be no union at all, the torn cellular membrane, or the naked aponeurosis will inflame and become sloughy, a considerable quantity of matter will be collected, and, perhaps, the cranium will be denuded. But even in this case, if the surgeon takes proper measures, and refrains from being too much in a hurry to cut, things will be more prosperous than may be expected. Let him take care to keep the inflammation under by proper means; let him have patience till the matter is fairly and fully formed, and the sloughs perfectly separated; and when this is accomplished, let him make a proper number of dependent openings; and let him, by bandage and other proper management, keep the parts in constant contact with each other, and he will often find, that, although he was foiled in his first intention of procuring immediate union, yet he will frequently succeed in this his second; he will still save the scalp, shorten the cure, and prevent the great deformity arising, particularly to women, not only from the scar, but from the total loss of hair.

Many persons have erroneously thought, that, when the pericranium is stripped off the cranium by external violence, or is afterwards cast off, the scalp cannot unite to the denuded cranium, which must of necessity exfoliate. However, these notions are now well known to be unfounded. The exposed part of the skull, unless much injured by contusion, or improperly irritated by stimulating applications, will generally live, throw out granulations, and become united to the separated scalp, without any exfoliation whatever.

Punctured wounds of the scalp are more apt than cuts to inflame and give trouble, and are indeed frequently the cause of severe and alarming symptoms.

According to Mr. Pott, if the wound affects the cellular membrane only, and has not reached the aponeurosis, or pericranium, the inflammation and tumour affect the whole head and face, the skin of which wears a yellowish cast, and is sometimes thick set with small blisters, containing the same coloured serum; it receives the impression of the fingers, and becomes pale for a moment, but returns immediately to its inflamed colour; it is not very painful to the touch, and the eye-lids and ears are always comprehended in the tumefaction, the former of which are sometimes so distended as to be closed; a feverish heat and thirst generally accompany it; the patient is restless, has a quick pulse, and most commonly a nausea and inclination to vomit.

Cases are most disposed to assume this form in persons of bilious habit, the inflammation being in fact erysipelatous. The disorder is somewhat alarming to look at, but it is not often attended with danger. Mr. Pott remarks, that the wound does, indeed, neither look well, nor yield a kindly discharge, while the fever continues; but still it has none of that look which bespeaks internal mischief; the scalp continues to adhere firmly to the skull; nor does the patient

suffer the tenfive pain, and fatiguing restlessness, which generally attend mischief underneath the skull.

Such erysipelatous inflammation commonly soon yields to phlebotomy, lenient purges, and sebrifuge medicines, particularly those of the neutral kind. When the inflammation is gone off, it leaves on the skin a yellowish tint, and a dry scurf, which also, in time, disappears. Immediately the disorder subsides, the wound puts on a healthy aspect, and heals without trouble.

Surgeons must carefully distinguish from the foregoing case another kind of erysipelatous swelling and inflammation to which the scalp is liable, as one of the effects of inflammation and supuration of the dura mater. In this last important disorder the febrile symptoms are much higher, the pulse harder and more frequent, the anxiety and restlessness extremely fatiguing, the pain in the head intense; and as, in these circumstances, the swelling of the scalp is most frequently the immediate precursor of matter forming between the skull and dura mater, it is generally attended with irregular shiverings, which are not followed by a critical sweat, nor afford any relief to the patient. When the inflammation is confined to the parts on the outside of the skull, the erysipelas generally appears within the first three or four days; but when the dura mater is affected, it seldom comes on till several days after the accident, when the symptomatic fever is got to some height. In the simple erysipelas, although the wound be crude and undigested, yet it has no other mark of mischief; the pericranium adheres firmly to the skull, and, upon the cessation of the fever, all appearances become immediately favourable. In that which accompanies injury done to the parts underneath, the wound not only has a spongy, glassy, unhealthy aspect, but the pericranium in its neighbourhood separates spontaneously from the bone, and quits all cohesion with it. In short, says Mr. Pott, one is an accident proceeding from a bilious habit, and not indicating any mischief beyond itself; the other is a symptom, or a part of a disease, which is occasioned by injury done to the membranes of the brain; one portends little or no ill to the patient, and almost always ends well; the other implies great hazard, and most commonly ends fatally.

When the wound is small, and reaches to the aponeurosis and pericranium, disagreeable, and even alarming symptoms sometimes arise. In the case alluded to, the inflamed scalp does not rise into that degree of tumefaction as in the erysipelas; neither does it pit, or retain the impression of the fingers of an examiner. It is of a deep red colour, unmixed with the yellow tint of the erysipelas; it appears tense, and is extremely painful to the touch. The ears and eye-lids are seldom comprehended in the tumour, though they may partake of the general inflammation of the skin. It is generally attended with acute pain in the head, and such a degree of fever as prevents sleep, and sometimes brings on delirium. A patient, thus affected, may be more freely bled than one labouring under an erysipelas. Warm fomentations are proper in both cases; but emollient poultices, which are forbidden in erysipelatous diseases, may be employed in the present instance with much advantage.

In exceedingly urgent cases, Pott recommends making a division of the wounded part down to the bone, to the extent of half an inch, or an inch, as the best means of stopping the fever, and preventing the aponeurosis and pericranium from becoming sloughy.

Mere contusions of the scalp, unattended by fracture, or injury of the parts within the cranium, are not of serious importance, considered abstractedly. It frequently happens, that when a severe bruise has been inflicted on the scalp, a large tumour, containing extravasated blood, quickly rises

INJURIES.

upon the head, or blows on this part with stones, sticks, &c. But, notwithstanding the immense disfigurement attending this sort of accident, if the skull and its contents be free from injury, the case is not of a dangerous nature. The effused blood generally admits of being removed by absorption, provided the surgeon is careful to keep the patient's bowels well open with saline purges, and apply to the tumour itself linen wet with the saturnine lotion, or with a lotion composed of spirit of wine, vinegar, and the muriate of ammonia. Many surgical authors countenance the plan of discharging the collection of blood by a small puncture. As far as our observations extend, this practice should be avoided in the generality of instances. When an opening is made, suppuration within the swelling becomes inevitable. On the contrary, abscesses may frequently be prevented altogether, by allowing the absorbents to do the office of taking away the effused blood, assisted by the means already recommended. It is not to be denied, however, that matter will sometimes form, and then the method of making an opening for the discharge of the contents of the swelling is undoubtedly proper.

With regard to those tumours of the scalp, which are the consequence of blows, falls, &c. and which are filled with effused blood, J. L. Petit made a remark, which has been repeated by all subsequent writers, namely, the facility with which the centre of the swelling may be depressed, while the circumference seems hard and prominent, circumstances which may easily impose upon the inexperienced surgeon, and lead him to mistake the case for a fracture of the cranium with depression of the bone. If, upon such a supposition, he immediately makes an incision into the tumid scalp, he may give the patient a great deal of unnecessary pain, and endanger his own reputation.

It is observed by Mr. Pott, that in this case the touch is so liable to deception, that recourse should always be had to other circumstances and symptoms, before an opinion is given. If a person, with such tumour occasioned by a blow, and attended with such appearances and feel, seems to labour under dangerous pressure upon the brain, a division of the scalp, in order to enquire into the state of the skull, is right and necessary; but if the patient is well, or not seriously affected with any symptoms of compression, the mere feel of some thing like a fracture, nay, we may add, even the actual existence of a fracture itself, will not authorize or vindicate cutting the scalp.

For an account of the symptoms of pressure on the brain, see COMPRESSION and EXTRAVASATION.

Inflammation of the Dura Mater, and Suppuration under the Skull.—The symptoms attending an inflamed or sloughy state of the membranes of the brain, in consequence of external violence, are all of the febrile kind, and never at first imply any unnatural pressure upon the brain. When, in these cases, the symptoms of pressure come on, it is not until the latter end of the disease, that is, until a considerable quantity of matter is formed, which matter must press like any other fluid.

The late eminent Mr. Pott has written a most able description of the inflammation and suppuration of the dura mater from external violence. The following observations are chiefly from his pen.

When there is neither fissure nor fracture of the skull, nor extravasation, nor commotion underneath it, and the scalp is neither considerably bruised nor wounded, the mischief is seldom discovered or attended to for some few days. The first attack is generally by pain in the part which received the blow. This pain is soon extended all over the head, and is attended with a languor or dejection of strength and spirits, which are soon followed by a nausea and inclination

to vomit, a vertigo or giddiness, a quick and hard pulse, and an incapacity of sleeping. A day or two after this attack, if no means preventive of inflammation are used, the part stricken generally swells, and becomes puffy and tender, but not painful. Neither does the tumour rise to any considerable height, nor spread to any great extent. If this tumid part of the scalp be now divided, the pericranium will be found of a darkish hue, and either quite detached, or very easily separable from the skull, between which and it will be found a small quantity of a dark-coloured ichor. If the disorder is so advanced, that the pericranium is quite separated from the skull, the latter will be found somewhat altered in colour from a healthy bone.

From this time the symptoms generally advance more hastily and more apparently; the fever increases, the skin becomes hotter, the pulse quicker and harder, the sleep more disturbed, the anxiety and restlessness more fatiguing; and to these, says Mr. Pott, are generally added irregular rigours, which are not followed by any critical sweat, and which, instead of relieving the patient, add considerably to his sufferings. If the scalp has not been divided, until the symptoms are thus far advanced, the alteration of the colour of the bone will be found to be more remarkable; it will be found to be whiter and more dry than a healthy one; or, as Fallopius has observed, it will appear rather like dead bone.

There will be more sanies or fluid under the pericranium, and this membrane will have a more livid aspect.

In this state of matters, if the dura mater be denuded, it will be found to be detached from the inside of the cranium, to have lost its bright silver hue, and to be smeared over with a kind of mucus or pus. Every hour after this period all the symptoms are exasperated; the head-ache and thirst become more intense, the strength decreases, the rigours are more frequent, and, at last, convulsive motions, attended in some with delirium, in others with paralysis, or comatose stupidity, finish the tragedy.

If the scalp is now divided, a very offensive discoloured fluid will be found lying on the bare and altered cranium. If, at this period, a perforation is made in the bone, matter will be found between it and the dura mater, generally in considerable quantity, but different in different cases and circumstances. Sometimes it will be in great abundance, and diffused over a very large part of the membrane; and sometimes the quantity will be less, and consequently the space which it occupies smaller. Sometimes it lies only on the exterior surface of the dura mater; and sometimes it is between it and the pia mater, or also on the surface, or in the substance of the brain.

The foregoing mischief is entirely the consequence of the contusion which the head has suffered. But it deserves attention, that as the inflammation and separation of the dura mater are not immediate consequences of the violence, so neither are the symptoms immediate, seldom coming on until some days have passed.

We have next to consider the case where the scalp has been wounded, either by the accidental violence, or by the surgeon making an incision immediately afterwards for the examination of the bone. Here the wound will, for some little time, have nothing particular about it; but after a few days, any favourable appearances which it may have put on will vanish; the fore will lose its florid complexion and granulated surface; will become pale, glassy, and slabby; instead of good matter, it will discharge only a thin discoloured sanies; the lint with which it is dressed, instead of coming off easily, as in a kindly suppurating sore, will stick to all parts of it; and the peri-

cranium, instead of adhering firmly to the bone, will separate from it all round to some distance from the edges.

This alteration in the face and circumstances of the fore is produced merely by the diseased state of the parts underneath the skull, as is demonstrably proved, by observing that the bad aspect of the wound, and the spontaneous separation of the pericranium, are always confined to that part which covers the altered or injured portion of the dura mater, and do not at all affect the rest of the scalp; nay, observes Mr. Pott, if it has by accident been wounded in any other part, or a portion has been removed from any part where no injury has been done to the dura mater, no such separation will happen. The detachment above will always correspond to that below, and be found no where else.

At first the exposed part of the skull appears whiter and more dry than natural, and in proportion as the dura mater suppurates or becomes spongy, the bone inclines more and more to a kind of purulent hue, or whitish yellow. It deserves notice, likewise, that if the blow has occurred near a future, and the subject is young, such future often separates so as to let through it a loose painful fungus. At this period thro' the head and face are frequently attacked with erysipelas.

The above described effects of certain contusions of the head are frequently found to accompany fissures and undepressed fractures of the cranium, as well as extravasations of fluid, where the bone is entire; and on the other hand, says Mr. Pott, all these do often happen without the concurrence of this individual mischief. All this is matter of accident; but let the other circumstances be what they may, the spontaneous separation of the altered pericranium, in consequence of a severe blow, is almost always followed by a suppuration between the cranium and dura mater; a circumstance, which Mr. Pott points out as highly worthy of attention in fissures and undepressed fractures of the skull, because it is from this cause principally that the bad symptoms, and the hazard in such cases, arise.

The situation of extravasated blood within the cranium is often uncertain; but that of inflammation and suppuration of the dura mater, in consequence of external violence, is almost surely indicated, even when the skin is quite free from wound, or other mark of injury, by a puffy, circumscribed, indolent tumour of the scalp, and a spontaneous separation of the pericranium from the skull under the swelling.

It should be understood that none of the bad symptoms are owing to the section of the pericranium, but to the inflammation of the dura mater. Hence, though the scalp may be so wounded or torn by any accident, as to leave a part of the skull quite bare, the pericranium being separated by the violence, yet if the force has not been such as to affect the dura mater, the alarming train of evils above explained do not follow. Here the best practice is to lay down the scalp in its natural situation again, and give it the opportunity of uniting.

It remains for us to consider the treatment of the respective cases, where there is either danger of an inflammation of the dura mater coming on, or where the affection actually prevails, attended with the formidable symptoms already detailed.

Every man of experience will coincide with Mr. Pott, that of all the remedies in the power of art, for inflammations of membranous parts, there is none equal to phlebotomy, and that if any thing can particularly contribute to the prevention of the ills likely to follow severe contusions of the head, it is this kind of evacuation; but then it must be made use of in such a manner as to become truly a preventive; that is, it must be made use of immediately and freely.

There will often be some difficulty in persuading a person, who has had what may be called only a knock on the pariet, to submit to such discipline, especially if he finds himself tolerably well; yet, in many instances, the timely use or the neglect of this single remedy, makes all the difference between safety and fatality. It is true, that by this method patients must sometimes be bled, who would escape inflammation of the dura mater without such evacuation; yet, let it be remembered, that the loss of blood, however necessary in these cases, never endangers life, while it is frequently the means of preserving it. In short, we must agree with Mr. Pott, that if every person who meets with a severe blow on the head were to be bled, as he undoubtedly ought to be, many a very valuable life would be preserved, which, for want of this kind of assistance, is lost. Acceleration, or hardness of pulse, restlessness, anxiety, and any degree of fever, after a smart blow on the head, are always to be suspected and attended to. Immediate, plentiful, and repeated evacuations have, in many instances, removed these complaints in persons, to whom, Mr. Pott believes, very terrible mischief would have happened, had not such precaution been used. From these observations, however, let it not be concluded, that early bleeding will always prove a certain preservative; like all other human means it is fallible; but, if it sometimes fails, it also succeeds to a greater extent than any other known plan.

When the inflammation of the dura mater has produced matter under the cranium, the fluid should be discharged through a perforation of the bone. This operation ought always to be done immediately when the above described symptoms manifest the nature of the case. The spontaneous separation of the dura mater, if attended with general disorder of the patient, with chilliness, horripilation, lassitude, and fever, was invariably considered by Mr. Pott a sure indication of mischief underneath, and an urgent reason for perforating the bone without delay. In some cases one perforation will suffice; in others, more openings must be made. This variation will depend upon the space of detached dura mater, and the quantity of matter collected.

The repetition of blood-letting, of cooling laxative medicines, the use of antiphlogistic remedies, and a most strict observance of a low diet and regimen, are as indispensably requisite after trephining as before. The perforation obviates the dangerous effects of the confinement of matter; but it does nothing more; and the inflamed state of the parts under the skull still calls for our most earnest attention. See Pott on Injuries of the Head.

Fractures of the Skull.—Whenever the head is stricken with a certain degree of violence, the effect is not limited to a vehement concussion of this part of the body, or to the bruising and wounding of the scalp; the bone forming the cranium are also liable to be broken. When the weapon, or thing with which the blow is given, presents an angular or a projecting surface, the fracture generally happens where the violence is immediately applied; but it may occur at a different part of the head, when produced by a body of a certain width. The possibility of fractures happening in a situation more or less distant from that which received the blow, is explicable on the principle of the unequal resistance offered by the parietes of the cranium at different points of their extent. It is to such cases that the name of *couper fissure* is given.

In order to explain the manner in which counter-fissures are produced, let us suppose a blow to fall upon the os frontis, with a force equivalent to twenty, which bone, being in the situation of the forehead somewhat thick, makes a resistance equal to twenty-five. The solution of continuity,

INJURIES.

ity, therefore, cannot happen directly in the place stricken; the force is transmitted to the orbital process, a part which is thin, easily broken, and only capable of making a resistance expressed by twelve; consequently the violence, though weakened in its transmission, is still sufficient to fracture this last process. The foregoing reasoning coincides with experience. Many fractures of the orbital processes of the os frontis are met with in practice, while that part of the bone, which forms the forehead, remains free from injury. This first species of counter-siffure, though not exactly in the situation where the external violence was applied, happens on a part of the same bone which received the blow. There are other cases, where counter-siffures occur on some bone adjoining that which was stricken, notwithstanding the check which the impulse must experience in crossing the sutures. Thus, blows on the parietal bone frequently break the squamous portion of the os temporis.

Such counter-siffures as happen to a part of the skull, diametrically opposite the point which received the blow, notwithstanding the equal thickness of the bones in both places, admit of explanation by the imperfect spherical form of the cranium. Richerand, *Nofog. Chir.* tom. 2.

Fractures of the inner table of the skull, while the external is simply contused, are explicable by its great fragility, whence it has also been named by several authors *vitreous*.

Direct fractures, as well as counter-siffures, differ in point of situation, the extent of the solution of continuity, their particular shape, and the symptoms with which they are followed. Sometimes the crack is exceedingly fine and minute, which case is often called a *capillary siffure*. Sometimes the edges of the breach are attended with a separation, more or less considerable. In some cases, the fracture runs in a straight line; in others it is stellated. In certain examples, the splinters of bone are beaten inwards, and compress the brain: these instances are usually named *fractures with depression*. On other occasions, the broken pieces keep their proper level. But even in the latter sort of case, the brain may suffer a dangerous degree of pressure from an extravasation of blood under the bone, such pressure, indeed, as may urgently require the application of the trephine. Yet, it ought to be well understood, that this operation is not performed because the skull is broken, but because the brain is dangerously compressed by a quantity of extravasated blood, that lies confined under the bone, and was poured out of vessels, which were ruptured by the same violence as broke the bone itself.

Not only may fractures of the skull be complicated with extravasation, they may be conjoined with the effects of concussion. Depressed fractures are frequently accompanied with an actual laceration of the membranes and substance of the brain. The recoveries which have been known to follow the most terrible wounds of this organ, as detailed in the Memoirs of the French Academy of Surgery, are both curious and surprising. But, generally speaking, the danger of all injuries of the head is in proportion to the mischief and violence done to the brain. A fracture of the skull, could it be occasioned, and exist without the least irritation and disturbance of the brain and membranes thereof, would be attended with no serious symptoms, and, of course, would require only simple treatment. In short, the breach of continuity would be repaired with callus, just like a similar injury in any other bone. It is the nearness of the brain, and the manner in which it is affected, either by the depression or inequality of the bone, or by the blow itself, which constitute at once the importance and danger of all fractures of the cranium. The ignorant and injudicious are

apt to think, that because the skull is broken, the trepan must be employed, as a matter of course. Perhaps the doctrines of M. Quesnay, Pott, &c. might sanction the invariable use of the trephine; for, if the argument be allowed, that this operation is proper as a *preventive* of the bad symptoms to be apprehended in cases of fractured skulls, there cannot very well be any cases where the practice would not be justifiable. Let not an opinion of such consequence, however, be taken up too hastily, and we shall presently adduce convincing reasons against its validity.

We must first consider what are the symptoms by which the existence of a fracture of the skull may be known? It must be acknowledged, considerable obscurity prevails in the diagnosis of such accident, unless it so happen, that the nature of the case admits of being ascertained by the eye, or the touch. What are termed the *rational* symptoms are exceedingly fallacious. When a fracture of the skull occurs, attended with a wound of the scalp, and a denudation of the broken part of the bone, the surgeon may both see with his eyes, and feel with his fingers, what has happened. The existence of a fracture may likewise be ascertained by the touch, even when the soft parts are entire, if the solution of continuity in the bone is splintered, or accompanied with a considerable depression. When several of the fragments are entirely detached, a palpable crepitus will often render the nature of the accident still more clear.

Setting out of consideration such symptoms, there are none which can be regarded as characteristic of a fracture of the skull. Some writers direct us to enquire whether the patient was sensible, at the time of receiving the injury, of any noise, like that of a pot breaking. But how are we to gain information on this point from patients who are always stunned at first, and often remain senseless and speechless a long while afterwards? Other authors lay stress on the bleeding from the nose and ears, a circumstance entirely incidental, or, at most, indicative of nothing else, than that the head has sustained some kind of blow, or concussion, without at all informing us of the degree of violence that has been applied. Besides, every one knows what slight shocks will cause this kind of bleeding in particular persons, so that it cannot be received as a proof that the blow has been very powerful. Even did it prove that the blow has been violent, it would not justify the inference, that the skull is certainly broken. In short, we may assert, that a fracture of the cranium, without depression, without extravasation, and without concussion, is generally not only not productive itself of any alarming effects, but is also unmarked by any particular symptoms. Its existence can only be ascertained by the eye or the touch; and therefore its diagnosis is only easy, when the injury is exposed in consequence of a wound. However, a surgeon need not be solicitous to find out an undepressed fracture; for if symptoms demand the application of the trephine, he is to apply it to the bone, whether it is fractured or not; and if these symptoms are absent, the fracture itself cannot be a just reason for the operation.

We must not take our leave of the diagnosis of these cases, without cautioning surgeons not to be too hasty in pronouncing the skull to be fractured. Bloody tumours of the scalp often feel so much like fractures of the cranium with depression, as to make the most experienced men incapable of a positive decision. These cases have already been noticed in the present article. When the bone is bare, it is possible to mistake a suture, or the furrow of a blood-vessel, for a fracture, and Hippocrates has gained considerable honour

INJURIES.

honour by the candour with which he acknowledged his having fallen into an error of this kind.

We shall conclude this subject with a few observations on the treatment of fractures of the skull. For the relief of these cases, there cannot be a doubt that the usefulness of trepanning has been most unreasonably magnified. The necessity of only practising this operation when it is absolutely requisite, must be manifest to every one, who reflects, that cutting away a portion of the skull is a proceeding by no means free from the hazard of very dangerous consequences. We have also the testimony of several eminent surgical writers, that it is an operation, generally speaking, attended with remarkable ill success. It is not our intention, however, to endeavour to insinuate, that the fatal terminations are not chiefly ascribable to the serious mischief which commonly exists when the operation is performed. Be this as it may, we cannot help looking upon trepanning as a thing, to which recourse should never be had without strong and urgent reason. Default, the most eminent of the modern French surgeons, entirely abandoned the operation in the latter years of his practice, as he found considerable success arise from the employment of evacuations. "C'est une observation fort ancienne, que le peu de succès de l'opération du trépan pratiquée à l'Hôtel-Dieu de Paris; soit, que par des sales, vicié par le grand nombre d'individus, qui s'y trouvent rassemblés, ou par l'humidité dont le voisinage de la rivière le charge contamine, exerce sur la place, que succède l'opération, ou sur les membranes du cerveau mises à nu, une influence délétère, que ce fait constant dépende d'une autre cause ignorée, l'opération du trépan est presque toujours suivie de la mort des individus." Richerand, *Nosographie Chirurgicale*, tom. ii. p. 266. Edit. 2.

That the operation of trepanning is itself not exempt from serious danger we most firmly believe. We have seen it prove fatal, when performed with a view of relieving a violent inveterate head-ache. Yet we cannot bring our mind to believe, that Default was right in rejecting the operation altogether. There certainly are cases in which it may be the means of preservation as well as others, in which it may exasperate circumstances and render them fatal.

We have noticed that, in fractures of the skull, the operation of trepanning was advised by Pott, as a *preventive* of ill consequences. It gives us pleasure to state, that this practice is now never adopted by the most eminent surgeons in this country, great as their veneration is for so distinguished an authority. Many modern writers of the highest reputation have forcibly remonstrated against the method, as Mr. Default, of Paris; Mr. Dease, of Dublin; Mr. John Bell, of Edinburgh; and Mr. Abernethy, of London.

The reader cannot be surpris'd, that fractures without depression are not, abstractedly considered, a just cause for trepanning, when he is informed, that the skull is often broken and depressed, and yet the symptoms may not be such as to demand the operation, and the patient has the best chance of recovery when it is not performed. The more the present subject is studied, the greater will be the conviction, that there is only one genuine reason for trepanning, and that is, when symptoms of a dangerous degree of pressure on the brain exist, which symptoms are enumerated under the head of *EXTRAVASATION*. When they prevail, the operation is to be done, whether the skull is broken or not; whether it be depressed or retain its proper level.

Mr. Abernethy has related several cases of fracture of the cranium with depression, which terminated favourably, although no operation was performed. This judicious fur-

geon thinks, that these cases, as well as a great many others on record, prove, that a slight degree of pressure does not derange the functions of the brain for a limited time after its application; and all those patients whom he had an opportunity of knowing for any length of time after the accident, continued as well as if nothing of the kind had happened to them. In Mr. Hill's *Cases in Surgery*, two instances of this sort are related, and Mr. Hill knew both the patients for many years afterwards; yet no inconvenience arose. Indeed, it is not easy to conceive that the pressure which caused no ill effects at a time when the contents of the cranium filled its cavity entirely, should afterwards prove injurious when they have adapted themselves to its altered size and shape. Severe illness, it must be confessed, does often intervene between the receipt of the injury and the time of recovery; and many surgeons might be inclined to attribute this to the pressure on the brain; but it occurs quite as formidably when the depressed portion is elevated. If a surgeon, prepossessed with the opinion, that elevation of the bone is necessary in every instance of fracture of the skull with depression, should have acted upon this opinion in several of the cases which Mr. Abernethy has related, and afterwards have employed proper evacuations, the patients would probably have had no fatal symptoms, and the recoveries would naturally have been impeded to the particular mode of treatment; yet these cases ended well without any operation.

It cannot be too often repeated, that the necessity of trepanning depends entirely on the urgency of the symptoms, which are known to proceed from the existence of pressure on the brain. (See *EXTRAVASATION*.) To trepan the skull merely because it is broken, is as absurd as to cut the arm because it is fractured: it is only adding one species of violence to another. We have seen that, even when the fracture is depressed, it does not necessarily follow that the operation is proper: in fact, it is always improper, unless there are evident signs that the degree of pressure, thus produced, is the cause of exciting dangerous symptoms.

If, then, fractures of the cranium with depression do not invariably require trepanning, it may readily be conceived, that the operation must be still less frequently necessary when the fracture is undepressed. In such case, indeed, the fracture itself can never demand this proceeding. But, nevertheless, it may be right and indispensable on other accounts, since the brain may at the same time be dangerously compressed by an extravasation of blood, or, in the course of the disorder, by matter formed under the skull in consequence of inflammation. However, it should be well understood, that the inflammation and suppuration of the parts beneath the skull, which Mr. Pott was so anxious to prevent by trepanning early, do not arise from the occurrence of a breach in the cranium, but are chiefly, if not altogether, the consequences of the same violence, which was the occasion of the fracture. Hence, it is obvious, that removing a portion of the bone cannot have the least tendency to prevent the inflammation and suppuration, which must inevitably result from the external violence that was first applied to the head; but, on the contrary, such a removal being an additional violence, must rather have the effect of increasing the unavoidable inflammatory mischief.

A fracture of the skull, unattended with urgent symptoms, and not brought into the surgeon's view by any accidental wound of the integuments, often remains for ever undiscovered and unknown; and as no benefit could arise from laying it bare by an incision, such practice should never be adopted. The practitioner ought only to make himself

efficient in this way, when he can accomplish by it some better object than the merely satisfying his own curiosity. Now, since the removal of pressure off the surface of the brain is the only admissible reason for ever perforating the cranium, and since dividing the scalp cannot be useful, unless preparatory to such operation, it is clear that neither the one nor the other should ever be done, excepting such symptoms exist as unequivocally denote the prevalence of a dangerous degree of pressure on the brain, caused either by matter, extravasated blood, or depraved portion of the skull.

The true mode of preventing the bad effects frequently following, but not arising from simple fractures of the skull, (by which we mean cases unaccompanied by urgent symptoms of pressure,) is not to trepan, but to put in practice all kinds of antiphlogistic means. For this purpose, let the patient be repeatedly and copiously bled, both in the arm and temporal arteries; let him be properly purged; give him antimonials; keep him on the lowest diet; let him remain in the most quiet situation possible; and if, notwithstanding such steps, the symptoms of inflammation of the brain continue to increase, let his head be flaccid, and a large blister be applied to it. When, in spite of all these measures, matter forms under the cranium, attended with symptoms of pressure, a puffy tumour of the injured part of the scalp, or those changes of the wound (if there be one), which Mr. Pott has so excellently described, and we have already related; not a moment should be lost in delaying to perforate the bone with a trephine, so as to give vent to the matter collected underneath.

Before concluding, we have one important caution to offer, which is, in all cases of injuries of the head from external violence, to continue an antiphlogistic regimen at least a month after any serious accident of this description; for it is by no means uncommon for inflammation of the brain to follow injuries of the head a very considerable time after the patients have had reason to fancy themselves in perfect safety. Pott on Injuries of the Head; Disease on Wounds of the Head: Hill's Cases in Surgery; Abernethy on Injuries of the Head; Cooper's Dictionary of Practical Surgery, &c.

Other subjects, immediately connected with the preceding, will be found under the articles COMPRESSION, CONCUSSION, EXTRAVASATION, and TREPPANNING.

INK, a liquor wherewith to write on paper or parchment.

INK, Printing. See PRINTING.

INK, Writing, is commonly made of coppers and galls, and gum arabic; but other astringent plants may serve the same purpose; such as oak-bark, red roses, logwood, or sumach. Mr. Boyle seems to doubt whether all astringent vegetables will do the same.

Many are the preparations and methods of compounding the materials for making of writing ink. For many years the ink most generally used by European writers has been the infusion of galls and other astringent vegetables, containing gallic-acid, rendered black by sulphate of iron, and thickened by the addition of a little gum or sugar. This composition, however, is liable to fade; but since the discovery of the method of totally discharging the traces of common ink by the application of the oxygenated muriatic acid, more serious consequences are to be apprehended from the universal use of the common atramentous fluid, than the decay of its colour from age; for it is well known that, while the sulphate of iron remains on the paper, the colour of the writing may be restored by washing the MS. with fresh infusion of galls. We have several receipts in Nichol-

son's Philosophical Journal, vol. iv. p. 479, 4^{to}, for composing ink capable of resisting the oxygenated muriatic acid.

Macquer, in the Chemical Dictionary, gives the following receipt for making good ink. In four French pints of common water or beer, let a pound of bruised galls be infused twenty-four hours without boiling; to this add six ounces of gum arabic; and when the gum is dissolved, six ounces of green vitriol, which will soon give it the black colour; the liquor is then to be strained through a hair-sieve.

The following method has been recommended by experience, and is easily and speedily practised. To a gallon of boiling water, put six ounces of blue galls, grossly pounded, and three ounces of coppers; stir the mixture well together, and then add six ounces of gum arabic pounded. After stirring the whole thoroughly, leave it to settle, and the next day strain it off from the dregs for use. See *IRIS lutea palestris*.

The following composition will make a very good black writing ink. Take a gallon of soft water, and boil in it a pound of chips of logwood for about half an hour; pour the decoction boiling hot on a pound of the best Aleppo galls powdered, and two ounces of pomegranate peels, put into a proper vessel. After having stirred them well together with a wooden spatula, place them in the sunshine in summer, or within the warmth of any fire in winter, for three or four days, stirring the mixture occasionally; then add half a pound of green vitriol powdered, and let the mixture remain four or five days more, occasionally stirring it; and then add four ounces of gum arabic dissolved in a quart of boiling water; and after the ink has settled, strain it off through a coarse linen cloth, and keep it well stoppered for use.

Mr. Delaval in his "Treatise on Colours," p. 37. informs us, that with an infusion of galls and iron filings, he had not only made an exceedingly black and durable ink, but by means of it, without the addition of any acid, dyed silk and woollen cloth of a good and lasting black. But this kind of ink, though the colour is far superior to that of any other, may be easily discharged, either by the smallest quantity of any acid, or even by simple water; because it doth not penetrate the paper in such a manner as is necessary to preserve it from the instantaneous action of the acid or of the water. During the action of the infusion of galls upon the iron in making this kind of ink, a very considerable effervescence takes place, and a quantity of air is discharged, the nature of which has not yet been examined.

Many of the more volatile kinds of oil may be used in writing, if reduced to a proper consistence by the addition of gum or resin. Tolerable ink may be made by dissolving 30 grains of common resin in 90 grains of oil of turpentine, and tempering the solution with 17½ grains of lamp-black, and 2½ of indigo. In a dry state, this composition resists the action of water, but not of spirit. Copal is much superior to resin; it will dissolve in only few liquids. It may be dissolved, however, in oil of lavender. The only inconvenience attending the use of copal in the composition of ink is, that it is soluble at a low temperature. Ink may be composed of oil of lavender, copal, and lamp-black in the manner following: Take oil of lavender 200 grains, copal, in powder, 25 grains, and lamp-black from 2½ to 3 grains. With the assistance of a gentle heat, dissolve the copal in the oil of lavender in a small glass phial, and then mix the lamp-black with the solution upon a marble slab, and other smooth surface. Put the composition into the bottle, and keep it from the air. After the repose of some hours, the ink must be

well shaken, and stirred with a piece of wire before it is used; if it be too thick, it must be diluted with a little oil of lavender, oil of turpentine, or alcohol. The facility of writing with this composition depends much on the quantity of the colouring matter. Nicholson's Journal, vol. ii. 8va.

As the duration of records, and other valuable writings, depends much on the goodness of the ink employed, Dr. Lewis has thought this subject worthy of his attention. The chief imperfection of common inks is, that they decay in time, and at last the writing becomes invisible. From experiments made by that author, he infers, that the decay of inks is chiefly owing to a deficiency of galls; that the galls are the most perishable ingredient, the quantity of these, which gives the greatest blackness at first (which is about equal parts with the vitriol) being insufficient to maintain the colour; that for a durable ink, the quantity of galls cannot be much less than three times that of the vitriol; that it cannot be much greater without lessening the blackness of the ink; that by diminishing the quantity of water, the ink was rendered blacker and more durable; that distilled water, rain water, and hard spring-water, had the same effects; that white wine produced a deeper black colour than water; that the colour produced by vinegar was deeper than that by wine; that proof spirit extracted only a reddish-brown tinge, and rectified spirit a paler brown; that the last mentioned tinctures sunk into, and spread upon the paper; and hence the impropriety of adding spirit of wine to ink, as is frequently directed, to prevent mouldiness or freezing; that other astringents, as oak bark, billost, floc-bark, &c. were not so effectual as galls, nor gave so good a black, the colour produced by most of these, excepting oak-bark, being greenish; that the juice of sloes did not produce a black colour with martial vitriol; but that, nevertheless, the writing made with it became black, and was found to be more durable than common ink; that inks made with saturated solutions of iron in nitrous, marine, acetous acids, in tartar, or in lemon juice, were much inferior to the ink made with martial vitriol; that the colour of ink was depraved by adding quicklime, which was done with an intention of destroying any superabundant acid which might be supposed to be the cause of the loss of the colour of the ink; that the best method of preventing the effects of this superabundant acid is probably by adding pieces of iron to engage it; and that this conjecture was confirmed by an instance the author had heard, of the great durability of the colour of an ink in which pieces of iron had been long immersed; and lastly, that a decoction of logwood used instead of water, sensibly improved both the beauty and deepness of the black, without disposing it to fade. The same author observes, that the addition of gum arabic is not only useful, by keeping the colouring matter suspended in the fluid, but also by preventing the ink from spreading, by which means a greater quantity of it is collected on each stroke of the pen. Sugar, which is sometimes added to inks, was found to be much less effectual than gums, and to have the inconvenience of preventing the drying of the ink. The colour of ink is found to be greatly injured, by keeping the ink in vessels made of copper, or of lead, and probably of any other metal excepting iron, which the vitriolic acid can dissolve. The foregoing experiments point out for the best proportions of the ingredients for ink; one part of green vitriol, one part of powdered logwood, and three parts of powdered Aleppo, or blue galls. The best menstruum appears to be vinegar or white wine, though for common use water is sufficient. If the ink be required to be of a full colour, a quart, or at most three pints, of liquor may be allowed to three ounces of galls, and to one ounce of each of the

other two ingredients. Half an ounce of gum may be added to each pint of the liquor; though the more gum we can employ, consistently with due freedom of writing, it is probable that the ink will be the more durable. The ingredients may be all put together at once in a convenient vessel, and well shaken four or five times each day. In ten or twelve days the ink will be fit for use, though it will improve by remaining longer on the ingredients; or it may be made more expeditiously, by adding the gum and vitriol to a decoction of galls and logwood in the menstruum. To the ink, after it has been separated from the feculencies, some coarse powder of galls, from which the fine dust has been sifted, together with one or two pieces of iron, may be added, by which its durability will be secured.

It has been often remarked, says the same ingenious writer, that the inks used in former times were far more durable than those of later years; many modern records being more decayed than manuscripts of much greater antiquity, of which we have instances in the Letters of Camillo Paderni, published in the Philosophical Transactions for 1753, and 1754. Dr. Lewis made several experiments, in order to recover the composition of this durable ink. Instead of oil which is used in the printers' ink, he mixed both lamp-black and ivory-black with a solution of gum arabic; this liquor wrote of a fine black colour, but when dry, it rubbed off entirely by moisture. Concluding, therefore, that the colour could not be sufficiently fixed on paper without an oily cement, and as oils are made mucible with watery fluids by the intervention of gum, he mixed some of the softer printers' varnish with about half its weight of a thick mucilage of gum arabic, working them well together in a mortar, and beat this mass with lamp-black, adding water by little and little, and continuing the rubbing, till the mixture became of a due consistence for writing. This produced characters of a full brownish black colour, which could not be discharged by rubbing, nor washed out so readily as the foregoing. Instead of the printers' varnish, or boiled oil, linseed-oil was mixed in the same manner with mucilage and lamp-black, and the mixture diluted with water; and the ink thus obtained was much the same as the other. To prevent the discharge by water, some of the more sinking kinds of paper, or common paper made damp as for printing, must be used, which will admit the ink to sink a little into its substance; and thus the characters will be as fixed as can be desired. Such Dr. Lewis found to be the ancient inks, that were so durable. Pliny and Vitruvius expressly mention the preparation of foot, or lamp-black, and the composition of writing ink from lamp-black and gum. Dioscorides sets down the proportion of three ounces of the foot to one of gum. This mixture was formed into cakes or rolls, and dried in the sun, which were occasionally tempered with water, as the Indian ink is with us for painting. The ancients were sensible that these inks were liable to be discharged by water, and endeavoured to obviate this imperfection, according to Pliny, by using vinegar, instead of water, for tempering the mixture of lamp black and gum, which promotes the sinking into the paper. After all, none of these inks can be discharged otherwise than by design; which is the case with respect to the vitriolic inks, and those of printed books and copper-plates.

In the course of Dr. Lewis's experiments, a farther improvement occurred to him, which was that of using the common vitriolic ink, instead of water, for tempering the ancient mixture of gum and lamp-black. By this method the writings will have the durability of those of former times, with all the advantage that results from the vitriolic ink fixing itself in the paper. Common writing ink may, in

many cases, be improved by a small addition of the ancient composition, or of the common Indian ink. Lewis's *Comerice of Arts*, &c. § 16.

Mr. Atle, in his "Origin of Alphabetical Writing," inculcates the necessity of making ink durable; and for this purpose suggests a comparison of the rolls and records that have been written from the 15th century to the end of the 17th, with the writings that remain from the 5th to the 12th centuries. There are in excellent preservation; but the former, though of more modern date, are defaced to such a degree that they are scarcely visible. Mr. Atle agrees with Dr. Lewis in the opinion, that the ancient inks were composed of foot or ivory black instead of the galls, coppers, and gums, which form the composition of our's. Besides their black ink, the ancients used various other colours, as red, gold and silver, purple, &c. Green ink was frequently used in Latin MSS, especially in the latter ages; and it was frequently employed in signatures by the guardians of the Greek emperors till their wards were of age. Blue or yellow ink was seldom used except in MSS., but, according to Mr. Atle, the yellow has not been much in use for these 600 years. Some kinds of characters, particularly the metallic, were burnished. Wax was used by the Latins and Greeks as a varnish, especially by the former, and particularly in the 9th century. This continued a long time in vogue. Dr. (Sir Charles) Blagden, in the *Phil. Transf.* vol. lxxvii. p. 451, &c. has proposed a new method of recovering the legibility of decayed writings. With this view he made some experiments on parchment and vellum MSS., with which he was furnished by Mr. Atle, employing those chemical re-agents which seemed best adapted to his purpose, viz. alkalis, both simple and phlogisticated, the mineral acids, and infusion of galls. The general result shewed, that the ink anciently used, at least in these MSS., was of the same nature as the present; and the greater durability of the more ancient inks appeared to depend very much on a better preparation of the material upon which the writing was made, viz. the parchment or vellum. He suspected, however, that the ancient inks contained a rather less proportion of iron than the more modern; and perhaps more gum was used then, or possibly they were washed over with some kind of varnish, though not such as gave any gloss. It occurred to our author, in the course of his experiments, that perhaps one of the best methods of restoring legibility to decayed writings might be to join phlogisticated alkali with the remaining calx of iron. In order to bring this idea to the test, he made several experiments, for which we refer to his paper, *ubi supra*. The method now commonly practised to restore old writings is the wetting of them with an infusion of galls in white wine. This has certainly a great effect: but, like the phlogisticated alkali, it is apt to stain the substance in which the writing was made. Sir Charles Blagden suggests, that a phlogisticated alkali, better adapted to this purpose than the common, might be prepared, by rendering it as free as possible from iron, diluting it to a certain degree, or substituting the volatile alkali for the fixed. This would serve to bring out a prodigious body of colour upon letters which were before so pale as to be almost invisible, and it would be preferable to the infusion of galls in this respect, that it produces its effect immediately, and may be confined to those letters only for which such assistance is wanted.

In the "Monthly Review" of the volume of *Transactions* above cited, the following method is proposed for preventing ink from decaying. It consists in washing over the paper on which the writing is to be made with the colouring matter of Prussian blue; and by writing upon it afterwards with

common ink, a ground of Prussian Blue is formed under every stroke; which will remain strong after the black has been decayed by the weather, or destroyed by acids. The ink will thus bear a larger proportion of vitriol at first, and will have the advantage of appearing blacker when first written.

INK POWDER may be prepared, by infusing a pound of galls powdered, and three ounces of pomegranate-peels, in a gallon of soft water for a week, in a gentle heat; and then straining off the fluid through a coarse linen cloth. Add to it eight ounces of vitriol dissolved in a quart of water, and let them remain for a day or two; preparing in the mean time a decoction of logwood, by boiling a pound of the chips in a gallon of water, till one-third be wasted, and then straining the remaining fluid while it is hot. Mix this decoction and the solution of galls and vitriol together, and add five ounces of gum arabic, and then evaporate the mixture over a common fire to about two quarts; when the remainder must be put into a vessel proper for that purpose, and reduced to dryness in *balneo Mariae*, i. e. by hanging the vessel in boiling water. The remaining mass, after the fluid is wholly exhaled, must be well powdered; and when it is wanted for use, may be converted into ink by the addition of water.

A portable or extemporaneous ink may be made without galls or vitriol, by mixing half a pound of honey and the yolk of an egg, adding two drams of gum arabic finely levigated, and thickening the whole with lamp-black to the consistence of a stiff paste; which being put to a proper quantity of water, may be used as an ink.

INK, Indian, or Chinese, is an admirable composition, in vain attempted to be imitated in Europe. It is not fluid, like our writing inks, but solid, like our mineral colours, though much lighter. They make it of all figures, but the most usual is rectangular, about a quarter of an inch thick. Some of the sticks are gilt with figures of dragons, birds, flowers, &c. In order to do this, they have little wooden moulds, so curiously wrought, that we could hardly equal them in metals.

To use this ink, there must be a little hollow marble, or other stone, with water in it, on which the stick of ink must be ground, till the water becomes of a sufficient blackness. It makes a very black shining ink; and though it be apt to sink when the paper is thin, yet it never runs or spreads; so that the letters are always smooth, and evenly terminated, how big soever they be. It is of great use in designing, because it may be weakened or diminished to any degree; and there is abundance of things which cannot be represented to the life without it.

From an analysis of this ink, Dr. Lewis concludes that it contains an animal substance soluble in water, and consists of a black powder, mixed with some animal glue. He tried to imitate it, by mixing some lamp-black, prepared from linseed-oil, by hanging a large copper pan over the flame of a lamp to receive its smoke with as much melted glue as gave it sufficient tenacity for being formed into cakes. These cakes, when dry, answered as well as the genuine Indian ink, in regard both to the colour, and the freedom and smoothness of working. Ivory black, and other charcoal blacks, levigated very fine, had the same effect with the lamp-black. It appears from three receipts for the preparation of Indian ink, in *Du Halde's History of China*, that the colouring material is lamp-black, to which is added, in one of them, a quantity of horse-chestnuts, burnt till the smoke ceases. The conglutinating matter, in one of the prescriptions, is a thin size of neat's leather; in another, a solution of gum tragacanth, and in the other, a mixture of size, with a decoction

coction of certain vegetables, unknown to us. Du Halde observes, that the Chinese have inks of different goodness and price; that the most essential difference proceeds from the quality of the lamp-black, and that the best is the foot of oil, burnt in lamps, in apartments fitted up for this purpose.

The Chinese have often attempted to use this in their porcelain, to give the colour of black to the figure traced on white vessels, but it has been a vain attempt; for however beautiful and strong the figures might appear when first laid on, and even when the vessels were dried, it all disappeared on the baking, and they came out quite white as they were put in. The colours for this use must be such as can penetrate the varnish, and endure the fire. Mineral colours are found to have these qualities, and these alone therefore are to be employed; such light ones as this black burning off from the surface, and wholly disappearing. *Obs. sur les Costumes de l'Asie*, p. 320.

INK is also an appellation given to any coloured liquor used in the same manner as black ink; as red, green, blue, yellow, &c. inks. Red writing ink is prepared by infusing a quarter of a pound of the raspings of Brazil wood for two or three days in vinegar; boiling the infusion for an hour over a gentle fire, and afterwards filtering it, while hot, through paper laid in an earthen cullender; then put it again over the fire, and dissolve in it, first, half an ounce of gum arabic, and afterwards alum, and white sugar, of each half an ounce. Red ink may be also made of vermilion, by beating together the glair of four eggs, a tea-spoonful of white sugar, or sugar-candy, powdered, and as much spirit of wine, till they be of the consistence of oil; then adding such a proportion of vermilion as will produce a red colour of sufficient strength; the mixture should be kept in a small phial, or well-stopt ink bottle, and well shook before it be used. Gum-water is often used instead of the glair of eggs; but thin size made of isinglass, with a little honey, is much better for the purpose. Red ink may be made by tempering the solution of copal with red sulphuret of mercury, e.g. take of oil of lavender, 120 grains, copal, in powder, 17 grains, and red sulphuret of mercury, 60 grains, dissolve the copal in the oil, and then mix the sulphuret with the solution upon a smooth surface. This, and also the black ink made with copal, possess a permanent colour, and other essential properties of the ink used in printing. The oil of lavender being dissipated with a gentle heat, the colour is left on the paper surrounded with copal, a substance insoluble in water, in spirits, in acids, or in alkaline solutions. For red printing ink, see PRINTING.

Green ink may be made, by putting an ounce of powdered verdigris to a quart of vinegar, and straining the fluid, after it has stood two or three days; or, instead of this, the crystals of verdigris dissolved in water will answer the purpose; then dissolve in a pint of either of these solutions, five drams of gum arabic, and two drams of white sugar.

Blue ink is made by grinding indigo with honey and the white of eggs, and making it fluid with water.

Yellow ink is made by an infusion of saffron in water, with a little alum and gum arabic; or, by boiling two ounces of Avignon, or French berries, in a quart of water, with half an ounce of alum, till one-third of the fluid be evaporated, and then dissolving in it two drams of gum arabic, and one dram of sugar, and afterwards a dram of powdered alum.

In general, inks of all colours may be made by using a strong decoction of the ingredients used for dyeing, mixed

with a little alum and gum arabic. See the several colour BLUE, GREEN, &c.

INKS, *Sympathetic*, or *Secret*. Every sort of liquor with which a person may write, so that the letters do not appear till there is some particular means used to give them a colour different from that of the paper, is called by the name of *sympathetic ink*; and of this there are a great many kinds described in the writings of Baptista Porta, Lemery, and other authors.

All these inks may be regularly distributed into different classes, according to the different means which are to be used to make them appear; and these are in general the four following. 1. By giving a new liquor, or the vapour of new liquor, a place on the paper, on which the letters are written with the natural invisible ink. 2. By exposing the paper to the air, by which means the letters at first invisible will appear. 3. By passing gently over the letters a matter of some remarkable colour reduced to fine powder. And 4. By exposing the paper to the fire.

This last is by much the best method, and is so general, that it may be prudently used to all papers suspected of containing any secret writing, as it seldom fails to discover it. All the common inks of this kind, however, when they have been once made to appear, either by fire or by any other method, can never be made to disappear again; but there is one kind described by Mr. Hellot, in the Memoirs of the Academy of Sciences at Paris, and since tried many times with us, and elsewhere, which, though the letters it gives are in themselves invisible, and appear like those of some other of these inks, on their being held to the fire, yet they after that will fade and disappear on the paper again, and may be reproduced in this manner several times. This, therefore, is the first known ink of a fifth general class, of which future researches may discover perhaps more.

Of the first class of sympathetic inks, or those which do not appear till the paper on which they are written be made to imbibe another liquor, or the vapour of another liquor, are the following kinds.

To two or three parts of unslaked lime put one of yellow orpiment; powder and mix the two, adding fifteen or sixteen times as much water as there was orpiment; stop up the phial with a cork and bladder, and set it in warm embers; shake the phial now and then for five hours, and warily decant the clear part, or rather filtrate it. In the room of this preparation may be used a saturated solution of common brimstone, made by boiling the brimstone either with quicklime, or in strong alkaline ley. In the mean time, burn a piece of cork thoroughly, and when well inflamed, quench it in common water, or rather in brandy. Being thus reduced into a friable coal, grind it with fair water, whereas gum arabic has been dissolved; and it will make a liquor as black as the common ink.

While these are doing, dissolve, in three times as much distilled or strong vinegar, over warm embers, a quantity of red lead, or of saccharum saturni, in thrice the quantity of water, for three or four hours, or till the liquor have a sweet taste. This liquor will be as clear as common water. Solutions of lead in aquafortis answer the same end, except that, when written with, they are apt to corrode the paper.

The liquors thus prepared, write any thing on paper with this last sort, dry it, and nothing will appear. Over the place, write what you please with the second liquor: it will appear as if written with common ink; when dry, dip a small piece of rag or sponge, in the first liquor, rub it over the written place, and the black writing will vanish; and that wrote with the invisible ink will appear black and legible.

Again

Again, take a book four or five inches thick, and on the first leaf write any thing with the last liquor; turn to the other end of the book, and rub there with a rag, dipt in the first liquor, on that part, as near as you can guess, opposite to the writing, and leave also the rag there, clapping a paper over it; then nimbly shutting the book, strike four or five smart strokes thereon with your hand, and turning the other side uppermost, clap it into a press, or lay it under a good weight for a quarter of an hour, or even half that time; then will the writing done with the invisible ink be found legible there.

The above operation may be varied, by writing the invisible characters with the solution of bismuth in nitrous acid, and exposing them to the vapours of liver of sulphur, or moistening them with a solution of liver of sulphur.

Dissolve white or green vitriol in water, and writing with the solution, nothing will appear. Boil galls in water, and dip a linen rag in the decoction, and with it rub the place before writ, and it will appear black and legible. Rub it over again with spirit of vitriol, or its oil, and the writing will disappear again; rub it over again with oil of tartar per deliquium, the letters will appear again, but of a yellow colour. If the blackness of ordinary ink be destroyed by a sufficient quantity of nitrous acid, the writing made by it will remain invisible till it be moistened with liquid fixed alkali.

The golden sympathetic ink.—This is made by dissolving in aqua regia as much gold as that menstruum can take up, and then adding to the liquor five or six times as much water; in another vessel there must be some tin dissolved in aqua regia; and when that menstruum has also taken up as much of the metal as it can, there is to be added to it an equal quantity of common water. The letters must be written on white paper with the solution of gold, and the writing being dried in the shade, the letters will not appear, at least not for seven or eight hours afterwards; dip a pencil in the solution of tin, and rub that over the solution of gold with which the letters were written, and they will appear of a beautiful purple. It might be supposed, that any other metals which were soluble in the same acid menstruum would equally produce this effect; but experiment shews, that this is not the case; and silver and copper, though both soluble in aquafortis, yet produce no change of colour by these precipitations made by mixing the solutions of them on paper; and this example of such an effect in the solutions of gold and tin, is an exception to the general rules in the solutions of metals, and their effects on one another.

The purple colour of these letters may be again effaced by rubbing some simple aqua regia over the paper, and may be made to appear again by rubbing over that the solution of tin. Kunkel, Cassius and Orschal, with some other writers, made the first steps towards this discovery, by their attempt to give crystal, by means of gold, the colour of the oriental rubies. There are, beside these mineral preparations, some vegetable ones, which give the same phenomena, but these are the more certain.

Of the second kind of sympathetic inks, or those which appear on being exposed only to the air, is the golden ink made by adding to a solution of gold in aqua regia, so much water that the liquor shall not stain a white paper: letters written with this will not appear till the paper has been exposed some hours to the open air, and they will then begin to acquire a colour by degrees, till they at length become of a deep violet colour, tending to black. If, instead of exposing the paper to the air, it be kept in a box close shut up, or closely folded in other paper, it will remain invisible two

or three months; but at the end of that time it will begin to appear, and will by degrees become of a deep violet colour. So long as the gold remains united to its dissolvent, it is yellow; but the acid that dissolves it being of a volatile nature, the greater part of it evaporates, and leaves no more than is just necessary to colour the calx of gold which remains upon the paper.

The second of these is the silver ink, made by a solution of silver in aquafortis, weakened by distilled water, till it will not stain the paper. Letters written with this will be invisible for three or four months, if shut up in a box; but if they be exposed to the sun they become legible in about an hour, because by this means the evaporation of the acid is accelerated. The letters written with this ink are of a slate colour; and that from the sulphureous nature of the aquafortis, every thing that is sulphureous blackens silver. This blackish colour, however, is not permanent; for the sulphureous part finally evaporating, the letters are left to their natural appearance, and are of a fine true silver colour, if the silver that was used was fine, and the place open.

In this class there may also be placed several metallic dissolutions; as that of lead in vinegar, and of copper in aquafortis, which give at length a brownish colour upon the paper; as also the solution of tin in aqua regia, of mercury in aquafortis, of iron in vinegar, of emery and several of the pyrites in spirit of salt. But all these, though they give letters which are after some time legible, on being exposed to the air, are also made to appear instantly on the paper, holding them to the fire. Each of these solutions gives its own particular colour; but they have all this disadvantage, that in time they eat away the paper, and the letters are seen in the shape of so many holes.

Of the third class of ink, or that which appears on rubbing over the paper with a brown or black powder, are almost all the glutinous expressed juices of plants, which are themselves of no remarkable colour, the milk of animals, or any other thick and viscous fluids. To use these, the letters must be written on a white paper, and when dry, there is to be thrown over them the fine powder of any coloured earth, or other such substance; and the writing will afterwards appear coloured, because its viscous quality remains sufficiently in it for the entangling and retaining this fine powder, though it falls easily off from every other part of the paper. Mem. Acad. Science, Par. 1737.

Among the methods which Ovid teaches young women to deceive their guardians, when they write to their lovers, he mentions that of writing with new milk, and of making the writing legible by coal-dust, or soot.

“Tuta quoque est, fallitque oculos, e lacte recenti

Litera: carbonis pulvere tange: leges.”

De Arte Amandi, l. iii. v. 629.

Ausonius proposes the same means to Paulinus, and he afterwards teaches other methods of secret writing. Auson. Epist. xxiii. v. 21, &c. Eneas, in Poliorceticis, cap. 31, and Gellius, lib. xvii. cap. 9, mention the like. Pliny, lib. xxvii. cap. 8, mentions the milky sap of certain plants for a similar purpose.

Of the fourth class, or those inks which become visible on holding them to the fire, there are a vast number; and indeed all insulions, the matter of which is readily burnt to a sort of charcoal by a little fire, will answer this purpose. The nicest of this kind is the sal ammoniac ink, made by dissolving a scruple of sal ammoniac in two ounces of fair water. Letters written with this solution are invisible on the paper, till it is held before the fire, or has an

iron a little heated passed over it. The rationale of this is, that the inflammable part of the sal ammoniac is burnt to charcoal by a heat which is not sufficient to scorch the paper; and this is the case with all the rest of this class. The letters written with this solution are, however, of no great duration; for the salt being apt to moisten in the air, the letters soon spread, and run together in a confused manner.

Dr. Lewis says, that all the salts which he has tried produce this effect in a greater or less degree; nitre, alum, tartar, very weakly; sea-salt more strongly; fixed alkaline salts still more so; but sal ammoniac the strongest of all. Metallic solutions, made in acids, and diluted so as not to corrode the paper, act in the same manner. The juice of Lemons and milk have also been used as sympathetic inks, the writing with which appears upon the application of heat sufficient to decompose the oily and mucilaginous parts of these liquors.

The fifth class of sympathetic ink contains only one yet known kind.

This, though in itself invisible, becomes of a blueish green when held to the fire; and this colour disappears again as the paper cools, and is to be produced again on holding it again to the fire; and this for a long time, and a repeated series of trials. It may also, according to the different manner of treating it, be made to appear blue, green, yellow, red, and some other colours. This property of the tinging matter of bismuth ore was published at full length by a German lady, in 1795.

A certain German chemist shewed the academy at Paris a salt of rose-water, which became blue on holding it to the fire, and at the same time shewed the ore from which he procured the salt, which he called an ore of marcasite, a name given by many to the bismuth ore. He added, that this was the mineral from which the fine blue smalt of Sneeberg was prepared, and that no other ore but this afforded it, and that he made the tincture from this mineral with aquafortis, which he fixed with sea-salt.

This was the substance of what the German declared, and from what Mr. Hellot, in 1736, took the hint for his discovery of this remarkable ink. The salt was, after many experiments, at length found to be produced from an arsenic ore; and it was found, that all the cobalts and ores of bismuth afford a tincture capable of these changes by fire.

The method of preparing it is this: pour upon two ounces of arsenic ore, grossly powdered, a mixture of five ounces of aquafortis, and five ounces of common water. After the first ebullition is over, place the vessel in a gentle sand-heat, and let it stand there till no more air-bubbles seem to ascend; after this increase the fire, so as to make the liquor boil for about a quarter of an hour; after this the liquor will become of a reddish colour, and when cold it is to be decanted clear off from this sediment into a phial; and after standing in that some time, it is to be again decanted off from what is precipitated there; and so on for three or four times till it is quite clear; for it must not be filtered, lest the acid should take something from the paper that might spoil the effects. When the liquor is clear, there must be added to it two ounces of white sea-salt: this mixture is to be evaporated over a gentle sand-heat, till there remains only a dry saline mass. When the liquor is grown hot, it changes from its orange colour to a fair red; and when the aqueous humidity is evaporated, it becomes of a beautiful emerald colour, and from this, as it dries up, it changes by degrees to a dirty green, like that of verdigris in the cake. As it becomes nearly dry,

it must be stirred about with a glass rod or pebble, to keep it from uniting into a mass; and it must not be kept over the fire till perfectly dry, because by that means the colour is often lost, and the salt from green-becomes of a dusky yellow; but if it be taken from the fire while it is green, it gradually becomes reddish as it cools, and finally is of a rose-colour. The manner of using this sympathetic ink is this: write with it on a fine and smooth paper, or draw with a black-lead pencil the figure of a plant or tree on the paper; and then trace over the same lines with this liquor; let it dry in the open air, and then rub off the black lines with bread, and the paper will appear altogether fair, though the lines made by the ink are in reality sunk deep into it. On holding this paper to the fire the lines will all appear, and the figure of the plant or the letters will be painted in a beautiful blueish green, which will continue so long as the paper is warm; but when it is cold again, they will wholly disappear. The lines, therefore, disappear much sooner in winter than in summer; and in very hot weather it is often necessary to lay the paper on a marble, or other very cold body, in order to produce this effect. At any time, if the paper be scorched in the experiment, the colour of the lines will not disappear again, even if ice be laid upon them. If the writing be exposed for three or four days to a humid air, the lines will appear of a fine pale red. If the impregnation of the ore of bismuth, instead of sea-salt, have alum added to it, and the whole process be continued as before described; and if letters be written with the red liquor as it is taken out of the vessel, the letters will not appear even on holding it to the fire; but if the paper be wetted over with a clear solution of marine salt, and then left to dry, and afterwards held to the fire, the letters will appear blue. The same also will be the effect, if the writing be exposed to the vapour of hot spirit of salt. When this preparation is thus made with alum, instead of common salt, the liquor never becomes green, but continues red, and never changes colour in the drying, or afterwards. The green colour seems to be wholly the effect of the sea-salt; for not only this aluminate impregnation, but others in which other salts had been employed, were always found to be of a different colour.

Glauber's salt, used instead of common sea-salt, left the mass red in the same manner as alum did. Nitre added, instead of sea-salt, gave the precipitate or dried salt a beautiful purple colour, which became white on the instant that water was poured upon it, and a rose-coloured tincture was drawn from it, which gave lines or letters on paper, which continued invisible as long as they were cold, but assumed a beautiful red on holding the paper to the fire; which colour they retained no longer than while the paper continued warm, disappearing afterwards in the same manner with the green colours made by the sea-salt; and if a simple solution of sea-salt be rubbed over the paper, and suffered to dry, and the paper be afterwards heated, the lines appear blue. Borax has the same effect in this preparation with the nitre. All these experiments were made with the neutral salts; but in order to try what would be the effects of alkalis in the mixture, Mr. Hellot added to three ounces of the impregnation of the ore in aquafortis, pure salt of tartar, till the ebullition ceased; but the consequence of this was no great precipitation, but merely the subsiding of a small white sediment; this mixture being evaporated nearly to a dryness, the remaining mass, so long as it was warm, appeared of a beautiful purple; but this became paler as it dried, and turned white in an instant on pouring

ing water upon it. This dissolved in water, in the manner of the others, gave lines on paper of a faint rose-colour, which appeared or disappeared in the manner of those made by the other solutions, according as the paper was hot or cold; and the wetting of the paper with a solution of sea-salt, had the same effects on this as on the others, making the lines appear blue on holding to the fire. Mem. Acad. Par. 1737. See *Colours from MIXTALS*.

The ink may be easily made by digesting zaffre, commonly sold by druggists, in aqua regia; and thus is obtained the soluble part of zaffre, which is the calx of cobalt. This solution is then to be diluted with a little common water. In exposing the paper written with this solution to the fire, care must be taken not to heat it too much; for in this case, the writing will not again disappear by exposure to cold. This ink, says Macquer, the author of the Chemical Dictionary, may be applied to the drawing of landscapes, in which the earth and trees destitute of verdure, being drawn with common ink, give a prospect of winter; and which may be made to assume the appearance of spring, by exposure to a gentle heat, which covers the trees with leaves and the earth with grass, by rendering visible those parts of the landscapes which are drawn with this sympathetic ink; and, as the solution of regulus of cobalt or zaffre in spirit of nitre acquires a reddish colour by the application of heat, the red solution might be contrived to represent the fruits and flowers.

INK-*fish*, in *Ichthyology*. See **CUTTLE-*fish***, and **SEPIA**.
INLIGATION, INLAGATIO, a reitoring of one outlawed to the protection of the law and benefit of a subject.

The word comes from the Saxon *inlagium*, i. e. *inlagare*.
Terms of Law.

INLAGH, INLAGATUS, he that is of some frankpledge, and not outlawed. It seems to be the contrary to *uillagh*.

INLAND implies any thing situate in the main land, or heart of a country, far from the sea-coasts.

Hence inland bills, in traffic, are such bills as are payable in the same land, wherein they are drawn. See **BILL**.

INLAND Navigation, is applied to the passage of boats, barges, and vessels on canals and navigable rivers, within a country, to distinguish it from navigation, properly so called, by means of ships on the open seas or the largest of the lakes. No country in the world can vie with the British islands at the present day, for the extent and importance of their artificial inland navigation or **CANALS**, under which article we have given a connected view of these, and of the navigable rivers and railways, forming altogether a system of improved communication no where to be equalled; and yet nearly the whole of them originated and was completed by individuals without the assistance of the state. See also the names of the several canals, rivers, &c. for further information.

INLAYING. See **VENEERING**, **MOSAIC**, and **MARQUETRY**.

INLEASED, in our *Old Writers*, signifies entangled or ensnared. It is used in the champion's oath. 2 Iust. 247. Blount.

INLETS, *Bay of*, in *Geography*, a bay on the coast of New Holland, so called by Cook, in June 1770, lying between cape Palmeriton and cape Townhend.

INLI, a town of Corea; 45 miles W. of Hoang-tcheou.

INLISTING, in a *Military Sense*. See **LISTING**.

INMATES, such persons as are admitted, for their money, to live in the same house or cottage with another man, in different rooms, but going in at the same door; being usually supposed to be poor, and not able to maintain a whole house themselves. These are inquirable in a court-leet.

No owner or occupier of a cottage shall suffer any inmates therein, or more families than one to inhabit there, on pain of forfeiting 10s. per month to the lord of the leet.

INN, in *Geography*, a river which rises in the country of the Grisons, about 12 miles S.W. of Zula, and runs into the Danube near Passau.—Also, a river of Austria, which runs into the Danube near Esferding.

INNS, a place appointed for the entertainment and relief of travellers.

Inns are licensed and regulated by justices of the peace, who oblige the landlord to enter into recognizances for keeping good order. See **ALIHOUSES**.

If a person who keeps a common inn refuses to receive a traveller into his house as a guest, or to find him victuals and lodging, on his tendering him a reasonable price for them, he is liable to an action of damages, and may be indicted and fined at the king's suit. (1 Ventr. 333.) By the yearly acts against mutiny and desertion, the constable, and in his default a justice of the peace, may quarter soldiers in inns, livery-stables, ale-houses, and victualling-houses. The rates of all commodities sold by innkeepers, according to our ancient laws, may be assessed; and innkeepers not selling their hay, oats, beans, &c. and all manner of victuals, at reasonable prices, without taking any thing for litter, may be fined and imprisoned, &c. by 21 Jac. 1. c. 21.

Where an innkeeper harbours thieves, persons of infamous character, or suffers any disorders in his house, or sets up a new inn where there is no need of one, to the hindrance of ancient well governed inns, he is indictable and fineable; and by statutes such inn may be suppressed. (1 Hawk. P. C. 225.) Action upon the case lies against any innkeeper, if a theft be committed upon his guest by a servant of the inn, or any other person not belonging to the guest; though it is otherwise where the guest is not a traveller, but one of the same town or village; for in that case the innkeeper is not chargeable; nor is the master of a private tavern answerable for a robbery committed on his guest. It is said that even though the travelling guest does not deliver his goods, &c. into the innkeeper's possession, yet if they are stolen he is chargeable. An innkeeper is not chargeable for any thing out of his inn, but only for what is within it; yet where he of his own accord puts the guest's horse to grass, and the horse is stolen, he is answerable; he not having the guest's orders for putting such horse to grass. The innkeeper may justify stopping the horse, or other things of his guest, for his reckoning; and may detain the same until it be paid. Where a person brings his horse to an inn and leaves him in the stable, the innkeeper may detain him until such time as the owner pay for his keeping; and if the horse eats out as much as he is worth, after a reasonable appraisement made, he may sell the horse and pay himself. But when a guest brings several horses to an inn, and afterwards takes them all away, excepting one, this horse so left may not be sold for payment of the debt of others; for every horse is to be sold, only to make satisfaction for what is due for his own meat.

Any person found tipping in an inn, is adjudged within the statutes against drunkenness; and innkeepers, or ale-house-keepers, permitting tipping in their houses, are liable

to the penalty of 10*l.* &c. by 1 Jac. cap. 9. 1 Car. cap. 4. 21 Jac. cap. 7.

INNS. Our colleges of municipal or common law professors and students, are called inns: the old English word for houses of noblemen, bishops, and others of extraordinary note, being of the same signification with the French word *hôtels*.

INNS of Court are so called, as some think, because the students there are to serve and attend the courts of judicature; or else, because anciently these colleges received none but the sons of noblemen, and better sort of gentlemen, who were there to be qualified to serve the king in his court; as Fortescue affirms. And in his time he says, there were about two thousand students in the inns of court and chancery, all of whom were *filii nobilitatis*, or gentlemen born. But this custom has gradually fallen into disuse; so that in the reign of queen Elizabeth, Sir Edward Coke does not reckon above a thousand students, and the number at present is very considerably less; for which judge Blackstone assigns the following reasons: 1. Because the inns of chancery being now almost totally filled by the inferior branches of the profession, are neither commodious nor proper for the resort of gentlemen of any rank or figure; so that there are very rarely any young students entered at the inns of chancery. 2. Because in the inns of court all sorts of regimen and academical superintendence, either with regard to morals or studies, are found impracticable, and therefore entirely neglected. Lastly, because persons of birth and fortune, after having finished their usual courses at the universities, have seldom leisure or resolution sufficient to enter upon a new scheme of study at a new place of instruction; whereas few gentlemen now resort to the inns of court, but such for whom the knowledge of practice is absolutely necessary in such as are intended for the profession. *Comm. book i. p. 25.*

Our inns of court, justly famed for the production of men of learning in the law, are governed by masters, principals, benchers, stewards, and other officers; and have public halls for exercises, readings, &c. which the students are obliged to attend, and perform for a certain number of years, before they can be admitted to plead at the bar. These societies have not, however, any judicial authority over their members; but instead of this they have certain orders among themselves, which have by consent the force of laws. For lighter offences persons are only excommunicated, or put out of commons; for greater, they lose their chambers, and are expelled the college; and when once expelled out of one society, they are never received by any of the others. The gentlemen in these societies may be divided into benchers, outer-barristers, inner-barristers, and students.

The four principal inns of court, are the Inner Temple, and Middle Temple, heretofore the dwelling of the Knights Templars, purchased by some professors of the common law about three hundred years ago; Lincoln's Inn and Gray's Inn, anciently belonging to the earls of Lincoln and Gray. The other inns are the two Sergeants Inns.

INNS of Chancery were probably so called, because anciently inhabited by such clerks as chiefly studied the forming of writs which regularly belonged to the curators, who are officers of chancery.

The first of these is Thavies Inn, begun in the reign of Edward III. and since purchased by the society of Lincoln's Inn. Besides this we have New Inn, Symond's Inn, Clement's Inn; Clifford's Inn, anciently the house of Lord Clifford; Staple's Inn, belonging to the merchants of the staple; Lion's Inn, anciently a common inn with the sign of the lion; Farnival's Inn, and Bernard's Inn.

These were heretofore preparatory colleges for younger students; and many were entered here before they were admitted into the inn of court. Now they are mostly taken up by attorneys, solicitors, &c.

They all belong to some of the inns of court, who formerly used to send yearly some of their barristers to read to them.

INN, or *Inner*, in the *Mange*, is applied differently, according as the horse works to the right or left upon the volts, or as he works along by a wall, a hedge, or the like. For along or by a wall, the leg that is of a side with, or next the wall, is the outer, and the other the *in* or *inner* leg. And if upon volts, the horse works to the right, the right heel is the inner, and the left the outer heel, and so of the other parts of the body, furniture, &c. The direct contrary of this will happen, if the horse works to the left.

INNATE AIR. See AIR.

INNATE FORCE. See VIS *Instita*.

INNATE HEAT. See HEAT.

INNATE IDEAS, or Principles, are certain primary notes or characters, by whom supposed to be stamped on the mind of man when it first receives its being, and which it brings into the world with it.

But the doctrine of innate ideas is abundantly confuted by Mr. Locke. See IDEA.

INNATE, in *Natural History*, particularly in that branch of it which treats of fossil remains or reliquia, is applied to such parts of the animal bodies as have been produced independently of any effort of the animal, and are either internal parts, as the bones, which often give the form to extraneous fossils, or external parts, as the scales and fins of fish, the horny covering in some of the amphibia, and the integument which incloses the whole of the body in insects, all of which are sometimes found in a fossil state, as Mr. William Martin observes in his "Outlines," p. 86. The genera of reliquia which do not depend on innate parts, but on fabricated parts of the animal parts, which are superadded to the body by some voluntary effort of the animal, are called conchyliolithus and crismatolithus.

INNER BARRISTER. See BARRISTER.

INNER POST, is an additional piece of oak timber brought on to the fore-side of the main post upon which the transoms are let on or seated; it adds to the security of the planks, as the main post is seldom sufficient before the rabbit for that purpose, and greatly strengthens the stern or main post.

INNER SEE, in Geography, a river which rises about five miles N.W. of Gusslar, and runs into the Leine, in the bishopric of Hildesheim.

INNER SOUND, a strait of the North sea, between the isle of Skye, and the N.W. coast of Invernesshire, in Scotland.

INNERSHON, a small island on the west side of the gulf of Bothnia. N. lat. 61° 34'. E. long. 17° 6'.

INNICHEN, a town of Germany, in the Tyrolse situated near the Drave; anciently called "Aguntrum;" 29 miles E. of Brixen. N. lat. 46° 41'. E. long. 12° 20'.

INNINGS, lands recovered from the sea, by draining and building.

INNITPOUR, in *Geography*, a town of Bengal; 48 miles N. of Dacca.

INNO, *Inno*, a hymn, or spiritual song.

INNOCENT I. pope, in *Biography*, was a native of Albano, and was unaniously elected to the popedom by the clergy and people, on the death of Anastasius in the year 402. He obtained from the emperor new and severe laws against the Donatists, in consequence of which that sect was

crucially

cruelly persecuted, and those who refused to return to the bosom of the Catholic church were punished with fines, banishment, the confiscation of goods, and in some instances with death. He espoused the cause of Chrysofom, and even refused to hold communion with the eastern churches, on account of their treatment of that eminent man. He was the first who persecuted the Novatians at Rome, by depriving them of their churches, and preventing their assembling in public, for religious worship; the Pelagians came likewise under his lash; he declared them not only unworthy of Christian communion, but of human society, and even of life. He died in the year 417, after having presided over the church about fifteen years. He was a person of great address, and a lively genius, and was well acquainted with the traditions of the church. His decretals sufficiently shew his usurping and domineering spirit, and his wishes to make the Christian world submit to his insolence; they have been frequently quoted by the advocates of the see of Rome, to demonstrate how early the popes claimed, as the successors of St. Peter, an universal authority and jurisdiction. Thirty-four letters, in the first volume of the "Letters of the Popes" have been attributed to this pontiff, but by many of the ablest critics the greater part of them has been regarded as supposititious.

INNOCENT II. pope, a descendant from a noble family at Rome, ascended the papal throne in the year 1130. He had already filled some respectable offices in the church, and is said to have led a most exemplary life from his infancy, and to have been distinguished for eminent abilities and strict probity, while he was at the same time of a most humane and courteous disposition. He was promoted to the sacred college by the title of cardinal St. Angelo, and was employed by several of the popes in important negotiations at home and abroad. Upon the death of Honorius II. he was elected his successor by a part only of the conclave, the rest choosing Peter de Leon, the son of a Jew, who took the name of Anacletus II., and was acknowledged by the kings of Scotland and Sicily, while Innocent was received by the other princes of Europe. Being driven from Italy, he fled to France, where he held several councils, at one of which he thundered out a sentence of excommunication against Anacletus, and all his adherents. He crowned the emperor Lotharius with great solemnity, and for the support of his new dignity granted to him, to his daughter, and to his son-in-law, during their lives, all the estates of the counts of Matilda. On the death of his rival, another pope was chosen by the same party, who took the name of Victor, but who, probably, feeling himself unequal to contend with the power of Innocent, threw himself at the feet of the pontiff, and thus put an end to the schism in the church. Innocent, having now no enemy to disturb his peace, took up his residence at Rome, and summoned a general council to meet in the Lateran in the year 1139. This was the most numerous council that had ever been held, consisting, it is reported, of a thousand bishops, besides a crowd of abbots and other ecclesiastics, who, besides other business, declared the ordinations of Anacletus null; excommunicated Roger, king of Sicily, and condemned the opinions of the famous Arnold of Brescia. Innocent, after this, was not contented with the pacific duties of his office, but actually marched in person, with his army, against the prince who seemed to set at his defiance the sentence of excommunication. Roger was too well skilled in military tactics to leave the event of the contest doubtful, he attacked the episcopal army, which he put to flight, and was so completely successful, as to take the holy pontiff prisoner, with several cardinals, and other persons of distinction. When Innocent was conducted into

the king's camp, he found, what he little expected, that he had fallen into the hands of a generous enemy; the victorious king sent some of his principal officers to beg his holiness's pardon, and to assure him he was ready to enter into an accommodation upon the terms which he had formerly offered by his deputies. Innocent readily assented; the terms were drawn up and executed, in consequence of which the pope absolved Roger from excommunication, and solemnly invested him with the kingdom of Sicily, the dukedom of Apulia, and the principality of Capua; while, on the other hand, the king acknowledged Innocent for lawful pope, and engaged to assist him whenever his aid should be required. Upon the recovery of his liberty Innocent returned to Rome, but the remainder of his life was spent in much disquiet. The last two years of his life were wholly occupied in reducing several cities which attempted to shake off the yoke of the apostolic see, and to recover their ancient liberty. The Romans also refused to obey him as their prince, restored their senate, and created their own magistrates. In the midst of these calamities the pope fell sick, and died in 1143, after a pontificate of nearly fourteen years. In private life he was most highly esteemed on account of the suavity of his manners, but from the several revolts which took place while he was head of the church, it has been suspected that his administration of government was not conducted with prudence and wisdom, and that his zeal for exalting the papal pretensions was not behind that of any of his predecessors. Forty-three of his letters are inserted in the tenth volume of the Collect. Concl.

INNOCENT III. pope, originally called Lotharius, was a descendant from the illustrious house of the counts of Segni, and born at Anagni about the year 1161. After pursuing his studies at Rome, he went to the university of Paris, where he was admitted to the degree of doctor. From this period he was advanced very rapidly in the church; was ordained sub-deacon by Gregory VIII., and preferred to the dignity of cardinal-deacon by Clement III., under the title of cardinal St. Sergius, and St. Bacchus. On the death of pope Celestine III. in the year 1198, Lotharius was elected his successor, being then only in his thirty-seventh year. Being at this period only in deacon's orders, he was first ordained priest, in order to his being able to undertake the high office of pope, when he assumed the name of Innocent III. From the moment of his exaltation, he seems to have set before him, as objects for his imitation, the character and conduct of pope Gregory VII., and with equal intrepidity and address, pursued his plans of ambition, till he arrived at a height of despotism, which the world beheld with wonder and astonishment, but to which the states of Europe submitted with a silence that was highly disgraceful to them. "Under this young and ambitious priest," says Gibbon, "the successors of St. Peter attained the full meridian of their greatness; and in a reign of eighteen years, he exercised a despotic command over the emperors and kings whom he raised and deposed; over the nations, whom an interdict of months or years deprived, for the offence of their rulers, of the exercise of Christian worship. In the council of the Lateran he acted as the ecclesiastical, almost as the temporal, sovereign of the East and West. It was at the feet of this legate that John of England surrendered his crown; and Innocent may boast of the two most signal triumphs over sense and humanity, the establishment of transubstantiation, and the origin of the inquisition. At his voice, two crusades, the fourth and the fifth, were undertaken; but except a king of Hungary, the princes of the second order were at the head of the pilgrims; the forces were inadequate to the design; nor did the effects correspond with the hopes
and

and wishes of the pope and the people." Innocent did not confine his efforts to the Holy Land, he promoted a crusade against the Albigenses. He first attempted to convert them by his missionaries, one of whom was murdered, which was the signal for the display of all his wrath; he did not even deign to institute an inquiry, but ordered the whole race to be purified with fire and sword, and to be treated with more severity than the Saracens themselves. Immense numbers of lives were sacrificed in his holy war, and barbarities practised, before unheard of; but the perpetrators of them were applauded and rewarded by the cruel pontiff, and the infernal spirit by which they had been actuated was impiously called zeal in supporting the cause of God and of the church. In 1215, the fourth general Lateran council was held at Rome, which was so managed by the all-controlling power of the pontiff, that instead of exercising the functions of a deliberative body, it was made use of only as an instrument to register canons and decrees which Innocent had drawn up, and which he permitted to be read for their approbation. In this council a sentence, which had been pronounced some time before, suspending Stephen Langton, archbishop of Canterbury, was confirmed. The pope, likewise, thundered out a sentence of excommunication against the barons, which they treated with merited contempt, and bravely persisted in defending those privileges, the charters of which they had lately compelled their monarch to sign. In the year 1216, Innocent undertook a journey to Pisa; but on his arrival at Perugia he was attacked with a violent disorder, which put an end to his life in a few days. According to Mr. Berington, "Innocent was learned, magnificent, perseverant, wise. In the knowledge of laws and politics he had no equal: he possessed the art of government, and was obeyed more from fear than love. Ambition was his ruling passion, to gratify which, he overstepped the bounds of decency and justice, playing as wantonly with the solemn censures of the church as if they had been instituted for the common purposes of wayward caprice or resentful vengeance. To look into him for the amiable virtues of life, or for those which should form the pastoral character, would be loss of time. The prerogative of the holy see, built up by adulation and misjudging zeal, filled his mind; its aggrandizement he sought sometimes, perhaps, from motives which the cool reasoner may excuse; and the meteor of universal empire gleaming on his senses, did not permit the operation of a dispassionate and unbiassed judgment. No tears were shed when Innocent fell, but those which Religion wept, too justly pained by the inordinate exertions and worldly views of her first minister." Innocent was the author of a variety of works, which are enumerated by Dupin, but the most valuable are his "Epistles," which threw considerable light on the ecclesiastical history of his time. His works have been collected in two volumes folio; the best edition is that published at Paris in 1682.

INNOCENT IV., pope, was a native of Genoa, and being distinguished for his learning and attainments, he was in early life made canon of Parma, from which he was promoted to the chancellorship of the Roman church. In 1227 he was raised to the purple by Gregory IX., and in 1243 he was elevated to the papal throne, when he took the name of Innocent IV. Previously to this he was on terms of strict intimacy with the emperor Frederic II., who had been engaged in a contest with the court of Rome, and that prince no sooner received the news of his exaltation, than he sent a splendid embassy to congratulate him upon his election, and to assure him that nothing should be wanting to re-establish harmony between the church and the empire. The pope, however, began to assume a dignity inconsistent with friend-

ship, and he plainly declared that he was resolved to maintain the highest pretensions of the apollitical see. Legates were dispatched to accommodate all differences, but it was of no avail, and hopes of reconciliation being at an end, Frederic prepared to reduce the pope to reason by the terror of his arms. Innocent, unable to resist the power of the emperor, fled for protection to his native city, where he was received with every mark of distinction. Here he assembled a council, consisting of about 140 prelates, some princes, and the ambassadors of most of the crowned heads in Europe; he laid before this august assembly the motives which induced him to call them together, describing the emperor as a tyrant, a persecutor of the church, and as guilty of heresy, sacrilege, and other grievous crimes. The council gave credit to the pontiff, and sanctioned the sentence of excommunication pronounced against him. This led to a most destructive war, which was carried on in Germany and Italy till the death of the emperor Frederic in 1250, who was succeeded by his eldest son Conrad, who took up his father's cause with too much zeal and intrepidity, as rendered Innocent fully sensible of his inability to withstand that prince with his own forces only. He accordingly made many unsuccessful attempts for obtaining assistance, and his army was defeated, which so affected the pontiff, that he fell sick and died in the month of December 1254, after he had presided over the church nearly twelve years. He had high notions respecting the power and authority of the papal see: he possessed considerable learning; was well acquainted with the divinity of the times, and was regarded as the best civilian of his age. He was author of a work entitled "Apparatus, Libris quinque distinctus, in totidem Libros Decretalium," first printed at Venice in 1570; and of several other pieces, besides twenty letters, which are inserted in the eleventh volume of the Collect. Council. He was not only learned, but a great encourager of learning, and is said to have been the first who gave red hats to the cardinals.

INNOCENT V., pope, was born at a town on the Hère, in Burgundy. When very young he entered the Dominican order of preaching friars, and pursued his studies in divinity with too much success, that he was appointed to fill the theological chair in the university of that city, and was considered as one of the most learned divines of the age. He obtained considerable preferment in the church, and about 1271 was nominated by pope Gregory X. archbishop of Lyons, and soon afterwards was promoted to the sacred college by the title of cardinal bishop of Ostia. On the death of Gregory he was unanimously chosen his successor in the papal dignity, and took the name of Innocent V. Besides reconciling those states of Italy which were carrying on the most bloody wars against each other under the opposite denominations of Guelphs and Gibellines, and bringing about a peace between the republics of Lucca and Pisa, he projected the mission of a splendid legation into the East, to obtain from the emperor, Michael Paleologus, the confirmation of the articles of union, but he died before he could carry his design into execution, after a short pontificate of about five months. He wrote "Commentaries" upon the Pentateuch, the Canticles, and the Gospels; "Notes on the Epistles of St. Paul;" and other pieces, which have been published since his death.

INNOCENT VI., pope, formerly called Stephen Aubert, was brought up to the study and practice of the law, and in 1335 he was professor of the civil-law at Toulouse, and chief judge of that city. In two years after we find him bishop of Noyon, and in 1340 he was translated to the see of Clermont. In 1342 he was raised by pope Clement VI. to the dignity of cardinal bishop of Ostia, and at the same time appointed grand penitentiary of the Romish church. In 1358

he was unanimously chosen pope, and took the name of Innocent VI. He made it his business to correct abuses, and also abolished the heavy impositions laid upon the clergy, when preferred to any new benefice or dignity. He retrenched all the unnecessary expences of the papal court, contenting himself even with a small number of attendants: he obliged the cardinals to follow his example, urging them to bestow the superabundance of their wealth in relieving the necessities of the poor. Innocent maintained the decrees of his predecessors against those Minorite friars who assumed the title of "Spiritual Brethren," and who contended against the right of the clergy possessing any property. Two of this description were arrested at Montpellier in the year 1354; the pope attempted to convert them from the error of their ways, but finding them obstinate, he gave them up to the inquisitors to be burnt alive. In the following year he sent a legate a latere to Rome to crown Charles, king of Germany, and his queen Anne with the imperial crown, but not before that prince had subscribed to the most humiliating conditions. After this, nothing occurs during the remainder of Innocent's pontificate which requires to be noticed. He died at Avignon in 1362, after he had filled the papal chair nearly ten years. He has been highly commended for his probity and the sanctity of his life: he was generous to the wants of the poor: an enemy to vice, the patron and protector of virtue in every condition of life. He left behind him many epistles, some of which have been printed, and others are preserved in the Vatican.

INNOCENT VII., pope, was born at Salmona, in Abruzzo, about the year 1339, obtained a high reputation for his knowledge of the civil and canon law, was made clerk of the apostolic chamber by pope Urban VI., and was afterwards employed to collect the revenues of the apostolic see of England. As a reward for his services in those situations he obtained considerable church preferment, and was at length raised to the sacred college under the title of cardinal prebiter of Santa Croce. On the death of Boniface IX. he was chosen to the popedom, and took the name of Innocent VII. Scarcely had he been consecrated, when a dreadful tumult broke out in Rome between the Ghibellines and the Guelphs: this led to other disturbances, which lasted during the pontificate of Innocent, who died in about two years after his elevation. He is represented as of a mild and pacific disposition; of a generous and beneficent temper; an enemy to all pomp and show; free from pride and ambition, and of great address in state affairs. He is much blamed for having been the occasion of elevating unworthy persons to the highest posts of dignity and trust. He is author of a discourse, "On Church Union," and some "Letters."

INNOCENT VIII., pope, was born at Genoa in the year 1432: at an early age he was sent to the court of Naples, where he lived several years during the reigns of Alphonso and his son Ferdinand, and received substantial marks of favour from both princes. After this he removed to Rome, and obtained considerable church preferment, till at length he was raised to the purple by the title of cardinal of St. Balbina in the year 1473. Upon the death of Sixtus IV. in 1484, he was elected his successor, and took the name of Innocent VIII., having been previously known by that of John Baptist Cibo. As soon as he was seated in his government, he attempted to procure another crusade, but without success. His efforts, however, contributed to bring much wealth into the apostolic treasury, part of which the pope appropriated to his own use; and the rest he expended on the repair of ancient works of art, or in support of a war in which he soon became involved with Ferdinand, king of Naples. Innocent spent the concluding years of his ponti-

ficate in endeavouring to maintain order and good government in the church, and in cultivating the arts of peace. He cleared the country of robbers and assassins, with which it was at that time much infested; adopted measures for the regular supply of Rome with provisions, and adorned it with many magnificent buildings. He died in the year 1492, aged 60, after he had filled the papal throne nearly eight years. He was possessed of a very moderate share of learning and talents, but secured the attachment of all ranks by the sweetness of his temper and the gentleness of his manner. His character, in a moral point of view, will not bear examination: he unblushingly acknowledged himself the father of a numerous progeny of natural children, and is said to have been the first of the popes who introduced that new and extraordinary proceeding of owning publicly his spurious issue, heaping upon them riches without measure. He left behind him some letters, and one to Henry VII., king of England, against citing the clerical orders before secular tribunals.

INNOCENT IX., pope, known originally under the name of John-Anthony-Pacchinetti, was born at Bologna in the year 1519, where he received his education, and was admitted to the degree of doctor in 1544. He now became a domestic in the family of cardinal Farnese, who sent him in the capacity of vicar to Avignon, and again to Parma. In 1566, he was sent by Pius V. as nuncio to Venice, where he had a principal concern in establishing the confederacy between the pope, the king of Spain, and the republic against the Turks. After this he was created patriarch of Jerusalem, president of the inquisition, and cardinal. In 1591, he was unanimously elected to the popedom, when he took the name of Innocent IX. He immediately projected grand plans of improvement, of an ecclesiastical and economical nature, none of which did he live to execute. He died in the second month of his pontificate, at the age of seventy-two.

INNOCENT X., pope, was born at Rome about the year 1575, where he was educated and brought up to the profession of the civil law, of which he was admitted doctor when he was only in his twentieth year. He obtained many instances of preferment in the church, and, in 1627, a cardinal's hat was presented to him by pope Urban VIII. He was next made prefect of the ecclesiastical immunities, supreme judge of the inquisition, and protector of the kingdom of Poland. On the death of Urban he was elected pope; he had already carried on an illicit commerce with his brother's widow, Donna Olympia Malachini, to whom he now abandoned himself; the administration of his temporal affairs, and the government of the church. All benefices, all employments, whether ecclesiastical, civil, or military, were disposed of by her to the highest bidders, without any regard to friendship or merit, or to the character of the purchasers. She induced the pope to forget all sense of right and wrong when it interfered with her wishes. In 1645, upon the application of the Dominicans, who were associated with the Jesuits in the mission to China, Innocent condemned the indulgence which the Jesuits had shewn to the Chinese idolatrous. The most remarkable transaction of his pontificate, was his condemning, by a bull, in the year 1653, the five propositions selected by the Jesuits from Janfenius's "Augustinus." He died in 1655, about the age of eighty-one, having filled the papal throne little more than ten years.

INNOCENT XI. was born at Como, in the duchy of Milan, in the year 1611. He was the son of a rich banker, and his first profession was that of a soldier, in which he distinguished himself by his gallantry. Quitting the military character he embraced the ecclesiastical profession, and

went to study at Naples, where he was admitted to the degree of doctor. Having filled, with high reputation, several offices in the church, he was raised to the purple in 1645, and, in 1678, he was elected to the papedom. He began his high career with abolishing abuses, and suppressing many gross superstitions then prevailing in the church of Rome. He likewise attempted, by wise institutions and judicious regulations, to reform the manners of the clergy, and to stem the torrent of licentious morals among the laity. In 1677, he suppressed "the right of asylum," enjoyed by foreign ministers at Rome, extending much farther than their places, the immunities of which it was not designed to violate. Most of the ambassadors from foreign courts readily acquiesced, but the minister from the court of France refused to submit to it, and the pope, unwilling to enter into a contest with Lewis XIV., allowed his ambassador to enjoy his ancient privileges. He had now a contest with the French king, about the right of disposing of benefices and church lands claimed by that monarch, and confirmed to him by an assembly of the clergy, which nearly terminated in a separation of the Gallican church from the Roman communion. It was on this occasion that Lewis summoned the famous assembly of bishops, which met at Paris in the year 1682, and drew up the four celebrated propositions declaring the power of the pope to be merely spiritual, and inferior to that of a general council, and maintaining the inviolability of the rules, institutions, and observances of the Gallican church. Innocent died in 1689, having presided over the Roman see twelve years and a half. He was virtuous and pious, but without pretensions to learning. His zeal for the reformation of abuses, the improvement of morals, and the restoration of church discipline, has given him a rank among the best of the popes.

INNOCENT XII., pope, originally named Anthony Pignatelli, was descended from an illustrious family at Naples, and born there in the year 1615, and succeeded to the papedom in 1691, as successor to Alexander the VIIIth. In imitation of the example of pope Innocent VII. he applied himself to the reformation of the church and court of Rome. He was unwearied in his endeavours to reform the corrupt manners of the clergy, which were not wholly unsuccessful, though he found that the entire accomplishment of the Herculean task was a consummation, which all his prudence and resolution were unable to effect. He was anxiously devoted to the interests of the poor, and the wealth which many of his predecessors had been accustomed to accumulate, or to bestow on worthless relatives, he devoted to the public benefit, employing it in the erection of hospitals, and other useful institutions, and particularly in the improvement of the ports of Anzio and Nettuno. Innocent died in the year 1700, at the advanced age of eighty-five, after presiding over the church about nine years. He had rendered himself universally respected by his talents, and beloved on account of his many virtues.

INNOCENT XIII., pope, formerly named Michael-Angelo Conti, son of Charles Conti, duke of Poli, was born at Rome in the year 1655. He rose successively to the highest offices in the church, till at length he was elected successor to Clement XI. in the papal dignity, in the year 1721. He died in 1724, leaving behind him a character for great wisdom, virtue, and learning. When a cardinal he distinguished himself above most of the members of the sacred college; but the infirmities to which he had been some years subject, prevented him from distinguishing his pontificate by any actions which are worthy of being recorded. As authorities for the foregoing articles, see Bower's Hist. of the Popes; Moreri, Gibbon, &c.

INNOCENTS DAY, the name of a feast celebrated on the twenty-eighth day of December, in commemoration of the infants murdered by Herod.

Heretofore it was the custom to have dances in the churches on this day, wherein were persons, who represented bishops, by way of derision, as some surgeons of the episcopal dignity; though others, with more probability, suppose it done in honour of the innocence of childhood. See *EPISCOPUS puerorum*.

By a canon of the council of Cognie, held in 1260, these were expressly forbidden; but they were not wholly suppressed, at least in France, before the year 1444, when the doctors of the Sorbonne addressed a spirited letter on this subject to all the bishops of the kingdom.

INNOMINATA ARTERIA, in *Anatomy*, the first large trunk sent off from the arch of the aorta. See *ARTERY*.

INNOMINATA glandula, the ischiyrenal gland. See *EYE*.

INNOMINATI, *Gli Innominati*, *Anonymi*, persons who have no names, a title by which the academists of Parma distinguish themselves.

Most cities in Italy have an academy, and each has its proper name. Thus those at Parma entitle themselves *Gli Innominati*, as if it was their character to have no name at all.

INNOMINATUM, Os, in *Anatomy*, the large bone composing the chief part of the sides of the pelvis, and receiving the articulation of the lower extremity. See *EXTREMITIES*.

INNOVATION, in *Law*. See *NOVATION*.

INNUENDO, of *innuo*, *I noo*, or *besoon*, is a word frequently used in writs, declarations, and pleadings, to ascertain a person or thing which was named, but left doubtful, before; as, he (*innuendo* the plaintiff) did so and so; mention being before made of another person. In common observation or writing, an *innuendo* denotes an oblique hint, or dilant reference; in contradistinction to a direct and positive charge.

INNY, in *Geography*, the name of two rivers in Ireland; one which rises in the county of Westmeath, and having passed through Loughs Derveragh and Iron, forms a boundary between this county and Longford, for several miles, after which it crosses the southern part of the latter, and flows into Lough Ree, an expanse of the Shannon; the other is a mountain stream in the barony of Iveragh, Kerry, which empties itself into Ballin Skelg's bay.

INOCARPUS, in *Botany*, from *ino*, *no*, a fibre, or nerve, and *carpus*, a fruit, because the drupa of this genus is composed of fibres or nerves. *Scircus* 277. *Forster*. *C. n.* 33. *Linn. Suppl.* 35. *Thunb. Nov. Gen.* 45. *Willd. Sp. Pl.* v. 2. 624. *Mart. Mill. Dict.* v. 2. *Juss.* 152. *Lamarck. Dict.* v. 3. 253. *Illustr. t.* 362. *Cials* and *order*, *Dicardaria Monogymia*. *Nat. Ord.* *Dumosa*, *Linn. Sapota*, *Juss.*

Gen. Ch. Cal. Perianth or one leaf (empanulate, according to Thunberg) in two, roundish, nearly equal ligaments. *Cov.* of one petal, tubular; tube cylindrical, longer than the calyx; limb longer than the tube, divided into five, linear, acute, undulate, often reflexed segments. *Stam.* Filaments ten, very short, inserted into the tube; the lower ones alternate; anthers ovate, twin, erect. *Pist.* Germen oblong, hairy, superior; style none; stigma a high-low point. *Peric.* Drupa ovate, incurved, compressed, large, single-seeded. *Seed.* A nut composed of woody fibres; kernel oval, compressed.

Ess. Ch. Calyx biid. Corolla funnel-shaped. Stamens in a double row. Drupa single-seeded.

1. *L. edulis*. *Willd. Sp. Pl.* v. 2. 624. (Gujanus; *Rumph. Amboin.* v. 1. 170. t. 65) A native of the Society, Friendly,

and

and New Hebrides Islands, in the South seas, and also of Amboina. Forster describes this as a lofty tree, having a trunk as thick as a man's body, with a brown chinky bark. Branches woody, spreading, variously divided. Leaves ovate-oblong, scarcely cordate, netted with abundance of veins. Flowery dusky white, scarcely half an inch in length. From Cook's last voyage we learn, that the nuts of *Inocarpus* are called *E-ijf*. The kernel of these, which is kidney-shaped, and about an inch in diameter, is eaten roasted by the natives. It is sweetish, but less pleasant than the chestnut, harder, and not so farinaceous. The bark is astringent, and used in the dysentery. In New Guinea, they smear their arrows with the expressed resinous juice.

INOCULATING, in Gardening, the art or practice of inserting the buds of trees of the same kind into their stocks or other parts. It is a sort of grafting which is often had recourse to in the summer season for raising different kinds of trees and plants, as it frequently succeeds better than that of the common method. It is usually executed in the manner described below. A sharp knife, with a flat haft for the purpose, and proper cuttings of the trees designed to be propagated being provided, a choice should be made of a smooth part of the stock which is to be inoculated; five or six inches from the ground, where intended to be dwarf, but when for a standard at the height of five and a half or six feet; and a horizontal cut made across the rind of the stock, as well as a slit, about two inches in length, downwards from the middle of that cut, taking care not to go deeper than the thickness of the bark, lest the stock be wounded; then having the cutting in readiness, the leaf should be cut off from the bud, leaving the foot-stalk remaining, but taking off the bud lengthways somewhat longer than the slit in the stock, with part of the wood adhering to it; which being done, slip the wood from the bark with the knife by means of a sudden jerk, observing whether the eye of the bud be left or not, as such buds as lose their eyes in stripping are useless: as soon as this has been done, the bark should be gently raised on each side of the slit in the stock with the handle of the knife, and the bud inserted into it, being careful to place it smooth between the rind and the woody part of the stock, cutting off that part of the rind of the bud which may happen to be too long for the slit: having thus exactly fitted the bud to the stock, they should be tied closely round with wetted strong bafs, taking care not to pass any ligature round the eye of the bud, which must always be left open and at liberty. In the course of three weeks, or a month, the buds will require to be loosened of the bandage, and which, if not executed in time, will be highly injurious to them; but they should not be wholly divided of the binding, it being proper to tie them again slightly, by which the bark of the stock will be prevented from becoming open, which sometimes takes place, and the bud is thereby greatly injured, if not wholly destroyed.

There is nothing further required until the following March, when the stock should be cut off about three inches above the place of inoculation, sloping it the contrary way to the bud. This length of stock left is beneficial in fastening the shoot which springs from the bud, and which might otherwise be blown out by strong winds: in the autumn following, however, it should be cut away quite close just above the bud, that the wounded part may the more readily become barked over.

It may be noticed, that the most proper season for this sort of work is, from the middle of June until the middle of August, according to the forwardness of the season, and the particular sorts of trees to be increased; but it may be easily known by trying whether the buds will come off well

from the wood or not. The most general rule is, when the buds are found to be formed at the extremity of the same year's shoots, which is a sign of their having finished their vernal growth. The first sort commonly inoculated is the apricot, and the last that of the orange-tree, which should never be done until the middle of August.

In doing this sort of work, choice should be made of cloudy weather, as when done in the middle of the day, in very hot weather, the shoots perspire so fast as to leave the buds destitute of moisture; nor should the cuttings be taken off from the trees long before they are used; but if fetched from some distance the leaves should be cut off, but all the foot-stalks left, and then wrapped up in wet moss, and put in a tin-box to exclude the action of the external air upon them. But the practice of throwing cuttings into water is highly improper, as it saturates the buds so with moisture, that they have no attractive force left to imbibe the sap of the stock, for want of which they very often miscarry, and disappoint the operator.

It has been remarked by Mr. Forfyth, that when the pear-trees which are grafted in the spring have not taken, he would advise the cutting them off a little below the graft at a joint or bud. The tree then throws out a great number of healthy shoots; all of which should be rubbed off, except so many as are sufficient to fill the wall; nailing those up to prevent the wind from breaking them. About the latter end of July the shoots will be fit to inoculate, which should then be done, leaving a little of the wood on the inside of the bud when inserted into the stock, and rubbing in some of the composition, tying on the bafs at the same time.

Having grafted some summer bonchrétiens with the bergamot de Pasque (or Easter bergamot) and pear d'Auch in the spring, most of which failed, he cut them off below the grafts, and in July following they had produced shoots from five to six feet long, which he inoculated in the latter end of that month with the before-mentioned sorts, which all took. About the beginning of September he ordered the bafes to be slackened; which being left too loose, the barks began to separate. He then made them be tightened, letting them remain till the following spring. About the beginning of April, when he saw the buds begin to shoot, he cut the shoots near to the buds; but finding many where the bark had not united, and some of the eyes apparently dead, he took a sharp penknife and cut out all the decayed bark, rubbing in some of the composition in a liquid state, till the hollow parts were filled up; he then smoothed it off with the finger even with the bark of the stock. He also rubbed some of the composition over those eyes that were in the worst state, being quite black, but with very little hope of recovery. "To his great astonishment, many of those which seemed perfectly dead recovered, and by the middle of July had shoots from five to six feet long (many of the shoots which took well having fruit-buds formed for next year), and covered a space of wall larger than a young tree would have done in eight years; all the cavities where he cut out the dead bark and applied the composition were, in the course of the summer, filled up with sound wood, and the bark between the stocks and grafts perfectly united.

"Three years ago he inoculated some brown beurrés and cranes with pear d'Auch, one of which now covers a wall sixteen feet high and fifteen long, and has more fruit on it this year than a maiden tree would have produced twenty years after planting." But he "never recommends inoculating or grafting of old trees, except when bad sorts, or more of any sort is wanted for a supply; in that case he would recommend to inoculate or graft with pear d'Auch, colmars,

INOCULATION.

colmars, and winter bonchrétians, which keep much longer than beurrés, crafanes, &c."

But for standards that have been grafted in the spring and have misfed, he advices that they should be cut below the graft, as, when so treated, they throw out a great number of shoots, which should by no means be too soon thinned, as in that case they will be liable to be broken by the wind. The weakest shoots may be begun to be taken off about the latter end of May or beginning of June. About the middle of the latter month they will have acquired considerable strength, then thin them, leaving as many strong regular shoots, and of those nearest the top of the stem, as will form a handsome head. If the stem be very strong, it will be necessary, perhaps, to leave more than are intended to be inoculated on purpose to receive the sap, which will flow in great abundance from a large trunk, and without this precaution be apt to burst the shoots. He has often seen shoots as large as his arm burst by a superabundance of sap. When that is likely to happen, the best thing is to scarify the shoots and rub a little of the composition into the wound. See BED, BEDDING, and GRAFTING.

INOCULATION, among *Gardeners*, signifies an operation in the management of some sorts of fruit trees, which is frequently denominated *budding*. See **BUDDING**, and the preceding article.

INOCULATION, in a *surgical and medical sense*, denotes the practice of designedly communicating from one person to another certain diseases, which is generally done by introducing some of the infectious matter into a small wound, or puncture, made with the point of a lancet. The common purpose of such operation is to diminish the severity and peril of a distemper, which, taken in a casual way, proves exceedingly destructive, and the hazard of catching which, at some period of life or another, is very considerable. A chief object of the plan is also, in general, to render the patient incapable of being again affected by the dreaded contagion. Hence inoculation is seldom performed, but for a disease with which the human constitution can only be affected once, as the small-pox and cow-pox. The latter, which is so mild as scarcely to deserve the name of a disease, being only communicable by contact, and existing originally no where except upon the teats and udders of cows, would never perhaps have troubled any other persons than a few milkers, had it not been for the discovery of the important fact, that persons who had undergone the complaint were made completely unsusceptible of the small-pox contagion. The cow-pox inoculation has now, therefore, been very generally substituted for that with variolous matter, and the beneficial consequences of this change are so truly important that the Jennerian discovery will ever be regarded as a most memorable event, not only in the annals of medicine and surgery, but in the history of the world. See **COW-POX** and **VACCINATION**.

Although it is our intention to devote this article to the history of the small-pox inoculation, we may here remark, that the measles have been propagated by inoculation. Dr. Home, of Edinburgh, was the first who actually made the experiment. Not being able to collect either matter, or a sufficient quantity of broken cuticle at the time of desquamation, to produce the disease, he drew blood from a superficial cutaneous vein, where the eruption was thickest. Cotton was then dipped in this blood, and applied to a wound made in each arm of the person about to be inoculated. In this manner Dr. Home inoculated twelve persons. The eruptive fever generally began six days after inoculation; the symptoms were less severe; the cough was milder, or entirely absent; and the inflammation of the eyes was trifling.

Notwithstanding Dr. Home's success, inoculation for the measles is seldom or never practised, others, who have made the experiment, not having given reports equally favourable.

Inoculation for the plague has likewise been tried, in order to ascertain whether that distemper might not be rendered less fatal and less prevalent in particular parts of the world. In Egypt, Dr. Whyte inoculated himself with matter taken from the buboes of an infected person. The attempt failed twice; and the third proved fatal in three days after the commencement of the symptoms. See **DR. WILSON'S** Hist. of the Expedition to Egypt.

In the present state of our information, inoculation for the plague appears unjustifiable. It was ascertained in Egypt, that many of the convalescents took the plague a second time; nor, in all probability, does inoculation render this distemper milder. Indeed, what M. Sonnini observes, seems to lead to a contrary conclusion; for he mentions, that a Russian surgeon, who was a prisoner at Constantinople, with a number of his countrymen, took it into his head to inoculate these unfortunate men with the plague, under the idea of rendering the contagion less destructive; but the result was, that two hundred lost their lives, as well as the surgeon, who had also inoculated himself. See **Sonnini's Travels** into Greece and Turkey, p. 497.

The idea of intentionally imparting any kind of disease to the human body would appear, to persons unacquainted with the reason of the thing, equally extraordinary and cruel. But the design and utility of the inoculation for the small-pox are now so fully known among all classes of society, as scarcely to need explanation. When it is remembered, that the small-pox contagion has, at various periods, nearly depopulated extensive kingdoms, and occasioned greater devaluation than the most destructive wars, any measure, calculated to render milder so terrible a disease, must be looked upon as a discovery of the very highest importance. It has been estimated, that, upon an average, before the introduction of inoculation, one out of every six persons affected with the natural small-pox, or sometimes even a half, perished; but that the proportion of deaths, among such as have been inoculated in the most improved manner, does not amount to more than one in several hundreds. Besides this circumstance, we have to mention, that before inoculation became common, the small-pox frequently committed ravages like the plague, and the fury of the distemper was always dreadful whenever the contagion made its first visit to a country. If, then, we are to hail the small-pox inoculation as a general and momentous benefit to society, on the principles just now specified, with what joy and admiration must we behold the discovery of a complete security against the small-pox infection, in the new and perfectly safe kind of inoculation with vaccine lymph. The small-pox inoculation materially alleviated the calamities arising from that contagion, by making the disease milder, and lessening its mortality. But, still, the distemper was not infrequently seen in a severe form; at least one out of every three or four hundred inoculated died; and the countenances of those who survived were often miserably pitted and disfigured. On the other hand, the vaccine inoculation hardly ever produces any serious disposition, and being followed by no eruption, cannot deform the face. Its safety and efficacy are daily receiving more and more confirmation from all quarters of the world, and we have no doubt that, after prejudices have had time to subside, the small-pox inoculation will be universally superseded.

The original introduction of inoculation, however, will always constitute a most memorable event in history, and is

a subject too interesting to be omitted in our work. After a few observations on the commencement of the small-pox, we shall therefore endeavour to give some account of the rise and progress of the practice.

Origin of the Small-pox.—The small-pox, like the measles, and several other diseases, is produced by a matter *spécié*, or, in other words, by a specific contagion, and it has originated from causes so perfectly incomprehensible, as to set at defiance all rational conjecture. From the silence of the ancient Greeks and Romans respecting a disease so very fatal, and of such peculiarity, as the small-pox, it is reasonable to conclude, that it date is subsequent to their times, and, consequently, that the world existed several thousand years before it was visited by this dreadful pestilence. Rhazes, an Arabian physician, who practised at Bagdad in the beginning of the tenth century, is one of the oldest writers on the small-pox, whose works are still extant. On this subject, however, he quotes several of his predecessors, the most ancient of whom is Ahron, who was a priest and physician at Alexandria, when that city was besieged by the Saracens. Ahron's book has, therefore, been deemed the first in which any notice is taken of the small-pox. The introduction of the disease, at that time, into Egypt, might have been by the armies of Amrou, which, in the kaliphate of Omar, poured in thither from Arabia.

The celebrated Dr. Friend conceived, that the Arabians might originally have derived the contagion from some of the more distant regions of the East, and Père D'Entrecolles, a missionary jesuit at Pekin, informs us, that, upon looking over some Chinese books, he found the small pox mentioned in them as a disease known in very ancient times. See "Lettres édifiantes et curieuses," tom. 21. p. 33. ed. 1781.

Mr. Holwell, a Bengal surgeon, has likewise endeavoured to confirm the accuracy of Dr. Friend's opinion, observing, that, "at the period in which the Aughtorrah Bhade scriptures of the Gentoos were promulgated, (according to the Paganis 3366 years ago,) this disease must then have been of some standing, as the scriptures institute a form of divine worship, with priests, or offerings, to a female divinity, styled by the common people Coote ka Tagooran, the Goddess of Spots, whose aid and patronage are invoked during the continuance of the small-pox season; also in the measles, and every cutaneous eruption that is in the smallest degree medicinal. See "An Account of the Manner of inoculating the small-pox in the East Indies," p. 7.

On the other hand, Dr. Woodville is unwilling to admit, that the supposed antiquity of the small-pox in India is at all proved by what DE trecolles and Mr. Holwell have observed. Her remarks, that the former has adduced no direct fact, in proving, that the disease was really described by the ancient Chinese physicians; while Mr. Holwell's reasons are not conclusive, not only as founded on the verity of the Hindu chronology; but because the Goddess of Spots was not supposed to preside over any particular eruptive disorder, but over all cutaneous affections that were medicinal. Besides, as Dr. Woodville justly notices, had the small-pox existed in India more than 3366 years, it could not fail to have been transported in early times both to the Greeks and Romans, by the constant intercourse, which they had by maintained with the Indian nation.

Dr. John James Reiske mentions, that, in an old Arabic MS. preserved in the public library at Leyden, he read, that, in the year of the birth of Mahomet, the measles and small-pox made their first appearance in Arabia. Disp. inaug. Lond. Bat. 1746. Now it appears also from some Arabian

annals, procured by that adventurous traveller, Mr. Bruce, that the era of the first appearance of the small-pox in Arabia attaches to that of the siege of Mecca, and that the Abyssinian army, commanded by Abrahah, was the first victim of its fury. Mr. Gibbon states, that the siege of Mecca happened only two months before the birth of Mahomet; a fact, which Dr. Woodville points out as deserving very particular notice; for if the year of the birth of Mahomet be ascertained to be also that of the siege of Mecca, the Arabian MS. cited by Dr. Reiske, and that written by Hameedy, the Arabian author mentioned by Mr. Bruce, perfectly coincide. According to Gibbon, Mahomet was born A.D. 569; which, on the above independent authorities, is to be considered as the period when the small-pox first made its appearance in Arabia.

From this era, to that of the conquest of Alexandria in 642, no traces of the existence of the small-pox are to be discovered; but the disease certainly spread into that city at the time it was invaded by the Saracens; and, as Dr. Woodville states, it may therefore be supposed to have been brought into Egypt by the Mahometan army, which, six years before, had invaded Persia and Syria, where this destructive pestilence probably had already made a considerable progress.

After this period, to the revival of literature in the 15th century, succeeded that general state of ignorance and barbarism, during which the present subject, in common with many others, is so obscured in the darkness of the times as to elude the most diligent research.

It is manifest from the works of Rhazes, that many of the Arabian physicians had written on the small-pox before the 10th century; and notwithstanding the Saracen history is silent on the ravages which must have accompanied the general diffusion of the small-pox during the empire of the caliphs, the progress and prevalence of the distemper are to be inferred from collateral evidence. Thus, the caliph Yezid, who died in 683, is mentioned as being pitted with the small-pox; and the caliph Abul-Abbas Alfassah actually died, in 753, of this disease.

The time when the small-pox contagion first spread into Great Britain is involved in doubt. Most writers suppose that the distemper was imported into Europe by the crusaders, upon their return from the Holy Land in the 13th century. The improbability of this statement is insisted upon by Dr. Woodville, who adverts to the known activity of variolous matter, the long time it retains its infectious quality, and the unlikely circumstance of the small-pox prevailing six or seven centuries over various parts of Asia, having free intercourse with Europe, before it was conveyed into this kingdom. It is indeed surprising, that the dreadful effects which must have attended the first introduction of the small-pox into this as well as any other country, have escaped the notice of all our historians and medical writers. But, by examining some of the MSS. of the Harleian and Cottonian collections, preserved in the British Museum, and bearing indubitable evidence of having been written before the year 900, Dr. Woodville succeeded in tracing the existence of the small-pox in our island, and on the neighbouring continent, long before the crusades took place. In these curious records the word *variole* occurs several times in the same sense in which it is now used. We likewise learn from the MSS. that the people in those early times lived in continual dread of the small-pox, as several prayers, exorcisms, and incantations, to which they had recourse for preservation, are to be found. Dr. Woodville refers us to No. 587, of the Harleian Catal. vol. i. and Bibl. Cotton. Caligula A. 15. No. 30.

INOCULATION.

The first British medical writers of any note were those of the 13th century, and they, as well as all their successors, from John of Gaddesden to the immortal Sydenham, &c. have bestowed much attention on this important dilemma.

History of Inoculation of the Small-pox.—The exact part of the world where inoculation was first adopted is quite unknown; nor do we possess any information of the circumstances which originally suggested the benefit that might result from the practice. From the Arabian physicians having been the first informed of the nature and treatment of the small-pox, it has been supposed that inoculation had its origin among them. (See Second Memoire sur l'Inoculation par M. de la Condamine.) Avicenna, who lived at Bokhara on the east coast of the Caspian sea, or his disciples, have in particular been suspected of being the authors of this valuable invention, in consequence of the countries between the Caspian and Euxine seas being the supposed centre from which inoculation spread to other places. Dr. Woodville, however, considers this conjecture as very ill-founded. He contends that we have no evidence that any of the people near the Caspian sea were the first practitioners of inoculation. Had the invention originated in this part of the world, the Tartars could hardly have been so ignorant of the practice, as, according to D'Entrecolles, they actually were in the year 1724. Nor is it probable that the method spread from west to east; for as the same author has observed, inoculation is more ancient in the eastern parts of China than it is in the western provinces of that empire. Dr. Woodville remarks that inoculation was certainly first introduced into Constantinople from the Morea; but as the event did not take place till towards the end of the 17th century, we may conclude, that, had the art been practised for many ages, at so short a distance from that metropolis, it would have been known there much sooner. Besides, in various countries, very remote from the Caspian sea, it is proved to have been an immemorial usage.

Inoculation was introduced into London as a foreign invention, and, from its success upon the younger branches of the royal family in 1723, became the subject of public conversation, when, to the great surprize of the learned, several communications proved that it was already a practice known in South Wales, where it had existed under the denomination of buying the small-pox as far back as tradition could be traced. The manner of inoculating, or buying the small-pox, here alluded to, was subject to variety. Some persons either rubbed the matter, taken from the pustules, when ripe, on several parts of the skin of the arms, &c. or pricked such parts with pins, or other pointed things, first infected with the same matter. Some scraped the skin with a knife, until the blood began to flow, before they applied the variolous pus. Others produced the distemper by holding a certain number of dried pustules, for a considerable time, in the palm of the hand. (See the Letters of Dr. Williams, Mr. Owen, and Mr. Wright, in the Philosophical Transactions for 1722, and Dr Jurin's account of the success of inoculation in 1723.) The inhabitants of the Highlands of Scotland have also for many ages performed a kind of inoculation by tying worsted threads, moistened with variolous matter, round the wrists of their children. (Monro on Inoculation in Scotland.) The same custom likewise prevailed in many other parts of Europe, Asia, and Africa; and, what is highly curious, the practice was, in several of these distant countries, termed *buying the small-pox*, just as it was in South Wales; for it was superstitiously imagined that inoculation would not produce the proper effect, unless the person from whom the variolous matter was taken received a piece of money, or

some other present, in exchange. The practice of buying the small-pox has been found to have prevailed from time immemorial, not only in South Wales, but also at Naples, Pavia, in Auvergne and Perigord, and among the peasantry in many parts of Germany, Denmark, and Sweden. See Second Mem. sur l'Inoculation, par M. de la Condamine; Murray's *Historia Infectionis Variolarum in Succia*; Schultz's Account of Inoculation, &c.

In Barbary and the Levant the variolous matter was also purchased, and inserted in a small incision made in the fleshy part of the hand between the thumb and the fore-finger. (See Shaw's Travels into Barbary and the Levant.) In Tripoli, Tunis, and Algiers, an incision was made on the back of the hand, between the thumb and fore-finger, and a little of the variolous matter put into the wound. According to Dr. P. Ruffel, inoculation is so ancient in these last kingdoms that nobody remembers its first rise; and it has been practised not only by the inhabitants of the towns, but also by the wild Arabs. (See Phil. Transf. vol. lvi. p. 140.) It appears, moreover, from this gentleman's account, that buying the variolous matter and inoculating have been ancient customs at Bagdad, Mosul, and Baffora, in Armenia, at Damascus, and all along the coast of Syria and Palestine. The Arabs assured Dr. Ruffel that the puncture might be made indifferently in any fleshy part; but he mostly found the mark between the thumb and fore-finger. Some of the Georgians had been inoculated in the same part, though most of them in the fore-arm. Some of the Armenians had been inoculated in both thighs; but the greater part, like the Arabs, bore the mark upon the hand.

D'Entrecolles, by obtaining access to several medical books at Pekin, discovered one in which an account was given of the introduction of inoculation into China. The author of the book here alluded to, lived in the latter part of the dynasty of Ming. Hence it has been concluded that inoculation has not yet been practised in China 200 years. But in Hindoostan the custom can be traced much farther back. The methods of practising this art by the Chinese and Hindoos are also so widely different, that they cannot have been derived from the same origin. The Chinese take from two to four dried variolous pustules, or scales (according to their size), between which they place a small portion of musk; the whole is then wrapped up in cotton, and introduced into the patient's nostril. The scales before used are kept in a close jar for several years, and when the Chinese are obliged to employ recent pustules, they think it necessary to correct the acrimony of the matter, by exposing it to the steam of an infusion of the roots of scorzonera and liquorice. They sometimes reduce the dried scales into powder, and form them into a paste for the purpose of inoculation.

Dr. Woodville very properly observes, that the application of variolous matter, wrapped in cotton, within the nostrils, must be an exceedingly precarious mode of communicating the small-pox, and may perhaps afford a reason why inoculation in China is less successful than in other countries; for if the matter acts in the way of inoculation, a troublesome inflammation of the Schneiderian membrane must ensue; and, should not this take place, the variolous effluvia, by being inhaled into the lungs, will produce the natural small-pox.

In Hindoostan inoculation is performed by a particular tribe of Bramins. They do not refuse to inoculate on any part; but, in males, they prefer the outside of the arm, midway between the wrist and the elbow, and, in females, the shoulder. The operator first rubs the part with a dry cloth for eight or ten minutes, and then slightly pricks it

INOCULATION.

at many points. He next takes a small pledget of cotton, charged with the variolous matter, moistens it with two or three drops of the Ganges water, applies it to the punctured part, fixes it there with a bandage, and orders it to be kept on for six hours. The bandage is then to be taken off, the pledget being left to fall off of itself. The matter in the cotton is always taken from pustules of the preceding year fresh matter, and such as is the product of the natural small-pox, being considered improper. See H. Bell's Account of the Manner of inoculating in the East Indi s.

It was immediately from Constantinople that the English first derived a full knowledge of the advantages of inoculation. The beneficial consequences of the practice among the Turks, were detailed by Dr. Emanuel Timoni, communicated by Dr. Woodward to the Royal Society, and published in the Transactions of that body for the year 1714. The Byzantine mode was to take some fresh variolous matter in a glass vessel, and drop it on punctures or scratches made with a needle or lancet in any fleshy part, but especially in the arm and fore-arm. The matter, which was dropped on the punctured place, was well blended with the drops of blood issuing from the wounds, by means of a blunt stile or ear-picker. The part was then kept covered with a walnut shell for a few hours, in order to prevent the matter from being rubbed away.

Another account of the Byzantine mode of inoculation was afterwards published by Dr. Pylarini in the same volume of the Transactions of the Royal Society for 1716. But the year before this gentleman's observations appeared, surgeon Kennedy had printed an account of the new method of inoculating at Constantinople, in his "Essay on External Remedies," and he seems to be the first British author on the subject of inoculation. Soon afterwards, lady Mary Wortley Montague, the wife of the English Ambassador at Constantinople, in her letters, confirmed the accounts of the remarkable manner in which the severity and mortality of the small-pox were diminished among the Turks by means of inoculation; and, in one of her epistles from Adrianople, she expressed her intention to try the experiment upon her own little son. See vol. ii. let. 31.

The mode of performing the operation at Constantinople gradually became more and more simple. We learn from Pylarini, that, in 1707, incisions were made in the forehead, cheeks, chin, and also in the extremities, for the purpose of inoculation. Timoni likewise, twelve years afterwards, mentions, that the operator is to make several little wounds in one or more places of the skin, and these succeed best in the fleshy parts of the arm. In the year 1717, the insertion of variolous matter, at a simple puncture in each arm, seems to have been the prevailing method of inoculation, as will appear by the following relation: Mr. Maitland, surgeon to the honourable Wortley Montague in his diplomatic character at the Ottoman court, informs us, that the ambassador's lady, being conversed of the advantages of inoculation, determined that her only son, then six years of age, should undergo the operation. For this purpose, she desired Mr. Maitland to procure the variolous matter from a proper subject, which being done, an old Greek woman, many years in the constant habit of inoculating, was employed to insert it. "But (says Mr. Maitland) the good woman went to work so awkwardly, and, by the shaking of her hand, put the child to so much torture with her blunt and rusty needle, that I pitied his cries, and therefore inoculated the *other arm* with my own instrument, and with so little pain to him, that he did not in the least complain of it." (Maitland's Account of Inoculating the Small-pox, p. 7.) The consequent disease was very mild, and, if the mode of buying the small-

pox be excepted, this inoculation, which was done at Pera, near Constantinople, in March 1717, was the first ever practised upon any English subject.

The inoculation of the small-pox was first regularly adopted in England in the month of April 1721. The practice, in all probability, would not have been so soon pursued by the faculty, had it not been for the enlightened and philo-sophic mind of lady Mary Wortley Montague. After this celebrated lady had witnessed the good effects of inoculation upon her son at Pera, she determined also to try it upon her daughter, then an infant three months old; but for certain domestic reasons, the operation was at that time deferred, so that this child was fortunately reserved to be the first example of inoculation in England, which was done by Mr. Maitland, in April 1721. According to Dr. Woodville, writers have universally erred, in dating this event in April 1722, and making it subsequent to the inoculation of the mal-factors at Newgate. He notices that Mr. Maitland's pamphlet, in which all the circumstances are stated, was published in February 1722, as appears by the advertisement prefixed to the work. Therefore Mr. Maitland, in saying April *last*, could mean no other than that in the year 1721. Besides, Mr. Maitland expressly mentions, that this was the first example of inoculation in England.

After the successful result of this case, Mr. Maitland performed the second inoculation ever done in this country, in the month of May 1721, upon the son of Dr. Keith, and with the best effects. Notwithstanding these confirmations at home of the favourable accounts of the practice which had been already received from Constantinople, and notwithstanding the firm and powerful patronage which the Byzantine inoculation met with in lady Mary Wortley Montague, it is a fact, that such was the suspicious caution with which the method was received, that several months elapsed before a third trial of it was made in London. Indeed, the very next experiment that was undertaken strikingly evinces the dangerous light in which inoculation was still regarded; for it was determined that several culprits in Newgate, who had forfeited their lives to the laws of their country, should, on submitting to be inoculated, receive full pardon by the royal prerogative. Six condemned criminals were inoculated by Mr. Maitland, on the ninth day of August 1721, in the presence of several eminent physicians and surgeons. These malefactors all obtained a remission of their sentence on very easy terms. None of them had the disease severely, and one, who had already had the small-pox, was of course not affected a second time. A seventh criminal, a young woman, was next pardoned, on condition of having the Chinese method of inoculating tried upon her, at the wish of Dr. Mead. Consequently, some cotton, moistened with variolous matter, was introduced in her nostrils; the distemper followed in a mild form; but the patient suffered violent pains in her head, from the commencement of the eruption to the maturation of the pustules.

After these public proofs of the safety and advantage of inoculation, objections and doubts were still adduced against the method. Some considered the cases too few, while others, in consequence of the small number and mildness of the pustules, thought it doubtful whether the genuine small-pox had been at all communicated. Hence, in the course of the following six months, Mr. Maitland inoculated only six subjects, who all recovered, though two, it must be confessed, had the small-pox so severely, as to be for some time in danger. See Maitland's Account of Inoculating the Small-pox, 1722.

Maitland's publication was immediately afterwards followed by a letter from Dr. Nettleton, who, in December

INOCULATION.

1721, and the two subsequent months, had inoculated with success upwards of forty persons at Halifax, in Yorkshire. This relation influenced the public very considerably in favour of the new mode of communicating the small-pox.

Early in the spring of the year 1723, inoculation began to be adopted in various parts of England; and by order of her royal highness the princess of Wales, it was practised first upon six, and afterwards upon five charity children, belonging to the parish of St. James's. The success of these trials induced her royal highness to have the princesses Amelia and Carolina inoculated on the nineteenth of April 1723, by surgeon fergeon Amaryd. Both these younger branches of the royal family passed through the small-pox, in a very favourable manner; and inoculation, in consequence of this illustrious example, was now making a rapid progress: when unfortunately the practice received a great check, by the death of the earl of Sunderland's son, and by that of lord Bathuril's servant, after being inoculated. A Miss Rigby also died, about eight weeks after her inoculation, making the third death. Therefore, out of 182 inoculations, in 1721 and 1722, three died; or nearly one in sixty.

About the time when the first death happened in London, accounts were received in town, stating that the practice had been tried to a much greater extent in New England. It appears that, after an absence of nineteen years, the small-pox had broken out with a great mortality at Bolton, in April 1721. This induced the Rev. Mr. Mather to publish the account of inoculation, as related in the Philosophical Transactions by Timoni and Pylarini. This publication, which was distributed to all the medical practitioners at that place, was the means of inciting Dr. Boylton to commence the practice of inoculation upon his own child, and two negro servants, at the latter end of June 1721. In the course of six months, he inoculated in and about Boston 244 persons. Of this number six died.

The reports which came from New England, were employed with great exaggeration by the opponents of inoculation, who seized with avidity every circumstance that might have the least tendency to retard the progress of the improvement.

During 1723, the practice of inoculation became much more general in England, the number of inoculated this year far exceeding the numbers in the two preceding years taken together. It amounted to 292, which, added to 182, makes the whole number of inoculations in the years 1721, 1722, and 1723, to be 474, of which number, according to Dr. Jurin, nine died.

It deserves notice, that several of these nine cases were not generally admitted as deaths altogether in consequence of inoculation. But even allowing that they were so, the chance of recovering from the inoculated small-pox must appear infinitely greater than from the casual. For it was proved, that at this time, out of 14,559 persons who had been affected with the natural small-pox, 2351 died; nearly one in six, or five out of thirty-one.

In 1724, there were only forty persons inoculated. Their royal highnesses prince Frederick and prince William, however, were in this small list. Dr. Jurin accounts for the seeming decline of inoculation this year, by the fact that people will not easily submit to a practice in which they apprehend risk, unless impelled by the dread of a greater danger. Now it appears that in 1724, the natural small-pox was much less fatal than in 1722 and 1723, and it is to this cause we are to refer the above small number of inoculations. That the practice had not fallen into disrepute is manifest; for Dr. Jurin informs us that in 1725 the natural small-pox was very mortal, and of course, people being frightened, resorted to

inoculation again in a larger number. Of the above-mentioned forty, one is recorded to have died.

In 1725 and 1726, 256 persons were inoculated, of which number four died.

In the years 1727 and 1728, the practice of inoculation did in reality begin to decline; for, though the small-pox was very prevalent and fatal, only 124 inoculations took place in these two years, and three of the cases proved fatal.

We find that up to 1729, 897 persons had been inoculated in England, of whom seventeen are reported to have died. But on the other hand, the records shew, that of 18,229 persons, who had been affected with the natural small-pox, during the first eight years of inoculation, 3008 died under the disease; or about one in six; whereas, the deaths by inoculation, admitting the utmost number contended for, does not exceed one in fifty. The reason why more died of inoculation at this early period of the practice than has been the case of late years, is justly ascribable to the better manner lately adopted of treating inoculated patients. Besides, formerly it was common to inoculate adults, in whom the disease is more disposed to assume a severe form than in children.

Inoculation was not regularly practised in Scotland till the year 1726, when Mr. Maitland performed this operation upon ten persons; but as one of these cases was unsuccessful, the practice was discontinued in that country for twenty years afterwards, and was not revived again without considerable difficulty. At Dumfries, indeed, where the casual small-pox had committed great ravages, inoculation was had recourse to in 1733; but in most other parts of North Britain the method was not introduced till 1753.

In Ireland, inoculation was first performed at Dublin in 1723. Twenty-five persons were inoculated in that and the three following years. Of this small number, three cases terminated fatally.

Inoculation at Hanover was first performed in 1724, by Mr. Maitland, upon his royal highness prince Frederick, and afterwards upon eight children of the Baron de Schullenberg. The example and success of these cases had the effect of establishing the practice in that country.

After 1729, inoculation was seriously on the decline in England; but it made considerable progress in the transatlantic world. In South Carolina, about the year 1738, not less than 800, or 1000 persons were inoculated, of whom only eight died. The account of this success contributed materially to revive the practice in Great Britain. In Philadelphia, likewise, inoculation proved soon afterwards still more favourable; and in St. Christopher's 300 slaves were inoculated, without the loss of one.

Such facts in favour of the practice, and the great fatality of the natural small-pox in Britain, soon led people to adopt inoculation more extensively than ever, and from the year 1758, this beneficial method may be regarded as having been completely and generally established, though partial opposition prevailed long afterwards.

In the year 1746, the institution called the Inoculation Hospital had its rise, though it was not at first so considerable an establishment as at present. Here the success of inoculation did not disappoint the hopes and zeal of its patrons; for out of 593 cases of persons successively inoculated, from the year 1751, only one proved unsuccessful.

In 1754, it was determined to inoculate the three royal children, who had not yet had the small-pox. In the mean time, his present majesty took the disease casually, so that only the prince Edward, and the princess Augusta, were inoculated.

INOCULATION.

inoculated. These great examples, and the public approbation of the practice declared by the College of Physicians, gained numerous advocates to the cause, which never afterwards lost ground, till the still safer and milder mode of inoculation with vaccine lymph was brought into notice by the immortal Jenner.

In France, Dr. Boyer is the first writer who has noticed inoculation, which he did in 1717. In 1723, the successful trials of inoculation in England were published at Paris by Dr. de la Cotte, and the consequence was a declaration by the physicians of that city, "that for the benefit of the public, it was lawful to make trials of inoculation." The practice was on the point of having a beginning in the hospitals, under the sanction of the duke of Orleans, the regent, when, unfortunately for the experiment, this nobleman died, and soon afterwards Dr. Hecquet published his "Raïsons de doute contre l'Inoculation." The sentiments contained in this publication, and in a thesis written at Paris in 1723, the reports of the ill success of inoculation at Boston, and the great mortality of the natural small-pox in London, in 1723, falsely ascribed to the new practice, soon brought the method into disrepute in France, and the design of trying it there was laid aside.

The French paid little attention to the subject again till 1752, when Dr. Buttimi, of Montpellier, published at Paris his "Traité de la Petite Verole communiquée par l'Inoculation." Two years afterwards, M. de la Condamine read his excellent memoir upon the advantages of inoculation, before a public assembly of the Royal Academy of Sciences at Paris. But, according to Dr. Woodville, the practice was not introduced into France till the 1st of April 1755, when, at the desire of M. Turgot, a child, four years old, was inoculated at Paris. On the 14th of May, M. Chastellux, aged 21, voluntarily submitted to the operation. About this time, Dr. Hoity, who had been attending the small-pox and inoculation hospitals in London, at the request of the French minister, published at Paris the following report:—"That out of 463 cases of persons last inoculated in the hospital, only one had been unsuccessful; whereas, in the Small-pox hospital, it appeared by the registers, that nearly one in four had died of the natural small-pox."—"That Mr. Ranby, principal surgeon to his majesty, had inoculated 1600 persons; and that Mr. Bell, pupil to Mr. Morand, had inoculated 903, without the loss of one."—"That in order to form a just comparative view of the fatality of inoculation and of the natural small-pox, it is only requisite to visit the two hospitals in London, the difference of their reports being so remarkable, that it must convince the most incredulous of the advantages of inoculation." Lastly, "with respect to the inoculation of other diseases along with the small-pox, that no instance of the kind has ever been produced; and that persons have been inoculated with variolous matter, taken from a patient affected with the venereal dilemma, yet have thereby received the infection of the small-pox only."

This statement had immense effect in promoting the introduction of inoculation into France; and in the year 1756, the family of the Duke of Orleans, and great numbers of the first rank, were inoculated by Drs. Tronchin, Hoity, and others. In 1758, the practice had diffused itself over various parts of France. The inoculated were not, however, very numerous, and one or two unsuccessful cases, joined with false reports, that some persons had taken the natural small-pox after undergoing inoculation, once more cast discredit upon the plan, and excited a violent controversy. The great fatality of the small-pox at Paris in 1763, being imputed to inoculation, the practice was forbidden by parlia-

ment. At length the faculty of physic, and that of theology, were called upon to decide, whether inoculation ought to be tolerated or proscribed. This measure served to increase the disputes; nor was it till a very late period that inoculation was extensively practised in France.

In Holland, inoculation was begun at Amsterdamm in 1748 by Dr. Tronchin, who, on finding one of his sons seized with the natural small-pox, immediately inoculated the other. This physician, after his return from Geneva, in 1754, inoculated a great many persons in Holland. Dr. Schwenke, at the Hague, likewise promoted the practice; and so did a society of physicians and surgeons at Rotterdam, who were associated for the purpose in 1757. The method was not, however, very generally adopted by the Dutch, till after 1764, about which time Morand and others had practised it at Amsterdamm with striking success.

Inoculation was first introduced into Denmark in September 1754, when the countess of Bernsdorff underwent the process. In 1758, two inoculation houses were established at Copenhagen; and, in 1760, the prince royal was inoculated with success.

In Sweden, the first trial of inoculation was made by Haartman in 1754. The rapid progress of the method in Sweden was owing to the encouragement afforded by the Swedish court. Dr. D. Schultz was deputed to enquire into the success of the plan at the inoculation hospital in London, and the accounts which he gave upon his return to Stockholm in 1755, led to the establishment of inoculation houses in different parts of Sweden. In 1757, the benefits of inoculation were commemorated by a medal.

Inoculation was first introduced at Geneva in 1751, whence it passed into Switzerland in 1753. In the latter country, it was first performed at Lausanne by a lady on her own child.

Inoculation commenced in Italy during the great mortality occasioned in Tuscany and Rome by the small-pox in 1754. Dr. Peverini was the first inoculator, putting out of consideration the custom which had long prevailed in the interior of the country, of women sometimes artificially communicating the small-pox to their children. In 1755, M. de la Condamine was at Rome, where, by his writings and personal influence, he succeeded in reconciling many to the practice. Before 1765, inoculation was practised with success at Venice, Padua, Verona, Brescia, Mantua, Bologna, Milan, Parma, &c. In short, Naples was the only important place where the method had not been introduced.

Inoculation was begun at Hanover almost as soon as in England. The opposition of De Haen, however, kept back the improvement in most other parts of Germany. The Prussians and Austrians were the last to adopt it. At Vienna, inoculation did not make any progress till 1765. The younger branches of the imperial family were inoculated in 1768, and shortly afterwards the emperor established an inoculation hospital in the suburbs of Vienna.

Owing to some unfortunate events of the first inoculations at Berlin, the practice was soon discountenanced in Prussia, nor was it revived till 1774, when Dr. Baylies was invited from Dresden to superintend the method.

Although some persons had been inoculated in Livonia by Dr. Sculenus at an earlier period, the practice was unknown at St. Petersburg till 1768, when it was established there under baron Dimdale. This event must have been to the Russian an immense blessing, since in their country, the natural small-pox used to rage with such severity, that it is said to have annually destroyed two millions of subjects. On the 28th of July, 1768, baron Dimdale inoculated the empress and the grand duke, both of whom speedily recovered.

INOCULATION.

The practice made rapid progress; an inoculation hospital was established; and at length Dimdale returned to England loaded with wealth and honours.

In Spain, inoculation was not extensively adopted before 1771, though it had been introduced by a surgeon forty-two years before at Jadrique, a small town in that kingdom, and had not been discontinued in that particular place. Dr. Don Miguel Gorman visited London for the purpose of learning the Suttonian method of inoculation, and returned to Madrid in 1772, where he practised the art upon several of the nobility to the great satisfaction of the court.

Of the Objections which were urged against Inoculation.—Having related the rise and first progress of inoculation in several parts of the world, it seems proper, before reciting the particular methods pursued by the Suttons and baron Dimdale, to notice the various objections and arguments which were adduced for the purpose of suppressing the practice of inoculation altogether. The clamour against the method, indeed, was for many years excessively violent; both physical and moral reasons were brought forward against the system, and men of different professions entered into the controversy.

1. To the objection that inoculation did not produce the genuine small-pox, and consequently could not secure any one from having the disease afterwards, the celebrated Dr. Mead made the following judicious reply. "Now I own I cannot undertake how contagion, that is the very feed of the disease, should produce not its own proper distemper, but another of a different kind. Neither, certainly, does it matter by which way the infection is received, provided it brings forth manifest marks of the disease. And as to those, who, after having been inoculated with success, are, notwithstanding this, said to have suffered the small-pox, I must protest that, after the most diligent enquiry, I have not been able to find out one convincing proof of this kind. But to speak plainly, if such a thing happened once, why do we not see it come to pass oftener? Or, what can a single example, supposing it to be true and certain, avail, when innumerable have produced nothing like it?"

2. One formidable objection was, the supposed danger that inoculation might be the means of communicating other terrible and fatal diseases, when the matter was taken from unhealthy subjects. The variolous matter being a poison *sui generis*, it cannot by inoculation communicate any other distemper. The venereal disease is known to be as communicable as any, yet several persons have been inoculated from patients labouring under considerable degrees of the venereal disease, and no ill consequences were ever yet known to follow. Mr. Burgess informs us that he knew of one instance where the matter was inadvertently taken by a surgeon from a young woman, who fell ill of the small-pox, after being admitted into St. Thomas's hospital to be bled. Three patients were inoculated from this matter, and had the small-pox in the most favourable manner. Nothing particular happened about the wounds, and the patients all grew up healthy subjects. See Burgess's "Account of the Preparation and Management necessary to Inoculation, 1754." Dr. Kirkpatrick also mentions in his "Analysis of Inoculation," that he was assured by a respectable surgeon, that a young lady was inoculated by an apothecary from a gentleman's servant, who had a venereal bubo together with the small-pox. The lady, notwithstanding, did very well, and never had the slightest symptom of venereal infection. The assertion, then, that other diseases may be communicated by inoculation remains quite unproved. That other diseases may follow the small-pox no man of common sense will deny; for it is no security against them. Nay, the debility which

it sometimes induces, may even promote the accession of ferociousness, consumption, &c.; but since inoculation tends so materially to diminish the severity of the small-pox, it may also have a great effect in lessening and preventing any circumstances, which are to be regarded as consequences of such severity.

3. Perhaps the disease may never attack in the natural way. This objection, one would think, must give way to the bare statement, that, previous to the practice of inoculation, the casual small-pox annually destroyed about two millions of lives in the Russian empire alone, and committed equal devastation in several other parts of the world. It has been observed by Dr. Jurin, in an ingenious paper inserted in the Philosophical Transactions, that it is difficult to ascertain the exact number who die without having the small-pox; but that of all the children that are born, there will, some time or another, die of the small-pox one in fourteen; and that of persons of all ages taken ill of the same distemper, two in eleven will fall victims to it.

From a table of burials it appears that in Edinburgh and St. Cuthbert's parish, during ten years, about one-tenth of the dead was killed by the small-pox.

It may likewise be noticed, that no individual is originally uninfected of the small-pox, and though a proportion of mankind might possibly escape the contagion, still the number of victims to the disorder casually taken would be very considerable. During the controversies concerning the advantages and disadvantages of inoculation, enquiries were made from house to house, in several towns, in order to ascertain the number of people, who had had the small-pox in one twelvemonth, when it appeared that nearly one died in every five who had taken the disease; and that of eighty-two persons who were inoculated in these places in the same year, not one died.

Dr. Nettleton, Dr. Whitaker, and some others, made an attempt to find out how many persons had had the small-pox, and how many had died of it in the year 1722. The result was as follows:

	Sick of the Small-pox.	Died.
In several towns in Yorkshire	3405	636
Chichester - - -	994	168
Haverfordwest - -	227	52
Total - - - - -	4626	856

This table will serve to depict the general event of the casual small-pox. The mortality was considerable; but it was even much greater at some periods, and in particular parts of the world. On the other hand, inoculation has sometimes been pursued with such remarkable success, that out of a thousand persons inoculated one after the other, scarcely one has perished.

We shall not swell this article with a detail of the numerous physical reasons urged against inoculation, the present state of knowledge renders such a talk unnecessary; and all the objections alluded to, have been so often and completely proved to be frivolous and unfounded, that of late years the practice has encountered no opposition, if we put out of present consideration the praiseworthy endeavours to substitute every where the vaccine for the variolous inoculation.

4. The moral and religious objections which were adduced against the practice of inoculation, gave rise to as much dispute as the medical differences of opinion, and certainly operated still more perniciously in prejudicing the mass of

INOCULATION.

people against the art. The plan of bringing diseases upon ourselves, was represented as a Circassian impiety, altogether irreconcilable to a Christian conscience. Those who adopted the practice were branded with the appellations of poisoners and murderers, and were said to be illigated by atheism, quackery, and avarice. One anonymous writer implored the interference of parliament. He observes, "while this hellish principle has so much hold upon mankind, 'tis highly necessary that there should be no doors left open for the practice, at least none that can be shut; that there should be no room for the covering of such horrid things from the reach of the law. Physicians they have already too much latitude in practice, to make havoc of mankind for the satisfaction of their judgment in physic, and increase of their experience; but every quack now may be a hireling to the devil, and, like that bouditti in Italy, be ready to do the drudgery of removing heirs, and other obstructing incumbents of many kinds, and to do this under the mask of a cure, inoculating death instead of a disease, and making use of an art never before practised, in a manner not foreseen, and by the laws not yet sufficiently guarded against." See a pamphlet entitled "The new Practice of Inoculation considered, and an humble Application to the approaching Parliament for the Regulation of that dangerous Experiment, 1722."

A sermon was preached on Sunday, July 8th, 1722, against inoculation, at St. Andrew's church, Holborn, by the Rev. Mr. Maffey. His text was "So went Satan forth from the presence of the Lord, and smote Job with sore boils from the sole of his foot unto his crown," chap. ii. v. 78. In this discourse, the Devil was depicted as having first put inoculation in practice upon Job. Inoculation was stigmatized as a diabolical operation, and an anti-providential project, that insults our religion, and banishes providence out of the world.

It is almost unnecessary for us to say, that Job's being afflicted with the small-pox was nothing more than an unwarrantable assertion, and a whimsical conceit of the Rev. Divine. The following epigram on the subject appeared in the Monthly Miscellany for March 1774.

We're told, by one of the black robe,
The Devil inoculated Job;
Suppose 'tis true, what he does tell,
Pray neighbours, did not Job do well?

Dr. Wagstaffe had asserted, that it never came into men's heads to take the work out of nature's hands, and raise distempers by art in the human body. (See "Letter shewing the Danger and Uncertainty of inoculating the Small-pox.") To this Mr. Maitland replied in his Vindication, "that the practice of physic is founded upon the principle of curing natural by raising artificial diseases. What is bleeding, but an artificial hemorrhagy; purging, and raising an artificial diarrhoea? Are not blisters, issues, and setons, artificial impollutions?"

The virulence and sarcasm by which the opposers of inoculation were actuated, are well exhibited in the rejoinder, made by another writer, to the foregoing very sensible observation. "Very good, sir, but go on,—what is correction at the cart's tail, but the noble art of muscular phlebotomy? What is burning in the hand, but the art of applying a caustic? What is hanging but an artificial quincy, which makes the patient feel for the ground, and chokes him? What is breaking on the wheel, but the art of making dislocations and fractures, and differs from the wounds and amputations of surgeons only by the manner and intention?"

—A Short and Plain Account of Inoculation, &c. by I. Maffey.

Dr. Maddox, bishop of Worcester, was an able and zealous friend to the cause of inoculation, and preached an excellent sermon in support of the practice. He observed, that it was needless to enter into a disquisition, which is the most proper method of designedly raising the small-pox in the human frame, by carrying the person that is to receive it to the contagious steams, or effluvia; or bringing to him the infected matter. Religious difficulties (if any still remain, concerning a practice that has preferred to many lives, and prevented the heaviest grief in so many families,) are exactly the same, in either method of voluntary communication.

For it is no more invading the prerogative of heaven to occasion one easy and voluntary conveyance of the infection than another, by a slight and hardly sensible rasure upon the arm, than communicating the same distemper, by invisible particles, to that tender organ the lungs, which are so frequently affected by the venom of this disease, when contracted by the breath, or receiving into the body infected particles in what is called the natural way.

Were this preventive method (continues the learned prelate) universally successful, and never once to fail in any instance whatsoever, it is scarcely to be presumed that any objection would be raised against a salutary expedient, to preserve from destruction to great a part of the human species as daily fall by this mortal enemy, when it attacks men as it were in the dark, ignorant of, and unprepared for the assault.

This method of inoculation would then be no more liable to censure than the making a voluntary wound, by incision, to form a necessary drain; or administering any operative medicine, which, upon repeated trials, had proved an unfailling security against any other dangerous and prevailing pestilence or contagion.

But, in order to excite and secure a dependence upon his divine providence, the great Governor of the world has appointed that no human affairs, not even our necessary subsistence, should be attended with such absolute certainty; a very wise appointment, that vain man might not fancy himself an independent being; but, among all the changes and chances of this mortal life, should still look up unto, because he can only be defended by, God's most gracious and ready help.

Experience alone must determine the good or bad consequences of this artificial infection, as it ought to do in all other medical attempts, which, in many instances, are, in reality, little more than curing or alleviating one distemper, by exciting or introducing another. And, in this view, the method now under consideration, of lessening the hazard of a very mortal disease, should be considered in the same light as every other antidote, or preventive attempt in physic or surgery, against any probable, almost certain malady, internal or external.

The philanthropic prelate forebore to derive any strength to the argument, from the great number of noble, venerable, and worthy persons, of every rank and profession, who were in his time the public advocates of this compassionate design: he wished to stand upon its own proper evidence and foundation.

He remarked, that a safe passage through this distemper, like the emancipating slaves, is a deliverance to vast numbers of people kept, as it were, in bondage; who, before they have undergone this abhorred disease, are excluded from many offices in life, and prevented from pursuing their necessary business; and it gives tranquillity and cheerfulness

INOCULATION.

to persons of better condition, who, under apprehension of this loathsome and infectious disorder, were all their former days subject to great anxiety and constant fear.

The bishop commented with great ability upon the advantage that inoculation affords of communicating the small-pox at the most favourable time of life, *viz.* infancy, when the disease is most inclined to put on a mild form. He mentioned, authentically, that, out of 1500 persons inoculated by Mr. Ferjeant Ranby, Mr. Ferjeant Hawkins, and Mr. Middleton, only three died.

He stated to his congregation, that, from the annual account within the bills of mortality, (in which many places in and near the city were omitted,) it appeared that, in twenty years, *viz.* from the year 1731 to the year 1750, inclusive, no less than 39,115 persons died of this fatal distemper; which, including the places not inserted in the weekly bills, must have been considerably more than 2000 every year, that fell in the two adjoining cities and parts adjacent. And, he noticed, that if only one in seven is supposed to die by the distemper taken in the natural way, then the whole number of persons who, in this period of twenty years, were thus infected, must have amounted to 280,000, of which number no less than 40,000 perished. But if one in every 200 should be supposed to die under inoculation, which is really more than fall by that artificial infection, instead of 40,000, only 1400 would have died in one district in twenty years, had inoculation been universally adopted. Thus the difference in that short period, in one spot, would have been no less than 28,600 lives preserved, besides the numerous posterity that might have been derived from them.

The learned divine insisted, that humanity, regard to our country, the dictates of reason, and the precepts of religion, are all in favour of the system of inoculation.

During the opposition to the introduction of inoculation, many affected to be actuated against it by religious scruples, and the practice was alleged to be unlawful.

In answer to this, the scriptures ask, Is it lawful to save life, or to destroy it? Luke, vi. 9. We should also remember, that, as the fall of man brought the danger of diseases into the world, so to evade, oppose, or destroy it, is not only his right, but duty, if in his power. When danger surrounds us, no conduct is more proper than to inquire into, and pursue the means of escape. To neglect our safety is to sink below brutes, which are taught by instinct to shun the evil to which they are exposed. Inoculation is certainly in many instances a means of saving life, and of moderating the severity of affliction. And, in a moral point of view, wilfully neglecting the means of preserving life must appear almost as bad as the guilt of murder.

The bringing of a distemper on ourselves was likewise represented by bigotted individuals as usurping the sacred prerogative of God.

As to the first part of this objection, if by distempers are meant sickness and pain, the same thing is practised daily in other instances, in concurrence with the scripture dictate, *viz.* of two evils choose the least. Inoculation is not done from a mere wanton desire of imparting any disease, but is performed in order that the patient may go through an unavoidable distemper with the least difficulty, and the greatest chance of recovery. The natural small-pox being highly pernici-ous, it must be a great desideratum to avoid it, and inoculation enables us to do so, by destroying that disposition in the body, without which the disease cannot take place.

Respecting the offence given to God, a reliance on providence does not imply that we are not to prevent or oppose the evils which we foresee, and which we have it in our

power to guard against by prudent precautions. Would these objectors, in other instances, refuse the means of lessening the malignancy and danger of disease, than which the practice of inoculation is no more? Let the assertors of the rights of God say, whether, when God permits the discovery of preserving ourselves, he forbids our using it? If our Maker offers us a remedy, it is offending him to reject it.

It was moreover objected, that the decrees of God have fixed the commission of every disease, and that our precaution cannot prevent what He has determined.

To this it was answered, that, however true it is, our days are determined, &c. yet it is God's revealed will, and not his secret purposes, which we are to regard as the rule of duty. God has required of us to have a tender regard of our lives; and they who disobey him therein are guilty of a degree of self-murder, and will never be acquitted of that guilt by the secret determination of Heaven concerning them. Besides, God, who has ordained the end, has also determined the means leading to it. St. Paul, in his dangerous voyage, had a special revelation to assure him, that all who were with him should escape; and yet, when the seamen were getting out of the ship, he declares, that if they did not stay in it they could not be saved. Acts, xxvii. 31. God purposed to preserve them in the way whereby they were afterwards delivered.

It was likewise contended that we ought not to do evil, that good may come.

On the other hand, it was acknowledged, that if inoculation is, in its own nature, a moral evil, it certainly should be rejected, however great its advantages may seem to be. The prospect of relief from any calamity in life should not tempt us to offend God. But they who make the foregoing objection proceed upon a mistake. Their principle is true with regard to moral evil, but is not so when applied to physical. It is certainly lawful to pull down one house to save a great number from being burnt. This is a physical evil, which can hardly take place without some degree of moral evil; and many other instances may be pointed out, where, for a greater good, a lesser ill is submitted to.

It was further objected, that the patient might die, and then his last moments would be distressed, and the future reflections of his friends grievous.

This objection led many to decline the practice of inoculation, even while they allowed the theory of it to be reasonable. They entertained hopes of escaping the distemper in the natural way, and they had fears of dying in this, and thus they were prevented from undergoing the disorder. But they should have considered what grounds they had for either their hopes or fears, and what was to be advanced to balance the account, in an examination of the different degrees of probability attendant on what they hoped for, and what they were afraid of, in the neglect or adoption of inoculation. Dying is an awful thing; but if inoculation was a *probable and lawful* means of preserving life in a time of danger, it was a duty to comply with it; and what reflection could be more peaceful than that of dying in the way of duty?

It was further objected by the religious opposers of the new practice, that fear was a dangerous passion in the small-pox, and that inoculation increased the causes of fear, by lessening our faith and trust in God.

When the small-pox was left to nature, such were its ravages, that, not to fear, would have been to sink beneath humanity; its consequences were too grievous to be viewed with indifference. Experience manifested the advantages
and

INOCULATION.

and general safety of receiving the disease by inoculation, and so far the practice was a remedy to that just alarm which enhanced the danger, when the distemper was left to itself. As to faith in God, none was desirable, except that which was agreeable to the scripture, and which could never have the effect of creating a disregard to calamities and danger. Inoculation was well proved to be a means of safety, and it would have been as rational to conclude that our lives could be preserved without eating and drinking, as that we should be delivered from danger without a prudent care for our own safety. We are to depend on the care of providence only in the way of duty. To boast of courage and trust in God, while we omit the means of escaping danger which surrounds us, is not faith but presumption.

Thus, when inoculation became a probable means by which life might be saved, the neglect of it, so far from being trust, was presumption.

We shall now take our leave of these theological disputes and scruples, which have now been long removed by the influence of right reason and found sense. When it was once well ascertained and universally believed that inoculation was really a means of preserving life, the idea of its being criminal to adopt the practice could not have much duration. A very able discussion of most of the foregoing objections was published in a pamphlet, entitled "Inoculation impartially considered, and proved to be consistent with Reason and Revelation," by the Rev. David Some, edited by Dr. Doddridge, 1750.

Of inoculation, as practised by the Suttons, Baron Dimsdale, &c.—The introduction of the Suttonian practice was regarded quite as a new era in the history of inoculation, from the novelty of the method, and its unparalleled success.

Mr. Robert Sutton, the first of this name, who acquired celebrity as an inoculator, resided at Debenham in Suffolk, where he practised surgery and pharmacy. From the year 1757 to 1767, he inoculated 2514 persons.

Two of his sons, Robert and Daniel, followed the medical profession, and after assisting him during the three first years of his practice of inoculation, Robert established himself as an inoculator at Bury St. Edmund's, while Daniel became assistant to Mr. Buntleat, a surgeon at Oxford. Daniel, on his return to Debenham, in the year 1763, suggested to his father a new plan of inoculation, in which he proposed to shorten the time of preparation to a few days, and not to confine the inoculated patients to the house, but to oblige them to be in the open air as much as possible during the whole progress of the distemper.

The father condemned this scheme as rash and dangerous. Its advantages, however, soon becoming manifest to patients, they evinced a desire of being solely under the management of Mr. D. Sutton. The consequence was, that the father and son separated about the end of the year 1763, when the latter opened an inoculating-house near Ingatstone, in Essex. Here, by public advertisements, he made known his plan of inoculating in an improved way peculiar to himself. The encouragement which he met with may be estimated from his receiving, during the first year, 2000 guineas, and above 6000 the second. His fame spread to the most distant parts of the kingdom; and the numbers that resorted to him for inoculation, constantly filled the village of Ingatstone, so that accommodations could hardly be procured for the purpose. His practice in Kent being also very extensive, he was obliged to employ several medical assistants. In 1767, Mr. D. Sutton removed to London, in hopes of reaching still more eminent; but his receipt fell far short of his expectation.

According to Mr. Houlton's statement, the number of persons inoculated by Mr. Daniel Sutton in the year

1764	was	1629
1765	—	4347
1766	—	7816

13,792

"To the above number," says he, "should be added 6000 that have been inoculated by Mr. Sutton's assistants; so that he may be said to have inoculated, within these three years, 20,000 persons."

Of this number, not one was allowed to have fairly died of inoculation. The venal pen of the preceding writer certainly exaggerated every thing, and great boast was also falsely made of the Suttons having a specific medicine for preventing too many pustules. However, no doubt was entertained that the Suttonian practice was incomparably more successful than any other.

Medical practitioners, struck with the advantages of the new treatment, set about the investigation of the causes. Sir George Baker published the following account of the manner in which Mr. D. Sutton practised inoculation. "All persons are obliged to go through a strict preparatory regimen for a fortnight before the operation is performed. During this course, every kind of animal food, milk only excepted, and all fermented liquors and spices are forbidden. Fruit of all sorts is allowed, except only on those days when a purging medicine is taken. In this fortnight of preparation, a dose of a powder is ordered to be taken at bed-time, three several times; and on the following morning a dose of purging salt. To children, only three doses of the powder are given, without any purging salt. The composition of this powder is industriously kept a secret. But, that it consists partly of a mercurial preparation, is demonstrated by its having made the gums of several people sore, and even salivated others. The months of May, June, July, and August, are preferred as the most seasonable for inoculation. But healthy people are inoculated at any season of the year indifferently. The autumn is held to be the worst season; and an aguish habit the least proper for this operation. No objection is made to any one on account of what is vulgarly called a scorbutic habit of body, or bad blood. The person who is to be inoculated, on his arrival at the house used for this purpose, is carried into a public room, where, very probably, he may meet a large company assembled under the several stages of the small-pox. The operator then opens a pustule of one of the company, chusing one where the matter is in a crude state; and then just raises up the cuticle on the outer part of the arm, where it is thickest, with his moist lancet. This done, he only presses down the raised cuticle with his finger, and applies neither plaster nor bandage. What is extremely remarkable, he frequently inoculates people with the moisture taken from the arm before the eruption of the small-pox, nay, within four days after the operation has been performed. And," says Sir G. Baker, "I am informed, at present he gives the preference to this method. He has attempted to inoculate by means of the blood; but without success. If the operator happeneth not to be at home when the new patient arriveth, this is looked upon as a matter of no importance. And so far is he from any apprehension of accumulating infection, that it is very common for persons, just inoculated, to lie in the same bed with a patient under any stage of the disease, as it may happen; nay, sometimes in a room where four or five people are sick. On the night following the operation, the patient takes a pill. This medicine is repeated, every other night, until

until the fever comes on. All this time, moderate exercise in the air is strongly recommended. In twenty-four hours after the inoculation, the operator can often distinguish whether or no the patient be infected. He every day examines the incision; and from hence seems to prognosticate, with some degree of certainty, concerning the degree of the future disease. In three days after the operation (provided that it has succeeded), there appears on the incision a spot like a flea-bite, not as yet above the skin. This spot, by degrees, rises to a red pimple; and then becomes a bladder full of clear lymph. This advanced to maturation like the variolous pustules, but is the last which falleth off. In proportion as the discolouration round the place of the incision is greater, the less quantity of eruption is expected. And, therefore, whenever only a small discoloured circle is observed, purging medicines, more than ordinary, and more frequently repeated, are held to be necessary.

"The preparatory diet is still continued. If the fever remains some hours without any tendency to perspiration, some acid drops are administered, the effect of which is to bring on a profuse sweat; but in some cases where the fever is very high, a powder or pill, still more powerful, is given. In general, during the burning heat of the fever, the inoculator gives cold water. But the perspiration beginning, he orders warm balm-tea or thin water-gruel. As soon as the sweat abates, the eruption having made its first appearance, he obliges every body to get up, to walk about the house, or into the garden. From this time, to the turn of the disease, he gives milk gruel, *ad libitum*.

"On the day following the first appearance of the opaque spot on the pustules, to grown people he gives an ounce of Glauber's purging salt. To children he gives a dose of it proportioned to their age. Then, if the eruption be small, he allows them to eat a little boiled mutton, and toast and butter, and to drink small beer. But in case of a large eruption, he gives them, on the third day after their having taken the first dose, another dose of the same salt, and confines them to the diet ordered during the preparation."

Sir George, after representing this as the practice of Mr. D. Sutton, ascribes its superior success to the free use of cold air. Dr. Glafs, of Exeter, in a publication which appeared shortly after that of the preceding gentleman, imputed the advantages of the Suttonian method to the patient being sweated; while another author, Mr. Chandler, differed from both the former writers, and referred the chief benefit of the plan to the infecting humour being taken in a crude state, "before it has been ultimately variolated by the succeeding fever." Baron Dimfdale likewise thought, that although the whole process might have some share in the production of the success, yet he believed the chief good was owing to the method of inoculating with recent fluid matter, and the management of the patients at the time of the eruption.

In November, 1766, baron Dimfdale published his well known work, entitled "The present Method of inoculating for the Small-pox." The instructions contained in this book have deservedly continued ever since, almost without exception, to regulate the practice of inoculation.

The baron, when the age is left to his choice, avoids inoculating children under two years of age. The subjects considered by him improper for the operation, are such as labour under any acute or critical diseases, or their effects; and also such as have evident marks of corrosive acrimonious humours, or manifest debility.

As for the most eligible season of the year, he thought, that persons generally had more pustules in the spring than any other time; and epidemic diseases (especially Ruxes,

intermittents, and ulcerated sore throats) being most frequent in the autumn, the baron did not look upon this as in general the most favourable season. But he was of opinion, that we might safely inoculate at all seasons, provided care were taken to screen the patients as much as possible from heat in summer, and to prevent them from keeping themselves too warm, and too much shut up from the weather in winter. He thought it prudent, however, to avoid inoculation while any peculiar epidemic diseases were prevalent. He recommended a preparatory regimen, so as to reduce the patient, if in high health, to a low and more secure state; to strengthen the constitution if too low, to correct what appears vitiated; and to clear the stomach and bowels as much as may be from all crudities and their effects. Young or middle aged persons, enjoying a good state of health, were strictly confined to a milk and vegetable diet for nine days previous to the operation, during which period they were ordered to take the following powder three times at bed-time, and a dose of Glauber's salt each succeeding morning. The powder was composed of eight grains of calomel, the same quantity of compound powder of crabs' claws, and $\frac{1}{3}$ th of a grain of emetic tartar. For women or children the dose was lessened, according to their age and strength. For those who were of a tender delicate constitution, or valetudinarians, he prescribed a milder medicine, and rather of the alternative than the purgative kind; indulging some with light animal food, and in case of lowness, with a glass or two of wine. The baron preferred the following method of inoculating. The patient to be infected being in the same house, and if no objection is made to it, in the same room with one who has the disease, a little variolous matter is taken from the place of infection, if the subject is under inoculation, or a pustule, if in the natural way, on the point of a lancet, so that both sides of the point are moistened. With this lancet an incision is made in that part of the arm where issues are usually placed, deep enough to pass through the scarf-skin, and just to touch the skin itself, and in length as short as possible, not more than one-eighth of an inch. The little wound being then stretched open between the finger and thumb of the operator, the incision is moistened with the matter by gently touching it with the flat side of the infected lancet. The baron generally performed the operation in both arms, and sometimes in two places in one arm, a little distance from each other. Neither plaster nor bandage is to be applied to the inoculated part. The baron preferred using such matter as was taken during the eruptive fever, it being then in his opinion endued with most activity. When the disease was to be communicated from an inoculated person, he took the matter, not from the secondary pustules, but from the place of inoculation. The second day after the operation, if the inoculated part is viewed with a lens, he says, there generally appears a kind of orange-coloured stain about the incision, and the surrounding skin seems to contract. At this time the baron used to prescribe the following medicine to be taken at bed-time: calomel and compound powder of crabs' claws, of each three grains, emetic tartar $\frac{1}{4}$ th of a grain. On the fourth or fifth day a hardness is perceptible to the finger. The part itches and appears slightly inflamed. He remarks, that a little clear fluid may be seen under a kind of vesication, the part resembling a superficial burn. In general, about the sixth day some pain and stiffness are felt in the arm-pit. This was regarded as a very desirable symptom, as foreboding the near approach of the eruptive symptoms, and the favourable progress of the disease. Sometimes on the seventh, more often on the eighth day, the symptoms of the eruptive fever appear; such as slight

remitting pains in the head and back, succeeded by transient shiverings and alternate heats, which continue in a greater or lesser degree till the eruption is perfected.

The inflammation in the arm at this time spreads fast, and upon viewing the incision with a good glass, it appears for the most part furrowed with an infinite number of small pustules, which increase in size and extent as the disease advances. On the tenth or eleventh day a circular or oval efflorescence is usually discovered surrounding the incision, and extending sometimes nearly half round the arm, but more frequently to about the size of a shilling, and, being under the cuticle, is smooth and not painful. This efflorescence was also regarded as favourable; it accompanies the eruption, every disagreeable symptom ceases, and the pain and stiffness in the axilla go off.

When the eruptive symptoms came on with more severity, baron Dimisdale used to direct a repetition of the last-mentioned powder, and on the following morning three or four stools were procured by a laxative draught.

The baron notices that sometimes the state of the incision is such for several days, that the effects of the inoculation can barely be perceived, the colour about the wound remaining pale instead of changing to red; the edges of the incision spread but little, they remain flat, and are attended neither with itching nor uneasiness of any kind. Nay, sometimes on the fifth, and even on the sixth day, the alteration is so little, as to make it doubtful whether the infection has taken place. Dimisdale sets down such appearances as unfavourable, and implying a late and more untoward disease. To prevent this, he used to direct the powder or pill to be taken each night, and in case it failed to operate by stool, or there was the least disposition to costiveness, an ounce of Glauber's sauce, or a laxative draught, was given in the morning, once or twice, as the case might require. The baron believed that these measures forwarded the inflammation, which he always wished to see, as he had constantly observed, that an early progress on the arm, and an early commencement of the eruptive complaints, portended that the distemper would be mild and favourable; and on the contrary, that when both were late, the symptoms proved more irregular and untoward. The patient, instead of being confined to his bed or room, when the symptoms of the eruptive fever came on, was directed, as soon as the purging medicine had operated, to keep abroad in the open air, be it ever so cold, as much as he could bear, and to drink cold water, if thirsty, always taking care not to stand still while abroad, but to walk about with moderation.

In certain cases, notwithstanding baron Dimisdale found the eruptive symptoms extremely violent, and the patients almost incapable of motion, and apprehensive of cold as the greatest evil, yet he persuaded them to rise out of bed and go out of doors, often supported by assistants, and he allowed them to drink as much cold water as they chose. No sinister accident was the consequence, but, on the contrary, the patients' spirits were revived, and every symptom seemed benefited by the method.

When any uncommon languor happened, a basin of thin broth, or a glass of wine, was allowed in the day, or some white-wine whey at bed-time. Indeed, such things were allowed at any time to tender, aged, or weakly persons. After the eruption was completed, if occasion required, they were indulged in a little well-boiled meat of the lightest kind, as chicken, veal, or mutton.

The practice of baron Dimisdale was certainly, in a great measure, an imitation of the method pursued by Mr. D. Sutton.

We shall conclude this article with a few necessary instructions and references.

1. The age of the person to be inoculated for the small-pox should be as little advanced as possible; but (if it can be avoided) not less than four months.

2. The matter, when convenient, should be taken from a young subject who has the small-pox in a favourable way, and fresh matter should have the preference to such as is old. It deserves particular attention, however, that it is chiefly for the sake of avoiding unprofessional blame that we choose matter from patients labouring under the disease mildly, since experience rather proves, that the lenity or malignity of the small-pox depends very little on whether the matter is taken from one patient who has the distemper favourably, or from another who has it severely. Nor can we wonder at this fact, since the contagion can only be of one sort. Therefore, were a patient much exposed to the casual small-pox, and no matter could be procured from any subject that had the distemper mildly, the surgeon should recommend inoculation with such matter as it would be in his power to obtain.

3. In inoculating, the operator is to make the slightest puncture, or scratch, imaginable in the arm over the place where the insertion of the deltoid muscle terminates. That part of the lancet which is besmeared with the matter, is to be repeatedly rubbed over the wound, and left the matter be wiped away, it is best not to pull down the shirt-sleeve till the part is quite dry. Some operators prefer introducing the lancet, armed with the matter, obliquely beneath the cuticle. When this mode is followed, it is proper at the time of withdrawing the lancet to press the wound with the finger, so that the parts in contact with the matter may wipe it off the lancet with more certainty.

The works on the inoculation for the small-pox are too numerous to be even mentioned: we would, however, particularly refer to Friend's History of Medicine. D'Entrecolle's Lettres Edifiantes et Curieuses. Avicenne's Opera. Mémoires sur l'Inoculation par M. de la Condamine. Philosophical Transactions for 1722. Monro on Inoculation in Scotland. Holwell's Account of the Manner of inoculating in the East Indies. Maitland's Account of inoculating the Small-pox. Mead de Variolis et Morbillis. Kirkpatrick's Analysis of Inoculation. Some's Small-pox impartially considered, &c. Murray's Hist Infectionis Variolarum in Suecia. Dimisdale's present Method of inoculating for the Small-pox. Jurin's Account of the Success of inoculating the Small-pox in 1721, &c. and his letter to Dr. Cotesworth. Woodville's History of the Small-pox, &c.

For an account of the inoculation for the cow-pox, now so deservedly preferred to the preceding practice, see COW-POX and VACCINATION.

A particular description of the SMALL-POX will be found under that word.

INOCULATION, *Hospital fer.* See HOSPITAL.
INOFFICIOUS TESTAMENT, in Law. See TESTAMENT.

INOM BARLEY, in Agriculture, a term applied to such barley as is sown the second crop after the ground has been fallowed, or cleaned from weeds.

INORDINATE PROPORTION, is where three magnitudes being in one rank and three others proportional to them in another, you compare them in a different order.

E. gr. If there be in one rank these three numbers, 2, 3, 9; and in another rank, these other three, 8, 24, 36, which are proportional to the precedent, in a different order; so that 2 be to 3 as 24 to 36, and 3 to 9 as 8 to 24; then casting

ing away the mean terms in each rank, you conclude the first 2 in the first rank to be the last, 9; as 8, the first of the other rank, to the last, 36.

INORGANIC, in *Natural History*, or unorganized bodies, are mineral substances which are not organized or constructed as animals and vegetables capable of life are; such are also called native fossils, to distinguish them from organic remains or reliquia. Martin's "Outlines," p. 1.

INOSARCION, a name given by the old Greek and Roman authors to a peculiar species of emerald, called also by some the Chalcedonian emerald. The great distinction of this from all the other kinds of this gem, was its not being of the pure, clear, and unvarying colours of the others, but having thick veins in it, which gave peculiar refractions and reflections to the light; and though the stone was in itself wholly green, yet when viewed in side lights, these veins gave all those changeable colours that ornament the feathers of a peacock's tail, or the neck of a pigeon.

INOSCULATION. See **ANATOMYSIS** and **ARTERY**.
INOWLOCZ, in *Geography*, a town of the duchy of Warfaw; 56 miles S.E. of Lencicz.

INOWLOCZAW, or **JUNGENESLAW**, a town of the duchy of Warfaw; 26 miles W. of Wladislaw.

INOWSAL, a small island near the northern coast of the island of Borneo. N. lat. 6° 45'. E. long. 117° 27'.

IN PACE, a Latin term, used among monks, to signify a prison, where such of them are shut up as have committed any grievous fault.

Formerly there used to be a great deal of ceremony at the putting a religious *in pace*; but now it is not much regarded. Such as are shut up in perpetual imprisonment, are also said to be *in pace*.

Sometimes, also, the words *requiescat in pace* are used by way of allusion to a custom in the Romish church, or praying that the soul of the deceased may rest in peace.

The same words are also frequently seen at the bottom of epitaphs, in lieu of those used by the ancient Romans, S. T. T. L. *i. e.* "Sit tibi terra levis, Light lie the earth;" or, "Sit humus cineri non onerosa tuo."

IN PALE. See **PALE**.

INPROMPTU, or **IMPROMPTU**, a Latin word frequently used among the French, and sometimes in English, to signify a piece made off-hand, or extempore, without any previous meditation, by the mere force and vivacity of imagination.

INQUEST, or **ENQUEST**. See **ENQUEST**, **ARREST**, **JURY**.

INQUEST of Office. See **OFFICE**.

INQUIRENDO, an authority given a person or persons, to inquire into something for the king's advantage.

INQUISITIO Post Mortem. See **Inquest of OFFICE**.

INQUISITION, in the *Civil and Canon Law*, a manner of proceeding for the discovery of some crime by the sole office of the judge, in the way of search or examination.

INQUISITION is also used, in *Common Law*, for a like process in the king's behalf, for discovery of lands, profits, and the like. In which sense it is also confounded with *Office*; which see.

INQUISITION, or the *Holy Office*, denotes an ecclesiastical jurisdiction established in Spain, Portugal, Italy, &c. for the trial and examination of such persons as are suspected to

entertain any religious opinions contrary to those professed in the church of Rome.

It is called inquisition, because the judges by their office take cognizance of crimes on common report, without any legal evidence, except what they themselves are able to explore.

Some people fancy they see the original of the inquisition, in a constitution made by pope Lucius, at the council of Verona, in 1184, where he orders the bishops to get information, either by themselves, or by their commissaries, of all such persons as were suspected of heresy; and distinguishes the several degrees of suspected, convicted, penitent, relapsed, &c. However this be, it is generally allowed, that pope Innocent III. laid the first foundation of the Holy Office; and that the Vaudois, and Albigenses were the first objects of it. That pontiff, in the beginning of the thirteenth century, sent Rannier, a Cistercian monk, and Pierre de Castellana, archdeacon of Maguelonne, to the country of Thoulouse, or Narbonne Gaul, in order to blow up a spirit of zeal and perfection against the prelates and princes. These missionaries were soon followed by others, among whom was the famous Spaniard, Dominic, founder of the order of Preachers, who returning from Rome in the year 1206, fell in with these delegates, embarked in their cause, and laboured, both by his exhortations and conduct, in the extirpation of heresy. These spiritual champions were to give an account to the pope of the number of heretics in those parts, and of the behaviour of the princes and persons in authority to them; and thence they acquired the name of inquisitors: but these original inquisitors had not any court, or any authority, they were only a kind of spiritual spies, who were to make report of their discoveries to the pope, and to excite the Catholic princes and people to extirpate heretics.

It has been generally said, that the tribunal of the inquisition was the invention of St. Dominic, and first erected by him in the city of Thoulouse; that, consequently, he was the first inquisitor; and that, although the year of its institution is uncertain, it was undoubtedly confirmed, in a solemn manner, by Innocent III. in the council of the Lateran, in the year 1215. See Limborch's *Hist. of the Inquisition*, by Chandler, book i. chap. 10.

This account is contended by Mosheim, who maintains, that St. Dominic was not appointed by the Roman pontiff to proceed judicially against heretics, and such as were suspected of heresy, to pronounce sentence according to their respective cases, and to deliver over to the secular arm such as persisted obstinately in their errors, and therefore, in this sense, was no inquisitor; though, according to the original meaning of the term, he was invested with the commission and authority of the Roman pontiff to extirpate heresy, and oppose its abettors, but without any judicial power: nay, it is farther urged, that the court of inquisition was not erected during the life of St. Dominic. The horrid war, which was excited by Innocent III. against the Albigenses in Narbonne Gaul, and which was carried on by the cross-bearers with the utmost cruelty from the year 1200 to 1229, when a treaty of peace took place between Raymond VIII. earl of Thoulouse, and Lewis VIII. king of France, which gave a mortal blow to the cause of heresy, prepared the way for the full establishment of the inquisition.

Inquisitors of the first kind had, in the course of this time, been placed in almost every city, whose inhabitants had the misfortune to be suspected of heresy, notwithstanding the reluctance which the people manifested to this new institution, and the violence with which they frequently expelled and

sometimes massacred these bloody officers of the popish hierarchy. At length, the council held at Thoulouse, in the year 1229, by Romanus, cardinal of St. Angelo, and pope's legate, went still farther, and erected in every city a council of inquisitors, consisting of one priest, and three laymen. This institution was, however, superseded in the year 1233, by Gregory IX. who entrusted the Dominicans, or Preaching Friars, with the important commission of discovering and bringing to judgment the heretics that were lurking in France; and in a formal epistle discharged the bishops of that painful office. Immediately after this, the bishop of Tournay, who was the pope's legate in France, began to execute this new resolution, by appointing Pierre Cellan and Guillaume Arnaud, inquisitors of heretical pravity at Thoulouse; and afterwards proceeded in every city where the Dominicans had a convent, to constitute officers of the same kind chosen from among the monks of that order. From this period we are to date the commencement of the dreadful tribunal of the inquisition, which in this and the following ages subdued such a prodigious multitude of heretics, part of whom were converted to the church by terror, and the rest committed to the flames without mercy. For the Dominicans erected first at Thoulouse, and afterwards at Carcassone, and other places, a tremendous court, before which were summoned not only heretics, and persons suspected of heresy; but likewise all who were accused of magic, sorcery, Judaism, witchcraft, and other crimes of that kind. This tribunal, in process of time, was erected in the other countries of Europe, though not every where with the same success. The method of proceeding in this court of inquisition was at first simple, and almost in every respect similar to that which was observed in the ordinary courts of justice. But the Dominicans modelled it after that of the tribunal, called in the Roman church the tribunal of peace; and hence arose that strange system of inquisitorial law, which in many respects is so contrary to the common feelings of humanity, and the plainest dictates of equity and justice. And that nothing might be wanting to render the spiritual court formidable and tremendous, the Roman pontiffs persuaded the European princes, particularly the emperor Frederic II. and Lewis IX. king of France, not only to enact the most barbarous laws against heretics, and to commit to the flames those who were pronounced such by the inquisitors, but also to maintain the inquisitors in their office, and grant them their protection in the most open and solemn manner. The edicts issued to this purpose by Frederic II. are well known; and edicts every way proper to excite horror, and which rendered the most illustrious piety and virtue incapable of saving from the most cruel death such as had the misfortune to be disagreeable to the inquisitors. The laws of Frederic, in relation to the inquisitors, may be seen in Limborch's History of the Inquisition, book i. chap. 12.

The edict of St. Lewis, in favour of these ghostly judges, issued out in the year 1229, is generally known under the title of *Cupientes*.

After the death of Frederic, who had long before repented the power he had given the churchmen, as having seen some of the fruits of it, pope Innocent IV. erected a perpetual tribunal of inquisitors, and deprived the bishops and secular judges of the little power the emperor Frederic had left them. And this jurisdiction, which depended immediately upon himself, he took care to introduce into most of the states of Europe. In 1251 it was established in Italy; in 1255 Alexander IV. appointed inquisitors in France, at the request of St. Lewis. But the inquisitors were so fiery hot, and made such horrible butchery among the reputed

heretics, that they raised an universal detestation even in some Catholic countries themselves. Hence it was that their reign proved very short both in France and Germany; though they were occasionally exerting themselves; and their power was established in many parts of France and Germany about the time of the Reformation by Luther; but afterwards gradually declined. Nor was even Spain entirely subject to them till the time of Ferdinand and Isabella, when their power was increased, under pretence of clearing the country of Judaism and Mahometanism.

The inquisition was first introduced into Spain in the year 1478; but the first inquisitor-general, and the supreme council of the inquisition, were not fixed till the year 1483. This tribunal is arisen to such a height in Spain that the king of Castile before his coronation subjects himself and all his dominions, by a special oath, to the most holy tribunal of the inquisition. It is under the direction of an inquisitor-general, appointed by the king, and confirmed by the pope; and this inquisition has power to name particular inquisitors in every place where there is any tribunal of the inquisition.

The inquisition was established in Portugal, at the pressing solicitation of king John III. about the year 1536; and both the Spaniards and Portuguese have established it in their territories in the western continent.

The power of the inquisition was very much limited in some countries, particularly at Venice, where it was introduced about the year 1289, and where it was received under such modifications, as proved a great check on its authority; the office consisting of secular and ecclesiastical persons, though the latter had been long endeavouring to bring it into their own hands, but could never prevail with the Venetian senate to agree to it. Indeed at Venice it seemed rather a political than a religious contrivance; and served rather for the security of the state, than that of the church. There are appeals from the subaltern inquisitions in Italy, to the congregation of the holy office residing at Rome.

The congregation was first formed by Paul III. in 1542, but finally established by Sixtus V. in 1588. The members of it, called supreme inquisitors, assemble thrice in the week, and every Thursday in the presence of the pope, who presides in it.

The officers or ministers of the inquisition are the inquisitors, who derive their power from the pope, either by word of mouth, or by his apostolic letters, and can be removed only by him, or by authority conferred by him on those cardinals who are the inquisitors-general; vicars-general, who manage the affairs of the inquisition during the absence of the inquisitors; assessors and counsellors, who give their advice in points of theology and law; the promoter fiscal, whose office it is to examine the depositions of the witnesses, to give information of criminals to the inquisitors, and to demand their apprehension and imprisonment, and, finally, when apprehended and admonished, to accuse them; notaries or registers, who write down the injunctions, accusations, and all the pleadings of the causes; the judge and receiver of the confiscated effects; the executor and officials, who apprehend and keep in custody criminals; the attendants or familiars; the cross bearers; and the visitors, who visit all the provinces of the inquisitors, and report to the inquisitor-general and council whatever was proper to be amended. The civil magistrature is entirely excluded from the cognizance of heresy; but the inquisitors require their assistance for the punishment of heretics, in consequence of the sentence which they pronounce; and they are severely threatened with the most grievous punishments, if they neglect their duty. The punishments inflicted by the inquisition on heretics are ecclesiastical

Infatigable and civil; the ecclesiastical or canonical are excommunication, deprivation of ecclesiastical burial, dignities, benefices, and offices. The civil are confiscation of goods, which is inflicted on all who are convicted of heresy, or confessions, whether they repent or persist in their heresy, because they are declared to incur the punishment, *ipso jure*, as soon as they fall into heresy; disinheriting the children, inasmuch that though they are Catholics, they can never inherit the estates of their fathers who died in heresy; infamy, which excludes from all public offices, from bearing witness, making wills, &c. loss of all dominion, natural or civil, as power of parents over children, masters over servants, magistrates and princes over subjects, &c. and the deprivation of all property in every thing they have; imprisonment; ban, which is a kind of sentence of excommunication, by which any person is cut out of the commonwealth, so that he cannot enjoy the public protection, or discharge any public offices, or receive any benefit of law; disfranchisement, which declares heretics to be enemies of their own country and of the empire, so that any person, by his own private authority, may seize, plunder, and kill him, as an enemy and robber, even though he be a clergyman; nor is it lawful for any one to undertake their defence when apprehended; and those advocates who favour and plead for them, are pronounced infamous, and suspended from their office; and finally death, which is that of being burnt alive, in some cases heightened by being gagged with an iron instrument, so that in the midst of their torments they can utter only an inarticulate sound.

It is the constant practice of the inquisition to affect, in all their procedures, to inspire as much terror and amazement as possible; every thing is done with the profoundest silence and secrecy, and with the greatest rigour and pretended impartiality. When a person is seized, all the world abandons him; not the nearest friends dares to speak a word in his defence; that alone would be enough to render them suspected of heresy, and would bring them within the claws of the inquisition; nay, the nearest relations are bribed and constrained to accuse one another. The criminals are seized, examined, tried, tortured, and, unless they recant, are even condemned and executed, without ever seeing or knowing their accusers; whence the revengeful have a fair occasion of wreaking their malice on their enemies. By the forms of the inquisition, a person defamed only for heresy is obliged to make a canonical purgation, *i. e.* to purge himself with seven, more or less, compurgators; so that if he fails in one, two, or three, he is accounted guilty: besides, every one, though excluded by other courts, is admitted as a witness, a mortal enemy only excepted. The names of the witnesses are not shewn to the prisoner; nor is any circumstance discovered, by which he can obtain the knowledge of them. If two unexceptionable witnesses testify of different facts; yea, sometimes if there be only one, or a mere report, it is thought sufficient for ordering the torture; the evidence of two unexceptionable witnesses, who agree, is sufficient for the conviction and condemnation of any person. Those that are informed against are constrained to become their own accusers; and various arts are used to extort a confession from them. The advocate allowed them is under the direction of the inquisition, and employed chiefly in order to betray them; moreover, when the crimes cannot be proved against them, they are only absolved from prosecution, but their crimes and names are recorded against them. The use of torture for discovering secret crimes lying concealed in the mind, is a flagrant instance of injustice; and persons are put to the torture upon half full proof of the crime, *i. e.* faulting, defamation, one witness of his own

knowledge, or when the tokens are vehement, or violent. These tortures are used under a pretence of discovering the truth, and they are varied and continued with the most wanton cruelty. After these, and many other shocking processes, when the inquisition has done with the criminals, and condemned them to death, they are turned over to the secular arm, with much prayer, and pious intreaty, that their lives may not be touched.

Time is no manner of security in point of heresy; nor does the grave itself shelter the accused from the pursuits of the inquisition; even the deceased have their trials, and they proceed in all their form and solemnity against the dead carcasses. The executions are always deferred till the number of the condemned is very great, that the multitude of sufferers may strike the deeper horror, and make the scene more terrible and shocking. See *ACT of Faith*.

The inquisition is very severe in the Indies. It is true, there must be the oaths of seven witnesses to condemn a man; but the deposition of slaves or children are taken. The person is tortured till he condemns himself; for his accusers are never brought to confront him. Persons are accused for the slenderest expression against the church; or even for a disrespectful word of the inquisition.

The standard of the inquisition in Spain is a piece of red damask, on which is painted a cross, with an olive-branch on one side, and a sword on the other; with these words of the psalm, *Exurge, Domine, & judica causam meam*.

The standard of the inquisition in Portugal hath their supposed founder Dominic's picture on one side, and on the other side the cross, between an olive-tree and a sword, with this motto, *Justitia & misericordia*.

See on the subject of this article Limborch's Hist. of the Inquisition, by Chandler, passim. Mosheim's Eccl. Hist. vol. iii. p. 113; &c. Svo.

INQUISITORS, in Law, are sheriffs, coroners *super visum corporis*, or the like, who have authority to enquire into certain cases, *ex officio*.

IN QUO, Medium in quo. See MEDIUM.

INROLLMENT, the registering, recording, or entering of any lawful act, or instrument, in the records of chancery; as a recognizance acknowledged, or a statute, or a fine levied.

Inrollments are also made in the rolls of the exchequer, king's bench; and common pleas; in the hustings at Guildhall, London; and by the clerk of the peace in any county. See REGISTER.

INROLLMENTS, Clerk of the. See CLERK.

INSAG, in Ornithology, a name given by the people of the Philippine islands to one of the several species of parrots, common in their woods. The insag is a very beautiful bird; its body is of a very bright green, and its head of a fine florid red.

INSANITY. See MENTAL Derangement, MANIA, and MELANCHOLY.

INSANUM PARLIAMENTUM. See PARLIAMENTUM.

INSCHI, or **INSCHI kua**, in the *Materia Medica*, a name given by some authors to the common ginger.

INSCONCED, in the *Military Art*, denotes that part of an army that have fortified themselves with a *scence*, or small fort, in order to defend some pass, &c. See SCENCE.

INSCRIBED, in Geometry. A figure is said to be inscribed in another, when all the angles of the figure inscribed touch either the angles, sides, or planes of the other.

INSCRIBED Hyperbola, is such an one as lies entirely within the angle of its asymptotes; as the conical hyperbola doth. See HYPERBOLA and CIRCUMSCRIBING.

INSCRIPTION, a title, or writing affixed to any thing, to give some farther knowledge thereof; or to transmit some important truth to posterity.

Antiquaries are very curious in examining ancient inscriptions found on stones, and other monuments of antiquity. Sanchoniathon, contemporary, as it is said, with Gideon, drew most of the memoirs whereof his history is composed from inscriptions which he found in temples, and on columns, both among the heathens and the Hebrews.

It appears, indeed, that the ancients engraved upon pillars the principles of sciences, as well as the history of the world. Those mentioned by Herodotus shew, that this was the first way of instructing people, and of transmitting histories, and sciences, to posterity. This is confirmed by Plato in his *Hippias*, wherein he says, that Pisistratus engraved, on stone pillars, precepts useful for husbandmen. Pliny assures us, that the first public monuments were made of plates of lead; and that the treaties of confederacy concluded between the Romans and the Jews were written upon plates of brass; that, says he, the Jews might have something to put them in mind of the peace and confederacy concluded with the Romans. The Greeks and Romans were much addicted to inscriptions, and were extremely fond of being mentioned in them: and hence it is that we find so many in those countries of ancient learning, that large volumes have been composed; as the collection of Gruter, &c.

Since Gruter's collection, Th. Reinefius has compiled another huge volume of inscriptions. M. Fabretti published another volume at Rome in 1669, wherein he has corrected abundance of errors which had escaped Gruter, Reinefius, and other antiquaries, &c. and added a great number of inscriptions omitted by them. Since all these, Grævius has published a complete collection of inscriptions, in three volumes folio.

INSCRIPTION, *Academy of*. See **ACADEMY**.

INSCRIPTIONS, *Notes, or Abbreviations, used in*. See **CHARACTER**.

INSCRUTABLE, **UNSEARCHABLE**, in *Theology*, is usually understood of the secrets of Providence, and the judgments of God, which cannot be found out, or into which human reason cannot penetrate.

INSE, in *Geography*, a town of Prussia; 22 miles W. of Tilsit.

INSECTS. See **ENTOMOLOGY**.

INSECTS, *Anatomy of*. Many parts of this subject have been already considered in the article **ENTOMOLOGY**, to which we refer the reader: our present object is to supply what has not been inserted there.

Organs of Motion.—A striking difference is observed in the position of the hard parts, which constitute the essential organs of motion, between this class and the mammalia, birds, &c. In the latter, the bones are placed in the centre of the limbs, and are surrounded by the muscles, which are covered externally by the skin; while in the former, the resisting matters, which are analogous to bones and perform their functions, are hollow, placed externally, supply the place of skin, and contain the moving powers in their cavities.

The structure and appearances of the external coverings vary considerably in the different orders of this class. In the crab, lobster, &c. a hard calcareous crust covers the whole body and limbs, serving for skin and skeleton. In the perfect insects the surface of the body is covered by horny substances of various degrees of hardness and resistance. The larvæ have coverings of a softer kind, and approaching more nearly, as far as external characters go, to the skin of mam-

malia and of the neighbouring classes. Yet this is analogous in its functions to the calcareous and horny crusts; for it receives the insertion of the muscles, and therefore constitutes the chief agent of locomotion.

The sensible characters of the calcareous crust of the crab and lobster (their *shell* as it is commonly called) resemble those of the shells of testaceous animals, and in some degree those of bone: but the chemical constitution is in some respects different. The very valuable researches of Mr. Hatchett have made us acquainted with the chief circumstances of the composition of these matters. After having detailed his experiments on shells and on the coverings of the echini, he proceeds: "It was now requisite to ascertain if phosphate of lime is a component part of the substance which covers the crustaceous marine or aquatic animals, such as the crab, lobster, prawn, and cray-fish. Pieces of this substance, taken from various parts of those animals, were at different times immersed in aceticus and diluted nitric acid; those which had been placed in the diluted nitric acid produced a moderate effervescence, and in a short time were found to be soft and elastic, of a yellowish-white colour, and like a cartilage, which retained the original figure. The same effects were produced by aceticus acid, but in a less degree; in the latter case also the colouring matter remained, and was soluble in alcohol. All the solutions, both aceticus and nitric, afforded carbonate and phosphate of lime, though the former in a larger proportion. There is reason to conclude, therefore, that phosphate of lime, mingled with the carbonate, is a chemical characteristic, which distinguishes the crustaceous from the testaceous substances; and that the principal difference in the qualities of each, when complete, is caused by the proportion of the hardening substances, relative to the gluten, by which they are cemented; or by the abundance and consistency of the gelatinous, membranaceous, or cartilaginous substance, in and on which the carbonate of lime, or the mixture of the carbonate and phosphate, has been secreted and deposited. And as the presence of phosphate of lime, mingled with carbonate, appears to be a chemical character of crustaceous marine animals, there is every reason to conclude that Linnæus did right not to place the echini among the testaceous ones. The presence of phosphate of lime, in the substance which covers the crustaceous marine animals, appears to denote an approximation to the nature of bone, which, not only by the experiments of Mr. Gahn, but by the united testimony of all chemists, has been proved principally to consist, as far as the ossifying substance is concerned, of phosphate of lime." *Philos. Transf.* 1799. In a recapitulation of these researches, in the *Transactions* for 1800, he says, "it was proved, that the crust which covers certain marine animals, such as crabs, lobsters, cray-fish, and prawns, consists of a strong cartilage, hardened by a mixture of carbonate and phosphate of lime; and that thus these crustaceous bodies occupy a middle place between shell and bone, though they incline principally to the nature of shell." Similar results to these were obtained by Merat-Guillot, who has described his investigation in the *Annales de Chimie*, t. 34. From 100 parts of lobster crust, he obtained 60 of carbonate of lime, 14 of phosphate, and 26 of animal matter. In 100 parts of cray-fish crust there were 60 of carbonate, 12 of phosphate, and 26 of animal matter. So far as the horny coverings of insects have been examined, they correspond in chemical properties to horn, hoof, scales of serpents, feathers, &c. and do not owe their firmness to calcareous matter, which seems not to be an essential part in their formation. See **HORN**.

An interesting enquiry arises here, concerning the mode
of

of formation of these coverings; but our data are hardly sufficient to resolve it satisfactorily. "Some observations," says Cuvier, "seem to prove that there are testaceous animals, which lose their shells entirely at certain periods, and are supplied with new ones. But this reproduction might be effected by development like that of the antler; and if it be also a development, which produces the interior layers of those shells, which do not drop off, it may be compared to that which forms the inner lamina of the horns of cows, sheep, and other ruminating mammalia, and also to the production of the epidermis in all animals: that is to say, it is a desiccation, a kind of death of a membrane, which appeared to have some sort of organization, as long as it was protected from the contact of the external air, or had not acquired completely its characteristic solidity. All the hard parts which hold the place of bones in invertebral animals seem to be developed in this manner. In the crab and lobster, for example, that which serves at the same time for integuments and skeleton, grows no more when it has once attained its perfect hardness; yet the soft parts still continue the progress of their development. When they are too much confined by the hard covering, that separates and is detached: but another is found under it, which was in a state of formation while the former was detaching itself, or, as we may say, dying. This new covering is at first soft, sensible, and even vascular; but a quantity of calcareous matter, previously collected in the stomach, is very soon conveyed to it, hardens it, obstructs the pores and vessels, and renders it, in short, perfectly similar to that of which it has supplied the place. Insects do not acquire their perfect hardness until they have taken their last form, and have no further change of skin to undergo; but all the skins which they had cast off before, although softer, were dead, and already replaced by others, developed before they were discharged. Thus all the hard external organs of white-blooded animals, whatever their consistence and chemical nature may be, should rather be compared, in their mode of growth, to the epidermis, to hollow nails, and horns, than to true bones." *Leçons d'Anatomie comparée*, t. 1, p. 118.

Epidermis.—Crustacea and insects, whether in their larva or perfect state, have a true epidermis; but, as this integument, when it has once become dry and hard, is no longer susceptible of that extension which is necessary to accommodate the growth of the animal, it is separated at certain periods, which are definite in each species, but influenced considerably by the atmospheric temperature: the animal quits its skin, passing out from it as from a sheath. This process is called moulting; the insect, in many cases, is several days preparing for it, and sometimes perishes. Most of the larvæ of the papilio and bombyx kinds change their covering seven times before they pass into the state of chrysalis. The bombyx cæja has ten successive coverings.

This most singular process is not analogous to the mere separation of the cuticle in the human subject; for the parts which are detached in insects, in many cases afford attachment to the muscles of the animal. Thus, in the crustacea the whole skeleton is shed, and this takes place annually. "These frequent moultings," says Lyonet, "of the caterpillar of the phalæna colusæ are the more singular, inasmuch as the caterpillar does not simply change its skin, but casts its whole external covering, in which we observe the head, jaws, cornæ, all the scaly parts composing the lips, the curri, the spinning hole, the antennæ, and even the scales enclosed within the head, and affording attachment to several muscles; also the stigmata, the nails, scales, and hooks of the feet, the hairs, the anus, in short all the visible external

surface of the animal. In disposing itself for this operation, it passes some days without taking any nourishment; the muscles, and other interior organs of the head, are detached from the old cranium, and withdrawn into the neck; they form a new covering, similar to that which they have left, but larger, and at first soft. When the new skin, and all the other parts, which contribute to the covering of the caterpillar, are formed, the old one is opened, and the animal withdraws from it by an operation so much the more difficult in consequence of the weakness caused by the soft state of the new organs, which will not allow it to act with vigour, nor to take any nourishment for some days.

"The caterpillar, thus newly clothed, exhibits different proportions from those which it had before moulting; the head, legs, and all the horny parts are sensibly larger in comparison to the rest of the body; these therefore do not increase afterwards. The body and soft parts of the animal only grow, until they become again too large for their covering, and a new moulting is necessary." Lyonet, *Traité Anatomique de la Chenille*, p. 7.

Rete Mucosum.—The place of this organ is held in the crustacea, by the calcareous shell, which immediately succeeds the epidermis; its colour is commonly a dull green, sometimes red, blue, white, or black. Alcohol, acids, and particularly the application of heat, often produce remarkable changes in these colours, as we may observe in the lobsters brought to our tables. In larvæ a layer of mucous substance is seen between the epidermis and the muscles; and the colours of this vary infinitely in the different species. It is particularly remarkable for its brilliancy in caterpillars, and the larvæ of some hymenoptera; it gives to their bodies the purest and most lively tints, of which the shades and symmetry are admirable. Red, purple, violet, blue, green, yellow, scarlet, black, &c. are distributed in the most regular and striking manner. Probably the brilliant colours of the perfect insects are owing to the mucous body dried and blended with the horny covering. For whilst the lepidoptera are in their chrysalis state, the small coloured scales which will afterwards adorn their wings, appear like the mucosity which is under the skin of the caterpillars. The colours of the spiders are also owing to this mucous matter, which is found under their skin, and has the appearance of small glandular points marked by different shades of colour. But in the coleoptera, and in several other orders, the colours seem to reside in the horny tissue, as those of the testacea do in their calcareous shells.

Nothing can be seen in this class, which can be compared to the cutis; there is a pellicle under the shell of the crustacea, but it is fine, transparent, and has very little consistence. The layer which is separated from larvæ in their moultings, is of the same nature and thickness as that which is under it and succeeds. The coverings of the contracted chrysalises, such as those of the lepidoptera and diptera, cannot be regarded as a true skin; it is rather a horny epidermis. Lastly, in their perfect state, insects have nothing in their coverings which can be compared to cutis. The hairs of insects seem to be productions of their epidermis; for they are discharged with that in moulting, and are supplied by new and longer ones. The scales of the wings and body in the lepidoptera and some other orders, are small horny plates, differently coloured, implanted in the skin, and placed one over the other, like tiles in the roof of a building. The plumes of some insects are prolongations or threads of the wings, furnished with long hairs on their sides.

Joints.—The crustacea and the proper insects agree in the kind of their articulations; the particular nature of which arises from their hard parts being placed externally to the

muscles. The former being made like sheaths, and having their cavities filled by the muscles, cannot be articulated by simple and plane surfaces; their joints therefore exhibit no specimens of arthrodia and enarthrosis. All their moveable articulations may be reduced to three kinds. Where the parts require a solid point of support, the ginglymus is employed; the horny coverings of the limbs, being tubular, must rest on each other in two points of their circumference at least, and this arrangement necessarily determines the ginglymoid form. Where a solid point of support is not required, the parts are merely suspended by ligaments, or are articulated by a kind of setting in. In the latter construction one part enters and is received into the hollow of another. Thus the thighs of insects are set in the thorax, and the rings of the abdomen are set into each other. Since the part which receives, and that which is received, are segments of a spheroid, the latter may perform a twisting motion; it may be pushed more or less completely into the cavity, either equally in its whole circumference, or to a greater degree on one or the other side; but flexion properly so called cannot be performed. The parts which are connected by ginglymus, and which are chiefly the different portions of their legs, have deep notches on that side where the flexion is most extensive; the interval is filled with a plant membrane, and there is no other ligament. The articular tubercles and excavations are so arranged that they cannot be luxated without fracture.

Muscles.—The muscular system of the crustacea is confined to the motions of the legs, tail, and false feet; there are no muscles for moving the head on the thorax, since the two parts are consolidated into one piece in this order. The antennæ, the jaws, and the palpi, have particular muscles, but we shall not consider them at present. The tail is a very principal part of the body in most crustacea. It consists of a very strong and moveable member, which they employ with great effect both in jumping and swimming. It is composed in several monocluc of long threads, which in the polyphemus (molucca crab) are solid and moveable at their bases only. In the crabs it is short, flattened, and curved under the body in a depression placed between the legs. The cancer bernhardus (hermit crab) has a soft tail without scales, which it introduces into empty shells or hollow stones.

The tail deserves a particular description in the lobster, where it is formed of six chief segments, and terminated by five plates. The former are not all of exactly the same figure; they are convex above, and cover one another like tiles; below they are narrower, and united by a loose membrane which allows them considerable mobility. In the latter situation, at the angle of union between their dorsal and lower portions, they have a kind of firm fins, bordered with ciliated processes, and formed of several articulations. These are called false or swimming legs (*pedes natatorii*). These admit of being moved from before backwards, and a little from without inwards, by means of small muscles contained in their interior, but not differing sufficiently from those of the true legs to merit a particular description.

The five plates, which terminate the tail, consist of two pairs and a single one; the latter is placed in the middle, and articulated directly to the last segment. The opening of the anus is found under it. In some species it is divided in its middle, so as to admit a slight motion. Each of the lateral pairs is supported by a common piece articulated to the last segment of the tail. The internal plate of each pair is simple, and ciliated, like the middle one, only at its extremity; but the external is in a manner articulated, or rather formed of two pieces; the first of these covers by its extremity, which is denticulated, the smaller which succeeds, and of

which the edge is set with very close cilia. The muscles which move this tail are so singular, as to merit a distinct description.

The muscles of the tail, in the lobster, form two masses, separated from each other by the intestinal canal. In the dorsal mass, which is the thinnest, and least complicated, three kinds of fibres may be observed. The first constitutes a muscle attached to the dorsal portion of the thorax towards its posterior fourth part. It is then directed obliquely backwards and outwards towards the sides of the first segment of the tail, in which it is inserted. The portion of one side acting separately, will carry the tail towards the right or left; when both act together, they will extend the tail, and maintain it in the extended state. The second and third series of muscular fibres are extended through the whole length of the tail in two parallel and contiguous lines. They arise from the upper and lateral portions of that septum of the thorax, on which the branchiæ are applied, by several digitations. When it has arrived at the first ring of the tail, a small interfection is observed on the surface, and we observe that a small bundle of fibres turns off to be inserted into this first angular segment; and a similar insertion takes place in each of the succeeding rings. This disposition gives to the internal band the appearance of a twisted cord. The external portion of the dorsal mass is formed of distinct longitudinal fibres. These three orders of muscles have much analogy to the straight dorsal muscles of caterpillars, as we shall see in the sequel.

The ventral mass of the muscles of the tail is much thicker and more complicated than those of the back. In order to give a clear notion of its composition, we shall describe it as observed in three aspects. In the first place, from the back; the muscles which we have described, as well as the intestinal canal, having been removed; secondly, from below, the scales which cover the under surface of the tail, and the nerves having been taken away; and thirdly, on the inside, a longitudinal section having been carried through the muscle in its middle line, in order to expose the internal structure.

The ventral muscle of the tail, on its dorsal aspect, arises in the interior of the thorax, above the intricate bony texture, containing the muscles of the legs. It is then divided into a right and left portion; each of which is formed of three broad digitations. Over the first segment of the abdomen, its longitudinal fibres dip under others, which turn round and embrace them. The rest of the muscle, in the whole length of the tail, is thus formed of two series of convex fibres curved in parallel directions, placed laterally with regard to each other, and separated from right to left by a channel in which the intestinal canal is lodged.

On the under surface three very distinct orders of fibres may be seen. The first is produced from the inferior surface of the digitations which arise from the bony frame-work of the thorax. The second consists of oblique fibres, which are a continuation of the former, extending from the middle line, in which the nervous cord is placed, to the sides of the rings at the angle of union between their dorsal and ventral portions. Each of these angles, from the first to the sixth, has two strong bundles. The third series is made up of transverse bundles describing arcs, of which the convexity is downwards. These muscular flattened hoops correspond to the interfections of the rings, and seem to form derivative pulleys for the oblique fibres just mentioned.

Lastly, the ventral muscle of the tail, divided longitudinally in its middle, resembles a rope with the strands rather obliquely disposed. The fibres belonging to the transverse bundles are distinct and narrower.

From this singular complication it results, that the muscle, when

when insulated from all its adhesions, constitutes a very close twist, the threads of which, instead of acting in the longitudinal direction, move obliquely in the canal which they occupy between the neighbouring fibres.

The legs of the crustacea vary in number and size. Their figures are very different in the monouli; sometimes they hold the place of palpi, jaws, fins, branchia, &c. They differ considerably in form in the crabs, particularly the first pair. We shall describe the legs of the crab and lobster as an example of these organs. They are usually five in number on each side, and each has six articulations. The first pair is considerably the largest, and forms what we call the claws.

The hip, or haunch, is attached to the chest, and moves only from before backwards. It supports one division of the branchia, as well as the second piece of the member, which corresponds to the thigh. The latter is flattened, short, nearly square, smooth, and a little curved. The plane of its articulation is parallel to the length of the piece; and as the two muscles which move it are inserted into the two most remote points, the thigh is situated horizontally. It has a hinge-like motion on the hip, combined of the two directions from before backwards and from within outwards. Its motion on the leg, which is very limited, takes place only from below upwards, and produces the approximation of the limb to the chest. The third portion corresponding to the leg is also rather flattened, particularly at its femoral extremity. It is slightly curved in the direction of the thigh, so as to correspond to the convexity of the thorax. Towards the tarsal end it becomes larger and rougher: its motion on the thigh is very limited. The fourth articulation is intermediate between the pincer and the leg, on which it moves in a very distinct angle. The pincer composes the fifth, and by far the largest piece. It is terminated on the outside by a pointed and serrated projection; and it receives on the opposite side a moveable pointed piece or pollex, capable of being opposed to it, which, with the other, constitutes the pincer. The motion of this on the fourth piece is from without inwards. The two following pairs of legs resemble the former on a smaller scale, with this difference, that the two pieces, composing the pincer, are of equal size. The two last pairs of legs differ from the three others in not being terminated by a pincer, but by a single nail. In every other respect they resemble the two preceding pairs.

Muscles of the Legs.—Each articulation has an extensor and a flexor muscle. The extensor of the hip is situated in the interior of the thorax, on the horny piece which supports the branchia, rather in front of the hip, which it draws forwards. The flexor arises from the same part farther back, and produces the contrary motion to the preceding.

The extensor of the thigh is stronger than the flexor; it is attached to the inner and front part of the hip, and to the superior eminence of the thigh. It depresses rather than bends. The flexor, or rather the elevator of the thigh, is shorter than the former: it occupies the posterior internal surface of the thigh, and is inserted into the inferior eminence.

The extensor of the leg is placed in the hollow of the thigh, of which it occupies the whole breadth; it is inserted into the external border of the leg. The flexor is less powerful, lies under the extensor, and is fixed to the inner edge.

The extensor of the first piece of the tarsus is attached to the whole upper edge of the leg, and is inserted into the highest eminence of the fourth piece. Its flexor arises

from the lower edge of the leg, and is inserted into the lower eminence.

The extensor and flexor of the pincer occupy and divide the interior of the fourth piece: their functions are determined by their situation. The extensor of the moveable piece or pollex is a very small muscle, occupying the upper part of the pincer: its flexor occupies all the rest of this part, is a very bulky muscle, and has a flattened oblong bony tendon in its middle. From this muscle arises the great power of the animal in seizing and holding objects.

Organs of Motion in the Larvæ of Insects.—As insects undergo considerable changes of form at certain epochs of their life, they exhibit remarkable differences in their organs of motion. Hence it becomes necessary to describe them in their various states. All the winged insects, which undergo a complete metamorphosis, differ very considerably in their first state from that which they have in the sequel; and the most striking of these differences regard the moving powers. At this time they are called larvæ or caterpillars; and they preserve this form for a longer or shorter time after quitting the egg. They are covered with a flaccid and soft skin, divided into segments or rings susceptible of motion on each other, by means of small muscular bands situated in the interior of the body. Frequently their motions are performed simply by crawling on these rings, after the manner of reptiles; or, by reeling successively each of the segments of the body on the plane which supports it. Such is the case with the larvæ of the diptera, and of most of the hymenoptera. Sometimes the surface of these rings is furnished with spines, stiff bristles or hooks, in order to give them a firmer hold on bodies: this may be observed in some flies, ætli, tipulæ, &c.

On the under surface of the body in some orders, there are six feet near the head, each of which is formed of three articulations: the last is horny and terminated in a hook. By opposing these to each other the insect can hold any object, hook itself to it, and then draw the rest of the body towards this fixed point. This formation is seen in the coleoptera, and many of the neuroptera. The six feet are very short, and hardly susceptible of any useful application in some other coleoptera, viz. such as live in the interior of wood, as the cerambyces, rhagia (Fab.), &c. The latter move in the hollows which they excavate by means of their jaws, by which they attach themselves, and with the assistance of plates or tubercles, with which their skin is furnished on the back and belly; their mode of proceeding may be compared to that of sweepers in chimnies.

Lastly, the lepidoptera, and some hymenoptera have, besides the six horny articulated feet, a variable number of false feet, not articulated, terminated by hooks disposed in circles and half circles, and attached to the skin on retractile appendices or tubercles: they move by fixing themselves to bodies by means of these organs.

The larvæ of such insects as undergo an incomplete metamorphosis, as the hemiptera, and of such as pass through none at all, as the aptera, except the flea, do not differ from the perfect insect in the feet.

After this general statement of the external organs of motions in the larvæ, we shall particularly describe the muscles of some. We shall first mention those of the proper caterpillars; then those of a scarabæus, which lives underground; of a hydrophilus, which inhabits the water; and of a cerambyx, which is found in the hollows of wood.

1. *Muscles of Caterpillars.*—The deepest stratum of muscles in the caterpillar is formed of four principal rows; two corresponding to the back, and two to the belly: their direction is longitudinal. Those of the back are separated from each other

other by the longitudinal vessel, and from those of the belly by the tracheæ. They begin at the union of the first and second rings, by two fasciculi slightly separated from each other, which are inserted into a kind of tendinous line produced by the union of the second with the third ring. The same structure exists in the subsequent rings. On the third, the fibres of the two fasciculi, although still distinct, are much more considerable; on the fourth the internal fasciculus alone has its fibres separate. The muscle is continued, without any apparent interfection, over all the other rings. It diminishes in thickness towards the opposite end of the body, and forms again several fasciculi; at first three, then four, and, lastly, five or six. The body is shortened when these muscles act in conjunction with those of the belly: it is curved upwards when they act alone.

The longitudinal muscles of the belly are separated from each other by the medullary cord, and from those of the back by the tracheæ. Their direction is precisely the same with that of the dorsal muscle. They commence at the union of the two first rings by several fasciculi, which are united into one mass over the third ring. Their fibres are separated again behind, higher or lower according to the species, and form four or five muscular cords, which terminate towards the last pair of false feet. These assist the dorsal muscles in shortening the body when both sets contract together; but they antagonize them, when they act separately, for they then incurvate the body downwards.

Between the long muscles of the back and the skin shorter ones are found, having an oblique direction. Some are extended from without inwards, towards the dorsal line, between the annular interfections. Others occupy the same interval, but have an opposite direction, passing from within outwards, so as to describe with the former the figure of the letter V. These two orders of oblique muscles have not every where the same quantity of fibres. In the first rings they are narrow and long; those of the fourth, fifth, and sixth are much shorter; further back they become much longer and more numerous in some species, while in others they still continue broad and short. These muscles act separately on each ring, which they shorten by their simultaneous contractions; but, as they do not extend over the whole length of the ring, the parts corresponding to the folds, over which the oblique muscles do not pass, are elongated, when, by the action of the latter, the diameter of the ring is diminished: thus progression is facilitated.

Under the long muscles of the belly is found another situation, of which the fibres are oblique. These very much resemble the oblique muscles of the back; and may be distinguished, according to their directions, into two orders. Those of one set are found nearer to the middle ventral line, in which the knotted nervous cord is found; and ascend from within outwards, in the intervals of the rings. The others are not so oblique, with the exception of the three superior pairs. These muscles, therefore, form, with the preceding, an angle, similar to this kind of A.

The oblique muscles which run from within outwardly, or the next internal, have many fibres. They usually consist of three or four distinct fasciculi. Those which extend from without inwardly, or the most external, have fewer fibres, and never more than two fasciculi.

The action of these muscles appears to be similar to that of the oblique muscles of the back; but it is probable that they also extend immediately the skin of the feet on which they are situated.

Besides the longitudinal and oblique muscles of the back and the belly, caterpillars have some which are lateral; that is to say, muscles situated below and above the stigmata

or apertures, which ought to be described separately. These muscles are of three kinds, the *straight*, the *transverse*, and the *oblique*.

The straight lateral muscles are situated between the annular segments, above the stigmata. They are all placed longitudinally one over the other. Their points of attachment are covered by the transverse muscles. They seem intended to bend the body towards the sides when they act separately; but when they contract, in concert with the long muscles of the back and abdomen, they shorten the body, and thereby assist its progression.

The transverse lateral muscles are of two kinds: some, which are longer than the others, arise from the intervals unoccupied by the attachments of the straight lateral muscles, and are inserted at the termination of the oblique external muscles of the abdomen. Their fibres are disposed somewhat in the form of a fan. The others have the fasciculi formed of parallel fibres; they are shorter, and are extended in each of the rings between the straight, lateral, and oblique muscles of the abdomen. These muscles diminish the diameter of each ring, and consequently lengthen it in each of its folds. This mode of action is necessary for progression.

The oblique lateral muscles are situated on each side of the straight. They proceed in an oblique direction from below upward, under the insertion of the straight lateral muscles, which they assist when they act together.

Such are the muscles of the body in general; but the true and false feet, and the head, have particular muscles, which must be described separately.

The muscles of the true or scaly feet are situated within the three articulations of which these feet are formed. They may be distinguished into those which move the articulations, and those which act on the *unguis*, or claw, that terminates them.

The muscles of the first joint consist of five or six fasciculi, which arise from the superior margin of this articulation, and are inserted into the superior margin of the next. The muscles of the second joint are nearly equal in number, and are inserted into the superior margin of the third.

The muscles of the *unguis* terminate by two tendons; but they are formed of several fasciculi, some of which arise from the second and third joints in two very distinct layers; others from a line which corresponds with the convexity of the *unguis*; and lastly, others from the line which answers to its concavity. These tendons are inserted into two tubercles at the superior extremity of the *unguis*, on the concave side, towards its point. They serve to bend the *unguis*, which probably recovers its position by the elasticity of its articulation.

There are two muscles to each of the membranous or false feet. Their direction, with respect to the body, is almost transverse. They extend from the centre of the feet, into which they are inserted towards the back, and beyond the stigmata, whence they arise by lateral bands or less oblique. Their use is to draw the centre of the foot inwardly, and to retract the hooks with which the limb is armed. It is probable that the contractions of the oblique muscles of the abdomen produce the opposite effect.

With respect to the muscles of the head, we shall at present describe only those which produce its entire motion. We shall notice the others in treating of the different functions to which they are subservient. The muscles which act on the head, bend it upward, downward, and towards the sides. Those which bend it upward are very numerous. They arise from the second and first ring, and are inserted into different points of the vertex; some near the middle

line, others more laterally. They form, in general, two fasciculi. The most internal is the least bulky. The lateral flexors are very oblique. They arise from the inferior or abdominal part of the body, and extend to the lateral parts of the occiput. The inferior flexors, which bend it downward, appear to be the continuation of the straight muscles of the belly. They consist of eight or nine fasciculi.

2. *Muscles of the Larva of a Scarabæus.*—The larvae of the scarabæus have the body arched, and convex superiorly, and concave on the side next the feet. The back and the belly are separated by a membranous border, which has folds, and is situated under the stigmata. These larvae have only six articulated feet, none of which are membranous. On opening these larvae longitudinally, either on the back or the belly, we observe three layers of deep-seated muscles—the lateral, the dorsal, and the ventral.

The dorsal layer is formed of two tolerably distinct series of fibres. One series is external, and occupies the intervals of the ten first rings; that is to say, those which are furnished with the stigmata. The muscles which compose this series are narrow, and preserve a longitudinal direction. The second series is produced by fibres, which are somewhat oblique, and extended in the same space, but more towards the middle line. These muscles are broader and stronger towards the head, and more narrow and less fibrous towards the tail. They terminate between the tenth and eleventh ring by a very narrow fleshy band. These muscles seem intended to shorten the dorsal portion of each of the rings: this action diminishes the convexity of that part, and thereby serves to assist progression.

Near the middle line, between the ninth and tenth ring, there are two small muscles a little oblique; but between the twelfth and the last ring we observe only one series of small short muscles, which occupy all the convexity described by the curvature. The action of these muscles is obviously the same as that of the preceding, to which they are accessories.

When the first layer of dorsal muscles is removed, we find fibres precisely similar underneath, but running in the opposite direction. Finally we observe, in the dorsal layer, lines of very short muscular fibres above the inferior plane of the ninth and tenth ring. The use of these little muscles is probably the same as that of all the preceding, though their action is less apparent.

The ventral layer very much resembles that of the back. These muscles, like the dorsal, form planes of opposite directions; the most deep-seated proceeding from the internal side, while those which are nearest the skin ascend from the external side. This produces a small but very regular rhomboidal figure in the middle of each ring on the line bisecting the belly. The action of these muscles is the opposite of that of the dorsal layer.

On the last segment, and towards the part that answers to the anus, we observe a bundle of transverse fibres, which, by their contraction, doubtless serve the purpose of a sphincter.

The lateral layer of muscles is composed of three kinds of fibres, which are very distinct with respect to their course. They represent a lace passed through the meshes of a net. All these muscles are situated behind the stigmata, and inserted into the folds which separate the belly from the back on both sides.

Those of the first order are completely transverse. They extend over the union of each ring with the succeeding in the space included between the ventral and dorsal muscles. It is obvious that they must diminish, by their contractions, the

diameter of the body, and consequently extend it longitudinally. These muscles are in general very narrow.

The second set is formed by oblique fibres which ascend from without inwardly towards the middle ventral line, from the union of one inferior ring to the union of the preceding. These muscles are broad and very strong, they serve to form the folds of separation between the back and the belly.

The muscles of the third order are less oblique than the preceding, to which they appear to be accessories. Each of the muscles which compose this division arises from the middle of a ring, and is inserted under the head, where the preceding muscles are inserted, that is to say, on the ventral side.

It should be remarked, that the two last rings have no lateral muscles.

The muscles of the head are very strong, the flexors are attached to the ventral muscles above the union of the second ring with the third. They are formed of three principal fasciculi, which approach each other, and are inserted into the posterior and inferior part of the head, at the base of that scaly piece called, by Latreille, *ganache*. The extensors or levators of the head consist also of three fasciculi, but they are longer and stronger than the former. They have their origin in the side, and penetrate under the transverse and oblique muscles; one is attached to the sixth ring; another to the fifth, and another to the fourth. They are inserted into the posterior lateral parts of the head.

3. *Muscles of the Larva of a Hydrophilus.*—The larvae of the hydrophilus are elongated. Their body is somewhat flat, and all its rings are distinct. They not only walk very quick, but they even swim with great velocity, in consequence of different inclinations suddenly and successively given to the body.

These larvae, when opened longitudinally, likewise exhibit four different kinds or divisions of muscles: those of the belly, those of the back, and those of both sides.

The ventral muscles very much resemble those of caterpillars: they are formed of two distinct layers. The deeper, or that which first appears on the belly, when examined through an opening on the back, is composed of longitudinal fibres with interfections which correspond to each ring; the second layer, or that which is next the skin, is entirely covered by the preceding; it is composed of oblique fibres, which cross each other in the form of an X, and which are extended longitudinally in each ring.

The dorsal muscles are long, extending from the head to the tail, and forming on each side two rows of fibres, which appear twisted over each other like ropes. They are broadest towards the head. Their fibres are inserted partly into the inferior border of an anterior ring, and partly into the superior border of the next ring.

These long muscles cover some which are oblique, and cross each other in the form of an X. They extend from the middle part of one ring to the anterior edge of that which succeeds it.

The deep-seated lateral muscles, which are numerous, have a transverse direction. Each ring has three or four, and their course is such, that they resemble the letters N or M lying on one side, thus $\Sigma \Sigma$.

Beneath the transverse lateral there are some longitudinal muscles that have a small degree of obliquity; they form a pretty large surface, which is uninterrupted throughout its whole length, and confounded with the oblique muscles of the belly. Their fibres determine the chief motions of the

body, in the same manner as the long muscles of the back and belly.

The muscles of the feet are the same as in the perfect insect.

The head has no particular muscles. The long muscles of the back, being inserted into the occiput, become extensors. The first transverse lateral pair are inserted beneath the head, and produce the lateral flexion. The long oblique muscles, which terminate at the inferior part of the head, become real flexors.

4. *Muscles of the Larva of a Cerambyc.*—In the larvæ of the cerambyces we find the same muscles as in those of the scarabæi; but as the shape of the body differs considerably in these two kinds of larvæ, there results some variation in the form and extent of the muscular organs.

A great part of the head of the larva of the cerambyces can be drawn within the skin whenever the animal pleases. Very strong muscles, similar to those we have described in the scarabæus, are appropriated to this function. As the head, which is very large, enters into the body, the extremity which receives it is somewhat thicker than the same part of the scarabæi, and the muscles which move the rings are more extensive than theirs.

The flat fleshy tubercles which we find continued along the back and belly, are a kind of feet, which this larva uses in progression. They move by the alternate contractions of the correspondent muscles: this larva, therefore, moves with equal facility on the back and on the belly.

Of the Organs of Motion in Perfect Insects.—The great variety of motions which insects are capable of performing, entitles them to hold the first rank among the animals that have no vertebræ. We discover, in these minute beings, all the requisites necessary to produce those voluntary actions, the execution of which astonishes us in vertebral animals of far greater magnitude. They even unite several functions which are very seldom found combined in the other classes; for insects walk, run, leap, swim, and fly with as much facility as the mammalia, birds, and fishes exercise one or more of these faculties.

Insects are probably indebted for this advantage to the numerous articulations of which their bodies are formed. We must therefore pay attention to their different articulations, before we proceed to examine the actions they permit or produce.

1. *Of the Head.*—For a description of the manner in which the head is articulated to the thorax, see ENTOMOLOGY, under the division *Caput, or Head.*

The muscles which move the head are situated within the thorax. We shall describe here only those most generally met with. The levators or extensors of the head are commonly situated in the superior part of the corselet, and the depressors inferiorly.

Immediately beneath the middle dorsal part of the corselet, we find a pair of muscles which arise from the anterior portion of the scutellum, when that part exerts; or from the superior part of the pectus. These muscles are inserted into the posterior and superior part of the head, on the edge of the occipital hole: they draw the head back, and lift it up when it is depressed.

On the lateral parts of this first pair we find another which is more slender: the insertion of this pair likewise takes place at the occipital hole, but more outwardly. They arise obliquely from the lateral parts of the corselet. These muscles turn the head to one side when they act separately; they raise it, and bring the mouth into the middle line when they contract together. It will be easily conceived that

insects which have the head articulated like a knee, these rotatory muscles are much stronger and more conspicuous.

The flexors of the head are also four in number, two on each side. The first pair arises in the internal inferior part of the pectus, from a small horny process, which, in the coleoptera is of a square form, and has the four angles terminated by solid branches. These muscles extend directly to the inferior part of the occipital hole. From their position they doubtless move the head directly backward. The second pair, which are much shorter, arise from the inferior lateral part of the corselet, and proceed to the side of the preceding, with which they concur in their effect when they act together; but when one of the two contracts separately it bends the head to the side.

2. For the description of the *thorax* or corselet, of the *pectus* or breast, and of the *abdomen* or belly, see ENTOMOLOGY, under the respective divisions.

3. *Of the Members.*—For an account of the number and structure of the feet, see ENTOMOLOGY under the division *Members.*

The motion of each joint is performed in a single place. It is provided with two muscles only, which are enveloped in the preceding joint. They are an extensor and a flexor.

In the coleoptera the coxæ move by a kind of rotation on their longitudinal axis, which is situated transversely, and forms, with the middle line of the body, an angle more or less approaching 90°. As the femur is attached to the internal extremity of the coxa, the distance between the thighs is greatest in those insects in which the femur is most bent with respect to the coxa, to which it is articulated. It is obvious, therefore, that the position of the plane in which this flexion is made, depends upon the situation of the coxa: when it is turned forward, the plane is vertical; when turned backward the plane is always more oblique; and in the insects that swim, it is even horizontal. It appears, then, that the almost imperceptible motion of the coxa determines the most remarkable movements of the feet.

The muscles of each pair of coxæ and femora are situated in the superior of the corselet or of the pectus. To obtain a proper view of them, it is necessary to cut the body of the insect in a vertical direction. Over the last pair in the pectus there is a scaly substance, in the form of a Y. The stalk of this part affords an origin to a muscle which turns the coxa backward, and is inserted into its posterior edge. The muscle which turns it forward arises from the back, and is inserted by a thin tendon, into its anterior edge.

The muscle which extends one femur, while it is approximated towards the other, is very considerable. It arises from the whole branch of the piece in the form of a Y, and is inserted into the internal edge of the head of the femur. Its antagonist is situated within the body of the coxa.

The muscles which extend the two pairs of anterior femora, arise from the corresponding dorsal parts, and not from particular internal substances: the flexors, however, are always situated within the body of the coxæ.

The muscles which turn the coxæ arise also from the parietes of the corselet; viz. the muscle which moves it backward, from the dorsal part, and that which moves it forward, from the lateral part. In the water beetles, which, as we have observed, have the posterior coxa consolidated and immovable, these muscles seem to extend to the femur, which is therefore furnished with four, two extensors and two flexors.

The other orders of insects have nearly the same conformation as the coleoptera.

The muscles of the tibia are situated within the femur. The extensor, which is short and slender, is attached to its external edge (the femur being supposed extended in the longitudinal direction of the body): the flexor is much stronger and longer. It is situated on the inner side, and in the whole of the superior part.

There are likewise two muscles to each joint of the tarsus: one, which is small, and placed on the superior or dorsal surface, acts as an extensor. The other, which is more conspicuous, and situated on the inferior side, acts as a flexor.

For the description of the wings, see ENTOMOLOGY.

The muscles that move the wings are not yet well ascertained. They appear to be two kinds. Some, which are small and short, are fitted to extend or fold the wings, at the same time that they move them to or from the body: the others, which are somewhat longer, are calculated to produce the motions of elevation and depression which the wings perform.

The elytra of the coleoptera, orthoptera, and hemiptera, do not appear to assist in the action of flying, at least they are not moved in the same manner by the muscles of the pectus.

Organs of Sensation.—On comparing together all the nervous systems, we find only one common part, which is a single tubercle, situated at the anterior extremity of the system, and always producing two lateral transverse fasciculi or crura, which unite it to the rest of the system. This part appears always to correspond to that named cerebellum in man. The cerebellum of animals that have red blood and vertebra, is always preceded by several pairs of tubercles, forming usually a larger mass than the cerebellum itself, and united to the rest of the system by two longitudinal fasciculi or crura, which are interwoven in crossing with those of the cerebellum. This union takes place in such a manner that both are confounded in the common mass which forms the root of the medulla oblongata, and medulla spinalis, and leaves no space between them. These tubercles make what we call the cerebrum.

In the white-blooded animals, or those that have no vertebra, there are also tubercles corresponding to the cerebellum, but they are much smaller, removed from each other, and connected with the cerebellum only by separate nervous filaments. The crura of the cerebellum leave a large interval between them, which receives the œsophagus as in a collar.

The two fasciculi, forming the medulla spinalis, are intimately united in vertebral animals, and no trace of their separation remains, except a longitudinal furrow before and behind. But, in the animals which have no vertebra, when this production exsils, it is formed below the œsophagus by the union of the two crura of the cerebellum. These two fasciculi commonly remain distinct throughout the greater part of their length, and are only united at different places by knots from which the nerves proceed. This production, however, frequently does not exist. In some animals with white blood, which have no elongation of the medullary substance, as in the mollusca, the nervous trunks, which are derived from the crura of the cerebellum, enlarge and form ganglia, or two or three nerves unite with each other to produce a common ganglion; and in general it is only from their ganglia that the nerves which are distributed throughout the body take their origin.

In those white-blooded animals that have a knotted and double medullary production, that is to say, in the insects, crustacea, and certain worms, the nerves all arise from the

knots or ganglia of the medulla, or from some of the anterior ganglia of the cerebellum.

In the red-blooded animals the nerves of the spine arise from the medulla spinalis in two bundles of medullary filaments, which unite after the posterior bundle has formed a ganglion. They afterwards separate into two trunks, the anterior of which communicates with the great sympathetic nerve by one or two filaments, and a ganglion is always formed at the place where they unite.

The great sympathetic nerve, which is constantly found in all red-blooded animals, exists in none of those with white blood; unless we should regard as that nerve, the two nervous cords which unite all the ganglia, and which are commonly called medulla spinalis in the crustacea, insects and worms. Were this opinion adopted, a medulla spinalis would be no longer attributed to those animals, and the absence of that production would then be the common character of all the white-blooded classes.

Instead of having the parts, which represent the brain and medulla spinalis enclosed in bony cavities, the lower orders of animals have them included in the common cavities, with the other viscera.

Brain and Nerves of the Crustacea.—The crustacea, which, in their organs of motion, very much resemble the other insects, though those of circulation and respiration are exceedingly different; have also a similar nervous system, at least in the essential parts.

In such of the genus cancer as have long tails, the middle part of the system is a knotted cord, which extends from one extremity of the body to the other. The short-tailed kind, commonly called crabs, have a medullary circle in the middle of the abdomen, whence the nerves of the body proceed like radii.

In these animals the brain is placed at the anterior extremity of the snout, and consequently at a considerable distance from the mouth, which opens under the corselet. On this account the cords which make the collar of the œsophagus are more elongated than in other animals.

A. Brain of the common Cray-Fish, (Alfusus Fluviatilis, Fab.)—The brain of this animal forms a mass which is broader than long, and distinctly divided on the superior surface into four round lobes. Each of the middle lobes produces an optic nerve from its fore part. This nerve proceeds directly into the moveable tubercle which sustains the eye, and is there dilated and divided into a multitude of filaments, which form a pencil, and unite to all the small tubercles of the eye.

Four other nerves arise from the inferior surface of the brain; these proceed to the four antennæ, and detach some filaments to the neighbouring parts. The cords which form the collar, arise from the posterior part of the brain. About the middle of its length, each detaches a large nerve, which extends to the mandibles and their muscles. These cords unite under the stomach in an oblong ganglion, which furnishes nerves to the different pairs of jaws. On leaving this part, the two cords remain near each other throughout the whole length of the corselet, where they form five successive ganglia, placed between the articulations of the five pairs of feet: each foot receives a nerve from its corresponding ganglion, which penetrates to the extremity of the foot: the nerve of the forceps is the largest. The medullary cords extend into the tail, where they are so intimately united that it is not possible to distinguish them. They form six ganglia, the five first of which produce each two pairs of nerves; the last produces four, which are distributed as radii to the scaly fins that terminate the tail.

The hermit crab, (*Pagurus, Fabr. Bernhardus, Linn.*) the

the tail of which is not covered by articulated scales, appears to have much fewer ganglia than the cray-fish. We have observed only five.

In the *squilla*, Fabr. there are ten ganglia, without reckoning the brain: that at the union of the two cords which form the collar, transmits nerves to the two forceps, and to the three pair of feet which immediately succeed them, and which in these animals are ranged almost on the same transverse line; this ganglion is therefore the longest of all. Each of the three following pairs has a particular ganglion. There are afterwards six ganglia in the length of the tail, which distribute their filaments to the thick muscles of that part. The brain produces immediately four trunks on each side, *viz.* the optic, those of the two antennæ, and the cord which forms the collar. As the antennæ are placed more posteriorly than the brain, their nerves are directed backward.

B. In the Common Crab (*Cancer Manas*, Linn.)—The brain of the crab resembles that of the cray-fish in its form and situation: it also furnishes analogous nerves, but they are directed more towards the sides, in consequence of the position of the eyes and the antennæ. The medullary cords which form the collar, detach each a nerve to the mandibles, but the cords are prolonged much farther backward than in the cray-fish before they unite. They join only in the middle of the thorax, at which place there is produced a medullary mass of an oval ring-like figure, which is eight times the size of the brain. The nerves which proceed to the different parts arise from the circumference of this ring. It furnishes six nerves on each side to the jaws and the five feet, and there is a single nerve which arises from the posterior part, and proceeds to the tail. This medullary ring may be said to represent the usual knotted cord, but if it has any ganglia they are not visible.

C. In the *Oniscus Asellus*.—The two cords which compose the middle part of the nervous system in this animal, do not perfectly join. We can distinguish them throughout the whole of their length. There are nine ganglia, exclusive of the brain; but the two first and the two last are so close together, that the number may be reduced to seven.

D. In *Monoculi*.—We know not the nervous system of the molucca crab (*Limulus gigas*, Fab. *Monoculus polyphemus*, Linn.) In the *monoculus apus* of Linnaeus, however, the indistinct nature of that system, joined to some other peculiarities of organization, would almost induce us to class the animal with the inarticulated worms. The brain is a small globule, nearly transparent, situated under the interval of the eyes. The medullary cord is double, and has an enlargement at each of the numerous articulations of the body; but the whole is so thin and transparent, that the real nature of the cord can scarcely be ascertained.

Brain and Nerves of the Larva of Insects.

A. Coleoptera.

1. *Larva of the Scarabeus Nasticornis*.—We shall give a particular description of the nerves of this larva, because their distribution is essentially different from that which takes place in the other coleoptera.

The brain is situated under the great scale which covers the head immediately above the origin of the œsophagus: it consists of two approximated lobes, which are very distinct at the front and back part. Four nerves arise from the anterior part, two on each side, which are lost in the cirri and parietes of the mouth.

From the lateral and somewhat posterior parts of the brain, there arises a pair of nerves, which, embracing the

œsophagus, proceeds inferiorly to form the nervous cord we shall presently describe.

Another pair departs from the inferior surface of the brain, or that part which rests upon the œsophagus: these are first directed forward; they afterwards turn inward, and proceed above the middle and superior part of the œsophagus, in order to approach each other. When they come in contact, they unite and form a small ganglion, which produces a single nerve; this nerve, continuing to proceed posteriorly, passes below the brain, and accompanies the œsophagus to the stomach. It there enlarges again into a ganglion, which furnishes some small nerves that are sent to the stomach, and one more considerable, which is continued along the intestinal canal, and sends off, at regular distances, lateral filaments, which are lost in the coats of this tube. This nerve is analogous to that which Lyonet has described under the name of *recurrent*, in the caterpillar of the *cistius*.

The medulla spinalis, which, as we have shewn, is formed by the posterior pair of nerves of the brain, is very thick at its origin: it forms a large fusiform ganglion about 0,005 metre long, and half a millimeter broad. Four or five contractions appear on its anterior part, but they are so slight that they seem only transverse furrows. The posterior part of this ganglion is smooth.

From the lateral parts of this large ganglion, which extends very little beyond the third ring of the body, a great number of diverging nervous filaments are produced. Those which are nearest the head ascend a little; those which succeed them proceed almost transversely; and the last are directed more and more posteriorly: the length of each is in proportion to its distance from the anterior part of the ganglion. The two most posterior filaments are therefore the longest.

2. *Larva of the Stag Beetle (Lucanus Cervus)*.—The nerves of this larva differ greatly from those of the preceding, although the perfect insects are so nearly allied in genera.

The brain consists of two contiguous and almost spherical lobes; these produce four nerves anteriorly for the antennæ and the parietes of the mouth: two inferiorly, which first proceed forward, then turn back, pass again under the brain, and form a nerve known under the name of *recurrent*. Lastly, two posteriorly, which form a collar round the œsophagus, and join underneath, to compose the nervous cord of the body. This cord is formed of eight ganglia, which extend to the ninth ring of the body. The distances between these ganglia are very unequal; they are joined by very slender and closely approximated nervous filaments. The first ganglion, from the head, is very large, and almost spherical; it is followed almost immediately by the second, which is one-half less, and which is distinguished from it only by a kind of contraction; the first produces four pairs of nerves on each side; one ascends to the head, the other three diverge and are lost in the muscles of the abdomen, and in those that move the head. The second ganglion, besides the two nerves that unite it to the third, produces two other nerves, which are also directed backward, and lost in the muscles of the fourth ring. The third ganglion, and those that follow as far as the eighth, are similar to the second; with this difference, that they are much more distant from each other, and that they produce longer filaments, in proportion as they are situated more inferiorly. Lastly, the eighth and ninth ganglia are so close together, that they seem to form but one, with a slight contraction in the middle. This double ganglion produces three pairs of nerves,

nerves, which are much elongated, and extend to the parts near the anus.

3. *Larvæ of the Cerambyx, Hydrophilus, Carabus, and Staphylinus*.—The nerves of these larvæ being very similar, it will be sufficient to describe them in one genus only. We shall take for our example the larva of the great diver (*Hydrophilus piceus*).

The brain in this animal is situated in the head, above the origin of the œsophagus; it is formed of two lobes which lie very close together. From its anterior part it detaches some filaments to the palpi, the antennæ, and the parietes of the mouth. Its lateral parts produce two cords which surround the œsophagus, and which are the origin of the nervous cord situated inferiorly. It is probable that recurrent nerves also arise from this inferior part, but we have not yet been able to discover them. The chief nervous cord is composed of ten ganglia, each of which produce three pairs of nerves that are lost in the muscles of the abdomen, and without any distinct appearance of their being distributed to the intestines. This induces us to believe that there is a recurrent nerve. The first ganglion is very large; it is prolonged posteriorly into two nervous filaments, considerably removed from each other; the second is almost similar, but the third is very near the fourth, which produces only a single filament posteriorly. All the others, as far as the tenth, present no peculiarity. The last is divided by a sensible contraction; from the first portion a single filament arises on each side, and from the second, three pairs of nerves are detached: thus four pairs of nerves arise from this ganglion. The fourth pair is directed to the rudiments of the parts of generation, which are very distinct in these larvæ in the last period of their growth.

4. *Larva of the Water Beetle (Dytiscus Marginalis)*.—The brain of this larva is spherical, and consists of a single lobe, situated in the head above the origin of the œsophagus; its anterior part produces some filaments for the mouth; and its lateral parts the two optic nerves; the latter are composed of two parts which are very distinct as to form. The first portion, or that which is next the brain, is of an oval figure, pointed at the extremity which joins the brain: the other extremity is rounded, and produces a slender nerve, which goes directly to the eye. It is nearly of the same thickness throughout the whole of its extent; but it is enlarged at its free extremity into a bulb, from which the nervous filaments of the eye arise.

The two cords which embrace the œsophagus are short and thick; they arise from the inferior surface of the brain, and immediately unite below the œsophagus, in a large square-shaped ganglion, which produces anteriorly the nerves of the mandibles, and posteriorly two cords, which pass from the head into the corselet. There is a greater distance between this first ganglion of the nervous medulla and the second, than between any of the others. It is more than double that which exists between the two next ganglia. The second ganglion is round; it produces two pair of nerves laterally; the anterior for the muscles which act upon the head, the posterior for those which move the anterior feet. There are two cords posteriorly, which are directed into the breast. The third ganglion is similar in every respect to the second; it furnishes nerves to the intermediate pair of feet. The fourth ganglion is also produced by the two cords which come from the preceding; it is situated on the union of the abdomen with the breast; it is more broad than long. Laterally it produces two pair of nerves, which run transversely parallel, and are lost in the muscles. The other eight ganglia are placed close behind each other, and the space between them is so small, that we can scarcely perceive

the two nervous filaments which unite them; they also decrease in thickness, without diminishing in breadth, as they extend posteriorly. They all furnish laterally a pair of very long nerves, which float in the abdomen, and for the most part terminate in the muscles that move the wings. One pair, however, proceeds to the rudiments of the parts of generation.

B. *Oribotera and Hemiptera*.—The nerves of the larvæ of orthoptera and hemiptera present no sensible difference from those we observe in the perfect insects. It will be sufficient, therefore, to describe the nerves of the latter.

C. *Hymenoptera*.—In the larva of the saw-fly (*Tenthredo*, Linn.) which has a large head furnished with eyes, the brain is very broad and short; it seems to form four bulbs of equal magnitude, and nearly spherical; the two external serve as the base of the optic nerves, which are slender, and which enlarge a little at their other extremity. The first ganglion is produced by two very small nerves, which arise from the inferior surface of the brain, and which, after having embraced the œsophagus, unite under the first ring of the body; it furnishes filaments to the muscles of the feet, and terminates posteriorly in two other nerves, which, at the distance of one line, produce a second ganglion, and so on in succession; the nervous cord is in this manner formed of eleven ganglia, without reckoning the brain; the farther the ganglia are removed from the head, the more they diminish in thickness; they are all nearly of a round form.

D. *Neuroptera*.—In the larva of the lion-ant (*Myrmecoleon formicarius*), the nervous system has some relation to that of the larva of the dipterous insects which we shall afterwards describe.

There is a brain situated in the head; it produces nerves analogous to those we have already pointed out in the other larvæ. The nervous medulla consists, in the first place, of two ganglia, which are composed of two lobes, situated close together; these two first ganglia are separate from the others, and contained in the part corresponding to the feet, or in the thorax. The remainder of the nervous medulla is enclosed in the abdomen; it consists of eight ganglia, placed in an exceedingly close series, and each formed of two lobes; the first is nearly double the size of the other seven. This succession of ganglia appears to the eye like the extremity of the tail of a rattle-snake; the last is round; the others are more broad than long. All these ganglia furnish nerves to the muscles. It is probable that this disposition and approximation of the ganglia have a relation to the changes which take place in the insect at the moment of its metamorphosis, as its abdomen then occupies six times the space it does in the larva state.

In those larvæ of neuroptera, which are nearly as long as the perfect insect, we find that the ganglia are separated in the usual manner.

The larva of the ephemera has eleven ganglia, without including the brain, which furnishes two large optic nerves. There are three ganglia in the thorax, and seven in the abdomen: the first six, reckoning all the ganglia, furnish more nerves than the five last.

The larvæ of the dragon-flies have a small two-lobed brain, which produces optic nerves, larger or smaller according to the species. The genus *æthna* has them the largest. The rest of the nervous system forms a series of ganglia of different sizes. In the *æthna*, the corselet contains six, the two last of which are the largest of all. There are seven small and equal ganglia in the abdomen.

E. *Lepidoptera*.—The nervous system of caterpillars con-

sists of a series of thirteen principal ganglia, which furnish filaments to all other parts of the body. The first of these thirteen ganglia is situated in the cavity of the head; it lies above the œsophagus, and supplies the place of the brain: it appears formed superiorly by the union of two round tubercles, inferiorly it is concave, and corresponds to the convexity of the œsophagus. This ganglion communicates with the rest of the nervous cord by two thick filaments, which embrace the œsophagus, and which are united below it to the anterior and lateral part of the next ganglion; it besides produces eight pairs of nerves.

The first partly unites with other filaments; produces some for the œsophagus, and forms several remarkable ganglia below the upper lip. The largest and most posterior, which Lyonet has named the *first* frontal ganglion, is prolonged posteriorly into a thick recurrent nerve, which is continued the whole length of the body, near the back; this recurrent nerve furnishes filaments to the œsophagus and its muscles; it penetrates into the dorsal vessel, and it afterwards re-appears, and glides along the œsophagus as far as the stomach. This nerve produces, at certain distances, very solid filaments, which keep the œsophagus attached to the skin of the back.

Besides the recurrent nerve we have just noticed, several filaments are furnished by the posterior frontal ganglion to the muscles of the œsophagus, and two to the *second* frontal ganglion; the latter also detaches several filaments to the œsophagus, and, in particular, a very remarkable one, which, by a sudden enlargement, constitutes the *third* frontal ganglion. This ganglion likewise affords several filaments to the œsophagus.

The second pair of the brain appears chiefly intended for the antennæ, though it furnishes several filaments to the neighbouring parts. The third pair terminates particularly in the antennæ, and the muscles which move them. The fourth pair is proper to the eye of each side; it accompanies the air-tube which goes to that part, and is divided into six branches, that penetrate into the six eyes, which, by their union, form that of the caterpillar. The fifth is directed a little backward, where it divides into two branches; one posterior for the adductor muscles of the jaw; the other anterior, which is lost in the membranes that cover the frontal scales. The sixth and seventh pair unite to form a ganglion from which several filaments are detached, to the œsophagus and its muscles. Finally, the last pair of the brain is entirely lost on an air-tube.

But besides these nerves produced by the first nervous ganglion, several others are detached from it, which we shall briefly notice. In the first place, we observe, that it furnishes several filaments to the dorsal canal; it afterwards gives origin to a pretty long filament, which terminates on the air-vessels, between the second and third ganglion. Lastly, it produces a nervous ring, which embraces the œsophagus inferiorly like a girth, and supplies it with several filaments. The second ganglion is intimately united with the third, and is distinguished from it only by a contraction. The nerves which proceed from the anterior part appear to be produced by the second ganglion, and those which arise from the posterior part, seem to belong to the third.

Besides the two filaments which form the collar round the œsophagus, and which unite the first to the second ganglion, the latter has four pair of very distinct nerves. The most anterior pair is sent forward to the mouth, but in its course it divides into two branches: one terminates in the tongue and the adjacent parts; the other branch proceeds to the lateral parts, where it sub-divides, to supply the mandible, the jaw, and upper lip, communicating, at the same

time, with the first ganglion, and with the second frontal. The second pair proceeds to the jaw, but detaches a number of filaments to the muscles of the neighbouring parts. The third pair is destined for the spinning apparatus; in its course it gives filaments to the silk vessels and muscles of the head. The fourth pair arises near the contraction, which indicates the union of the two ganglia, between the head and the first ring; it is lost in the fat, in the skin of the neck, and in the muscles inserted into the head.

The third ganglion, which, as we have observed, is united to the second, produces only three pairs of nerves: the posterior is merely the continuation of the nervous trunk of the other two pairs; the anterior is entirely lost in the muscles and the skin; the intermediate pair supplies that part also; but it is distributed chiefly to the muscles, which move the articulations of the leg.

We have already stated, that each ganglion communicates with that which precedes, and that which follows it by two filaments that are distinct from their origin, and are the bifurcation of a single trunk. The middle of this bifurcation, from the third to the eleventh ganglion, produces a small nerve, which Lyonet has named the *spinal frenum*: this single nerve is situated in the middle line; it presently divides into two branches, which follow the divisions of the air-tubes, and penetrate with some of them into the longitudinal vessel.

The fourth and fifth ganglia produce the same number of nerves, the distribution of which is also nearly similar; their anterior pair proceeds to the muscles, and to the skin of the rings to which it corresponds; the intermediate pair furnishes, more particularly, filaments to the muscles of the leg.

The sixth ganglion, which corresponds to the fourth ring of the body, also furnishes two pair of nerves, which are lost in the muscles and the skin.

The nerves of the five following ganglia are distributed nearly in the same manner.

The twelfth ganglion, and the thirteenth, which is the termination of the nervous cord, are very close to each other, though distinct. The distribution of the nerves, produced by the first, presents nothing remarkable. Those furnished by the second are very long, being sent to the last rings, in the skin and muscles of which the first pair is partly lost. The second pair is only subdivided when it has reached the first ring; it there produces a plexus, from which a number of filaments are detached to the great intestine. The trunk appears to end on the parietes of the rectum towards the anus.

F. *Diptera*.—The nerves of the larva of the *fratryomus* have some resemblance to those of the larva of the *scarabeus nasicornis*.

The brain is formed of two lobes, placed close together, and almost spherical; it is situated above the œsophagus, on a level with the second ring of the body. A number of small nervous filaments arise from its anterior part, and are distributed to the parietes of the mouth, to the mandibles, and to all the adjacent parts. These nerves are very distinct, particularly those which are removed from the middle line. The posterior part of these two lobes sends off two thick branches which embrace the œsophagus, and form the origin of the nervous medulla. This nervous cord is very short, and its diameter is one-half less than that of the brain; it consists of eleven ganglia placed very near each other, each of which produces one pair of nerves.

These nerves proceed directly backward. Swammerdam has erroneously represented this cord as twisted, like the tail of a scorpion, and producing nerves on the left side

only. It is true, that those which arise from the right side are parallel to the cord, while those of the left side remove farther from it. The ganglia, thus approximated, are eleven in number, and in a straight direction; they produce long nerves, which are lost in the muscles.

The nerves of the cheese-worm (*Musca putris*, Linn.) are distributed in a very curious manner. The brain is situated immediately above the origin of the œsophagus, behind the head; it is very large in proportion to the rest of the body; it is rounded posteriorly, and notched anteriorly, as if it were formed of two lobes.

A pair of nerves arise from the anterior part of the brain, proceed forward, and are distributed to the mouth, and even to the parietes of that cavity. It should be remarked, that these nerves experience a very conspicuous enlargement previously to their distribution.

Posteriorly the brain presents an aperture, which affords a passage for the œsophagus: the nervous part, situated on its sides, may be regarded as the cords which produce the medulla, and all below the œsophagus as the medulla itself.

Two pairs of nerves arise from the origin of the nervous medulla; these are directed forward, and principally distributed to the viscera, and to some of the muscles of the anterior rings. The third pair of nerves which this medulla produces is the most remarkable; it comes from the part which nearly corresponds to the third ganglion; we say nearly, because in this insect the ganglia are so close to one another, that the medulla seems to form only one piece on the surface of which we merely perceive twelve transverse wrinkles, which indicate the number of ganglia. This third pair extends almost transversely. At a certain distance from its separation it swells into a ganglion, and then divides into several filaments; these are the muscles which Swammerdam supposes are intended for the muscles of the wings, when they shall exist in the perfect insect.

Another pair of nerves, which go to the muscles of the body, arise from each of the other contractions; but they require no particular remark.

Brain and Nerves of Perfect Insects.

A. Coleoptera.

1. *In the Stag-beetle (Lucanus Cervus).*—We find in this insect, as in its larva, a brain composed of two approximated spherical lobes, situated above the œsophagus; its anterior part produces two pair of nerves, which terminate in the palpi and other parts of the mouth. There is probably a recurrent nerve, but our researches have not yet discovered it.

There are two ganglia on the lateral parts of the brain, which are almost as large as each of the lobes. In their form they resemble a pear, and rest upon the brain by their base; they are prolonged transversely into a large nerve on each, chiefly intended for the eye. Before the nerve arrives at that part, we observe it detach a slender filament, which enters into the great mandible; then, more externally, another filament which enters into the cavity of the antennæ; lastly, the nerve itself, having reached the eye, swells again into a bulb, and produces a number of nerves, which we shall describe when we treat of the organ of vision.

Posteriorly the brain produces two very long and slender nerves which accompany the œsophagus to the point where the head unites to the thorax, immediately above the articular condyle. The two nerves situated above the œsophagus, then, produce a ganglion of a long oval form, from which

several nervous filaments are detached to the muscles that move the mandibles, and those that act on the head. This ganglion terminates posteriorly in two parallel nerves, which proceed to the middle of the thorax, above the origin of the two pair of feet, and there form a second ganglion of an hexagonal figure; this ganglion furnishes filaments to the muscles of the feet, and likewise terminates posteriorly in two nerves, which extend above the union of the corselet, with the pectus; they there unite and form a third ganglion, which is crescent-shaped, with the convexity posterior; two other nerves proceed from this convexity, which almost immediately produce another ganglion of the same form, but smaller. This ganglion gives origin to five nerves: two lateral, destined to the muscles of the intermediate feet, into the coxæ of which we observe them enter: posteriorly two, which are slender, and distributed to the muscles of the hind feet and the wings. The fifth is situated in the middle line; it is also thicker, it swells almost immediately into an oval-shaped ganglion, which is divided posteriorly into two exceedingly slender filaments. These filaments, which pass into the abdomen, form a kind of bridge in the breast, in which they occupy the middle line, and leave between them the muscles of the feet and wings of either side.

2. *In the Scarabæus Nasicornis.*—With respect to the nerves, this insect differs in the perfect state from the description we have given of its larva. The optic nerves, which are very distinct and large, proceed to the eye, into which we observe them enter by a multitude of filaments when we make a horizontal section of that organ.

The nervous cord presents a very conspicuous difference. In the larva there is only a single ganglion; but the perfect insect has several, which are very distinct. The first is situated above the condyle; it proceeds from the two posterior filaments of the brain, and is distributed to the muscles which move the head on the corselet. Its posterior part produces two filaments, which pass into the breast, where they unite towards the middle part, and form a triangular ganglion; from the sides of which three pairs of nerves arise, and are distributed to the muscles. Its posterior angle detaches two parallel nerves, which proceed into the breast, where they form a third and a fourth ganglion, situated very near each other, and apparently divided into two lobes by a longitudinal furrow. All the other nerves of the body depart from those two ganglia by an irradiation, precisely in the same manner as in the larva.

3. *In the Water Beetles (Dytiscus) and the Ground Beetle (Carabus).*—The nervous system is entirely similar in these insects. The brain is formed of two large hemispheres, separated from each other by a longitudinal furrow. The anterior part produces the nerves of the mouth, and the lateral parts those of the eyes and antennæ. The nerves of the eyes are short, and differ greatly from those of the stag beetles; they are of a pyramidal form: their base corresponds to the eye, and their apex to the brain. We have not observed any recurrent nerves.

The two filaments which produce the nervous cord depart from the brain, not posteriorly, but inferiorly, on the side of the optic nerves: they are very short, as they pass immediately under the œsophagus. They furnish some filaments to the muscles and the œsophagus. The first ganglion they form lies under a kind of bridge, formed of horny substance, which is situated in the middle of the head, and which affords a point of attachment to the muscles of the jaws; it is of an elongated and quadrangular figure, and occupies almost the whole space that corresponds to the condyle above which it is placed. It is terminated posteriorly by two filaments which proceed in a parallel direction,

direction, and form a second ganglion in the middle part of the corselet. This ganglion furnishes nerves to the muscles of the anterior feet. We observe them enter into the cavity of the coxæ. The third ganglion appears bilobed, or formed of two oval bulbs, the union of which is marked by a longitudinal furrow. This ganglion is situated longitudinally above the anterior inferior edge of the breast. It sends filaments to the muscles of the intermediate feet. The fourth ganglion is very near the preceding; it is of a roundish form, and is distributed to the muscles of the posterior feet and the wings. The space between the fifth and sixth ganglion is very small: their form is round; and they furnish filaments to the muscles that move the abdomen on the breast. The remainder of the medullary cord is formed by a series of five ganglia, situated so close to one another, that they appear to the naked eye to form only one; but with a glass they may be observed very distinctly. We even perceive the two filaments produced by each to form the succeeding ganglion. The fifth presents a transverse furrow, which seems to indicate the union of two ganglia. The end of the medulla appears to float in the abdominal cavity, but above the intestines.

4. *In the Great Diver (Hydrophilus Picus, Linn.)*—The brain of this insect, which is situated in the head, and above the origin of the œsophagus, consists of two spherical bulbs closely united. The lateral parts give origin to the optic nerves which proceed towards the eyes without changing their diameter, but which terminate there by a triangular bulb that produces a vast number of filaments externally.

The anterior part of the brain detaches some filaments intended for the parietes of the mouth. We also remark, at the same place, a small spherical ganglion, which appears to belong to the recurrent nerve that accompanies the œsophagus.

Two filaments, which should produce the medullary cord, arise inferiorly: they embrace the œsophagus at their separation, unite immediately below it, and again, in the cavity of the head, to form a small ganglion, which furnishes nerves for the muscles of the mandibles and the palpi. Two nervous cords are detached from the posterior part of this first ganglion. Almost immediately after their origin, they pass under a horny arch, which is produced by the internal surface of the ganache. We observe that they re-appear posteriorly, and proceed into the corselet. They form a second ganglion exactly in the middle of the corselet; its figure is quadrangular. The anterior and posterior angles produce the nerves of the medulla, and the lateral those intended for the muscles of the anterior feet. The interval included between the second and third ganglion of the medulla is very great. The third ganglion corresponds to the insertion of the intermediate feet: it is large, and of a round form; it furnishes nerves to the wings, and to the intermediate pair of feet. Posteriorly it produces two cords, which, at the distance of about half a line, swell and form a fourth ganglion, almost as large as the preceding. This ganglion detaches, from its inferior part, a number of filaments for the muscles of the posterior feet, which are specially appropriated to swimming. Two other very short cords produced by the posterior part of this ganglion swell into a fifth, which is one-half less than the former, and which furnishes a fine cord posteriorly. This cord passes into a kind of longitudinal groove, formed above the horny appendix, that furnishes attachments to the muscles of the coxæ. A sixth ganglion is situated at the posterior and wide part of this appendix: at a certain distance, and exactly above the union of the abdomen with

the breast, a seventh appears. These two ganglia produce only one pair of nerves, which are distributed to the muscles.

There are only two ganglia in the abdomen; one corresponds to the middle part of the second ring; the other, which is the last and ninth, is situated above the union of the second segment with the third. The last ganglion but one is in every respect similar to the two preceding; but the ninth is one-half larger, and produces posteriorly four pair of nerves, which are distributed on both sides to the parts of generation.

B. *Orthoptera*.—*In the Cockroach (Blatta Americana.)*—The brain of this insect is composed of two lobes, separated by a very distinct notch anteriorly. The optic nerves arise on the sides, and its anterior part detaches some filaments to the parietes of the mouth, and to the instruments of mastication.

The nervous cords which form the medulla arise from its inferior surface. They proceed directly downward, and closely embrace the œsophagus. They afterwards proceed in a parallel direction, but very distinct from each other, towards the corselet. When they reach its middle, they form a very large ganglion, which produces three pairs of nerves laterally, and one posteriorly. The first lateral nerves ascend obliquely towards the head, and furnish filaments to the muscles that move it on the thorax, and which act on the antennæ and the parts of the mouth. The others are distributed to the muscles of the first pair of feet.

The posterior nerves proceed in a parallel direction backward. At the middle of the pectus they produce a still more considerable ganglion than the second, which furnishes laterally nerves to the intermediate and posterior feet, as well as to the muscles of the wings. It also sends off two cords posteriorly, which, by their union at the junction of the abdomen and the breast, form a fourth ganglion, situated on a projecting horny substance to which the muscles of the coxæ are attached.

After this fourth ganglion there is only a single nerve, which has, at certain spaces, small enlargements. Five of these swellings may be counted. Each produces a pair of nerves for the muscles of the rings of the abdomen: the first is the largest, and furnishes besides two nerves which ramify in the parts near the anus.

In the Great Green Grasshopper (Gryllus Viridiflms, Linn.)—The brain is situated in the head above the œsophagus: it consists of two lobes, which have the form of pears, united at their base, and prolonged at the other extremity into an optic nerve for the eye of each side. The anterior part also produces two nerves of a pyramidal form, the base of which rests upon the brain. Some filaments arise from the apex of the pyramid, which are lost in the mandible, the jaw and its galea, as well as in the upper lip.

Between these two anterior nerves we observe a small ganglion, which is produced by the union of the two filaments of the inferior surface of the brain. This is the recurrent nerve which follows the intestinal canal. Posteriorly, and a little inferiorly, we observe the origin of the two cords which form the nervous medulla. They embrace the œsophagus, below which they are immediately directed, and form a ganglion. This first ganglion is protected and covered by a kind of horny bridge of a reddish colour. It furnishes nerves to the muscles of the mouth, and to those of the head within which it is included. Posteriorly it produces two long nervous cords, which penetrate into the corselet. These two cords unite about the middle of the thorax before the appendix, which gives attachment to the muscles of the coxæ and the anterior pair of feet. At this union they form a large

a large bilobed ganglion, of an irregular quadrangular figure, the sides of which produce several filaments for the muscles of the anterior feet.

The posterior part of this second ganglion furnishes two filaments, which penetrate into the breast. The solid appendices of the coxæ, which afford insertions for the muscles, pass between these two filaments. They form a third ganglion, which corresponds to the middle space included between the two intermediate feet. This ganglion sends nerves to the muscles of the wings and the feet.

The fourth ganglion is also contained in the breast. It is situated before and between the posterior pair of feet. It is produced by two nervous cords from the preceding ganglion; and furnishes two posteriorly, which are so close to each other, that they appear to the naked eye to make only one cord. This nerve is received and contained in a kind of groove formed above the triangular piece, which affords an attachment for the muscles of the feet.

The other ganglia, which are all situated in the abdomen, are six in number. They are, the last excepted, of the same size and form, placed at equal distances, and produced by two similar and closely approximated cords. Each furnishes two pair of nerves for the muscles of the abdominal rings.

The last ganglion of the medulla is one-half larger than the five preceding. It is situated below the parts of generation, to which it is distributed by four pair of filaments.

In the Mole-cricket (Acheta Gryllo talpa.)—The brain of this insect is also composed of two rounded lobes, which are particularly distinct at the posterior part. We can clearly perceive the origin of the nerves of the palpi, of the antennæ, of the smooth eyes, and of the eyes properly so called. In general the nerves of the principal medulla are similar to those we have described in the cock-roach. The two first ganglia are produced by two nerves. The first, which is in the corselet, supplies the muscles of the head, breast, and anterior feet. The second, which is larger, and in the breast, gives filaments to the muscles of the wings, and of the intermediate and posterior feet. It also sends two nerves posteriorly, which produce the abdominal ganglion. The cord then becomes single and flat, like a ribband, and contains only four ganglia, occurring at different distances. Each produces two pairs of nerves, which are directed posteriorly, and distributed to the muscles. The first corresponds to the middle part of the first abdominal ring; the second to the third, the third to the fifth, and the last to the sixth.

This last ganglion is the most remarkable of all. It is of an oval shape, and produces, from the whole of its circumference, nerves which are distributed to the neighbouring parts. Two, which are longer than the others, diverge as they proceed backward, and thus represent a bifurcation of the medullary cord. These branches furnish filaments to the parts of generation.

C. Hemiptera—*In the oval Water Scorpion (Nepa Cinerea, Linn.)*—The nervous system of this insect consists of three ganglia. The first, which supplies the place of the brain, is situated in the head. It is formed of two approximated lobes. These lobes are pyriform, and touch each other at their base. Their funnits are directed obliquely forward towards the eyes, in which they terminate, and thus answer to the optic nerves by their anterior extremities. The middle and anterior part of these lobes also produce some filaments for the parts of the mouth. Posteriorly, the brain detaches two cords, which embrace the œsophagus as they pass below it. They unite at the origin of the breast in a tetragonal gan-

gion: each of the angles of which produces or receives several nerves. The anterior receives the two cords which come from the brain; the posterior, the two which are the continuation of the medullary cord. Each lateral angle produces a fasciculus, composed of four nerves, which are directed to the muscles of the breast and anterior feet. We observe one of them enter into the cavity of the coxæ.

The two nerves produced by the posterior angle of the second ganglion proceed in a parallel direction backward. Having arrived in the breast above the horny appendix, to which the muscles of the coxæ of the intermediate and posterior feet are attached, they swell into a large round ganglion, considerably more voluminous than the brain. A vast number of nerves are detached from the edges of this ganglion, like solar rays. The two most remarkable filaments are exceedingly long and slender. They extend from the breast nearly as far as the anus: we have observed them to terminate by three minute branches in the parts of generation of the male, furnishing, at the same time, some filaments to the adjacent parts. All the other filaments, which proceed from this third and last ganglion, are destined to the muscles. We can very plainly distinguish those that belong to the middle and intermediate feet, as they are somewhat larger than the others.

D. Lepidoptera.—*In the Zig-zag Moth (Phalena Dissar, Linn.)*—The brain in this species is almost spherical. We, however, perceive a longitudinal furrow on the middle line. Its anterior part produces some exceedingly slender nerves. There are two large optic nerves on the sides, which proceed into the concavity of the eye, where they terminate by a bulb, which produces a great number of filaments.

The œsophagus passes immediately behind the brain, through a small triangular interval, the posterior sides of which are formed by the two cords of the medulla. These cords afterwards unite, and proceed in the form of a single trunk, on the middle part of which we perceive only a longitudinal furrow. Arrived in the corselet, it forms a ganglion, the surface of which is reddish. This ganglion produces two nerves posteriorly, which leave between them an interval that affords a passage for the horny appendices to which the muscles of the coxæ are attached. The two cords again unite behind these appendices in the same cavity of the breast, and produce a much larger ganglion, the lateral parts of which furnish nerves to the muscles of the wings and feet. It is prolonged posteriorly into a single cord, which again enlarges when it arrives above the articulation of the breast with the abdomen into a third ganglion.

It should be remarked, that this large ganglion, which has the form of a heart, is the only one, besides the brain, of a completely white colour. All the others exhibit darker shades, and we observe in them, when viewed by a glass, reddish points more or less elongated and sinuous, that resemble the blood-vessels of injected glands.

The third ganglion is prolonged into a single cord, which produces a fourth ganglion above the first ring of the abdomen. The latter, as well as those that succeed it, detach on each side a long slender nerve which passes under the muscular fibres, precisely in the same manner as the threads of the woof pass through the warp in cloth. Their direction is completely transverse. The fifth ganglion does not differ from the preceding. It is prolonged into a single cord, upon which we can still very distinctly perceive the longitudinal furrow. It is situated in the middle part of the third ring of the abdomen. The sixth ganglion is, in every respect, similar to the preceding; it is placed in the middle of the fourth ring. Finally, the seventh and last ganglion is much larger than those that precede it in the abdomen. It is of an

oval form, and situated upon the lunula that terminates the fifth abdominal ring posteriorly. Besides the nerves intended for the muscles of the fifth ring, which are detached from this ganglion in two distinct parts, it produces four other pairs posteriorly. These nerves appear to be distributed to the parts of generation, and to the muscles of the last abdominal rings, which, in the female, are elongated like a tail to assist in laying eggs.

E. Neuroptera.—The insects with naked wings, that is to say, the Hymenoptera, Neuroptera, and Diptera, which have frequently very large eyes, have also the optic nerves of a proportional size. This is particularly observable in the dragon flies. Their brain is formed of two very small lobes; but their optic nerves are dilated into the form of two large plates, which have the figure of a kidney, and which is spread upon all the inner surface of the eye next the head. The remainder of their medullary cord is exceedingly slender, and furnished with twelve or thirteen small ganglia, the last of which is, as usual, connected with the parts of generation.

F. Hymenoptera.—The brain of the bee is small, and divided into four lobes. It produces immediately the nerves which are distributed to the different parts of the mouth, and the two large optic nerves which are dilated and applied behind each eye as in the dragon flies. There are afterwards seven ganglia, three of which are in the corselet, and four in the abdomen. The nerves of the last chiefly supply the parts of generation.

G. Diptera.—The aspidiform fly (*Musca tenax*, Linn.) has a small brain, formed of two lobes, which are situated very close together, but distinguished by a longitudinal furrow; the anterior part produces a large nerve, which is afterwards distributed to the antennæ and the proboscis.

The optic nerves are very thick, cylindrical, and equal in diameter to the length of the brain, on the lateral parts of which they rest; they terminate at their extremities in very large bulbs, which correspond to the breadth of the eyes.

The first ganglion of the medulla is produced by two cords, which come from the posterior part of the brain, and embrace the œsophagus as a collar; it is very slender, and situated in the breast; it furnishes a pair of filaments to the muscles of the anterior feet.

The second and the following ganglia, in all three in number, are united to each other merely by a single cord. The last ganglion is one-half larger than that which precedes it. Posteriorly it produces eight or nine filaments, which are intended for the parts near the anus; the first of the three is situated in the breast, where it furnishes nerves for the muscles of the wings and the feet; the other two ganglia are in the abdomen; the last but one is placed above the union of the third ring with the fourth; and the last on the interior and inferior edge of the fifth ring.

In the hornet-fly (*Ailus crabroniformis*) we also observe a single cord uniting the abdominal ganglia, which are six in number.

The brain is similar to that of the syrphus; but the bulbs, formed by the optic nerves, are still broader, in proportion to the extent of the eyes they have to invest.

H. Gnathoptera.—In the great scolopendra (*Scolopendra morifans*) the brain has a very singular form: it is, as usual, composed of two lobes, which are almost spherical; it produces laterally the optic nerves, which are very short, and may be observed to divide long before they reach the eye. The filaments are four in number; but two nerves arise anteriorly, which are so very thick, that they appear a part of the brain, to which they are equal in diameter. These nerves are particularly intended for the antennæ, into which

we observe them enter, and in which they may be followed on account of their magnitude.

The two cords which embrace the œsophagus proceed directly downward, and form a large ganglion at the union of the first ring with the head. The first ganglion produces two nerves posteriorly, and several towards the sides. A ganglion, precisely of the same shape, is placed above each of the articulations: thus there are, in all, twenty-four very distinct ganglia; the last of all is smallest, nearest the preceding, and seems to float in the abdomen; each detaches three pairs of nerves; one which ascends towards the head, a second which runs transversely; both these are distributed to the muscles of the abdomen: the third descends, and then proceeds backwards and upwards; it furnishes filaments to the lateral muscles, and to those of the back.

Organs of Sense.—We have very little to observe on this subject, in addition to what will be found in the article ENTOMOLOGY, under the divisions, *Organs of Taste, Palpi, Olfactory Organs, Eyes, Stemmata, Organs of Hearing.*

Few subjects in comparative anatomy and physiology have given rise to more various and contradictory opinions, than the organs of sense in some classes of animals. Much misunderstanding on this point has clearly arisen from the inconsiderate application to animals, of inferences drawn from the human subject. Thus, it has been supposed that those which possess a tongue, must have it for the purpose of tasting; and that the sense of smell must be wanting, where we are unable to ascertain the existence of a nose. Observation and reflection will soon convince us, that the tongue, in many cases (in the ant-eaters among mammalia, and almost universally in birds) cannot, from its substance and mechanism, be considered as an organ of taste; but must be subservient merely to the ingestion and deglutition of the food. Again, in several animals, particularly among insects, an acute sense of smell seems to exist, although no part can be pointed out in the head, which analogy would justify us in describing as a nose.

However universally animals may possess that feeling, which makes them sensible to the impressions of warmth and cold, very few possess, like the human subject, organs exclusively appropriated to the sense of touch, and expressly constructed for the purpose of feeling, examining, and exploring the qualities of external objects. This sense appears, according to the present state of our knowledge, to exist only in three classes of the animal kingdom; viz. in most of the mammalia, in a few birds, and probably in insects. All the observations and investigations of the structure of the antennæ, those peculiar organs which exist universally in the more perfect insects; and of the use which these animals generally apply them to; lead us inevitably to the conclusion, that they really are, what their German name implies (Fühlhorn) the literal translation of which is feeling horns) proper organs of touch; by which the animal examines and explores surrounding objects. Such organs are particularly necessary to insects, on account of the insensibility of their external coat, which is generally of a horny consistence; and also from their eyes being destitute in most instances of the power of motion.

We are not warranted in considering the tongue as an organ of taste in all animals, because it is subservient to that function in the human subject, and in some other instances. We have already observed, that this organ, in many cases, serves merely for taking in the food; and it is at least very doubtful whether it possesses the sense of taste in many others. Yet, on the contrary, we should not be warranted in denying the existence of the sense in these animals, nor even in such as are entirely destitute of a tongue; for this function may

be exercised by other parts. The organ which is commonly considered as the tongue of insects, merely serves for taking in the food. But the accurate observations of professor Knoch, (in his Contributions to the Knowledge of Insects, in German,) renders it very probable, that the posterior pair of palpi, or feelers, possesses the power of taste in several of this class.

Numerous facts have long ago proved, that several insects can distinguish the odorous properties of bodies, even at considerable distances. But the organ in which this sense resides, has not hitherto been clearly pointed out. Since all red-blooded terrestrial animals smell only through the medium of the air which they take in at inspiration, several naturalists have supposed, that the stigmata of insects are to be considered as organs of smelling. Others ascribe this office, and with some probability, to the anterior pair of palpi.

There is no doubt that several insects possess the sense of hearing, but the organ of this sense is very doubtful. In some of the larger animals of the genus cancer, a part can be distinguished which seems to be analogous to the vestibulum of the former classes. A small bony tube is found on each side at the root of the palpi; its external opening is closed by a finer membrane; and it contains a membranous lining, on which a nerve, arising from a common branch with that of the antennæ, is expanded. The latter circumstance might favour an opinion, that the antennæ themselves are organs of hearing; but this is refuted by considering the exquisite sense of hearing, which some insects possess, who have no true antennæ, as the spiders; and by experiments on others, which shew that the sense of hearing is not weakened by removing the antennæ.

The compound eyes and the stemmata have been described in the article ENTOMOLOGY. The former are found in different numbers in most of the aptera, as also in the larvae of many winged insects. When these undergo the last or complete metamorphosis, and receive their wings, they gain at the same time the large compound eyes. Several genera of winged insects, and aptera (as the larger species of monoculi) have stemmata besides their compound eyes. Further investigation is necessary to shew how these eyes enable the insect to see; and to determine the distinctions between two such very different organs. Blumenbach considers that the stemmata are designed for seeing near objects, and the polydrous eyes for distant ones; because butterflies have the latter only in their winged or perfect state, while in the caterpillar state they have only stemmata. He acknowledges, however, that this opinion is very doubtful, because some insects, which live completely underground, as the mole-cricket (*Gryllus gryllotalpa*, Linn.) have both kinds of organs.

On the organs of the senses in this class, the reader may consult Lehmann, de sensibus externis animalium ex sanguine: commentatio premio regis ornata, Goetting, 1793, 4to. F. J. Schelver versuch einer naturgeschichte der sinnes werzeuge bey den Insecten und Würmern; Essay towards the Natural History of the Organs of Sense in Insects and Vermes; Goetting, 1798, 8vo. Organs of the digestive Functions.—For a general account of the parts about the mouth and their nomenclature, see ENTOMOLOGY.

Jaws of the Crustacea.—Moll of the genus cancer have at their mouth five or six pairs of organs, which must be regarded as jaws, since they move laterally in a horizontal plane; they are placed successively one over the other, and

the most exterior has been called by some anatomists the lip, but wrongly; since it is not single, and the two parts which compose it have lateral motion like the others. All these jaws are articulated under the thorax, anteriorly with respect to the feet, of which they seem to continue the series in front; and each of them has, on the inner side of its root, a membranous plate, which, slipping under the lateral border of the thorax, between the anterior branchiæ, serves to separate their lobes, and to compress them in the act of respiration. The feet have similar laminae for the posterior branchiæ, but they are deficient in those species which have the branchiæ under the tail, as the squilla. (Fab.)

These jaws, with the exception perhaps of the one or two most interior parts, are formed of two divisions; of one, which may properly be called the jaw, and another, which is its dorsal palpus or feeler. The latter is more elongated, and terminates in an articulated and pointed thread: the other has at its end, but in the two first pairs only, a feeler which does not end in a pointed bristle like the other. This arrangement is common to the crab, lobster, cray-fish, hermit crab, and, in general, to all the crustacea decapoda of Latreille. In the first the outer jaw is flattened, and joined so well to the corresponding piece and to its feeler, that the four pieces together form a kind of shield, which covers all the other jaws. But in the lobster and cray-fish the outer jaw is prismatic and strong; and the divisions of the feeler being nearly as large as the body of the jaw, the whole together resembles a foot, and has often been described as such by the ancient naturalists.

In the crustacea decapoda, the second jaw, reckoning from the outer one, resembles the first, whatever may be its form, except that it is smaller, and that its inner edge is extenuated and ciliated, instead of being denticulated. The body of the third is divided into two lobes, the fourth into four, and the fifth into two; all these three are thin and ciliated. The palpi of the two latter have generally a simple point instead of a thread. The sixth is merely a small, oval, membranous plate, without cilia or palpus. Some varieties are observed in the number and figure of the jaws in the crustacea. Thus, among the decapoda, the scyllarus (Fab.) has no thread-like process on the dorsal piece of the two first jaws; the third is undivided, and the fourth only divided into two without a dorsal piece in either. The fifth and last is the usual small oval plate. Among the branchiopoda there are still more remarkable differences: in the squilla (Fab.) the two first jaws are extremely slender and elongated, have the form of feet, and are terminated by a dilated rounded articulation, and a moveable hook. They really perform the office of feet, and not of jaws, and have no dorsal palpi. The third is a long plate, with three notches on its inner edge. The fourth is hid; its inner lobe is ciliated; the external is pointed, and has on its dorsal surface a small oval palpus of a single articulation. The fifth and last is a simple plate.

Notwithstanding all these varieties, it is still true that all the crustacea have many pairs of jaws, very different from each other in their functions; and that these organs must act on the food, and prepare it for the proper mastication in a peculiar manner. In fact, over all these organs are found the true mandibles, which are very strong in all the genera. The triturating part varies in form. In the lobster and cray-fish there is on the inside a blunt and truly molar surface, and on the outside a cutting edge divided into three rounded denticulations. In the hermit crab the denticulations are pointed and separate. In the crab there is a continuous cutting edge. The scyllarus (Fab.) has two separate denticulations; a pointed one in front, and a blunt one behind.

The

The structure of the mandible is the most singular in the squilla. It is divided into two parts; an anterior one concealed under the lip, directed according to the axis of the body, pointed, and having two rows of small denticulations; a posterior transverse one, with the cutting edge directed from below upwards, and possessing a row of stronger denticulations. All these mandibles have feelers: they are composed of three articulations, and dilated at the end in the lobsters, crabs, &c.; of three articulations, and pointed in the squilla; of a single piece in the scyllarus, &c.

The entomolocracea vary still more than the ordinary crustacea. The molucca crab (*monoculus polyphemus*, Linn.), has five pairs of maxillæ, short, compressed, and covered with small spines; each possessing a very large palpus like a foot, with four articulations, terminated by a pincer like that of the fore-feet of the crab and lobster. The pincers of the first pair are very large in the male. Those of the last are small, and accompanied by some scaly laminae. In front of these maxillæ is the upper lip, of a prismatic figure, having two palpi composed of two pieces, and terminated by pincers. The lower lip is behind the last pair of maxillæ, and is formed of two denticulated plates. The *monoculus apus* has two strong and toothed mandibles, then two pairs of small maxillæ without palpi, and lastly twenty-six other pairs of broad plates resembling maxillæ by their bases, and branchiæ in the rest of their extent, and of which the first has four palpi resembling articulated bristles: three of these are very long, and have been taken by some for antennæ. These twenty-six pairs of plates occupy nearly the whole under surface of the body.

The smaller entomolocracea have been very little examined in respect to the organs of the mouth. The family of the oniscii resembles the crustacea in the multiplicity of their jaws, as by their four antennæ; perhaps it ought even to be entirely associated to them. The first pair, which has also been called the lower lip, although it is clearly divided into two halves, is plane, and covers all the others: it has a very small feeler on its external angle. Next to this come two or three thin oblong pairs, of which the second is denticulated at its end: these have no palpi. The mandible is strong, denticulated, and has a small conical feeler. These organs are exceedingly diminished in the parasitic species, as in the cymothozæ (Fab.), which have only two pairs of maxillæ, like small scales, small, conical, obtuse mandibles without teeth, and in the middle of the whole a small conical tongue. The *pycnogonum ceti* (Fab.) has no visible jaws, although we can still discern two articulated palpi. The proper place of these, as well as of the other *pycnogona*, cannot at present be assigned. But some parasitic insects, which have been arranged among the entomolocracea, do not belong to that class, and have a sucker, like fleas. Such are the numerous calygi (Cuvier) found on the gills of fishes, &c.

Muscles of the Jaws.—The mandible is moved on the chest by two muscles. One strong and long approximates its loose edge to that of the opposite side, and at the same time elevates it. It is fixed by two distinct fleshy portions to the membrane which covers the thorax interiorly above and on the sides of the stomach. One of these pieces is anterior and smaller: it is composed of short radiated fibres, terminating in a slender bony tendon, articulated to the tendon of the first portion, of which it appears to be an angular production. The largest portion is less oblique; it is situated between the liver and stomach: its fibres, more numerous and also radiated, terminate at the extremity and front edge of the common bony tendon, which is itself fixed to the middle of the loose edge of the mandible, which it tends to elevate by drawing it towards that of the opposite side.

The other muscle is inserted in a particular eminence near the middle of the opposite or fixed edge. Its fibres are short and numerous. They pass downwards and backwards, and are fixed towards the middle line of the bony case of the chest. Their contraction will produce a contrary effect to that of the preceding muscle; that is to say, it will draw the edge of the mandible away from that of the opposite side.

There appear to be two other muscles in the crab, having the same functions; but they are situated at the articulated extremity of the mandible. Each articulation of the feeler contains two muscles, a flexor and an extensor; of which the former is the largest. The flexor is placed in the broadest part of the concavity of the mandible; it is inserted in a small bony tendon situated at the anterior edge of the articulation. The extensor is more slender, and attached to the fixed edge of the mandible; it is attached by a long and slender tendon to the posterior edge of the articulation of the first piece. The muscles of the two other pieces of the feeler are arranged nearly in the same manner.

The maxillæ are moved from within outwards, and reciprocally, by muscles analogous to those which we have just described as belonging to the mandibles; and the pieces which compose them, when they consist of several articulations, contain in their interior two muscles, an extensor and a flexor, very similar to those of the legs.

Moreover, each of the maxillæ, and particularly of the lower ones, has, on the piece corresponding to the lip in the legs, one, two, and sometimes three laminae directed interiorly to the cavity of the branchiæ; these will be considered in the account of respiration.

Jaws of Insects.—III. In the *Gnathoptera* (Cuvier.)

—This order observes no common law, like all those which are founded on negative characters only; it must be divided into families, in order to obtain some general rules. The first, that of the millepedes, affords none; for the uly have only small mandibles, under which is a conical piece composed apparently of the lower lip and the maxillæ consolidated together, without any feeler. The scolopendræ have small mandibles, larger maxillæ without palpi, a pair of palpi under them, and a large lower lip, of which the articulated and pointed palpi form together a strong pincer. The second family, or the arachnides, has strong mandibles which cannot cut, but are armed at their extremity with a moveable hook, often forming a pincer, with a prominence of the body perforated for sucking. The maxillæ are scarcely visible, and only serve to support palpi, which are always very long, and in the form of feet, and sometimes enormous, as in the scorpions, where they resemble the claws of crabs. In the phrynes, where they furnish the animal with a formidable weapon, there is neither lower lip nor labial palpi. We might contest the propriety of calling these organs mandibles, since they serve for sucking and not for masticating; but their position, and the analogy of other insects, forbid us to refuse them this name. Fabricius has founded the character of his class of ungnata on the small moveable hook which terminates them.

The third family, that of the ricini, or fleas of birds, has only mandibles, between which is a small rostrum, and appears to have neither maxillæ nor lips. Those of the lepidifera and podura have not been sufficiently examined.

2dly. In the *Neuroptera*.—This order is not much more constant than the preceding in the forms of the mouths of the insects belonging to it. We meet first with the beautiful family of the agnatha, insects destined to live scarcely a few instants in the perfect state, and possessing merely what is necessary for copulation and laying. They have no occi-

tion for eating, and possess only an imperfect mouth, without any mandible, and with membranous maxillæ attached to the whole length of the lower lip.

The family of the odonata, or libellulæ, which are the most strongly armed, and the most cruel of insects, is of a nature quite opposite to these. Their mandibles have an anterior, hooked, and, as it were, cutting portion, and a posterior truly molar surface, with four pointed tubercles. It is curious to observe in these insectivorous insects the same characters as in the quadrupeds which are nourished by similar food. The maxillæ are divided into long pointed denticulations like needles, and have palpi without articulations. An enormous lower lip covers all this apparatus; it is divided into three or four lobes, of which the lateral ones are themselves sometimes terminated in the form of pincers.

The other neuroptera are less distinctly characterized. They have, in general, stronger or weaker mandibles; maxillæ with articulated palpi, which are two in number for each maxilla in the myrmeleon and the asea'aphus, and solitary in the others; a lower lip, terminated by a tongue, which is simple in most kinds, divided into four in the termes and plocus, having two very large and club-shaped articulated palpi in the myrmeleon; and no particular characters in the other genera.

The most curious mouth, in this order of insects, is that of the panorpa. Its mandibles are small, and placed at the end of a long snout; of which the under part is filled by a lip, and very elongated maxillæ consolidated together. Here the subdivision of the lip commences, into the horny piece (ganche of Latreille) at the basis, which supports the labial palpi, and the tongue, or membranous organ, placed at the extremity between the labial palpi.

3dly. *In the Hymenoptera.*—This natural family, the most interesting of the insect tribe, by the numerous and varied distinctions with which the different species are endowed, has, in the structure of its mouth, a character of which the first appearance has just been indicated in the panorpa. Part of the basis of the maxillæ, and the horny portion of the lower lip (the ganche), are there united by a membrane, and are always moved together. The portion of the jaw beyond the feeler covers the tongue more or less, and serves it for a sheath, which is sometimes very complete.

The hymenoptera, which suck the nectar of flowers, may be recognized by the prolongation of their maxillæ and lower lip, which are often much longer than the head, but admit of being folded up so as to be withdrawn under the production of the mandibles. This kind of organ is sometimes placed on a pedicle, which admits of being moved backwards and forwards. This may be seen in the bee and the neighbouring genera. In these elongated trunks the tongue forms the essential part, the true sucking tube: but it is always only rolled so as to form a half tube, and opens longitudinally below.

In the bee, one of the articulations of the labial palpi is prolonged, and forms the first sheath of the tongue; the outer portion of the jaw is prolonged in a similar way to form a second sheath; Fabricius calls this structure lingua quinquefida. In the Eucera (Fabr.) two scales of the basis of the tongue, which are clearly seen in the bee, where they are very small, are prolonged as much as the tongue, and the organ is therefore a lingua septemfida. In other genera the labial palpi do not serve for sheaths, and the trunk is therefore trid, as in the Iphex arenaria, &c. Even where the tongue is not prolonged into a trunk, it is always opened below; and this is a character peculiar to the hymenoptera, whence it results that their mandibles

assist them but little in procuring their food, but serve them merely as armour, and as instruments for working. What they might chew would arrive with difficulty at the under surface of the tongue to be swallowed; but the latter organ imbibes nutritious matter in the liquid form, or in a state of minute division, as the pollen of plants, &c. These genera with short tongues present very interesting differences in the form of the organ. It is sometimes simple and conical, as in the evania, or formed like an oval spoon, as in the firex, the mutilla, and the hornet, or dilated and grooved, as in the leucopis, or divided into three pieces, as in the tentredo, or into three conical and villous bristles, as in the scolia, or more or less equally and deeply divided into three or four lobes, as in the vespe, and most of the genera separated from that of Iphex, &c. These different configurations determine the kind of food which the animal employs, and the situations in which it procures it. The differences of the maxilla are less important: it forms in front merely a scaly piece, covering the tongue above, and having its length proportioned to that of the tongue.

The palpi vary more in their absolute and relative length, in the form and number of their articulations. The bee has exceedingly small maxillary palpi. The same may be said of the firex, but the labial palpi are here large and club-shaped. Most others have them filiform or setaceous, and with several joints. The upper lips sometimes assume a peculiar form for a particular office. In the leaf-cutting bees, for example, it forms a scaly shield, protecting the trunk, upon which it is folded back, that it may not be injured by the edge of the leaf which the mandibles cut.

4thly. *In the Coleoptera.*—These, although they are excessively numerous, form a natural order. Their lower lip is not placed between the maxillæ, as in the preceding order, but really below, so as to conceal a part of them, when the mouth is observed from below; consequently they are articulated between the lip and the mandibles, and not suspended with the lip in a common membrane, as in the case in the hymenoptera. The opening of the pharynx is also formed upon the tongue, and not below it, as in the hymenoptera, so that the produce of mastication takes that direction naturally. Such are the true characters of the mouth in this order; but that of having the maxilla free from adhesion to the lip is not exclusive, as Fabricius seems to have supposed, when he founded on this idea the name of cleutherata, which he has given to these insects.

There seems to be only one family in this order, of which the character is determined in a striking manner by the organization of its mouth; it is that of the carnivora. All of these have prominent mandibles and maxillæ, which are also hooked and cutting, four maxillary and two labial palpi; consequently they are terrible enemies to other insects. The chief circumstance, by which they are distinguished from each other, is the figure of the horny and membranous part of the tongue, which are more or less lobated: they may also differ in some unimportant accessory, as the spines of the maxillæ, &c.

Another family, as natural as the preceding in all the circumstances of its external and internal organization, that of the lamellicornia, possesses scarcely any common characters in the parts of the mouth. Some have enormous projecting mandibles, more or less resembling the horns of the stag (lucanus); others have only short but strong mandibles (the dung-beetles, geotrupes of Latreille); in others they are membranous and scarcely visible (the cetonix, Fabr. the scarabæi, the copris.)

Some have strong maxillæ well furnished with teeth (the melolonthæ,

INSECTS.

melonothæ, Fabr.) ; others have them simply ciliated (the cetonizæ), or in the form of a pencil (the lucani.)

The same variations take place in the lips and palpi, and are not merely observed between the different genera. For, although great pains have been taken to subdivide this family into numerous genera, none of these arrangements are founded on a perfectly similar conformation of the mouth. Nothing can prove more clearly the impracticability of the project, so resolutely perflited in for thirty years by M. Fabricius, of establishing a method of infeciology on the conformation of the mouth only.

A third natural family of the coleoptera, that of the rostricornia, is characterized by having its mouth at the end of a long snout. Such of the others as are well determined, for example, the herbivora, the lignivora, &c. have no striking character common to all the genera, although there is a certain resemblance.

The different configurations of the palpi, of the horny and membranous portions of the tongue, of the maxillæ, &c. have been carefully described by naturalists : but their labours have not hitherto furnished any general remarks which suit our present purpose.

5thly. In the *Orthoptera*.—This order is very uniform in the structure of the mouth ; it possesses always strong mandibles and maxillæ, under which is the lower lip. A moveable upper lip covers the mandibles more or less completely. The maxillæ are strongly denticulated, and have always an articulated feeler, and another not articulated, which sometimes grows so broad as to cover and protect the maxillæ, whence it has been called galea : but often it is as slender as a thread. The lower lip has always two articulated palpi, between which is a more or less divided tongue. The pharynx opens upon the tongue, as in the coleoptera, not under, as in the hymenoptera ; so that these insects are true masticators : the principal differences of the genera are founded on the division of the part called the tongue, and on the equality or inequality of the portions. Thus, in the mantis there are four, pointed and equal : in the phasma the two middle ones are much the shortest. The acheta, locustæ, and acridia of Fabricius, have the two outer ones broad and rounded ; and the intermediate one short and pointed. The blattæ and the forficulæ have two oblong ones ; the truxalides (Fabr.) the grylli, and the pneumoræ, have only two rounded ones, &c.

6thly. In the *Larvæ of Insects*.—These organs are not distributed in the larvæ, as in the perfect insects : many larvæ with jaws produce perfect insects, which have none, such are all those of the papilio, and several of the diptera. Different larvæ have often similar jaws when the insects produced from them have very different ones ; as in the whole family of the lamellicornia.

The larvæ of insects which go through an incomplete metamorphosis, have the same kind of mouth as the perfect insects, with the exception of some modifications in the proportions of parts ; thus the mouth of all the orthoptera is the same in the three states. The change of proportions just mentioned produces the most sensible effects in the neuroptera odonata or the libellulæ. Their mandibles and maxillæ are the same in the larva as in the perfect state. Their lower lip presents also the same divisions, but it is placed on a very long pedicle, with an angular turn or elbow in its middle, so that it remains commonly in its natural position under the maxillæ, but the animal can, by straightening the curved pedicle, carry it suddenly considerably forwards ; and, as the notches which terminate it will serve the purpose of pincers, they are employed for seizing the

small insects which come within reach. When the libellula has its wings, it no longer needs such an artifice : its lip is shortened, and confined to the ordinary functions.

The larvæ of the hymenoptera have very simple organs of mastication, consisting principally of small, short, and strong mandibles. The mouth of the larvæ of the coleoptera has the same parts as that of the insects ; but they are differently shaped. Thus the lucani, which in the perfect state have such enormous mandibles, and such peculiar pencil-shaped maxillæ, have, while larvæ, a nearly orbicular upper lip, immediately articulated with the front ; short, strong, thick, pointed mandibles, slightly arched externally and on the inner side ; towards their loose extremities they have three denticulations on one plane, and towards their bases a striated and plane molar surface : it is plain that these are in their mouth instruments for cutting and chewing wood. The maxillæ are terminated by two small hooks, of which one is moveable, a very singular structure, and support a feeler of four articulations. The lower lip is broad, and in a manner truncated, and has two palpi ; each composed of two pieces.

The scarabæi differ remarkably from the lucani in their mouth ; but the two genera agree almost entirely in the mouths of the larvæ ; the same observation may be made of the melonothæ and cetonizæ, which are also very different from each other.

This small moveable hook may be considered as a second maxillary feeler ; these larvæ would then have six, while their perfect insects have only four. We must observe also, that the larvæ, both of the lucani and of the scarabæi, have two strong teeth on the upper surface of the lower lip near the pharynx.

The prioni (Fabr.) which have elongated mandibles like the lucani, have nothing of this kind in the larva state. There is a very large upper lip, lobated, rounded, villous, supported by a membranous lamina, then two strong, curved, cutting mandibles, furnished at their bases with two conical palpi, of which the rings enter one into the other, like the tubes of a telescope, and which are probably the rudiments of antennæ. A soft mass, consisting of three lobes placed behind the mandibles, represents, by its middle lobe, the lower lip with two very short rudiments of labial palpi, and, by each of the lateral lobes, the maxillæ properly so called with its proper palpi, composed of four conical articulations, of which the last is the smallest.

On the contrary, the dytisci, which have very slightly prominent mandibles, have them very long in the larva state. They represent two sharp hooks, perforated at the extremities, which serve for sucking. There are no visible maxillæ, but merely two long filiform palpi of five pieces ; while the perfect insect has four maxillary palpi. This is exactly the reverse of what we have just seen in the lamellicornia. Instead of the lower lip there are two tubercles, each of which supports a feeler of two pieces. The larva of the hydrophilus also wants the maxilla, but has four palpi ; the mandibles are short, cutting, and not perforated.

Of all larvæ, those of the lepidoptera differ the most widely from the perfect insects in respect to the mouth ; and, what is very singular, their mouth is constructed on the plan of that in insects with jaws, although it possesses no trace of these parts in the butterflies. Under a semi-orbicular upper lip, and under two strong, cutting, denticulated maxillæ, are three tubercles representing the lower lip and the maxillæ ; the latter seem composed of pieces, which enter more or less one into the other, and terminate by two small tubercles, of which the internal, armed with two

stiff bristles or teeth, is the maxilla properly so called; the other is the feeler. The lower lip has two very small palpi, and a hollow point in the middle: this is the spinning hole, through which the silk comes out, employed by the caterpillar for forming its cocoon.

The Muscles.—When the upper lip is moveable, it is drawn backwards by two bundles of fleshy fibres situated within the cranium, and which are themselves divided into two planes. The motions of the mandibles are analogous to those of the hips in insects. At the basis, on the side corresponding to their convexity, there is a kind of condyle, or convex rounded eminence, received into a small cotyloid cavity, excavated in the temporal scale in front of, or below the eye. On the side corresponding to the cutting edge of the mandible, there is commonly observed, at least in large insects, such as the scarabæus monoceros, the prionus, the capricorne (cerambyx), the lucanus cervus, the locusta, a kind of solid tendinous plate, which is apparently prolonged into the interior of the solid parietes, and affords attachment to muscular fibres implanted in it laterally, as the barbs of a feather are on the common shaft. These muscles approximate the jaws to each other, or shut the mouth. Those which separate the mandibles and open the mouth are much shorter, and not one-tenth of the size of the preceding. They are inserted in a small apophysis, corresponding to the convex external line of the mandible, on the outside of the condyle. Lyonet has described and figured these muscles in the larva of the phalæna cossus. He calls them adductors and abductors; but he has regarded as so many distinct organs, the fasciculi of fibres inserted into the common tendon; so that he has distinguished nearly eleven muscles or bundles destined to close the mouth, and three principal planes for the purpose of opening it. These fibrous planes are found in all other insects; but very great varieties are observed in their number and relative disposition. These differences depend evidently in the first place on the very different insertions of the tendinous plates, which are to be considered as prolongations of the muscles: they seem also to be modified by the length and size of these plates. The latter always have a relation to the form and extent which the internal parietes of the mandible and of the cranium afford for their insertion.

Salivary Organs.—No excretory organ, for the purpose of supplying a salivary secretion, has been hitherto discovered in the crustacea; but the place of salivary fluids is supplied in the following manner. The branchiæ, placed at the sides of the body, under the edges of the corselet, are compressed and agitated by the cartilaginous plates connected to the jaws and feet; at this time, the water in contact with the branchiæ flows along these plates, and comes out at the two sides of the mouth; hence, when a crab or lobster is taken out of the water, much froth is observed to issue from that part. This water, although foreign to the body, may serve to moisten the food, when the animal eats out of water. At other times no saliva can be needed, as in the cetacea and fishes.

Many insects furnish, during mastication, more or less fluid, which is often acid, and of a penetrating odour, and supplies the place of saliva. In the carabæ it is black and fetid, very corrosive in some grylli; and capable, in the larva of the cossus, of softening and dissolving the wood of the willow, on which the animal feeds.

The sources of these fluids are not yet known in all species; probably, however, they are produced by organs analogous to each other, and those of one species may serve as an example of the rest. The larva of the cossus has two long spongy vessels, like all the secretory organs of insects, very

much convoluted, and opening into a large reservoir, which communicates with the mouth by a small canal. This organ seems to produce a liquor, necessary to the animal for the purpose of acting on the wood by which it is nourished. It is deficient, or very small in most of the caterpillars.

Organs of Deglutition.—It. In insects with jaws. The membranous extremity of the lower lip, in the coleoptera, and the orthoptera, which has been called a tongue, scarcely deserves that name. But in the second of these families there is a real fleshy tongue, loose only at its point, and analogous in figure to that of quadrupeds. The odonata, among the neuroptera, have a structure somewhat similar; but the tongue of the hymenoptera is only a membranous tube, often open below, and forming the extremity of the lower lip. In the wasps, and in all the hymenoptera, which have no trunk, it has an arched form, being open and concave below, and more or less divided into pieces. The bees, and all the hymenoptera which have a long trunk, possess a complete tube with annular fibres: suction is performed by the successive contraction of these fibres.

2dly. In insects without jaws. Since deglutition is the first act of nutrition in these insects, the form of the organ employed in suction determines the species of juice which the animal can imbibe, and consequently influences very considerably its way of life. The relations of the natural families of these animals to their organs of suction, are much more constant than they are to the instruments of mastication in the other half of the class. There are four orders of insects without jaws, *viz.* hemiptera, lepidoptera, diptera, aptera; and there are three kinds of suction particularly belonging to the three first of these. The hemiptera have a stiff proboscis enveloped in a sheath; the lepidoptera a membranous trunk spirally convoluted; the diptera a trunk terminated by two fleshy lips. Hence the names of rhyngota, glossata, and antiata applied by Fabricius to these three orders; which he has preserved the same as in the Linnæan arrangement, and which many others had adopted before.

The greatest varieties are observed in the diptera. In this order the organ consists essentially of a fleshy trunk, divided below into two lips more or less prolonged, and capable of being applied to the object which is to be sucked; two tentacula are detached to the root of this trunk. Between the latter is a pointed scale, sometimes employed to cut the vessels from which the fluid is to be sucked, but often serving only to cover other pieces, which are much sharper and more appropriate to this function. In the stratiomyis, and the common flies, there is merely a single short point under the scale. The syrphi and rhingie have in addition a stiff bristle under each palpus. In the rhagio there are three bristles under the scale, and the middle of them is the strongest. The tabani have four, all pointed and sharp like the blades of lancets; hence these insects have the power of inflicting the severest wounds on the skin. All the parts are much elongated in the genera empis and bombylius; the trunk is more particularly extended than the bristles in the latter, which indeed have only one bristle under the scale. In the empis all the parts are equally prolonged, and there are four bristles.

In the myopa (conops, Linn.) the trunk is elongated into a slender tube with an angle at its middle; there is a short scale without any bristle. In the asilus and stomoxys (conops, Linn.) the trunk is hardened, and assumes a horny texture, so that it is capable of cutting. There is a single bristle within it in the stomoxys, and three in the asilus. The trunk is reduced almost to nothing in the hippoboscæ; and the single bristle is long and flexible.

All these genera have palpi of a single piece. The tipulæ and culices have them articulated, and often very long; the trunk of the tipulæ is short, with large lips, and no bristle; that of the culices is long, slender, and contains a fine bristle.

In the æstri, all the external organs of the mouth are withdrawn within the head, so as to expose externally only three rather prominent points.

The hemiptera (rhyngota, Fabr.) are more uniform in the structure of these parts than the diptera; in general they have a tube composed of some articulated pieces, and open above in its whole length. This tube contains three fine bristles nearly as long as itself; it exhibits scarcely any other varieties except in its position and inflexions.

The lepidoptera (glossata, Fabr.) are equally uniform in the structure of these parts: their tongue is formed of two membranous plates, curved transversely in their whole length, so as to form a tube, and, when the insect does not employ it, convoluted spirally, and lodged between two flat villous palpi, composed commonly of three pieces. The differences depend on the variable length of this organ, which is sometimes very inconsiderable, and on the figure of the palpi: they are not of importance in connection with our present subject.

Among the aptera, the louse has only a simple and short sucker, inclosed in a small prominence: the flea has one with two bristles, inclosed in a sheath of three pieces, opened longitudinally above.

Intestinal Canal.—It is straight in the crustacea, and uniform in its size, with the exception of the stomach. The latter is very different in the crustacea decapoda, and in the branchiopoda, it possesses, in the former, a singularity of structure, which is remarkable as the only example of the kind in the whole animal kingdom; that is, it is supported by a bony apparatus, a species of skeleton, and consequently does not collapse when empty. The destination of this apparatus is not less extraordinary than its existence; it serves to support five hard and moveable teeth, which perform in the cavity of the stomach a true mastication. They are placed before the pylorus, and allow no substances to pass through that opening until they are perfectly triturated.

The stomach is found in the thorax above the mouth, and the œsophagus communicates with it by a large aperture. The anterior portion is more capacious than the posterior, and the teeth are placed where the cavity begins to grow narrower. On the superior surface, or that which is opposed to the mouth, there is a thin transverse plate occupying the middle of the stomach. This supports the first tooth or bony oblong plate, consolidated to the superior surface of the stomach, directed towards the pylorus, and terminating behind in a tubercle.

On this posterior extremity is articulated a second plate, directed backwards, bifurcated like the letter Y; and on each of its lateral divisions another is articulated, which turns forwards and outwards, and reaches the lateral extremity of the first transverse plate. The two argest teeth are fixed on these two lateral pieces. They are oblong, have flat crowns, which are grooved transversely, and the grooves and inequalities vary in the different species. In the cancer pagurus of Linnæus, the crown is finely striated, has large denticuli at its lower edge, and a prominent part in front which is not striated. In the lobster there are nine transverse ribs, of which the three front are much the largest.

From the point of union of the transverse portion with the lateral of each side, another lateral piece is continued, proceeding lower than the first, and having at its extremity

a lateral tooth smaller than the preceding, placed rather before and below its anterior extremity, and having three and sometimes even five small, sharp, and bent points. The two small teeth with curved points seize the nourishment which comes from the mouth; they convey it between the two teeth with flat crowns, which bruise it between each other and against the first single plate.

When it has undergone this operation, the aliment passes through the narrow part of the stomach, where its course is still interrupted, first by a fleshy oval prominence corresponding to the interval of the two large lateral teeth, and afterwards by a sharp crista, which divides the pylorus into two half canals.

There are muscular fibres in this stomach, which approximate the bony pieces, and the teeth which they support: there are exterior muscles which separate the teeth from each other, and are attached to the neighbouring, and particularly the lower parts of the thorax. These muscles must be subject to the will, which is another remarkable singularity belonging to these stomachs.

The teeth are discharged from the stomach when the old flesh is shed; and are supplied by new ones.

After this large stomach, which is always dilated, comes a very slender intestine, which takes a straight course to its termination at the end of the tail. Towards its middle a thick ring is observed, on the inside of which there is a strong valve, and the commencement of a very long cæcum.

These circumstances have been ascertained in those cancers which have long tails, as the cray-fish and the lobster, also in the parasitical species (the hermit crab), and in the crabs, as the cancer pagurus, puber, and mænas: the structure may therefore be considered as common to all the crustacea decapoda. The branchiopoda possess a small membranous stomach, shaped like a triangular prism, furnished on each side of its posterior extremity with a row of small pointed teeth, and followed by a very thin intestinal canal, continued from one end of the body to the other, and nearly uniform in size throughout.

In the onisci the front of the canal is a little swollen compared to the continuation.

In the rest of the class of insects we find as many varieties in the structure of the alimentary canal, as in all the classes of vertebral animals together. There are not only differences between the families and species, but often very considerable ones between the larva and perfect states of the same insect; and all these varieties bear a very accurate relation, which in many cases can be very clearly appreciated to the animal's kind of life, whether of shorter or longer duration. Thus the voracious larvae of the scarabæi and butterflies have intestines ten times as large as the winged and sober insects, if we may be allowed to use that term, to which they give birth.

There are the same general resemblances in the natural families of insects, as in the rest of the animal kingdom; thus all the coleoptera lamellicornia, all the carnivora have similar intestines in each of their states, &c. Here, as in the other classes, the length and complication of the intestinal canal indicate a vegetable nourishment; shortness and thinness, on the contrary, shew that the animal is carnivorous, &c.

I. In the *Coleoptera*.—We shall select for description some very natural families, which are remarkable for any peculiarities of structure, and shall notice together the intestinal canal of the larva and of the perfect insect, in order to exhibit in the clearest view the very striking difference between these two states.

1. In the coleoptera lamellicornia. The last mentioned point

point is very clearly exemplified in this family. The larva of all the genera, which compose it, have a large and short alimentary canal, divided into the following parts. 1. A short and weak œsophagus. 2. A straight cylindrical stomach, colourably thick and muscular, surrounded by three circles of small cæca, placed, one at the commencement, one at the middle, and the third at the end of the cylinder. The cæca are numerous, weak, and fleshy: the one of the third circle are ramified in the larva of the scarabæi properly so called (his geotropes of Latreille). In the melonothæ the cæca of the first circle have small lateral denticulations, which may be regarded as to many smaller cæca. The upper and lower circle in the lucani are composed of a small number of large cæca, while the middle is made up of very numerous small ones. Probably they all secrete and pour into the stomach some dissolving fluid. 3. A short intestine of much thinner fibres, and rather shorter in length than the stomach. Its origin, which is rather expanded, receives above the hepatic vessels; it terminates at the posterior extremity of the body of the larva. 4. An enormous colon, or large intestine, three times as large as the stomach, and filling all the posterior third of the body. It possesses two smooth bands, between which are transverse folds, producing a cellular appearance like that of the human colon. Its course is in a direction contrary to that of the small intestine; that is, it returns from behind forwards, and lies upon that intestine. 5. A rectum turning from before backwards upon the colon, in order to terminate at the anus. It is slender and straight, without any inequality.

We should have expected that the perfect insect would retain some trace of such strongly marked peculiarities; yet there is really no vestige of them discernible. All these insects, lucani, scarabæi, melonothæ, cetonizæ, have a long slender canal, four or five times longer than the body, very much convoluted, and possessing hardly any dilatation. Sometimes the anterior portion is merely a little larger and folded transversely.

2. In the coleoptera carnivora. As the habits of these animals are very different from those of the preceding, their alimentary canal is different in both states. In the perfect state it consists, of, 1st, a long and very dilatate œsophagus. 2. A first stomach, nearly spherical in its shape, with muscular parietes and transverse wrinkles. 3. A second stomach, membranous, elongated, and villous; not on the inside, as those of certain vertebral animals are, but on the outside. The villi are vessels which draw from the surrounding nutrient fluid, the gastric juice which they pour into the stomach, according to the laws of secretion in insects; considered as animals which have no circulatory organs. 4. An intestine of moderate length, between once and twice the length of the body, small and uniform in its diameter throughout. 5. A conical and rather long cæcum inserted near the anus. Near the margin of the anus are found two vessels, which secrete the acrid fluid almost constantly voided by these animals when they are seized.

Such is the structure of the genera separated from the carabi, the cicindelæ, and the dytisci; their larvæ have no dilatation like a stomach; their canal is small, all of one size from the mouth to the anus, and about one-half longer than the body. A cæcum, however, may be observed near the anus in the larvæ of the dytisci.

3. In the coleoptera clavicornia. The hydrophilus picens, in its perfect state, has very long cylindrical intestines (four or five times longer than the body), uniform in size throughout, and forming large convolutions in the abdomen. The larva, which is much more carnivorous, has short intestines (half as long again as the body), of which

nearly two-thirds form an elongated stomach, villous externally; the rest is smooth, and divided by a contraction into two parts. The filpæ, on the contrary, have in their perfect state such a stomach, followed by a small intestine twice as long as the body.

4. In the coleoptera lignivora. The larvæ of the prioni and cerambyci have very large intestines, with their fibres nearly uniform throughout, and forming four folds, each of which is as long as the body. The commencement, which alone can be compared to a stomach, is rather corrugated transversely like a colon. The perfect insect has first a membranous and round stomach, then an oval one, which is insensibly contracted into a cylindrical canal, suddenly growing smaller at the insertion of the hepatic vessels, and continuing so to the anus. The whole canal is at most twice as long as the body.

The larva of the lamia, Fab. has first a very distinct stomach, then a knotted small intestine, which is suddenly changed into a large intestine longer than itself.

5. In the coleoptera filicornia, of the family of the vesicantia; the meloe possesseth an enormous oval stomach, filling nearly the whole abdomen. The front is covered with strong circular fibres; and a cylindrical valve, analogous to the valvula coli of man, is observed at the cordia.

In the family of the lucifuga, the tenebrio has a cylindrical elongated stomach, a first intestine, which is rather slender, and another somewhat larger. The whole canal is about three times the length of the body. The blaps has a muscular cylindrical stomach, another equally large but membranous, separated from the former by a slight constriction, and a small intestine which is a little enlarged towards the anus. The proportionate length of the whole is about the same as in the last instance.

6. The brachelytra, or staphylini, resemble the carnivora in the villosity of the stomach, as they do in their habits.

11. In the Orthoptera.—These, in the class of insects, seem analogous to the ruminants among the quadrupeds, at least in respect to the complication of the stomach, and some suppose that their aliment may be seen brought back into the mouth for the purpose of a second mastication. As they undergo an imperfect metamorphosis, their alimentary canal is the same in the larva as in the perfect state. It consists in general of the following parts. 1. An œsophagus of the usual kind. 2. A first membranous stomach. In most genera this is a simple dilatation of the œsophagus, of which the internal membrane is smooth and folded longitudinally. In the locusta it is rather, and in the blatta considerably larger than in the other genera. In the acheta it is an oval bag, having quite a lateral position, connected to the side of the œsophagus like a cæcum, with one opening for the reception and discharge of its contents. 3. A second stomach or gizzard, small, nearly round, possessing a very thick muscular coat, and armed internally with scales or teeth. In the locusta and acheta these are longitudinal rows of fine and numerous scales, placed one over the other like the tiles of a roof, and directed backwards. In the blatta there is a single row of six or eight large curved teeth, denticulated like the bills of birds of prey, and directed backwards. 4. The cæca or third stomachs are immediately round the posterior orifice of the gizzard, and vary in number. The locusta and acheta have two large ones, and this has given rise to the remark that the grylli have four stomachs like the ruminating man-malia. The internal membrane is much folded, and its extremity receives many small secretory vessels, which pour out gastric juice. There are five of these cæca in the gryllus, and eight or ten in the blatta. 5. The intestinal canal varying in length and diameter.

The earwig is said to be very different from the other orthoptera in having only a simple elongated stomach, a very short intestine, and a dilatation with longitudinal folds near the anus.

III. *In the Hymenoptera*.—The bees have a first stomach, which is membranous and transparent, pointed in front, large and divided into two portions behind. In this organ the nectar of the flowers is converted into honey: it is the reservoir of this matter, which they deposit in their hives by the act of vomiting. The second stomach proceeds from the interval of the two divisions; it is elongated and swollen laterally towards the middle. The hepatic vessels are inserted immediately after the pylorus. The first intestine is small, and scarcely equal in length to the second stomach: the rectum is large but still shorter.

The first stomach of the wasp is smaller; the second longer, and particularly much more muscular. The larvæ of both genera have an immense cylindrical muscular stomach, filling nearly the whole abdomen, and followed by a very short intestine.

In the sphex the structure resembles that of the bee; the parts are only larger in proportion to their length.

IV. *In the Neuroptera*.—The family of the odonata, which is truly carnivorous, has very short intestines in its three states: they do not exceed the length of the body. In the libellula grandis, Linn. a short œsophagus is succeeded by a small oval muscular stomach, striated longitudinally; then comes a straight large intestine or second stomach, with a constriction placed far back at the entrance of the hepatic vessels. The interval between this part and the anus is very short, and folded longitudinally. In its larva, the œsophagus has a circular dilatation: the constriction of the cordia produces a kind of valve. From this point the canal has a bright yellow colour, as far as the insertion of the hepatic vessels; its last portion is white and much thicker; and contains the singular respiratory apparatus, which we shall describe afterwards.

In the family of the agnatha, the ephemera, during its larva state, has merely a straight uniform canal, without any convolution, which becomes extremely thin in the perfect insect.

V. *In the Hemiptera*.—These possess in general a simple, oval, and muscular stomach, of considerable size, followed by a small intestine of moderate length, near the end of which is a small cæcum. Such at least is the case in the nepa, notonecta, &c.

VI. *In the Lepidoptera*.—The caterpillars have a large, short, straight, intestinal canal, without any considerable inequalities. The œsophagus is the slenderest portion, the stomach is elongated and contracted at the pylorus. After the pylorus the intestine is larger than in the rest of its length; it is contracted towards the anus. At the latter part it has the strongest circular fibres; on its parietes other fibres are found, variously decussated and ending in two white lines, which extend over its whole length, one above, and the other below. The diameter varies in different situations, according as the contents are accumulated. Sometimes the distinction between the stomach and intestine can scarcely be observed.

This canal is obviously calculated for solid and abundant food. The butterfly, which subsists entirely on the juices of vegetables, has a very different digestive apparatus. Among the diurnal insects of this order, the atalanta has a slender œsophagus, with a membranous dilatation on its side, like a crop, more or less rounded in its figure, and often full of air. Then comes a second elliptical membranous stomach, the sides of which present many hemispherical cellular pro-

minences; and afterwards a third, cylindrical, and rather muscular, followed by a small intestine of moderate length, terminated by a rather larger rectum.

VII. *In the Diptera*.—In general their intestinal canal is tolerably long in both states. It is five times the length of the body in the larva of the stratomy, and consists of a short œsophagus as slender as a thread, a very small oval stomach, and an intestine, of which the first half is wrinkled transversely, which becomes afterwards larger and smoother to the insertion of the hepatic canals, below which it is suddenly constricted and remains narrow. The differences between this and the larva of the syrphus are very slight; and the distinctions between both and their perfect insects are not more obvious. However, Swammerdam represents four small cæca, after the stomach, in the larva of a fly which inhabits cheese; Cuvier has not found them in the diptera dissected by himself.

VIII. *In the Gnathoptera*.—The scolopendræ have a long canal contracted behind; the uli have an equally long and cylindrical one. We have already mentioned that of the oniscus.

IX. *In the Aptera without Jaws*.—The louse has two small swellings at the origin of the stomach, which is elongated; the intestine is not longer than the stomach; it is small, and terminated in front of the anus by a muscular enlargement.

Hepatic Vessels.—Although the crustacea have a heart and blood-vessels, most of them have not a liver, properly so called. The organ which produces bile in them consists of a considerable number of small tubes ending in cul-de-sacs. The structure is analogous to that of the pancreas of fishes, which consists, as we suppose, of the multitude of cæca opening at the origin of the intestine.

The appearance of the hepatic cæca in the crustacea discloses their nature and office; they are yellow, have spongy sides; produce a brown and bitter liquor, which gives its peculiar taste to the soft substance in the body of the lobster; for the hepatic cæca, with the stomach, fill nearly the whole thorax of these animals; and, in the hermit crab, they fill also a great part of the tail.

The squilla, Fab. is an exception to this rule; these animals have a liver of a firm texture, very much resembling a conglomerate gland, consisting of lobes arranged on each side of the alimentary canal in its whole length.

In the insects, properly so called, there is still less appearance of liver than in the common crustacea. Since they can have no glands on account of the absence of blood-vessels, the bile, like all the other secretions, is produced in them by fine vessels with spongy sides, floating in the fluid, which bathes all the parts, and deriving from it, by the organization of their tissue, the elements proper for the formation of this liquor.

These vessels exist equally in the larva and in the perfect insect: the fluid, which they form and contain, tinges them with its own colour. They are usually yellow, sometimes, as in the scabaxi and cerambyces, of an opaque white; and in other instances, as in the dytici, of a deep brown. Their bitter taste arises from this fluid, which would probably be found to possess many of the qualities of bile, if it could be procured in sufficient quantity for analysis.

The number of these vessels is variable; when it is large, they are short, so that the extent of surface is nearly the same. Sometimes they all end in a common excretory tube, which terminates in the intestine. This is the case with the gryllo-talpa. They are commonly inserted after the stomach, but sometimes not till near the middle of the intestinal canal, as in the grylli; or even towards its end, as in the libellula. The onisci alone have them inserted near the œsophagus; in

these

these insects they are only four in number, large, undulated, as long as the body, and of an orange colour.

Among the neuroptera, the libellulæ have a considerable number of short ones, surrounding the intestine at a small distance from the anus, where it becomes large. The same structure exists in the common grylli. In the gryllo-talpa there is a large packet of these vessels, terminating by a common canal in the middle of the large intestine. The larvæ and the perfect insects have the same structure in these genera. This resemblance seems moreover to exist, with respect to the hepatic organs, even in orders where the metamorphosis is the most complete in all other parts; the number at least is not changed. It is considerable in the hymenoptera, but generally amounts only to two in the coleoptera. In the latter they are generally found parallel to the intestinal canal, and make numerous windings. Their insertion is immediately after the stomach in the larvæ of the scarabæi, the dytisci, the carabi, &c.

The caterpillars and the perfect insects produced from them have two, each of which is sub-divided into three, placed in the former, at the sides of the posterior half of the canal, and forming their principal folds completely in the back of the body. Among the hemiptera, the nepæ seem to have only two. The larvæ of the stratiomyis and lyrrhus, of the order diptera, have four, which end in the intestine by a common trunk.

Coverings and Supports of the Alimentary Canal.—We have mentioned already that the stomach of the crustacea is supported in its situation by its muscles; the remainder of the canal is maintained only by vessels, and by the compression of the surrounding parts.

In the proper insects, the intestinal canal is retained in its place by the tracheæ only; there is neither mesenteric vessel nor cellular substance; consequently when an insect is opened and placed in water, all the folds of its canal rise, and are developed from the specific tightness derived from the air in the tracheæ.

The fine membrane lining the abdomen, and enveloped by the rings of the skin and their muscles, may be called peritoneum.

But the most remarkable circumstance belonging to insects in their larva state, and existing in them exclusively, among all invertebrated animals, is the portions of cellular texture filled with fat, which may be compared to omenta, and may have the same functions. They seem particularly designed to supply the materials of nutrition to the animal, during all that time, in which, as a chrysalis, it eats nothing, as the fat of the omenta supports life in those quadrupeds, which pass the winter in a lethargic sleep. When the animal changes its coverings and its form, and becomes a perfect insect, these fatty organs probably furnish the prodigious quantity of materials, which the sudden development of so many parts must require; consequently they are not found in the latter state.

The forms, colour, and consistence of these masses vary. In the caterpillars they are oblong, swollen, full of a white fat like cream. In the larvæ of the scarabæi they are large semi-transparent membranes, with many opaque and white grains; in those of the grylles and stratiomyis they have a flattened appearance, like narrow ribbands irregularly joined. They are inconsiderable, or do not exist at all, in the larvæ of insects, which undergo an incomplete metamorphosis, which eat during their whole existence, and never pass into the chrysalis state. In all the orders they receive numerous air-vessels.

Aliment prepared in Insects.—The nutritive fluid prepared in the alimentary canal is taken up by a particular order of vessels,

called absorbents, in the four first classes of the animal kingdom; these convey it into the blood-vessels, in which it passes to all the organs of the body. The application of the new matter furnished by digestion to the parts of the system is performed in some other way in insects, as they seem to have neither absorbing nor blood-vessels (excepting the crustaceous insects).

Cuvier is of opinion that the nutritive process is performed in this class by *imbibition*. We arrive, says he, at this conclusion by proofs of different kinds; some are direct, but negative; others supply only inductions; their union will probably suffice to produce conviction. In the first place, he continues, no vessels are found in dissecting insects; I have sought for them with the greatest attention, and by the assistance of the microscope, in those organs, which in other classes contain them in the greatest abundance, as the choroid coat of the eye, and the membranes of the intestinal canal; I have never found any thing like them, although the tracheæ and the nerves are very easily discovered, and the innumerable ramifications of the former may be traced with the naked eye. Lyonet, who has described and represented in the larva of the cossus parts a thousand times smaller than the principal blood-vessels would be, could never discover any thing of that kind.

There is indeed in insects an organ, to which many anatomists have given the name of heart; it is a membranous tube, continued through the whole length of the back, both in the larva and in the perfect state, exhibiting alternate contractions and dilatations, which seem to pass successively from one extremity to the other; but, notwithstanding this circumstance, which seems to indicate an organ of circulation, this tube produces no branches, and we can neither attribute to it the functions of a heart, nor discover any other purpose to which it is subservient. Lastly, those naturalists who have observed with the microscope the transparent parts of insects, have discerned only a fluid at rest, bathing them on all sides.

Such are the negative arguments on this subject; those drawn from induction refer principally to two points; *viz.* the mode of respiration in insects, and the form of the secretory organs.

In animals which have a circulation, it is continually collected in a central reservoir, whence it is forcibly expelled to all parts; it always arrives at the organs from the heart, and it is always sent to the heart before it comes back again. It may then have been modified from its source by the action of the air; and, in fact, before it is brought by the aorta and its ramifications to the parts which are to be nourished by it, it circulates through the lung or gills. If this arrangement is not found in insects, the reason probably is that their nutritive fluid is not contained in vessels, that it does not come from a common source, and consequently that it could not undergo any modification in a separate organ before arriving at the parts. It continually and quietly bathes all the parts, which are to draw from it substances suited to their wants; the action of the air should therefore reach it every where, and this point is very completely secured by the disposition of the tracheæ, as there is no point of the body to which the fine ramifications of these vessels do not penetrate, and where the air does not immediately exercise its chemical action; in a word, as the blood cannot go in search of the air, the air is every where brought in contact with the blood.

The secretions of insects are never performed by complex glands; their organs consist, in all cases, as we have just seen in the example of the liver, of long and slender tubes, floating in the cavity of the body, without being connected

ned together, or fixed in any way except by the tracheæ. This appears clearly to be a necessary consequence, and therefore a very probable indication of the absence of blood-vessels. When the powerful agents of circulation exist, they convey with facility the nutritive fluid to the most remote points of the glands; the intertexture of the blood-vessels forms a thick and close tissue, in which the peculiar vessels of the gland are placed. When, on the contrary, there is neither heart nor blood-vessels, nor any force to impel the fluid towards the secretory organs, the latter require a more powerful attractive force; and as this can be exerted only by means of the tissue compounding their sides, it becomes necessary that they should be unstretched, loose, long, and slender, in order to augment their surface.

Organs of Circulation in the Crustacea.—The heart of the crustacea decapoda is very differently formed from that of the branchiopoda. In the former it is oval, circumscribed, and placed nearly in the middle of the thorax; in the others it is elongated, and extends from one end of the body to the other, so as to form apparently a connecting link between the heart of the decapoda and the dorsal vessel of the other insects. In this point of view it has led me naturalists into error: we shall, however, find a structure which is more analogous to it in the red-blooded worms.

The decapoda (the crabs, lobster, cray-fish, hermit crab, &c.) have an aortic heart, like that of the mollusca. It receives the blood from the branchiæ by a large vessel, which lies longitudinally in the chest to receive this blood by lateral vessels. Cuvier states that this is the case in the hermit crab; but he thinks that in the lobster the branchial veins form two trunks, which go directly to the two sides of the heart. When one of the veins of the branchiæ is injected, the fluid arrives at the heart by the route just indicated. From the same posterior part of the heart arises an arterial vessel, which goes directly backwards, and supplies the organs of generation and the muscles of the tail. The anterior portion produces other arteries, varying in number according to the species.

Each pedicle of the branchiæ contains two principal vessels; an artery and a vein. The venous trunks all go to the heart; and, as we have already stated, by a single trunk in the decapoda; but, in the branchiopoda, where the heart is elongated, they all terminate in it directly, so that a pair of veins enters at each ring of the body. The branchial arteries do not come from the heart. When the latter organ is injected, the fluid does not enter the branchiæ, although it will pass easily from the latter to the heart. In the *Equilula falcinata*, Fabr., Cuvier observed a large longitudinal vena cava, extending from one end of the body to the other, under the intestine, and consequently on the opposite surface to that occupied by the heart. Its tissue is much thinner than that of the heart, and transparent, and it produces as many pairs of branchial vessels as the heart receives from those organs. This anatomist has very little doubt that the same vessel will be found in the decapoda, but he had not examined them for this purpose since he first saw it in the other division.

The circulation of the crustacea is then the same with that of the gelthropodous mollusca; viz. a double circulation, of which the aortic system only possesses a ventricle; and even this ventricle does not deserve the name in the branchiopoda, if so much resembles in them a vessel by its elongated form. Under this point of view the circulating system of these animals resembles that of red-blooded worms.

The heart of the crustacea, even in the decapoda, has no auricles and valves have not hitherto been observed in it.

It is hardly necessary to state, that the blood thrown by

the heart into the arteries, passes through the veins into the vena cava.

The motions of the heart may be seen in the small molluscs of this country, but their extreme smallness prevents us from following the distribution of the vessels. The anatomy of the mollusca crab is not yet known.

Circulation of Insects.—All insects have in their back a longitudinal vessel, filled with a transparent fluid, and for a long time regarded as the heart, after the statement of Malpighi, who described it in the silk-worm, and represents it as a knotted canal, that is divided at intervals by constrictions. He conceived that each dilatation was a particular heart, and that these different organs transmitted the blood to each other; but he remarked at the same time that the successions of the pulsations was not regular, and that the fluid sometimes took a retrograde course. Lyonet has given a better account of this dorsal vessel. It is an uniform canal, proceeding from the head to the opposite extremity, and enlarging a little in its course, but closed at the two ends. It possesses on each side a certain number of transverse muscular fasciæ, somewhat in the form of wings, which are fixed by their opposite ends to the general covering. Its dilations and contractions are produced by these, which are exterior muscles, and not by its own tissue.

Lyonet assures us, that he has not been able to discover any vessel produced from this, and proceeding into the body, although he has described tracheæ and nerves a thousand times smaller than these vessels must be if they exist. Cuvier has tried all known methods of injection, without any greater success. Swammerdam indeed mentions that he injected small vessels from it in the grylli; but we cannot help entertaining doubts on this subject, until the experiment shall have been repeated with success.

The dorsal vessel of insects cannot then in any manner perform the functions, nor deserve the name of a heart. Perhaps, like all other parts of this kind in insects, it is a secretory vessel; but we are at present quite unable to determine what liquor it secretes, and for what use. Its contents are transparent, light yellow, viscous, miscible with water, easily dried, and then becoming hard and cracking like gum.

Besides the analogy of its contractions, its situation might favour the idea of its being a heart. The latter organ is placed near the back in almost all the mollusca, and in all the crustacea; and this is the position of an organ, which can hardly be regarded in any other light than as a heart, in the arachnidous insects (aranea, phalangia, and scorpions). It may be observed very easily in the spiders; and may be seen beating through the integuments of the abdomen in the species which have smooth bodies. On removing the integuments we expose a hollow oblong organ, pointed at its two ends, and advancing as far as the thorax by its front end; two or three pairs of vessels very manifestly pass off from its sides. If we add to this account, the fact, that the spiders have no tracheæ, but that their respiration is circumscribed within a small number of vesicles, and that they appear to have glands, we shall be induced to believe that their circulation is more complete, and more analogous to ours than that of other insects.

Respiratory Organs.—The class of insects exhibits two very different arrangements of the organs belonging to this function: the crustacea have gills, resembling those of fishes and of many mollusca; other insects have air-vessels distributed to all parts of their bodies. The branchiæ of the former extract air from the water in which they live, in the same way as the gills of fishes act. The respiration of insects produces in the air the same effects as that of the warm-blooded animals. Experiments shew us that oxygen is consumed

fumed in this case, and that the residue of the air is rendered impure by the admixture of carbonic acid gas.

An important result of respiration seems to be the maintaining the irritability of the moving powers: hence the definitive result of this process, with respect to the fibre, is power in executing the motions which it has to perform. Thus the energy of the motive force will be in proportion to the quantity of respiration. The organization of insects corresponds to this theory: they are the only class among the lower ranks of animated existence, which possesses the faculty of flying, and we consequently find the tracheæ carrying air over the whole body, so that respiration is carried on at all points. In those insects which do not fly, the force of the muscles may be estimated by the rapidity of their other motions. The running of the millipede and the jumping of the flea, shew that they belong to a very irritable class of animals; the case is analogous to that of the ostrich and casowary, which run with great celerity, although they are birds without wings.

Respiration of the Crustacea.—Their branchiæ are larger in proportion than those of most of the mollusca. In the decapoda they are attached to the base of the feet, under the lateral and descending edge of the thorax, which confines them within a narrow space. The branchiopoda have no gills in this situation, but under the tail, between the fins, and floating loosely in the water.

In the crabs the structure is in some respects peculiar. Each gill represents a triangular elongated pyramid, attached by its basis only, and having the point directed upwards. The middle of the pyramid is divided by a plane, proceeding from the apex to the basis, and composed of a double membrane; and the body of the pyramid is formed by a large number of plates placed one over the other, perpendicular to the vertical plane just mentioned, and consisting merely of doublings of the double membrane. A large vessel runs along each of the two longitudinal edges of this plane, and penetrates at its basis into the thorax of the animal; one of these is arterial, and the other venous. If we inflate them, immediately all the small laminae which compose the pyramid are distended with air. In the same way the blood is expanded over all the surfaces, and is thus favourably disposed for the action of the water.

There are seven of these pyramids on each side. As the edge of the thorax, which embraces and confines them, is inflexible, a particular mechanism became necessary for renewing the water which washes the surface of the organs. This effect is secured by two plates of a substance resembling parchment, articulated on the chest near the maxillæ, very elongated, and passing obliquely, the one within, between the branchiæ and the body, the other without, between them and the edge of the chest. By compressing the branchiæ, these plates squeeze the water from the intervals of the laminae, and when the pressure is remitted, they allow the introduction of a new portion of fluid.

The branchial pyramids, although placed in a similar situation, are more numerous and complicated in the decapoda with long tails, as the lobster, cray-fish, and palinurus, Fabr. They have rows of cylindrical filaments, instead of laminae, piled on each other on the two sides of the vertical plane; so that their surfaces resemble the shag of velvet. There are several thousands of these filaments in a pyramid; each of them is formed of an artery and a vein united: each pyramid has two, its large artery and large vein ending in the body.

These vilous pyramids of the long-tailed decapoda are arranged in groups, between vertical laminae, of which one ascends behind each group. These laminae are attached to

the first articulations of the feet, which cannot move without moving them, and without either compressing or setting free the branchiæ. The lobster and cray-fish have five groups of four pyramids each, and a solitary one before and behind, of which the anterior is very small. This will make twenty-two gills on each side. The first group is attached to the most exterior pair of maxillæ: and the solitary pyramid in front to the pair concealed by the former. The second group is connected to the claws, and the others to the following feet, except the last, which has only a solitary pyramid. In each group the exterior pyramid is attached to the pedicle of the parchment-like plate, and moves with it: the three others adhere to the body of the animal, and have no separate motion. The first solitary pyramid is also attached to its plate; but the last is fixed to the body, and has only a rudiment of a plate behind it. Moreover, two other plates are attached to two maxillæ, anterior to those of which we have already spoken, and support no gills: yet they are placed obliquely against these organs, and contribute to their compression and relaxation. The action of all these plates occasions the expulsion at the two sides of the mouth of all the water in contact with the branchiæ.

The tail of the branchiopoda, particularly of the squiller, bears on its under surface five pairs of fins, forming broad membranous and ciliated oars, divided into two large lobes, an exterior, which is rather anterior; and an interior, which is a little posterior. The gill is attached to the root of the fin at its inner edge. It consists at first of a conical pedicle composed of the two large vessels: from this proceeds a row of cylindrical tubes, gradually diminished in size from the basis towards the apex: each of these is curved, and forms a long conical and flexible tail, which also supports a very numerous row of long and loose filaments. Each gill contains a very considerable number of these, and resembles, on the first view, a large brush: it is only by separating the filaments that the regularity of their insertion and succession can be perceived. It is almost unnecessary to add that each filament contains two vessels; and that each tail and each tube has the same vascular arrangement, just as in the general pedicle. The branchiæ float in the water, are moved like the fins, and are even agitated between the two lobes of the latter: consequently no mechanism is required for renewing the water in contact with them.

Tracheæ and Respiration of Insects.—Some remarks on this subject will be found in the article ENTOMOLOGY, under the division *Stigmata*. We shall enter here more minutely into the anatomical details.

We have already stated that the surrounding element, the air, distributed by means of an infinite number of tubes, exerts its action on all points of the interior of the body. These canals have been called tracheæ, on account of their analogy to the trachea or large vessel which conveys air into the lungs of such animals as possess those organs. Their structure is remarkable: they are composed of three membranes, an internal and an external one of the common structure; and a middle one composed of an elastic thread, possessing a fine metallic lustre, rolled spirally, or in a double spiral course round the canal, from one extremity of the tube to the other, and admitting of being unrolled with a little address. By this the sides of the tube are constantly maintained circular, so that the passage of the air is always free. Yet all the tracheæ are not provided with this part in their whole length: some, which Cuvier calls vesicular, are dilated at certain intervals, so as to form merely membranous pouches that provide with this elastic support.

The tracheæ communicate externally by small lateral holes pierced on each side of the body, and called stigmata; or some-

sometimes by one or two tubes opening into the anus. The latter structure belongs to the true aquatic insects; some of which, as the larvæ and chrysalides of the libellulæ, have in the rectum a particular apparatus for this purpose, which we shall describe.

The tracheæ of the larvæ do not resemble those of the perfect insects any more than the other organs: indeed the differences in this respect are often still more surprising.

We shall describe the organs successively in the most remarkable families.

Those of the caterpillars are the best known, through the admirable description given by Lyonet of that insect. A nearly cylindrical tube, receiving air by ten stigmata, extends on each side of the body. Its branches go off in a radiating manner, from points exactly corresponding to the stigmata; those at the beginning, which go to the head, are larger than the succeeding ones. We observe here, once for all, that no part is unprovided with these air-vessels, and that the very membranes of their trunks even receive small branches. In the caterpillar they are strong, opaque, and of a fine silvery colour, which, however, depends in part on the contained air; for the brilliancy is lost, both here and in other families, when they are macerated and filled with water or spirits of wine. The air-vessels of the butterflies, produced from these caterpillars, have a very different appearance; they are thinner, less numerous, and possess almost throughout small yellow or white elliptical bodies of a fatty nature: such at least is their appearance in the *atalanta* and the *phæna pavonia*.

A much more considerable change is observed in the coleoptera lamellicornia: the larva has fasciuli of cylindrical, silvery, and very fine tracheæ, distributed from each stigma over the surrounding parts. In the perfect insect they are of a dead white, swelled every where into small oval or irregularly-figured vesicles, with very thin sides: they resemble trees much loaded with leaves. Examples of this arrangement may be seen in the melolonthæ, the fearabei, the coprides, the lucani, &c.: and it occurs in no other families.

The hymenoptera and the diptera have two large vesicles at the basis of the abdomen, and some small ones: but the number is always inconsiderable.

The *hydrophilus piceus* has four large ones at the basis of the abdomen; and, as this is a strictly aquatic insect, they may assist the animal, as the swimming-bladder of fishes does, in raising or depressing itself in the water.

The principal air opening in the aquatic larvæ is generally near the anus, that they may the more readily reach the air: in this case the two lateral trunks of the tracheæ are of great size, apparently for the purpose of holding a larger supply of the fluid; and the branches go off in the form of slender cylindrical threads. This arrangement is found in the larvæ of two very different families, the hydrophilus and stratiomyas. The latter, as all the aquatic larvæ of the diptera, can elongate its tail considerably in search of air without elevating the body; the anus is surrounded by small tracheæ in the form of radii. These insects suspend themselves at the surface of the water by means of their tails.

The larvæ of the libellulæ exhibit the most singular disposition of the respiratory apparatus. The orifices, which absorb the air, are found in the rectum, under the form of very small tubes, ranged in little groups in ten rows, which represent for many long pinnated leaves. A number of small tracheæ, equal to that of the tubes within, pass from the rectum into the body; and these terminate in four trunks extended through the whole length of the body. Two of these are of vast size, and appear to serve as reservoirs; for they send the air which they contain by transverse

branches into the other two smaller trunks, which proceed as usual along the sides of the body, and supply all parts with air-vessels. Each of them produces a recurrent branch, which, after having crossed the corresponding one, proceeds along the intestinal canal, and gives it an infinite number of small ramifications. Cuvier thinks that the air contained in these different trunks follows a determinate course, relative to the occasions of the parts to which it is distributed. The four trunks and the two recurrent branches are found in the perfect libellulæ; but they no longer derive their air from the anus. As the animal lives in the atmosphere, its tracheæ are supplied from stigmata, near each of which is a vesicle, serving probably as a reservoir. There is also a single row of larger vesicles along the back.

The tracheæ appear to be deficient in some insects, that is, in the arachnida, where we have stated that something like a heart is perceptible. There is however a single stigma at the basis of the abdomen in the spider: but it leads only into a vesicle, from which no air-vessels have been traced. Can this be the lung? and are there blood-vessels distributed on its sides?

Organs of the Voice.—By the voice we understand the sound produced by animals in expelling air from their lungs, through the glottis: in this sense it can be possessed by those animals only which have lungs, as the mammalia, birds, and reptiles. Several insects produce sounds, and often very considerable ones, by the motions of various parts of their body: but there are no express organs for this purpose. By these sounds they invite each other, and express their wants or their passions.

Organs of Generation.—Many very striking peculiarities are observed in the propagation of insects. The two sexes of one and the same species are often so extremely unlike each other, that they would rather be taken for completely different species, than for animals that could pair together. Among the bees and other neighbouring species, the greatest number of individuals have no sex; they are conceived and born without being defined, as in the ordinary course, to conceive or produce impregnation. Their copulation is performed in a very extraordinary manner in many instances. The act is performed on the wing, and some are winged only during the short season of copulation. Several copulate only once, and the act is very soon followed by death: the life of the animal may be prolonged by deferring the copulation.

In several, as the cochineal insect (*coccus cacti*), and the chigger (*pulex penetrans*), the pregnant female increases to an enormous size. The abdomen of the white ant (*termes fatalis*), when ready for laying, is calculated to be two thousand times larger than it was before impregnation.

Organs of Generation in the Crustacea.—These among the invertebral are what serpents and lizards are among the vertebral animals; their exterior organs are double; but, which is peculiar to themselves, their internal organs, both testicles and ovaries, are sometimes united into one.

The decapoda in general have two penises and two vulvæ: the openings of the latter are found at the basis of the third pair of feet. The two penises are quite at the back of the thorax, behind the fifth pair of feet: in this situation there is, on each side, a horny, pointed, tubular piece, opened longitudinally, which may be introduced into the vulva, and conducts the penis which passes through this tube. We see in the male, on the inside, two very tortuous vasa deferentia, each of which is continued to the root of the penis of its own side. In the lobster and cray-fish the two canals proceed from a testicle divided into six lobes, situated under the heart, behind the stomach, and between the two masses of hepatic vessels.

vessels. The testis is whitish, and has a glandular appearance. In the crabs the two canals are very large near the penises, become afterwards slender, and are so convoluted as to form the appearance of a gland on each side. These glands are not united.

In the common lobster the two ovaria are joined, so as to form a single one to all appearance. The two oviducts are short, straight, and go directly to the vulva: the latter are simple holes pierced in the substance of the coriolum, near the third pair of feet in the crab, and in the very basis of this third pair in the lobster and hermit crab.

The female crustacea attach their eggs, after laying them, to the filaments of the fins under the tail, and carry them in that situation until they are hatched.

Organs of Generation in the proper Insects.—The external parts are simple, and placed at the posterior extremity of the body in most insects. To this rule there are some exceptions, both in number and position. In the spiders they are double; and the male organs are placed on the maxillary palpi; the phalanga have a simple male organ, coming out from the root of the abdomen.

The libellule have the male organ at the basis, and not at the point of the abdomen; and hence arises their very singular attitude in copulation. The male seizes the neck of the female with the hooks at the extremity of his abdomen, until the female bends herself back, and brings the extremity of her own abdomen to the basis of that of the male.

The generative organs of the nulli are about the middle of the body.

I. Male Organs.—These consist in general of a penis with its coverings, of a common spermatic canal, and of two pairs of organs, which may be regarded as testicles and vesiculae feminales. Each of these pairs may be more or less subdivided; they vary in figure and in size.

1. In the Coleoptera.

a. In the Lamellicornia.—The genera separated from the scarabæi of Linnæus, as the melolonthæ, cetonix, trichix, scarabæi, &c. have numerous globular testicles and vesiculae in the form of tubes, as slender as threads, and excessively long. In the scarabæus nasicornis, for example, the two vesiculae feminales are more than twenty times the length of the body, and are convoluted into a packet or mass, which it is not very difficult to unravel. Their tube is a little enlarged before it joins the common canal. On each side there are six testicles of a small size, and producing each an excretory tube more slender than a hair: these six small tubes are united into one canal, which is joined to that of the opposite side precisely at the point where the vesiculae feminales are united. The common canal, resulting from these four tubes, becomes large and muscular, and then goes into a horny sheath, terminated by a kind of pincers, between the laminae of which the penis is placed. The latter is merely a small cylindrical tube. It appears that the two branches of the pincers are introduced into the vulva, and then separated so as to facilitate the entrance of the penis. Swammerdam has given a very accurate figure of these parts.

The melolontha resembles the *S. nasicornis*.

The organs are more complicated in the cetonix: there are twelve testicles on each side, and, besides the filiform vesiculae, which are probably thirty times as long as the body, there are two other short and thick pairs; the shortest of the latter has its extremity forked. The canals of the three pairs of vesiculae, as well as the canals of the two groups of testicles, join together at the same point to constitute the common spermatic tube, which goes to the penis.

The trichix resemble the cetonix.

The coprides, or dung beetles, and the lucani, or stag beetles, do not follow the same type: they have only one testicle on each side, and this is a globular and compact mass made up of the convolutions of a single tube. Their vesiculae feminales are also filiform, but not so long in proportion as those of the scarabæi.

b. In the Carnivora.—The organs are very simple in the dytiscus; there are two large vesiculae of moderate length, very little convoluted; two globular testicles covered by a yellowish matter, which may be removed; they are then easily unravelled into a single, filiform, slender and long vessel. The vas deferens is merely the continuation of this: it enters the vesiculae a little before that joins the opposite tube to form the common spermatic canal.

c. In the Clovicornia.—The structure of the hydrophilus is more complicated than that of the dytiscus: it has two oval testicles, each of which is formed by the convolutions of a single vessel. The vas deferens, which is as fine as a hair, swells into a small oval vesicle where it ends in the common canal. The principal vesiculae feminales are large, with strong sides, spirally convoluted, and terminating suddenly in a small vessel folded in zig-zag, and forming the appearance of another smaller testicle. There are, moreover, two accessory vesiculae, with thin sides, each divided into three branches, and into some small blind appendices. The common spermatic canal has a muscular enlargement towards its middle, and becomes again suddenly small to enter the penis. These parts are figured by Swammerdam, but rather rudely.

The *silpha atrata* has two large oval testicles, formed of an infinite number of small short vessels, resembling those brushes of which the hairs project in every direction. The vas deferens is small and short. There are two pairs of vesiculae, both cylindrical and tolerably large; one of them is folded in a serpentine manner round the intestine, and may be four or five times the length of the body: the other is much shorter. The common spermatic canal is cylindrical and short. The penis is also cylindrical, covered with horny pieces, but has no pincer. An oval bladder, of which the use is unknown, but which resembles in its position and figure the urinary bladder of the mammalia, is found at its internal basis.

d. In the Filicornia.—The common spermatic canal is eight or ten times the length of the body in the blaps mortifaga; four organs resembling vesiculae are connected to it at its origin. Two of these first make some very regular spiral turns, growing at the same time smaller; and then enlarge again and are irregularly folded. The two others have a zig-zag course, and are much shorter.

2. In the Orthoptera.—The grylli have two considerable oval testicles attached to the back: they are covered by a yellow mucosity, in which the tracheæ may be seen beautifully distributed. They are composed of small short vessels, which make up a kind of brush. The vas deferens is folded in the form of an epididymis: a little before joining the opposite one, to form the common canal, it is enlarged, because it receives two groups of vesiculae. One of these contains more than sixty, and the other above two hundred much smaller than the former. The four bundles fill nearly half the abdomen. Two small oval vesicles are found at the very point of union of the two vasa deferentia.

3. In the Hemiptera.—The water scorpion (*nepa scorpioides*) has two small, short, and cylindrical vesiculae, two large vasa deferentia convoluted like the epididymis, and divided at their origin, each into four small testicles, each of which is again prolonged into a very long filiform vessel. These eight vessels are convoluted into a mass.

4. In the *Lepidoptera*.—There are two different forms in this order: the bombyx pavonia will serve as an example of one, and the same has been imperfectly exhibited by Swammerdam and Malpighi in the silk-worm moth (bombyx mori). The common spermatic canal is divided into two vesiculae feminales, at first a little enlarged, and then prolonged in the form of tubes. They continue united to each other in half their length. The vasa deferentia enter in a very slender form into the swellings of the vesiculae. They gradually enlarge, and terminate on each side in a mass, which may be regarded as a testicle. Malpighi has represented the vesicles broken a little above the insertion of the vasa deferentia; and Swammerdam a little beyond this point. The testicles are smaller in the pavonia than in the bombyx mori.

The second form may be exemplified in the sphinx euphorbiae, and it is just the same as Swammerdam represents in the papilio urticae. The common canal, much longer, is divided into two long and slender vesiculae, each of which is joined by a vas deferens: but the two last, instead of having separate testicles, are united into a single rounded mass.

The preceding are the species of insects, in which Cuvier has hitherto observed the male organs: there are three others in Swammerdam, which agree with these in the principal points.

The bee, among the hymenoptera, has two large oval vesiculae, two rounded testicles, with long filiform vasa deferentia. There are two short and small accessory vesiculae: the common canal is enlarged before it enters the penis.

In the order diptera the stratiomyis has two oval testicles, formed, like those of the filpha and gryllus, of small vesicles: two vasa deferentia, and two simple filiform vesiculae. The common canal is of a middling size. In the fly, which lays in cheese, on the contrary, there is a very long common canal, very short vasa deferentia, and large oval vesiculae divided into two lobes.

II. *Female Organs*.—These are much more uniform than the male in the whole class. They consist, in general, of a common oviduct, opening at the vulva, and divided at its origin into two branches, each of which is again divided into a certain number of conical tubes of various length. The ova are so arranged in the interior of these tubes, that the largest are the nearest to the oviduct, and that the others gradually decrease in size to the point of the tube, where they are imperceptible. When the ova have been discharged, the tubes remain empty. They may be already discerned in the chrysalis, a little before the metamorphosis. Secretory vessels of various forms end in the oviduct, and deposit in it fluids for covering the eggs or for forming a shell.

The scarabaeus nasicornis has six oviferous tubes on each side, each containing five or six eggs: an oval vesicle and a small but rather long vesicle end in the oviduct.

The carabi have ten or twelve tubes, and the dytiscs twelve or fifteen; the oviduct has a simple and small bladder, which is prolonged further in the carabus.

In the filpha atrata there are seven or eight tubes, and each contains four eggs. The latter do not become large until they arrive in the branches of the oviduct, which are of considerable size.

The tubes are very numerous in the hydrophilus, and form two large branches; round the basis of each of these are five long and large secretory vessels containing a green liquor.

The butterflies have on each side four very long tubes, filled with a large number of eggs, and forming, particularly in the fruitful species, rows like strings of beads, four or

five times longer than the body. The common oviduct is so short as to be scarcely perceptible; it receives one or two vesicles, and two long vessels.

The grylli have on each side about thirty tubes, each of which does not contain more than three or four visible eggs: they are united by the tracheae, and by a mucous substance, into two oval masses. The common oviduct receives a vesicle and a long vessel.

The bees have the two last mentioned parts: their rows of eggs are numerous on each side. Cuvier thinks that he can perceive very small ones in the neuter bees, which would confirm the notion of their being imperfectly developed females.

In the filpha there are five, and in the notonecta six rows on each side.

The libellulae have two very long branches; their tubes are short, small, and almost imperceptible.

The various boring instruments which certain genera, as the gryllus, ichneumon, tenthredo, and cynips, employ for depositing their ova in suitable situations, may be arranged with the organs of the female sex. But, as these parts are completely external, and have been well described by naturalists, we shall not say any thing more on the subject.

Spinning Instrument of the Caterpillars.—Almost all the caterpillars spin themselves a covering, or at least an attachment of some kind, before their metamorphosis. The caterpillar of the bombyx mori is the most celebrated in this respect, since the thread composing its covering being abundant, flexible, brilliant, and easily wound off, forms the material from which our most splendid silks are formed. Other caterpillars, as that of the bombyx pavonia, form as large a quantity of silk, but it is hard, liable to break, and cannot be wound off.

The secretory organs producing the silk are the same in all caterpillars, excepting varieties in size, which is proportionate to the quantity of silk produced. These, like all the other secreting organs of insects, are two long tubes, commencing in a very slender and convoluted form; then growing larger to form a kind of reservoir, and terminating in an excretory canal so small that it can hardly be seen. The two canals terminate under the lower lip: and the animal draws out and elongates the ductile matter by moving its head from side to side.

Organs for producing Light.—Several animals of this class have the power of producing light; and the substance in which this property resides is sometimes diffused through the animal's body, sometimes collected into a particular organ. The luminous matter must be regarded as an animal secretion produced like any other animal substance. A very full and interesting account of this subject is contained in a paper by Mr. Macartney, in the Philosophical Transactions for 1810, from which the following passages are extracted.

“The power of emitting light has been observed in two animals of the crustaceous order, and seemed to reside in the whole body. One of these, observed by sir Joseph Banks, in the passage from Madeira to Rio Janeiro, resembled the common shrimp, but was less: it is named by Mr. Macartney cancer fulgens. The other was found in the Red sea by captain Horribus, appeared to be a monocoelus, and to belong to the genus limulus of Müller. Mr. Macartney calls it limulus noctilucus. A third crustaceous animal of the genus lycinus of Müller, possessing luminous properties, has been seen off the coast of Malabar. Of other insects some species yield light in the five following genera; viz. elater, lampyrus, fulgora, pausus, scolopendra.

dra. The only animals which appear to possess a distinct organization for the production of light are the four first of the last mentioned genera.

“The light of the lampyridæ (glow-worm) is known to proceed from some of the last rings of the abdomen, which, when not illuminated, are of a pale yellow colour. Upon the internal surface of these rings there is spread a layer of a peculiar soft yellow substance, which has been compared to paste, but by examination with a lens I found it organized like the common interstitial substance of the insect’s body, except that it is of a closer texture, and a paler yellow colour. This substance does not entirely cover the inner surface of the rings, being more or less deficient along their edges, where it presents an irregular waving outline. I have observed in the glow-worm, that it is absorbed, and its place supplied by common interstitial substance, after the season for giving light is passed. The segments of the abdomen, behind which this substance is situated, are thin and transparent, in order to expose the internal illumination. The number of luminous rings varies in different species of lampyris, and as it would seem at different periods in the same individual. Besides the luminous substance above described, I have discovered in the common glow-worm, on the inner side of the last abdominal ring, two bodies, which to the naked eye appear more minute than the head of the smallest pin. They are lodged in two slight depressions, formed in the shell of the ring, which is at these points particularly transparent. On examining these bodies under the microscope, I found that they were faces containing a soft yellow substance, of a more close and homogeneous texture than that which lines the inner surface of the rings. The membrane forming the faces appeared to be of two layers, each of which is composed of a transparent silvery fibre, in the same manner as the internal membrane of the respiratory tubes of insects, except that in this case the fibre passes in a spiral instead of a circular direction. This membrane, although so delicately constructed, is so elastic as to preserve its form, after the face is ruptured, and the contents discharged.

The light that proceeds from these faces is kept under the controul of the insect, than that of the luminous substance spread upon the rings: it is rarely ever extinguished in the season that the glow-worm gives light, even during the day; and when all the other rings are dark, these faces often shine brightly.

The organs for the production of light in the genus *elater* are situated in the corselet; these likewise consist of a peculiar yellow substance, placed behind transparent parts of the shell, which suffer the natural colour of this substance to be seen through them in the day, and when illuminated give passage to the light. On dissecting the organs of light in the *elater noctilucus*, I found that there is a soft yellow substance of an oval figure lodged in the concavity of the yellow spots of the corselet, which parts are particularly thin and transparent in this species. This substance is so remarkably close in its texture, that, at first view, it appears like an inorganic mass, but with a lens it is readily perceived to be composed of a great number of very minute parts or lobules closely pressed together. Around these oval masses the interstitial substance of the corselet is arranged in a radiated manner, and the portion of the shell, that immediately covers the irradiated substance, is, in a certain degree, transparent, but less so than that which lies over the oval masses: it is therefore probable that the interstitial substance in this situation may be endowed with the property of shining. In the *elater ignitus* the masses of luminous substance are extremely irregular in their figure;

they are situated nearly at the posterior angles of the corselet, and are more loose in their texture than the oval masses of the *noctilucus*, resembling rather in composition the interstitial substance which surrounds these masses in that species. The shell of the corselet is somewhat thinner, and more transparent along both sides of the margin, than at other places, but it is not, as in the *noctilucus*, elevated, and peculiarly clear and thin immediately over the seat of the luminous organ; consequently the light emitted by the *elater ignitus* cannot be very brilliant.”

In the *fulgora candelaria* and *linternaria*, Mr. Macartney has found the hollow organ, from which the light proceeds, to communicate freely with the external air, by means of a chink or narrow aperture, placed on each side of the root of the proboscis. This organ is lined by a membrane, between which and the horny part or shell there appears to be interposed a pale reddish soft substance, arranged in lines or stripes in the candelaria. It could not be determined, whether this furnishes the light, or is the pigment, upon which the colour of the proboscis depends.

The globes of the antennæ constitute the organs of light in the *pausus spherocerus*.

“It is worthy of remark,” says Mr. Macartney, “that in all the dissections I have made of luminous insects, I did not find that the organs of light were better or differently supplied with either nerves or air-tubes, than the other parts of the body. The power of emitting light likewise exists in many creatures, which want nerves, a circumstance strongly marking the difference between animal light and animal electricity.” Swammerdan’s *Book of Nature*, or *History of Insects*: Lyonet *Traité Anatomique de la Chenille*, qui rouge le bois de saule: *Cuvier Leçons d’Anatomie comparée*.

INSECTS infesting the human body. The parasitic animals, which are most commonly found inhabiting, and deriving their nutriment from, the internal cavities of the human body, are the three species of worms, which are denominated, by naturalists, *ascaris*, *lumbricus*, and *tenia*; that is, the maw-worm, or thread-worm, round-worm, and tapeworm; to which may be added the *trichuris*, which is occasionally seen. (See these words.) The external parts of the body, again, afford a nidus and sustenance to one or two of the insect tribes, especially the *pediculi* of the head and of the *pubes*; the former of which are sometimes bred in great numbers, and infect other parts of the surface, producing a loathsome and very obstinate disease, the *morbus pedicularis*, or lousy disease. (See *PITHIRIASIS* and *PRURIGO*.) It is not our object, however, to treat of these under the present article; but merely to notice briefly the occasional existence of various species of the winged insects, in the different cavities of the human body, especially in their first state, that of *larva*, caterpillar, or grub; and to point out the manner in which they are probably introduced.

The medical writers of the sixteenth and early part of the seventeenth century have recorded instances of various reptiles and other animals, which were dislodged from their abode in different parts of the body, such as frogs, lizards, serpents, &c.; which may be found on consulting the collections of Borlæi, Marcellus Donatus, Schenck, and others. But their credulity was at least equal to their learning and industry, and subsequent observation has not confirmed their statements, which probably originated from gross ignorance of the economy of these creatures, or from wilful deception on the part of those from whom they were said to have been discharged. On the other hand, the microscopic philosophers not only peopled every organ of the body with worms and animalcules; but believed that all contagion

INSECTS.

consisted of the same beings, which, according to their nature, communicated scabies, and syphilis, small-pox, dysentery, the plague, and every other infectious disorder. (See the learned dissertation of Dan. Le Clerc, entitled "Historia Lator. Lumbricorum," p. 274, et seq.) But more accurate investigation has likewise caused these notions to be exploded; and the catalogue of parasitic creatures, which infest the human frame, in addition to the worms, &c. above-mentioned, is reduced to a few varieties of the insect tribes.

It is well known, that the internal cavities and passages of some animals, especially the nostrils and adjoining sinuses, the stomach, and rectum or straight gut, in horses, sheep, and cows, are the situations in which alone certain insects are apparently intended by nature to breed, and to be nurtured in their first stage of existence. This is the case especially with the several species of *astus*, the grub or larva of which is called a *bot*. (See an ample history of this insect, under the article *BOTTS*.) The *ova*, or eggs of these insects are introduced into those passages by the parent insect, or are conveyed thither by licking with the tongue; inhaling odorous matters, &c. Now, although there does not appear to be any species of insect destined particularly to be nurtured in the human body; yet it appears beyond all question, that the larvæ of some of the winged insects are occasionally hatched and nurtured in the nostrils and sinuses, as well as in the stomach and intestines of man.

The want of accurate investigation, since the subject of entomology has been well understood, leaves us in a state of uncertainty as to the number of insects which are thus nurtured within the human body. It seems probable, however, as we might, perhaps, have anticipated, that the most frequent instances which occur, are those of our most common domestic insect, the varieties of the *fly*. The larvæ of several of the species of the fly (*musca*, Linn.) are aquatic, or at least inhabit moist and wet places, and therefore seem to be adapted to exist in the fluids of the human stomach; and the author of this article is in possession of some larvæ of the common *house-fly*, the *musca domestica minor* of Degeer (Histoire des Insectes, tom. v. tab. 2. fig. 4.), which were rejected alive from the stomach of a man by vomiting (see Edin. Med. and Surg. Journal, for Jan. 1811, p. 41.); and of others of the same fly, which were passed by stool by another person. The larva of another species of *fly* is also figured in the Journal, just referred to, by Dr. Chevre, now of Dublin: and several examples of the larvæ of *flies*, discharged from the human intestines, are on record. Dr. Wahlbom, of Upsal, has related the case of a girl, who, after suffering considerable pain in the stomach and left side, discharged by stool a number of larvæ on several successive days, after which she was relieved from the complaint. "One of these larvæ, while it was kept in a phial, was converted into a *fly*, which proved to be the *musca nigra* of Linnæus." (Faun. Suec. 1105.) Dr. Wahlbom also states, "that a few years ago there was a girl in Upsal, from whom a large quantity of worms were brought away, and these were *fly-worms*. N. Faun. Suec. 1064;" for an account of which he refers to Dr. Du Bois' Treatise de Tania. (See Med. Chirurg. and Anatom. Cafes and Experiments, communicated to the Royal Academy of Sciences at Stockholm, translated from the Swedish, 1757, case 24.) Ruyfch has described and delineated both the larvæ, and the flies which originated from them, after they were discharged (it is affirmed) by urine, by a nobleman, in considerable quantities; and Tulpius has mentioned a similar case, and has also figured the larvæ, which closely resemble those in the writer's possession.

It must be acknowledged, however, that the bladder is the least probable *nidus* for the larvæ of insects, and we cannot readily conceive how they should find their way into that cavity; while, on the other hand, mistakes may be made upon such a subject with the greatest facility, as Vallisneri long ago remarked. These larvæ might have crept or fallen into the uterine, or the *ova* might have been deposited there, and the larvæ afterwards observed in the urine. An instance of this kind of mistake was related to the writer by an eminent surgeon. A lady was in great alarm, from the belief that the frequently passed from the bowels several little red worms, extremely lively in their motions, which were found in the excretions. But it was strongly suggested, that these worms must be inhabitants of the water-closet; and upon accurate examination, the suggestion was confirmed; they proved to be the larvæ of the common *gnat*, which are well known to be aquatic in their mode of life. In all cases, therefore, it is necessary to be cautious in examining all the circumstances, before it be concluded, that insects, found in the excrementitious discharges, actually passed from the human body.

There is another species of insect, which, in its state of larva, or caterpillar, appears to be not unfrequently an inhabitant of the cavities of the human body, though not so commonly as the different species of fly; we mean the common *black beetle*, the *televrio molitor* of Linnæus. The grub of this insect is a sort of caterpillar, about an inch and a quarter in length, and equal to a large cross-quill in circumference, with six feet near the head, but destitute of feet at the other extremity: its body is divided into thirteen sections. The introduction of this larva into the human body, or of the *ova* from which it is hatched, will be readily understood, when we mention that it lives principally in flour or meal; whence from the time of our oldest writer on insects, Mousset, it has been known by the appellation of the *meal-worm*. This writer has given a rude figure of the grub. (See his *Insectorum Theatrum*, Lond. 1634, lib. ii. cap. 20. p. 254.) Two cases, in which this meal-worm was discharged from the human body, have come to the knowledge of the writer of this article. (See Edin. Med. and Surg. Journal, above quoted.) Another is mentioned and figured by Dr. Kellie, of Leith, in the same Journal. And Tulpius has given a figure of the same larva, two of which, he says, were passed from the bladder of a woman of fifty years of age, and a similar one from the nose of another woman, who had previously suffered severe headache. (See his *Observ. Med.* lib. ii. cap. 51. tab. 7. fig. 3; and lib. iv. cap. 22.) The discharge of two from the bladder was probably inferred, by mistake, from the grubs being found in the uterine which received the urine: but the escape of the one from the nose is probably correctly stated; for in this way the larvæ passed in one of the cases, to which we have just alluded, and the nose, or the adjoining cavities, are common receptacles for the *ova* or larvæ of other species of insects, as we shall presently shew. Forestus has recorded some cases, in which the grubs were most probably of the same nature. He mentions the circumstance, which he witnessed, of a girl who rejected from the stomach two beetles, one at the interval of two days after the other, and likewise a living worm or grub, which was, in all probability, the grub of the beetle. He also mentions the ejection of a species of caterpillar, "vermem eruce similem," by vomiting, after which a severe pain of the stomach of considerable duration was removed. Foresti Opera, lib. xxi. obs. 25.

Several of the insects above-mentioned were discharged from the nose, in which cavity, in brute animals, the ex-

istence of larvæ is very common, and the *ova* appear to be actually deposited there by the parent insect. Mr. Bracy Clark questions the existence of human botts (*ægrus bominis*); but that insects of this species sometimes find a *nidus* in the nasal passages of the human subject, is proved by a case, related by Dr. Heyham, of Carlisle, in which three botts were discharged from the *astrum* of Highmore, or *sinus* of the cheek of a woman, after that cavity had been perforated by a trocar. An intolerable hemieria was occasioned by their presence, and ultimately proved fatal. (See Medical Communications, vol. i. art. xxx. and plate i. figs. 2 and 3.) An example of a *centipede* lodging in the frontal *sinus* is recorded in the Edin. Medical Essays, vol. v. p. 991. In tropical climates, as we learn from Dr. Lempriere, the maggots or larvæ of the large blue fly, which are constantly buzzing about the sick, are generated in the nose, mouth, and gums, in the last stages of fever, when the patients sleep or doze with their mouths open, the nurses finding great difficulty in preventing the deposition of the *ova* in those parts. This author mentions one instance, in the lady of an officer, who had escaped from the attack of fever, but in whom "these maggots were produced, which burrowed and found their way by the nose through the *os ciliiforme*, into the cavity of the cranium, and afterwards into the brain itself, to which she owed her death." Lempriere, *Obs.* on the Dis. of the Army in Jamaica, vol. ii. p. 182.

It is probable that those cases on record, in which worms were said to be coughed up from the lungs, were in reality instances of the larvæ of insects, bred in the posterior cavities of the nose, and removed by the agitation of coughing into the throat, and thence expelled. See a case of this sort, related by the late Dr. Percival, in his *Med. Essays*, vol. iii. p. 272, in which two masses of grumous blood were brought up by coughing, as large as a nutmeg, one of which, when opened, "was found to contain a considerable number of worms, like maggots, in a very lively state."

Besides the larvæ of *flies*, of the *black beetle*, and of the *ægrus*, above-mentioned, scarcely any other insects are described upon good authority, as being nurtured in the human body, if we except the *millepedes*, which are mentioned by some authors. It is impossible to say much on the subject of destroying these larvæ by medicine; since their existence cannot be ascertained before they are actually discharged and seen. The symptoms produced by the irritation which they excite, consist only of severe pains in the parts where they happen to be, which of course cannot be distinguished from pain occasioned by other causes. If the existence of the worms was known, or could be surmised, perhaps the internal exhibition of the oil of turpentine might be resorted to with success; for it appears that this liquor is poisonous to all the insect tribe, as well as to worms. Experience has now decidedly proved its efficacy in the destruction of the tape-worm. (See *Edin. Med. and Surg. Journal*, for April and July, 1810.) It has been used with success in the way of glyster in the case of ascariæ; and Dr. Lempriere found it serviceable when injected into the passages infested by maggots.

INSECTS, Anatomical Use of. The insect-world affords us numerous uses, and those many of them such as no one would at first thought imagine, and which no other operations or operators could so well effect. In the minutæ of anatomy, where knives cannot be introduced, the maggot or the ant may be employed with great success. Skeletons of *testes* have been prepared by burying them in an ant-hill, and that in so accurate and perfect a manner, that all who have seen them, have admired by what means they could be so nicely finished; and the secret of the great

Ruyfel, by which he cleared away the parenchymatous substance from his vascular preparations, was of this kind. After injecting the vessels of any part with wax, all that remained to the completing of these preparations, was the taking off the parenchymatous or fleshy matter from between and among them. Other anatomists of his time did this by the knife, or by maceration in water and other liquors; but it appeared a sort of magic to them, that his were always not only much sooner executed, but to a greater nicety and perfection than their's ever possibly could be. His method was only to put a number of the common flesh-eating maggots to the substance; and these regularly eat away all the flesh, their heads getting into crevices which no instrument could reach, and the whole substance of the injection remained unhurt, as their soft bodies could glide between its nicest parts without injuring them; and the wax being no food for them, was in no danger of being eroded, even in its smallest pieces. The several sizes of the worms or maggots bred from the eggs of different flies were of great use in the perfecting of the preparations; for while the larger sort eat the more fleshy parts, where the vessels are large and but few in number, the middle-sized maggots got into the interstices of the more vascular parts, and the most minute of all, which are usually also the most numerous, kept about the surface, and eat away between and among the capillary vessels.

The maggots produced from flies are not the only animals fit for this kind of business. There are several species of beetles of the smaller kinds, whose eggs hatch into a six-legged worm, which eats as much and as nicely as the fly-maggots. All these may be employed very successfully in the preparations of the parts of animals.

These nice anatomists are not confined to animal substances; they often exert their power also on vegetables. Many of them feed on the leaves and fruits of plants; and some species of these work so nicely, that they eat away all the outer membrane and internal parenchymatous substance of the leaves, so as only to leave the net-like plexus of vessels standing. Yet these being unhurt shew the true figure of the leaf, and are a sort of vegetable skeletons, but very poorly imitated by art in the common way, by long macerations in water; this method usually destroying and washing away many of the smaller vessels, which the tender mouths of these creatures spare. If they exert their skill often upon leaves in this manner, they do it also sometimes with equal, if not greater, success upon fruits. As in the leaves, those which have the tenderest parenchyma and the finest ribs succeed best; so also it is in fruits. The leaves of the rufous or butcher's broom are often found thus beautifully anatomised; and of all fruits, none succeeds so well as that of the stramonium, or thorn-apple. Wherever this plant grows in any plenty, the fruit towards autumn, while it is yet full of juice, is attacked by a small worm, which eats away all the parenchyma, and leaves every vessel standing in its place; and this not only in the outer coat of the fruit, but in the very inner cells of the seeds. These vessels remain exactly in the shape of the fruit, and, growing white with the air, exhibit the most elegant and beautiful skeletons imaginable, while yet standing on the plant. The animal which effects this, is a hexapode worm produced from the egg of a small beetle: and differs very little from some of those which so elegantly eat away the fleshy parts from the injected anatomical preparations. These are gregarious animals like some species of the smaller caterpillars, and numbers of them are always at work together on the same leaf or fruit, so that the skeleton is soon made. They begin by piercing a number of little holes

into the substance of the leaf, and thence burrow under the integument till they meet one another; and this being done all over the leaf, they leave it, and go to work upon another.

INSECTS, Vegetable Diseases of. All such vegetable affections or diseases are produced by different sorts of animals of the insect kind, are very numerous according to their nature and those of the plants; but the chief insects that affect plants of the fruit-tree kinds, are those of the aphid, acarus, ant, chermes, cicada, coccus, earwig, papilio, phalena, and thrips tribes.

And of the first sort there are a vast number of species, each tree being said to be infested by a different distinct species. Hence the author of the "Système Vegetabilium" has denominated them from the trees on which they are found; as the cherry aphid, the currant aphid, the plum aphid, &c. The males are few in comparison with the females, and have wings, while the latter are numerous and without them. See PUCKERON, and VINE-FRETTER.

The second is a highly destructive insect in houses where forcing is practised. It is not furnished with wings, but the female is oviparous. The species, as in the former case, are very numerous. It often commits great mischief on vines, peaches, nectarines, cherries, forced kidney-beans, melons, &c. See Red SPIDER.

And the third, or ant, is highly injurious to fruits, especially those of the peach kind, as they become in a state of maturity. They run all over the trees, and the best fruit is occasionally filled with them. It has been supposed by some that they are of use by devouring the alphides on the trees; but Mr. Forsyth is of a different opinion, and we have seen fruit much spoiled by them in various instances.

The best method of destroying them, according to the above author, is, by making holes in the ground along the side of the wall where the fruit-trees are, by an iron crow, so that the inside surface may be quite smooth. These insects, from being disturbed, soon come to the holes, and fall into them; when, being prevented from getting up by the smoothness of the sides, they may be readily destroyed by pouring water upon them. But more effectual methods are, either by mixing quick-lime with foot, and placing it on their tracks, or putting it in their nests, and then pouring water, or urine and soap-suds, upon it, so as to slack it, confining the heat by a turf or some earth. The heat thus produced soon destroys them. The powder of flavelacre, laid round the stems of the trees, is said to prevent their running upon them and thereby becoming injurious.

The fourth, or chermes, belongs to the order hemiptera; and there are several species. Their specific names are taken from the different plants on which they are generally met with: as the chermes graminis, or grass bug; chermes ficus, or fig-tree bug, &c. The last is one of the largest of the genus, being brown above and greenish beneath, and has four long wings, placed in the form of an acute roof. The larva is of an oblong form, and has six feet, but its motion is slow. When attempted to be caught, the chermes makes its escape rather by leaping than flying, by means of its hinder legs, which play like springs. Several of the species are provided at the extremity of their bodies with small sharp-pointed implements, but which lie concealed; and these they draw out in order to deposit their eggs, by making punctures in the plants that suit them. It is in this way that the fir-tree chermes produces that enormous scaly protuberance which is sometimes found at the summit of the branches, and which is formed by the extravasation of the juices occasioned by the punctures. The young larvæ shelter themselves in cells contained in the

tumour. These insects are capable of being destroyed in the same manner as the cocci tribe.

The fifth, or cicada, belongs to the same order as above, and the larvæ of many of this tribe void large quantities of frothy matter upon the leaves and branches of the plants and trees, in the midst of which they are always concealed, probably for protection, and to be shaded from the same influence. These insects should be destroyed, as the froth is unpleasant, and the leaves of the trees are often devoured, by rubbing off the larvæ with the hand, and afterwards watering the trees well with soft water, such as that of ponds or other exposed situations.

The sixth, or coccus, also belongs to the same order, and the males have wings, but the females none. It may be noticed, that the sorts most commonly met with when full grown, have somewhat the form of a boat with the keel uppermost, being apparently without feet, eyes, &c. while in this state resembling some sorts of galls or excrescences of the bark of trees or other plants.

It has been observed by Mr. Forsyth, that a "thin film, of a white cotton-like substance, is interposed between the flat part of the body and the tree." This is common, in a greater or lesser quantity, to all the species, and appears at first all round the edge as a kind of cement, to join it to the tree. The males are very few in proportion to the females, and not nearly one-fourth of their size; they are beautiful little flies, which, after a short but active life, terminate their existence without having tasted food, being provided with no sort of organs for that purpose.

It is likewise remarked, "that the peach, nectarine, and pear-tree, are very much infested with these insects: they frequently cut through the bark, and the trees then appear as if they had been scratched by cats." He has "seen some with this appearance all over them."

It is advised, that, "when these insects first appear on the bark, they should be scraped off with a wooden knife, and the stem and branches of the tree well washed with soap-suds and urine, applied with a stiff painter's brush. This should be done in February before the buds begin to come out. But if the outer bark is perforated, it must be cut or scraped off with a long knife; and if you find any brown spots in the inner bark, they must be carefully cut out. This disease is, it is supposed, one great cause of the canker, and of the death of the tree."

And it is added, that "when this disease has made its way through both barks, as is often the case, the branches on each side of the tree may be cut close to the stem, if it has an upright one; but if the tree be trained fan-fashion, the best way is to head it near to the place where it was grafted." He states, that he has "headed old pear-trees which were so dead, except a small strip of live bark on one side, that you might rub the bark off them as easily as off a bundle of faggot-sticks that had been cut upwards of a year; yet these trees have shot out fresh branches to the length of seventeen feet in two years, and produced fine fruit the second year." It is advised to apply the composition immediately after heading or cutting, or paring off the diseased bark. See COMPOSITION.

It is further remarked, that "a very destructive species of the coccus tribe has done incredible damage to the apple-trees in the nurseries and gardens in the neighbourhood of London. Some nurserymen have lost several thousand apple-trees in one year. These insects attach themselves to their bark by their suckers, and by feeding on the juices of the tree, rob it of its nourishment. Such trees as are infested with them have a sickly appearance. These insects generally make their nests where branches have been cut off, or in hollow

hollow places, where the canker has eaten holes in the trees. Their first appearance is like a white down; on touching or rubbing them they tinge the fingers of a crimson colour, like cochineal. If suffered to remain long on the trees, they take wing, like aphides."

It is stated, by the same author, that the method that has been followed for these ten years to destroy them, is to "rub the places where their necks are with an old brush, such as painters use, till they are all cleaned off; and if the part be canker-eaten, to cut it clean out with a knife or chisel; he then takes of soap-suds and urine equal parts, and with this he washes the wound and the bark all round it; and with a brush applies the composition, mixed with wood-ashes and the powder of burnt bones, covering the wound all over with it. Afterwards he flakes some of the powder of wood-ashes and burnt bones, mixed with an eighth part of unlacked lime finely powdered and sifted over the hollows, or where knobs have been cut off."

And it is advised, that "at the same time that the trees are cleared of the cocci, the caterpillars should be picked off."

The writer remarks, that "the first time that he observed the new coccus which has done so much mischief to the apple-trees about London, was in a garden of his own at Chelsea, about the year 1782 or 3; and as far as he can learn, they were imported among some apple-trees, by the late Mr. Swinton of Sloane-street. Mr. Swinton afterwards removed his nursery to the King's Road near Chelsea college, which now goes by the name of the Foreign Nursery."

By some, train oil has been tried, laid on with a painter's brush, but without effect.

The seventh sort, or earwig, is often very destructive to fruit, particularly that of the peach kind. The method recommended by Mr. Forsyth for destroying them, and which he has long pursued with success, is to "take old bean-stalks, and cut them about nine inches long, tying them up in small bundles with some pack-thread, or with small yellow wilows, and hanging them on nails against the wall, at different parts of the trees. The first thing in the morning, being provided with a board about eighteen inches square, and a small wooden trowel, take down the bundles of bean-stalks one by one, strike them against the board, and with your trowel kill the earwigs as they fall out of the stalks. If you follow this up every morning, (or every other morning,) you will be able to keep them under," without much difficulty.

It is suggested, that this method answers for any sort of trees infested with earwigs. In some years the writer has "seen a great part of the fruits, especially the smooth-skinned sorts, destroyed by these insects, and a small green caterpillar; and in a scarce year of fruit, the leaves of peaches are frequently destroyed by them." It is advised, that "the shreds taken from trees that have been unnailed in autumn, should be soaked in boiling hot soap-suds for three or four days previous to their being used again; as this will kill the eggs of earwigs and other insects that may be deposited on them."

The eighth, the papilio or butterfly sort, belongs to the order lepidoptera.

There are a great many species of this genus, mostly distinguished by the colour of their wings. The more common sorts, with their caterpillars, are well known; and Mr. Forsyth advises, that the caterpillars and chrysalides should be carefully picked off, and the trees well watered with clear lime-water and tobacco-water mixed well together. The ninth, the phalœna or moth kind, are extremely numerous, their caterpillars differing much in size, shape, and colour. After casting their slough several times, all of them

spin their cod, in which they are transformed to chrysalides. In this state they are often found rolled up in the leaves of fruit trees, especially those of the pear, plum, and cherry kinds. See PHALœNA.

And of the sphinx, or hawk moth kind, there are a vast number of species. Their caterpillars apply the hinder parts of their bodies to the branches of the trees, holding the rest erect; hence the name. But in general they spin their cod under ground. They appear early in the morning, or after sun set, flying heavily, and making a sort of noise. Several of the caterpillars are green, and some brown, yellow, spotted, or bled.

The phalœna nutria, or lackey moth, deposits its eggs in rings or circles round the branches of fruit trees, having the appearance of a necklace. See PHALœNA.

The tenth sort, or thrips, belongs to the order hemiptera, and there are several species. It is extremely small, so as scarcely to be discovered. This insect produces great mischief on fruit trees, devouring the fruit as well as the leaves. It is capable of being destroyed in a similar manner to that of the cocci.

But the nature of the various effects of these different insects, and the means of removing them, will be more fully considered and explained, in describing the several vegetable diseases that are produced by the attacks of different sorts of animals of this kind. See VEGETABLE Diseases.

INSECTS, Petrified, in *Natural History*. The works of the earlier writers on extraneous fossils, contain accounts of various insects said to be found in the earth. Mr. William Martin, a late and correct writer on this subject, seems, however, to doubt, whether the remains of any of the winged tribe of insects have been found enveloped in the strata; although such insects in a perfect and natural state of preservation are very common in pieces of amber. The limestone of Oening is said by M. Werner to produce specimens of the larva of the libellula or dragon-fly, and of the nepa or water-scorpion. Insects without wings, of the canker, monoculus, and oniscus genera, are not uncommon in some strata. In his "Petrificata Derbenensis," Mr. Martin describes and figures (tab. 45.) an insect found in the shale limestone of Ashford and Bakewell Moor, which he calls the Derbyshire oniscite, and expresses an opinion, which seems pretty well founded, that it differs essentially from the oniscite of the Dudley and Coalbrook-dale lime quarries. He also figures and describes a limated monoculite, said to be found in iron-stone, near Mansfield, in Nottinghamshire, but this probably is a mistake, particularly if others of the same kind were found near Chesterfield in Derbyshire. The late ingenious Dr. Woodward had persuaded himself, that all the many flies and insects preserved in amber, were of the vernal tribes, and concurred with other fossil subjects in proving, that the Mosaic deluge happened in the spring season of the year; later and more correct observations seem, however, to prove, that all the organic remains of the strata, and even most of those of the alluvia, cannot have relation to that event, since they differ essentially from the recent insects, animals, &c. to which they have a resemblance, and all such seem rather to have been created and lived, during the successive creation and deposition of the mineral substances, composing the strata in which they are imbedded, and long prior to the creation of the present race of animals and vegetables, of whose origin Moses has given us so succinct and satisfactory an account, as according with the present appearances of nature.

INSERTED COLUMN. See COLUMN.

INSERTION, a term frequently used, in *Anatomy*, to signify the implication of one part within another.

The insertion of the bones, muscles, and nerves in the members of an animal, is exceeding artful: the vena cava has its insertion in the right ventricle of the heart.

INSERTION is also used, in *Agriculture*, for the inclosing a graft within the cleft of a tree. See GRAFTING.

INSESSUS, or INSESSIO, in *Medicine*, a kind of half-bath or fennicupium, usually prepared with a decoction of several herbs proper for the lower parts, wherein the patient sits down to the navel.

It has several uses; as the easing of pain, softening the parts, dispelling a flatulent matter, and frequently promoting the menses.

INSHILLA, in *Geography*, a town of Africa, near the E. coast of Tunis; 108 miles S. of Tunis.

INSIDE GUARD, in *Fencing*, a guard with the broadsword, to secure the face and front of the body from a cut made at the inside of the position, above the wrist. See GUARD.

INSINUATION denotes a cunning, and covert way of creeping into any person's favour.

INSINUATION of a will, among *Civilians*, is the first production of it, or the leaving it with the regiller, in order to its probate. See WILL.

INSIPID, TASTELESS, that which has nothing in it pungent enough to affect the palate, tongue, &c. and to occasion that sensation we call *tasting*.

INSITION, INSITIO, in *Botany*, denotes the same with engraving; viz. the act of inserting and uniting a cion, bud, or the like, in the substance of the stock.

INSOKO, in *Geography*, a town of Africa, on the Gold Coast; 120 miles from the sea.

INSOLATION, in *Medicine*, from *in* and *sol*, the sun, a term used by some writers to express the disease, occasioned by the direct action of the sun's rays upon the human body, which has been called, in the Latin and French languages, *ictus solis*, and *coup de soleil*. See an account of this disorder under the head HEAT, in *Medicine*.

INSOLATION, in *Pharmacy*, a method of preparing certain fruits, drugs, &c. by exposing them to the heat of the sun's rays; either to dry, to mature, or to sharpen them, as is done in vinegar, figs, &c.

The word comes from the Latin verb *insolare*, which is used by Pliny and Columella; and signifies *to expose to the sun*.

INSOLVENCY, *Ab of*, in *Law*, an occasional act, frequently passed by the legislature; whereby all persons whatsoever, who are either in too low a way of dealing to become bankrupts, or not being in a mercantile state of life are not included within the laws of bankruptcy, are discharged from all suits and imprisonment, upon delivering up all their estate and effects to their creditors upon oath, at the sessions or assizes; in which case their perjury or fraud is usually, as in case of bankrupts, punished with death.

INSOLVENT, a term applied to such persons as have not wherewithal to pay their just debts.

A person dying, and not leaving estate sufficient to discharge these, is said to die insolvent.

INSPECTING *Field-officer of a District*, in *Military Language*, denotes an officer, selected from the line, and nominated by the War-office, to superintend and to vouch for the faithful distribution of monies which are issued to officers acting on detachment, or on recruiting parties, within the limits of his station.

All district pay-masters are strictly enjoined by the last general regulations to get their muster-rolls and pay-bills duly authenticated, not only before a justice of the peace, but to have them witnessed by the inspecting field officer. All the

recruiting officers, &c. within the limits of the district are accountable and subordinate to the inspecting field officer. It is the duty of the latter to be particularly minute in his examination of every thing which appertains to the recruiting service. They have the command of all recruiting parties of regiments of cavalry and infantry in their districts; they are authorized to give an intermediate approval of the recruits whom they judge fit for service, except in cases where regiments are so quartered, as to render it, in point of distance, equally convenient for the recruits to be sent to their own head quarters. The senior officer in each quarter is ordered to report to the field officer of the district. No officer is to leave his station even for one day, without reporting to the field officer who has the command of the recruiting parties in the district, or to be absent from it for more than one day, without the previous permission of the field officer. The field officers in their districts, are to be responsible for the dress, regularity, and good conduct of the officers, non-commissioned officers and private men of the several recruiting parties under their command. They are constantly to wear their uniforms whilst in their districts, and they are to see, that his majesty's orders respecting the due observance of discipline, regularity, and uniformity of appearance among the officers, non-commissioned officers and privates, be strictly and unequivocally adhered to.

Field officers of districts may order detachment courts martial, to be composed of the recruiting officers in their districts, in the usual number and ranks, and they are to approve of every such court martial, and to direct the punishment awarded thereby to be executed, mitigated or remitted, as they shall think expedient. They are to receive orders from the inspector-general of the recruiting service, respecting the nature of their returns; and all returns and reports are to come to the inspector-general through them. Each district field officer has an allowance of ten shillings a day, in addition to the full pay of his respective regimental rank, and he is to be reimbursed for the actual expence he incurs for stationary and postage of letters; which charge must be accompanied by a certificate upon honour.

Each district field officer is allowed to appoint a subaltern officer (not employed upon the recruiting service) to act as adjutant in the district. The pay or allowance of such subaltern is three shillings a day in addition to his full regimental pay; he is also authorized to nominate two sergeants, with the additional pay of sixpence each, one to act as sergeant major, and the other as clerk to the district.

Each field officer may moreover give directions to the hospital mate, who is placed under his orders, to examine the recruits when brought for inspection, and to give such medical assistance as may be in his power, to the several recruiting parties in the district he belongs to.

When colonels of regiments take upon themselves the whole direction of the recruiting service for their own corps, they must conform to the regulations which require returns to be made to the inspector-general of the recruiting service; and they must instruct their officers to send weekly returns to the regulating field officer, in whose district they are stationed, of all the casualties that have occurred. See pages 105, 106, 107, and 118 of the General Regulations.

INSPECTION denotes examination, survey, and superintendance of *general, regimental, and company duties*. A general inspection is made annually by the reviewing generals of districts. Every regiment, on this occasion, is minutely looked into, and a faithful account must be delivered by each commanding officer of the actual state of his regiment, together with all the casualties that have occurred during the

current year. The inferior economy of the corps is not only investigated to the bottom, but the discipline of the men is likewise examined. For a more particular explanation of the latter, see REVIEW.

INSPECTION, Regimental, is made once a month by the commanding officer. The clothing, the necessaries, arms, and accoutrements belonging to the different companies are examined by the lieutenant-colonel or major of the corps. Specific returns are made by the officers commanding troops or companies, by whom the debts and credits of the men, which have been made up and accounted for on the 24th day in each month, in infantry regiments, and on the 24th day in each second month in cavalry corps, are exhibited for examination at head quarters. This forms the ground-work or basis of the general inspection, at which the troop or company book should always be produced.

INSPECTION, Private, of Companies, is the first step towards the other two, and ought to be made every Monday morning, by each officer commanding a troop or company, or by his subaltern.

INSPECTION of Necessaries is an examination of the different articles which every soldier is directed to have in good repair. The regular or established proportion of necessaries that each soldier of cavalry and infantry is to be in possession of on the 24th day of each month, to entitle him to receive the balance that may be then due to him, consists of the following articles.

Cavalry.—3 shirts, 2 pair of shoes, 3 pair of stockings, 1 pair of gaiters, 1 forage cap, 1 fiddle-bag, 1 pair of canvas, or woollen over-hole, 1 canvas, or woollen frock or jacket, 1 stock, 1 black-ball, 2 brushes, 1 curry-comb and brush, 1 mane comb and sponge, and 1 horse-picker.

Infantry.—3 shirts, 2 pair of shoes, 2 pair of stockings, or 2 pair of socks, 1 pair of long gaiters, 1 forage cap, 1 pack, 1 stock, 1 black-ball, and 2 brushes.

INSPECTION, or Examination, Trial by. See EXAMINATION.

INSPECTOR-General of Cavalry, a general officer, whose particular duty is to inspect all cavalry regiments, to report the state of the horses, and to receive specific accounts from the different corps of their actual state; he communicates with the commander-in-chief, and whenever a cavalry regiment is ordered to be disbanded, it must be looked at by the inspector-general before it is finally broken.

INSPECTOR-General of the Recruiting Service, an officer of rank, through whom the field officers of districts, and colonels of regiments (when they personally manage the recruiting service of their own corps) transmit their several returns to the adjutant-general's office. All recruiting parties which are sent to the great manufacturing towns in England and Wales, as also to Scotland and Ireland, must be previously authorized to do by the inspector-general.

Two field officers have been lately appointed as permanent inspectors of clothing. These inspectors, or the inspectors for the time being, are directed to view and compare with the sealed patterns, the clothing of the several regiments of cavalry and infantry, as soon as the same shall have been prepared by the respective clothiers; and if the said clothing appear to be conformable to the sealed patterns, they are authorized to grant two certificates of their view and approval thereof; one of which certificates is to be delivered to the clothier, to be sent with the clothing to the head quarters of the corps, and the other to be lodged with the general clothing board, as the necessary voucher for passing the allotment of the allowance for the said clothing.

All clothing must be viewed, and certificates be signed by

both inspectors, except in cases where the absence of one of them shall be unavoidable; in all which cases the cause of such absence is to be stated by the other inspector, in his certificate of the view of the clothing.

Inspectors of clothing are to follow all instructions which may be transmitted to them from the commander-in-chief, the secretary at war, or the clothing board.

INSPECTOR of Hospitals, the next on the staff to the surgeon general.

INSPECTOR, a person to whom the care and conduct of any work is committed.

INSPECTORS, in the *Roman Law*, were such persons as examined the quality and value of lands and effects, in order to the adjusting or proportioning taxes and impositions to every man's estate.

The Jews also have an officer, in their synagogue, whom they call *inspector*, *יָרֵא*, *bbacen*. His business consists principally in inspecting, or overlooking the prayers and lessons, in preparing and shewing them to the reader, and in standing by him to see he reads right; and, if he makes mistakes, he is to correct him.

INSPICIENDO VENTRIS. See VENTRIS.

INSPIRATION, in *Physiology*, the act of drawing the atmospheric air into the lungs. See LUNG.

INSPIRATION, among *Divines*, &c. implies the conveying of certain extraordinary and supernatural notices, or motions, into the soul; or, it denotes any supernatural influence of God upon the mind of a rational creature, whereby he is formed to any degree of intellectual improvements, to which he could not, or would not, in fact, have attained in his present circumstances, in a natural way.

If a man were instantaneously enabled to speak a language which he had never learned, how possible soever it might have been for him to have obtained an equal readiness in it by degrees, few would scruple to say, that he owed his acquaintance with it to divine inspiration. Or, if he gave a true and exact account of what was doing at a distance, if he published a particular relation of what he neither saw nor heard, as some of the prophets did, all the world would own (if the affair were too complex, and the account too circumstantial to be the result of a lucky guess), that he must be inspired with the knowledge of it; though another account, equally exact, given by a person on the spot, would be ascribed to no inspiration at all.

Thus the prophets are said to have spoken by divine inspiration.

Some authors reduce the inspiration of the sacred writers to a particular care of Providence, which prevented any thing they had said from failing, or coming to nought; maintaining, that they never were really inspired, either with knowledge, or expression.

According to M. Simon, inspiration is no more than a direction of the Holy Spirit, which never permitted the sacred writers to be mistaken.

It is a common opinion, that the inspiration of the Holy Spirit regards only the matter, not the style, or words; and this seems to fall in with M. Simon's doctrine of direction.

Theological writers have enumerated several kinds of inspiration: such as an inspiration of *superintendency*, in which God does so influence and direct the mind of any person, as to keep him more secure from error in some various and complex discourse, than he would have been merely by the use of his natural faculties; *plenary superintendent* inspiration, which excludes any mixture of error at all from the performance so superintended; inspiration of *election*, where the faculties act in a regular, and, as it seems, in a common manner,

yet are raised to an extraordinary degree, so that the composer shall, upon the whole, have more of the true sublime, or pathetic, than natural genius could have given; and inspiration of *suggestion* when the use of the faculties is superadded, and God does, as it were, speak directly to the mind, making such discoveries to it as it could not otherwise have obtained, and dictating the very words in which such discoveries are to be communicated, if they are designed as a message to others. It is generally allowed that the New Testament was written by a superintendent inspiration: for without this the discourses and doctrines of Christ could not have been faithfully recorded by the evangelists and apostles; nor could they have assumed the authority of speaking the words of Christ, and evinced this authority by the actual exercise of miraculous powers: and besides, the sacred writings bear many obvious internal marks of their divine original, in the excellence of their doctrines, the spirituality and elevation of their design, the majesty and simplicity of their style, the agreement of their various parts, and their efficacy on mankind; to which may be added, that there has been in the Christian church, from its earliest ages, a constant tradition, that the sacred books were written by the extraordinary assistance of the Spirit, which must at least amount to superintendent inspiration. But it has been controverted whether this inspiration extended to every minute circumstance in their writings, so as to be in the most absolute sense plenary. Jerom, Grotius, Erasmus, Episcopius, and many others, maintain that it was not; whilst others contend, that the emphatical manner in which our Lord speaks of the agency of the Spirit upon them, and in which they themselves speak of their own writings, will justify our believing that their inspiration was plenary, unless there be very convincing evidence brought on the other side to prove that it was not: and if we allow, it is said, that there were some errors in the New Testament, as it came from the hands of the apostles, there may be great danger of subverting the main purpose and design of it; since there will be endless room to debate the importance both of facts and doctrines.

What has been above denominated *superintendent* inspiration in the language of Dr. Doddridge, Mr. Whitby expresses by inspiration of *direction*: and he thus distinguishes it from the inspiration by *suggestion*. 1. Where there is no antecedent idea or knowledge of the things written for the good of others, to be obtained from reason or a former revelation, an inspiration of suggestion must be vouchsafed to the apostles, in order to enable them to make such things known to the world. But where there is such an antecedent knowledge of the things to be indited, it can only be necessary that God should immediately, or by some special occasions, excite them to indite those things, and should so carefully prelude over and direct their minds, whilst writing, as to suggest or to bring into their memories such things as his wisdom thought fit to be written, and should not suffer them to err in the delivery of what was thus written in his name, or as apostles of God the Father and our Lord Jesus Christ. 2. In all their revelations of mysteries, or things which could not otherwise be made known to them, either by natural reason or antecedent revelation, they must be acknowledged to have had them by an immediate suggestion of the holy Spirit. 3. As for those things which they did know already, either by natural reason, education, or antecedent revelation, they needed only such an assistance or direction in them, as would secure them from error in their reasonings, or in the confirmation of their doctrines by passages contained in the Old Testament; and therefore a continual suggestion must

be necessary in this case. 4. In writing the historical parts of the Old Testament, or matters of fact relating to themselves and others, it is only necessary, that what is there delivered as matter of fact should be truly performed, as it is said to have been done; but it is not necessary that they should be related in that order of time in which they were performed, unless also that be affirmed of them; for this must be sufficient to assure us of the truth of what they thus delivered. Moreover, in writing the discourses contained in these books, it is not necessary that the very words should be suggested or recorded, in which they were first spoken, but only that the true intent and meaning of them should be related, though in diversity of words; though the promise made to the apostles by our Lord, that the holy Spirit should bring to their remembrance all things which he had said unto them, doth fairly plead for this exactness in what they have delivered of our Saviour's sermons; it being scarcely imaginable their memory, without divine assistance, should exactly give us all that was spoken in such long discourses. Lastly, it appears, says Dr. Whitby, that I contend only for such an inspiration, or divine assistance, of the sacred writers of the New Testament, as will assure us of the truth of what they write, either by inspiration of *suggestion* or *direction* only, but not for such an inspiration as implies, that even their words were dictated, or their phrases suggested to them by the Holy Ghost. Dr. Whitby cannot allow, 1. For any slips of memory in the compilers of the sacred books of the New Testament; for though these are allowed by some in matters of small consequence, as they are pleased to style them, yet it is of great consequence that we do not own them: for, if you grant they have slipped at all, by what rules can we affirm that they have not slipped above an 100 times, or even in most of their historical relations? 2. He cannot grant, that the apostles determined any matters of practice merely from rules of human prudence, without the guidance and direction of the holy Spirit. 3. Dr. Whitby does not allow that St. Paul doth not always use the best arguments, but such as are best suited to the capacities and notions of those to whom he writes: if so, by what rules shall we be able to distinguish betwixt his arguments, on which we may safely rely, as being absolutely true, and those which are only accommodated to the notions of those with whom he had to do?

Dr. Whitby next proceeds to lay down the arguments which prove, that the apostles were assisted and preserved from error by the Spirit of God, and were enabled to deliver to us an unerring rule of faith. These arguments are the following: 1. Their assertions concerning their own writings, and what they say respecting the declarations made, the doctrines delivered, and the directions given in them. 2. The things which God spake to his servants the prophets are styled the things which I command by my Spirit. (Zech. i. 6.) But the apostles were thus assisted. Peter says they preached the gospel by the Holy Ghost sent down from heaven; they spake as they were moved by the Holy Ghost; they style themselves prophets and apostles; they challenge a like illumination with the ancient prophets; they pretend to teach others in words taught them by the Holy Ghost. In all these sayings they must have been guilty of a false testimony concerning God, and must impose upon the church of Christ, if no such assistance of the holy Spirit was imparted to them. 3. The infallible assistance granted to the apostles is inferred from our Saviour's promise to them, repeated on different occasions. 4. The sacred records were to be a standing rule of faith through all ages; and therefore in all things propounded in them to our faith,

INSPIRATION.

They must contain a divine testimony, or a revelation of the will of God. 5. That the apostles and writers of the New Testament were assisted both in their preaching and writing by the spirit of God, is attested by Christians of all ages from the beginning.

Dr. Benfon, in his "Dissertation on Inspiration," published in his "Commentary on the Epistles," and included in bishop Watson's "Collection of Tracts," observes, that many of the difficulties and objections that have been raised concerning inspiration have been very much owing to the mistaken accounts given by some of the friends to revelation. What he takes to be the genuine account, appears, at first view, easy and natural, and also, upon examination, the most unexceptionable. It is this: as Moses retained in his mind the perfect and entire idea of the pattern shewn him in the mount, according to which model he was to make all things; so the apostles, and they alone, had in their minds the full and complete scheme of whatever they were to preach or write concerning the Christian doctrine. And according to that model they were to found and erect the Christian church. Not that they had the whole scheme of the Christian revelation in its utmost extent fully communicated to them at once, the contrary of this is evident; for on the day of pentecost, the twelve apostles of the circumcision do not appear to have received any more than the revelation of that gospel, which they were to preach to Jews only. It was some years after that they had the particular revelation concerning their going to the devout Gentiles, and concerning the gospel which they were to preach to them: and it was a long time before the particular revelation was communicated to the apostles of the uncircumcision, concerning their going among the idolatrous Gentiles, or what gospel they were to preach to them. And finally, different apostles of both classes had, besides the general scheme, different revelations communicated to them. What is meant is this, that they had by immediate revelation the whole scheme of what they were to preach to the Jews, before they addressed themselves to the Jews; and the whole scheme of what they were to preach to the devout or idolatrous Gentiles, before they addressed themselves to devout or idolatrous Gentiles; and that they retained in their minds constantly the complete idea of the whole scheme, after it was communicated to them. From this constant fund of knowledge, they were enabled clearly to determine (as far as any case required) what was, or was not, the Christian doctrine. This revelation of the whole scheme of the religion of Jesus is, as Dr. Benfon apprehends, what St. Paul understood by the word of wisdom, which stands first in the order of spiritual gifts; 1 Cor. xii. 18. Though the evangelists and prophets had some of the inferior gifts of the spirit, yet it was what they had received from the apostles, that they were to teach and to commit to faithful men, who were to teach others. The Old Testament prophets were not under a constant divine inspiration, unless we except Moses during the time in which he was erecting all things, according to the pattern shewn him in the mount; but the apostles had this fund of illumination constantly residing within them, from the time of its being communicated to the end of their lives. Christian prophets, being of an order inferior to the apostles, were neither under constant inspiration, nor had they at any time any more than particular revelations, relating to particular cases. Dr. Benfon supposes, that the books of the New Testament derive their infallibility from their being written, taught, reviewed, or approved of by some of the apostles, who alone had this fund of knowledge constantly residing in them. Whenever, therefore, they spoke or wrote concerning Christianity, this fund of revelation kept them right. But they were

reasonable creatures as well as inspired apostles, and therefore could speak or write about common affairs, as men that have the use of their reason, without any inspiration, can easily do; instances of which frequently occur. Upon this system, such things only are ascribed to inspiration, as (all circumstances considered) required inspiration; and such things to human reason, as human reason alone was capable of.

It appears by citations from the writings of the primitive fathers, Clemens Romanus, Polycarp, Justin Martyr, Clemens Alexandrinus, Origen, Tertullian, &c., that most of them maintained the plenary superintendent inspiration of the sacred writers, and particularly of the apostles. This kind of inspiration some have conceived necessary to vindicate the credibility of the doctrines and the authority of the precepts which they delivered under a divine commission. Others, however, have objected to this plenary inspiration; and allege mistakes and contradictions which occur in the history of their conduct and in their writings, (e. g. Matt. x. 19, 20; Mark, xiii. 11; compared with Acts, xxiii. 1-6. It has been said that the apostles did not seem to apprehend each other to be inspired, as appears by their debating with each other in the council at Jerusalem (Acts, xv.), and by Paul's blaming Peter (Gal. ii. 24.); and it is farther urged, that the Christians in those early days did not apprehend them to be infallible, since their conduct was in some instances questioned and arraigned. (Acts, xi. 2, 3. xxi. 20-24.) It has been also said, that Paul, who asserts himself to have been inferior to none of the rest of the apostles (2 Cor. xi. 5. xii. 11.) speaks of himself in such a manner, as plainly to shew that he did not apprehend himself under such a plenary inspiration (1 Cor. vii. 10. 12. 25. 40. 2 Cor. xi. 17.); nor do we find that any of the apostles introduce their discourses with such clauses as the prophets used, to declare that they spoke as the oracles of God. To this objection, however, it has been replied, that their distinguishing in the cases here referred to seems strongly to imply, that their decisions in other points of doctrine and duty were by "immediate revelation from Christ." It has been also pleaded, against the plenary inspiration above stated, that it is inconsistent with that diversity of diction or style which occurs among the sacred penmen. Is not the style, it is said, of all inspired writers the same, as being the style of the same spirit by which they were alike directed? It is argued on the other hand, that in some sense the style of all those writers is the style of the holy spirit, who spoke by them, and was the same in them all; but that the holy spirit should always employ the same style in conveying celestial truths to men, is no more necessary than that he should always use the same language. We have no reason to doubt that the sacred writers were permitted to employ the style and idiom most familiar to them, in delivering the truths with which they were inspired. So far only were they over-ruled in point of expression, by the divine spirit, that nothing could be introduced tending in any way to obstruct the intention of the whole. And sometimes, especially in the prediction of future events, such terms would be suggested as would, even beyond the prophet's apprehension, conduce to further that end. But this doctrine, it may be said, is liable to an objection from the gift of tongues conferred on the apostles and others for the promulgation of the gospel. In the languages with which those primitive ministers were miraculously furnished, it may be objected they could have no style of their own, as a style is purely the effect of habit, and of insensible imitation. This objection, however, is easily obviated: 1st, as they received by inspiration those tongues only of which they had previously no knowledge, it is not probable, at least it is not certain, that this gift had any place in the writings of the New

Testament; that in most of them it had not is manifest. But, 2dly, if in some it had, the most natural supposition is, first, that the knowledge of the tongue with which the Holy Ghost inspired the sacred writers, must have been in them precisely such a knowledge, and such a readiness in finding words and expressions, as is in others the effect of daily practice. This is even a necessary consequence of supposing that the language itself, and not the words of particular speeches (according to the notion of Dr. Middleton, in his "Essay on the Gift of Tongues") was the gift of the Spirit: And, 3dly, that their acquaintance with the tongues, supernaturally communicated, must have been such as would render their teaching in it best adapted to the apprehensions of the people with whom they would be most conversant, or such as they would most readily have acquired in the natural way. Now on this hypothesis, which on many accounts appears the most rational, the influence of habit, of native idiom, and of particular genius and turn of thinking, would be the same on the writer's style as though he had acquired the language in the ordinary way. Because Cicero and the Greek philosophers were of opinion, that if Jupiter spoke Greek, Dr. Middleton cannot conceive, that a style so unlike Plato's as that of the evangelists, can be the language of inspiration, or be accounted worthy of God. But it was not, we know, peculiar to the Greeks or to the apostolic age to set too high a value on the words which man's wisdom teacheth. See more on this subject in Campbell's Preliminary Dissertations, Diff. 1.

It has been observed, in reference to the subject of inspiration, that our Lord's evangelists report our Lord's discourses with very great variations in their particular expressions; and hence some authors have been led to give up the opinion of the inspiration of the evangelists, as writers. Thus they say, they are able to place the gospel history on the same unexceptionable footing with other credible histories, resting on independent testimonies, in consequence of their agreeing in all matters of importance, and appearing to be independent of each other, by their disagreement in matters of no importance. By this means they also disencumber the evidence of the gospel history of many objections insignificant indeed in themselves, but rendered of the greatest magnitude, and even absolutely insuperable by those who profess to maintain the plenary inspiration of the scriptures. Dr. Priestley is one of those writers who has adopted this hypothesis. He says, however, he is far from denying all inspiration; but only the universal and infallible inspiration of the scripture historians as "writers." When the prophets or apostles worked miracles, or delivered prophecies, and other messages from God, they must have been inspired. Paul also seems to say, that he received his knowledge of the gospel by a personal communication from Christ after his resurrection. (Priestley's Preface to his Harmony.) After all, it should be remembered that our Lord made an express promise to his apostles, that "the spirit of truth should lead them into all truth, and bring all things to their remembrance whatever he said unto them," John, xiv. 26; and this promise seems to warrant that notion of inspiration which we have stated towards the beginning of this article.

Michaelis, (Introduction to the New Testament) after weighing, with all that care and attention which so important a subject requires, the arguments which may be advanced on both sides, thinks it advisable to divide the question. To the epistles, inspiration is of real consequence; but with respect to the historical books, viz. the Gospels and the Acts of the Apostles, we should really be no losers if we abandoned the system of inspiration, and in some respects have a real advantage. We should be no losers if we considered the apostles, in historical facts, as merely human witnesses,

as Christ himself has done in saying, "Ye also shall bear witness, because ye have been with me from the beginning." (John, xv. 27.) And no one that attempts to convince an unbeliever of the truth of Christianity, would begin his demonstration by pre-supposing a doctrine which his adversary denies, but would ground his arguments on the credibility of the evangelists as human historians for the truth of the miracles, the death and the resurrection of Christ. Even those who examine the grounds of their faith for their own conviction, must treat the evangelists as human evidence, since it would be arguing in a circle to conclude that the facts recorded in the gospels are true, because they are inspired, when we conclude the scriptures to be inspired in consequence of their contents. In these cases, then, we are obliged to consider the evangelists as human evidence, and it would be no detriment to the Christian cause to consider them at all times as such in matters of historical fact. We find it no where expressly recorded that the public transactions which the apostles knew by their own experience, and of which St. Luke informed himself by diligent inquiry, should be particular objects of divine inspiration. We should even be considerable gainers, in adjusting the harmony of the gospels, if we were permitted to suppose that some one of the evangelists had committed an immaterial error, and that St. John has rectified some trifling mistakes in the preceding gospels. The most dangerous objections that can be made to the truth of our religion, and such as are most difficult to answer, are those drawn from the different relations of the four evangelists. Mr. Kiddle, in the beginning of the second section of his "Essay on Inspiration," entertains sentiments similar to those of Michaelis; now, if we advert to the sentiments of Grotius, already recited, and which gave rise to the famous theological disputes between the Dominicans and the Jesuits, will the distinction between the inspiration of the historical books, and that of the epistles, appear to be new? As to the writings of those that were apostles, Michaelis maintains that their inspiration depends on their authenticity. If they are written by the apostles, to whom they are ascribed, we consider them as divinely inspired; if not written by apostles, they can make no pretension to inspiration. But it may be asked, on what argument the position is grounded, that the writings of the apostles, if genuine, are inspired? It is answered, on the testimony of Christ and his apostles, which is credible and sacred, because they have confirmed their doctrines by numberless miracles. But, where is this evidence recorded? It is certain, in the first place, that the apostles must be regarded not only as prophets, but as greater than prophets. (Mark, xi. 9—11.) Again, if we consider Christ's more immediate promises of inspiration to the apostles, we shall find that he has given them, in the most proper sense of the word, at three several periods: 1st, when he sent the apostles to preach the gospel (Matt. x. 19, 20); 2dly, in holding a public discourse relating to the gospel, at which was present a considerable multitude (Luke, xii. 11, 12.); 3dly, in his prophecy of the destruction of Jerusalem. (Mark, xiii. 2. Luke; xxi. 14, 15.) It is true, that when we argue from their inspiration on these occasions to the inspiration of their writings, we draw a conclusion "a minore ad majus," but it is a conclusion to which no rational objection can be made; for if they were to expect inspiration for those speeches and answers, which were only temporary, and in which they appeared rather as advocates than teachers, how much more reason had they to expect inspiration in those writings which were to serve as a standard of faith to posterity? Michaelis conceives, that Christ alluded to the future writings of the apostles, when he said to Peter, "Thou art Peter" (*i. e.* a rock), &c. Another promise, first given to Peter, and afterwards extended to all the apostles,

apostles, occurs in Matth. xvi. 19. xviii. 18. If the authority here referred to was given to the apostles without reserve, it is manifest, that, as often as they appeared as teachers of the gospel, they were attended by a constant inspiration, and of course when they committed the precepts of Christianity to writing; or else, we must have recourse to the hypothesis, that the Deity permitted errors to intrude themselves into the morality of the gospels: this is highly improbable; but whichever hypothesis we adopt, we shall come to this conclusion, that the moral precepts, which are contained in the writings of the apostles, are for us commands of the Deity. Moreover, the promises which were given by Christ in the night preceding his death, of the continual assistance of the Holy Ghost, deserve particular attention; more especially as they are recorded in the gospel of St. John (ch. xiv. 16, 17. xv. 26, 27. xvi. 7—11.), who wrote with a particular view to support the authority of the apostles against the Gnostics. Besides, the apostles assert their own inspiration. Thus St. Paul does, Gal. i. 11, 12. 1 Cor. xi. 23. 1 Cor. ii. 13. xiv. 37, 38; and 1 Pet. i. 12. As to those books of the New Testament, which were written by the assistants of the apostles, viz. the gospels of St. Mark and of St. Luke, and the Acts of the Apostles, Michaelis hesitates in admitting their inspiration. See MARK and LUKE.

Among the heathens, the priests and priestesses were said to be divinely inspired, when they gave oracles.

The poets also laid claim to it; and to this end they always invoked Apollo and the muses at the beginning of any great work.

INSPISSATING, in *Pharmacy*, an operation whereby a liquor is brought to a thicker consistence, by evaporating the thinner parts.

Thus, juices, as that of liquorice, are inspissated.

INSBRUCK, in *Geography*, a town of Germany, and capital of the Tyrol, situated on the Inn. The suburbs without the walls are large, and occupied by palaces, churches, and convents. This town is the residence of the supreme representative and aulic chamber, of the revision-judicatory of the counties of the Lower and Upper Austria, and also of the regency or lords-justices. In the middle of the Franciscan church is a magnificent monument, on the top of which is a metal statue of Maximilian I. in a kneeling posture, surrounded by four others representing the Virtues; and in white marble are exhibited the exploits of that emperor. There are some other costly curiosities in this temple. The gymnasium of the Jesuits was converted by the emperor Leopold into an university in 1672, calling it "Cæsareo-Leopoldina;" and in 1745 Maria Theresia presented to it the collection of books, formerly kept at the citadel of Ambras, together with other books out of the imperial library at Vienna. This town was taken by the French in 1805: 28 miles N. of Brixen. N. lat. 47° 16'. E. long. 11° 30'.

INSTALLMENT, a settling or installing a person in a dignity, as that of a chancellor in one of our universities, &c.

The word is derived from the Latin *in*, and *stallum*, a term used for a seat in the church, in the choir, or a seat or bench in a court of justice, &c. though Vossius is of opinion the word is of German origin.

Installation is chiefly used for the induction of a dean, prebendary, or other ecclesiastical dignitary, into the possession of his stall, or proper seat, in the cathedral church to which he belongs.

This is sometimes also called *installation*.

Installation is likewise used for the ceremony, whereby

the knights of the Garter are placed in their rank, in the chapel of St. George, at Windsor; and on many other like occasions.

INSTANT, such a part of duration, wherein we perceive no succession; or it is that which takes up the time of only one idea in our minds.

The schoolmen distinguish three kinds of instants; a *temporary*, a *natural*, and a *rational* instant.

INSTANT, Temporary, is a part of time immediately preceding another: thus, the last instant of a day precedes immediately and really the first instant of the following day.

INSTANT, Natural, is what we otherwise call a *priority of nature*, which obtains in things that are subordinated in acting: as, first and second causes; or causes and their effects: for the nature of things requires, that if there be a second cause, there must be a first; and that there must be a cause, if there be an effect.

INSTANT, Rational, is not any real instant, but a point which the understanding conceives to have been before some other instant, founded on the nature of the things which occasions it to be conceived. For instance, as God has made several things voluntarily, which he could otherwise have let alone; there is a reasonable foundation to conceive God, such as he is in himself, before he had made any of those voluntary determinations: but as there was no real instant when God had not formed any determination, this instant is called a *rational* instant, by way of opposition to an instant of time.

INSTANTANEOUS ACTION. See **ACTION**.

INSTANTER, Trial, in *Law*. See **REPRIEVE**.

INSTAURATION, the re-establishment, or re-inauguration, of a religion, a church, or the like, to its former state.

The word is by some derived from the old Latin *instauratio*, which signified the stock of things necessary for the tilling and managing of grounds; as cattle, tools, harness, &c. The word *instauratio* is only of the middle age; but *instauratio* is of much greater antiquity, and by some is derived from *instaur*, like; as importing a thing's being brought to its former likeness or appearance.

INSTEP, in the *Manege*, is that part of the hinder leg of a horse that corresponds to the flank in the fore-leg, extending from the ham to the pasteron joint.

INSTERBURG, in *Geography*, a town of Prussian Lithuania, containing two churches, about 350 houses, and 3000 inhabitants. The principal articles of its trade are corn and beer; 44 miles E. of Königsberg. N. lat. 54° 35'. E. long. 23° 21'.

INSTINCT, a natural disposition, or sagacity, whereby animals are endued; and by virtue whereof they are enabled to provide for themselves, and know what is good for them, and are determined to preserve and propagate their species.

The term *instinct*, however, has been variously explained and defined. Instinct, according to Dr. Reid, is a natural blind impulse to certain actions, without having any end in view, without deliberation, and very often without any conception of what we do; and he considers instinct as one species of the mechanical principles of action, the other being habits. An ingenious writer, of whose observations we avail ourselves in the compilation of this article, defines instinct to be a tendency implanted in the minds of animals, when under the influence of certain feelings or sensations, to perform spontaneously, unerringly, independently of all teaching and experience, and without any determinate view

to consequences, certain actions necessary for the preservation of the individual and the continuation of the kind.

Instinct in brutes bears some analogy to reason in men. There have been many systems adopted to explain the principles which produce and direct the spontaneous actions of brute animals.

Many of the ancient philosophers ascribed to brutes an understanding differing only in degree from that of man, and attributed their inferiority to the want of proper and sufficient bodily organs. This system has been very strenuously supported by M. Helvetius, de l'Esprit, tom. i. p. 2. &c. Among the moderns the learned Cudworth endeavoured to explain the instinct of animals, by means of a certain plastic nature. Des Cartes thought that all the actions of brute animals might be explained by the simple laws of mechanism, and considers them as machines totally devoid of life and sentiment, but so curiously constructed by the Creator, that the mere impressions of light, sound, and other external agents, on their organs, produced a series of motions in them, and caused them to execute those various operations, which had before been ascribed to an internal principle of life and spontaneity. But the actions and manners of animals, which are totally incompatible with the mere principles and laws of mechanism, evince the absurdity of this opinion. The dogma of Des Cartes is said to have been first introduced by Pherecydes, the master of Pythagoras; and though Des Cartes had the merit of developing and applying this hypothesis, the doctrine was before published by the Spaniard Pereira. M. Buffon adopts the opinion of Des Cartes in part, but grants brute animals life, and the faculty of distinguishing between pleasure and pain, together with a strong inclination to the former and aversion from the latter. By these inclinations and aversions he undertakes to account for all, even the most striking operations of animals; affirming, that, in consequence of impressions made on the brain, by means of the sensitive organs, and by the re-action of the brain and nerves on the muscles, these machines acquire a motion conformable to the nature of the animal, and of the impressions of the different objects which act upon their organs, and excite desire or aversion. See BRUTES.

The pre-established harmony of Leibnitz has also been applied to explain the actions of brute animals. Others have considered the actions of animals as produced by the constant and immediate influence of the divine energy, directing all their inclinations and motions: such appears to have been the opinion of Mr. Addison, in the second volume of the Spectator. The late ingenious Herman Samuel Reimar, professor of philosophy at Hamburg, has enumerated and exposed these and other opinions, with regard to the instinct of animals, in his Observations Physiques, &c. published in two vols. 12mo. at Amsterdam and Paris, 1770: and, defining instinct, in the most comprehensive sense of the word, to be every natural inclination, accompanied with a power, in animals, to perform certain actions, divides instincts into three heads. The first, which he calls *mechanical instincts*, belong to the body considered as an organized substance, and are exercised blindly and independently of the will of the animal. Such are those which produce the motion of the heart and lungs, the contraction and dilatation of the pupil, digestion, &c. This class of instincts is possessed in common both by men and brutes, and in some measure even by vegetables. The second class comprehends those which he terms *representative instincts*, which consist partly in the power of perceiving external objects by their present impression on the senses, and partly in the faculty of rendering the ideas of these objects pre-

sent to the mind by the powers of imagination, or of memory, in a lax sense of the word. These are common to men and other animals, excepting that brutes possess only the faculty of imagination in common with us, and not that of memory, in the strict and proper sense of the word. Indeed this author endeavours to prove, that the knowledge of brutes does not merely differ in degree from that of man, but that it is of a kind entirely different from it; and that they are incapable both of memory and reasoning: the faculty of imagination serving to give them a confused idea of events that are past, by the view, or other impressions of objects that are present. The third and principal class of instincts is that which comprehends all those which M. Reimar calls *spontaneous*. This species of instinct is not attended with any power of reflection, determining the animal to decide freely between two different modes of action present to his imagination; nor is it merely corporeal or mechanical. It is put into action by the natural and primitive principle of self-love, implanted in all animated beings; or by a love of pleasure and aversion to pain, producing a voluntary inclination to perform certain actions which tend to their well-being and preservation. To the performance of these actions they are particularly prompted by their present sensations, by imagination supplying the place of memory, and by other causes. The wonderful effects produced by these instinctive appetites, are farther to be attributed to the exquisite mechanism in their bodily conformation, particularly in the structure of the various organs with which they execute their operations, and to the superior perfection and acuteness of their external senses, by which they are quickly and distinctly informed of those qualities of objects which most materially concern them. In order to account for the more curious and surprising operations of brute animals, M. Reimar adds two other principles, viz. 1st, an internal distinct perception of the precise power and proper use of their various bodily organs, together with an innate knowledge of the qualities of those objects around them in which they are interested; and, 2dly, certain innate and determinate powers and inclinations, impressed by the Author of nature, *a priori*, on the soul itself; by which they are arbitrarily, and without their own knowledge or consciousness, directed and irresistibly impelled to the performance of these various operations which they execute with such unremitting industry and art. These determinate forces, which constitute the principal part of M. Reimar's system, are no where so visible and distinguishable as in that numerous set of instincts which he classes under the title of the *industrious* instincts of animals. For a farther account of this system we must refer to the work itself, or to an abstract of it, with several of the author's illustrations, in the Monthly Review, vol. xlv. p. 533, &c.

The majority of philosophers, even in Des Cartes's time, maintained, that the actions of the brutes were moily *instinctive*, and not mechanical. This prevailing sentiment was altered a little by a wrong application of the principles of Locke. But the balance was soon afterwards restored to its former preponderance in behalf of *instinctive* principles; by the writings of lord Shaftesbury and Dr. Hutcheson; and still more particularly by those of Dr. Reid. Some authors, who, with Locke, reject innate notions and innate principles, both speculative and practical, allow that the mind acts sometimes *instinctively*; others, who reject Locke's ideal theory altogether, detail a great number of instinctive principles of mind; whilst a third class of writers will have the actions, that have been generally denominated *instinctive*, to be either habitual, associat'd, or mechanical. Nor does the matter rest here: for some authors of a very modern date go so far even

is to maintain that the word *instinct* is unphilosophical; since all that has been referred to this principle, whether in man or in the brutes, may be the result of experience, or of imitation.

Some writers confound the actions that have been generally deemed *instinctive* with those that spring from *reason*; some with those that spring from *mechanism*; and others with such as spring from *habit* and *affection*. But it is easy, we think, to distinguish them from each and all of these, by pointing out actions which differ from such as are called *rational*, *habitual*, or *mechanical*. An action is called *rational* when it is performed under the influence of a *motive*; that is, with a view to consequences: Thus, to worship the Deity for having created us, for his goodness towards us, and that he may reward us hereafter, is a *rational action*. Some are of opinion that the *motive*, or the end we have in view in our *rational actions*, is the cause of these actions; but for our part, as we think that the human mind can act not only in opposition to the strongest *external motive*, but against all external motives whatever, *properly so called*, we cannot help thinking it more correct to call them simply *inducements*, and to consider the mind itself solely and properly as the *cause*. *Mechanical* actions also have a cause as well as those that are rational; namely, *mechanism* or *organization*. But this cause is not an end proposed, or a *motive*; neither is it an inward feeling, disposition, or sensation: Thus a clock goes through its course of hours, minutes, and seconds, without a view to consequences, without *spontaneity*, and even without being able to check its own action. To this class belong the actions of the heart and arteries, the vermicular action of the intestines, and those of secretion and respiration in animals. *Instinctive* actions may be traced to a cause as well as both the preceding; but this cannot be referred to the class of *motives*, as they are not performed with a view to consequences; neither can the cause be said to be *mechanism*, as they are accompanied with *spontaneity*. The proper cause, however, is the *internal feeling, sensation, or disposition*, that leads to the performance of them, without design or intelligence, on the part of the animal. Thus an infant, in a few minutes after birth, seeks the breast without any knowledge whatever of its necessity for his preservation; and a pair of young birds, without teaching or experience, build their first nest with as much skill and exactness as the oldest of their tribe could do; and that, too, of the customary materials of their species, and in the situations best calculated for depositing and hatching their eggs. *Instinct* and *mechanism* have been oftener confounded with each other, particularly of late, than any other of those principles of action which we are considering; and yet we cannot help thinking that the distinction between *habit* and *instinct* will not appear as palpable as those we have already made, particularly as some *habits* are formed at so early an age that it is very difficult to ascertain whether the actions that spring from them are from *habit* or from *nature*. But supposing such a principle as *instinct*, such as we have described it, the actions that spring from it must differ from such as are habitual in this, "that the former must be from *nature*, and the latter *acquired*." Habit has been defined to be a facility of doing, and not only a facility, but also a proneness to do certain things from having done them frequently before. This definition, however, is manifestly not applicable to *habits of art*, but only to such as can be properly called *principles of action*. (See HABIT.) Instinctive actions agree with habitual ones of the latter kind in this, that they are both performed without intelligence, will, or design; and this has accordingly induced Dr. Reid to confound them, and to class them, very improperly we think, under the head of mechanical actions.

Their agreeing in a few particulars could not warrant him in reducing them to the same class, particularly when he tells us himself, that "the origin of one is natural, of the other acquired." But, besides this, the habitual actions of man seem to want altogether that *spontaneity* which we observe in the instinctive actions of the other animals; such as nest-building, for instance, and the operations of bees, described in a subsequent part of this article, or the migrations of birds of passage "through the pathless air without chart or compass." One instance of an action confessedly habitual will illustrate this more fully. Let us take that motion of the eye-lids which occurs almost every instant. This action cannot be the necessary result of mechanism, as we see that children do not, for some days after birth, close their eye-lids on the approach of external objects. But as soon as some object (suppose too much light) has made them feel inconvenience or pain, and thus produced a voluntary or mechanical motion of the eye-lids, this effect becomes gradually so intimately associated with its cause, that even the appearance of the candle will produce the effect. And, finally, habit gives us so great a proneness to this action, that we perform it constantly, amidst all our occupations, without consciousness, will, or spontaneity; and even without perceiving that, in every waking minute of our lives, we are several moments totally in the dark. And so far is this motion from being a voluntary act, that it requires a strong exertion of will and attention to check it, even for a short time; but do what we will, we can never check it altogether. To avoid being misunderstood, it will be necessary to illustrate more fully the distinction between *habits of art*, in which we acquire a facility only from frequent practice, such as playing expertly on the violin or harpsichord, and *those habits*, which, besides a facility, induce also a *proneness* to act; for instance, in that motion of the eye-lids just described, and many other awkward motions and habits learned from bad example and bad company. This is the more necessary, as it has not been illustrated sufficiently by any author with whom we are acquainted; and forcibly calls to our recollection the words of a French writer, who remarks: "Tout se tient dans un certain ordre de spéculations: Voulez vous développer une vérité? Il faut en éclaircir vingt autres, qui Pavoiennent, et dont la lumiere vient, pour ainsi dire, l'éclairer par réflexion." Habits of the latter kind may be properly called *principles of action*; *habits of art* cannot. These require thought, attention, and will in the performance of their operations; whilst the others require no small exertion of thought, attention, and will to check them. Nor can they, even thus, be completely overcome, until, by repeated exertions, a counter habit is established, which is the best way to obviate their effects. It was this that made Dr. Reid say, "I conceive it to be a part of our constitution, that what we have been accustomed to do we acquire not only a facility, but a proneness to do on like occasions; so that it requires a particular will or effort to forbear it, but to do it requires, very often, no will at all. We are carried by habit, as by a stream in swimming, if we make no resistance." Dr. Reid distinguishes these two species of habits as we do; but in some passages he seems to confound them, for he classes them and *instinct* under the head of mechanical principles. Thus, he says, "Habit differs from *instinct*, not in its nature but in its origin; the latter being natural, the former acquired. Both operate without will or intention, without thought, and therefore may be called mechanical principles." (See HABIT.) From both these passages it would seem that he meant habit in general; for the assertions are not qualified in any shape. If such was his opinion, his doctrine agrees exactly with that of Dr. Hartley, whose language affords

to opportunity for being in doubt about his meaning. But, for our part, we cannot help thinking it more philosophical to admit any possibly conceivable rapidity in our intellectual operations. That to suppose, that any action performed with so much correctness, and with such rapidity, as violin and harpichord playing in some instances, can be merely habitual, or automatic; that is, in every one of its minute sub-divisions altogether unconnected with the exertions of the will. In habits of art, then, we deem it more correct to admit the interference of the will; but in the other class, which only, because they give not merely a facility, but also a proneness to act, ought to be called principles of action, we see no reason for admitting its interference in any respect. A different opinion seems to be maintained in a late elegant treatise, for whose author we have a high respect. Upon this we shall offer a few remarks; but we have not as yet done with Dr. Reid. After having attentively examined what he has written on this subject, we do not think that he intended to include *habits of art* in the passages cited above. Surely so correct an observer of nature could not think, that in *habits of art*, such as pin-making and violin playing, we acquire, from frequent doing, "not merely a facility, but also a proneness to do the same thing on like occasions." In all habits of art we acquire more or less of facility, but surely no proneness, as Dr. Reid asserts of the habits he had in view in one of the passages cited above: for who can assert with any truth, that a violin-player feels a particular proneness, or inward impulse, to play upon that favourite instrument, as often as it is presented to him? And yet he has acquired a facility in playing, from having often played before. The truth seems to be, that Dr. Reid, after stating the distinction of habits already mentioned, threw the *habits of art* into the back ground altogether. This, indeed, is strongly confirmed by the circumstance, that in the essay and chapters to which we allude, he treats only of what can be called *principles of action*, which he defines to be "every thing that incites us to act;" and particularly when he tells us that *habits of art*, since they give only a facility, cannot with propriety be called principles of action. "Habit," he says, "is commonly defined a *facility of doing a thing, acquired by having done it frequently*. This definition is sufficient for habits of art; but the habits which may, with propriety, be called principles of action, must give more than a facility; they must give an inclination, or impulse, to do the action; and that, in many cases, habits have this force, cannot be doubted." It deserves to be remarked, that in this passage he does not say, that habits give a *proneness* (in his own words, an inclination or impulse) to act in every case, which he should have done, if he meant to bring habits of art under the observation. He only says, "that habits give an inclination or impulse in many cases;" which seems to prove, that he meant only "those habits, which may, with propriety, be called principles of action." This opinion is still further strengthened by the following extract: "Aristotle makes wisdom, prudence, good sense, science and art, as well as the moral virtues and vices, to be *habits*. If he meant no more, by giving this name to all those intellectual and moral qualities, than that they are all strengthened and confirmed by repeated acts, this is undoubtedly true. I take the word in a less extensive sense, when I consider *habits as principles of action*. I conceive it, &c." (as quoted above.) In this extract he tells us, that he takes the word habit in a confined sense, meaning only such *habits* as he calls *principles of action*. And he has already told us, that *habits of art* do not come under that denomination. If the latter part only of the paragraph be attended to, it seems to shew that Dr. Reid held the same opinion on this point with Hartley; but if the

whole be taken together, and interpreted with fairness, and considered in connection with our remarks on the subject, we think it will appear more probable, that Dr. Reid meant only a particular species of habits, those which he calls *principles of action*, and that he did not intend to characterize such habitual actions as violin and harpichord-playing, as *involuntary and mechanical*. It must not be concealed, that professor Stewart of Edinburgh seems to think otherwise of Dr. Reid's meaning; and that he has proved, partly in consequence of that opinion, that some of our habitual actions are under the guidance of the will. From the preceding remarks it will appear, that our opinion differs not from the learned professor's, if he means only *habits of art*: but if he means to bring the other class of habits under the influence of the will, (as it is probable he does, for he talks of habitual actions in general, and does not even hint at a distinction,) we cannot help thinking, as even analogy itself affords no support to this opinion, that he was swayed too much by an over-ardent zeal for premature generalization. It deserves to be remarked, as an additional proof of the fairness with which we have interpreted Dr. Reid's opinion, that he says nothing of *habits of art* in his chapter on habit, except mentioning one solitary instance, merely to shew "the power of habits and their utility;" whereas he expressly mentions, as belonging to that species which he calls *principles of action*, many "awkward habits in address, motion, looks, gesture, and pronunciation, acquired by frequenting bad company; to forbear which, when fully formed, a general resolution (he says) is not sufficient." He even affirms, that particular attention is necessary, on every occasion, to resist their impulse, until they be undone by the habit of opposing them: for *these habits operate without intention*." It is remarked by professor Stewart, on the subject of habitual actions, "that the circumstance of our inability to recollect our volitions does not authorize us to dispute their possibility." To this observation we have no objection; but when he further contends "that it does not add any force to the objection, to urge, that there are instances in which we find it difficult, or perhaps impossible, to check our habitual actions by a contrary volition;" we must remark, that this very circumstance, since it has not been obviated, renders the objection insuperable, and the doctrine against which it militates, so far as that relates to the species of habits which we have called *principles of action*, altogether inconclusive. Let any one try, by the most firm and persevering efforts, to check for a short time the most common of all habits, that of closing the eyelids, and he will find, though he may succeed for a few moments, that he cannot do so altogether. Nor is it an answer to this fact to say "that the contrary volition does not remain with us steadily, during the whole operation; but is merely a general intention, or resolution, which is banished from the mind as soon as the occasion prevents itself, with which the habitual train of our thoughts and volitions is associated." For the time requisite for trying this experiment, and being defeated in it, is so very short, that the contrary volition may be easily kept in view, all the while, without its dwindling away into "a general intention or resolution;" and besides, if the person who tries the experiment, thinks that he is unable to keep up the counter-volition steadily himself, he can easily have an assistant or two, to sit near him, and remind him to keep his thoughts and attention fixed upon the object in view. Some may perhaps urge that this motion of the eyelids is *insensible*; but by the learned professor himself it is allowed to be habitual. We may besides remark, that there is a wide difference between our being unable to recollect the volitions, which in this theory are supposed to precede all our habitual actions,

and that state of mind in which we are not only not conscious of any such volitions, but fully aware that the habitual actions occur, even when we are conscious of having exerted the strongest efforts of volition to prevent them. But to conclude this preliminary, but necessary, discussion, we may, by way of recapitulation, observe, if the exposition we have been giving be correct, that the difference between the four species of actions under one consideration consists nearly in the following circumstances. That *rational* actions are done with *intelligence, will, and design* on the part of the agent; *instinctive* actions *spontaneous*, but with no proper intelligence or design in the doer; *mechanical* actions without will, *spontaneity, design or intelligence*; and *habitual* actions, like mechanical ones, (we mean the habits that may be properly called principles of action,) without spontaneity, design, or intelligence; but differing in this, that they are *accidental* in their origin, and in many instances capable of being checked and even removed by contrary habits; whereas *mechanical* actions, properly so called, are in a manner *necessary* in their origin (for instance circulation, secretion and respiration in animals), and can never be removed or suppressed altogether, without the destruction of the animal, by any voluntary effort of ours.

As we are of opinion, that the origin at least of some of the actions of man cannot be explained, unless we admit the existence of such a principle as instinct, it becomes necessary to consider some of those actions of the lower animals, which are generally allowed to be instinctive. This step seems the more necessary, as the existence of instinct, even in the lower animals, seems of late to have been wholly denied, since it has been asserted, in a "New System of the Natural History of Animals," published in Edinburgh, in 3 vols. 8vo. by Peter Hill, in 1791; "that the laws of analogical reasoning do not justify the opinion, that the brutes act, on any occasion, absolutely without design." Whilst, on the other hand, it has been maintained by Mr. Smellie, in his "Philosophy of Natural History," "that between reason and instinct there is no difference, and that the reasoning faculty is itself the necessary result of instinct." Nothing can be more directly opposite than both these opinions; and like most extremes, nothing can be more easily shewn to be false. To prove that some of the natural operations of the lower animals are not performed with design, or with a view to consequences, in opposition to the former, many examples will not be necessary; and first, let us attend to the operations of the winged tribe. The youngest pair of birds, it is known, without instruction or experience, build their first nest of the materials commonly used by their species; in situations, whose privacy, &c. render them fit to afford them security, and convenient for incubation and the rearing of their young. It is also certain, that they shew equal skill with the oldest and most practiced of their tribe, in the neatness, accuracy, and symmetry of their work. It is further known, whenever the climate or situation, or any change of circumstances renders a change in the structure of nests necessary, that this change is made by all the individuals (young and old) of the same species equally, and that only when such a change is necessary. Thus, "in countries infested with monkeys, many birds, which, in other climates, build in bushes and clefts of trees, suspend their nests upon slender twigs, and, by this ingenious device, elude the rapacity of their enemies." It is moreover certain, that no improvement has been made, within the memory of man, in the art of nest-building, by any tribe, or by any of its individuals. Now the nature of all the arts with which we are acquainted is such, and their history shews us, that they were first invented by some person, and then improved in

the course of time, either by the inventor or by others, and finally brought to some degree of perfection. History and experience also shew, that human arts are best known and practiced with most skill and dexterity in general, by those only to whom they have been taught; and that in different ages and countries they all undergo considerable variations. But in the arts of animals we observe no such variations; nor can any individual be pointed out as the inventor, the improver, or the perfecter of any of them; for instance, of nest-building. Each of them is perfectly skilled in the workmanship of its tribe; we do not say that they know the nature and the rules of the different arts which they practice; but that they are acquainted with the mode of working in them to perfection. How many very simple arts do we daily see practiced by our species, without being able to practice them, or learn them ourselves. What a long apprenticeship is generally necessary before we can practice even some of the most common and necessary. A peasant spends months and years under his simple roof, and yet is not able often to build such a hut as that he inhabits. Birds require no such teaching or experience: they served no apprenticeships; and yet a pair of young birds kept solitary and sequestered from their infancy, build exactly such another nest as that in which they themselves had been brought into life. But what is the inference to be drawn from these facts? If the natural actions of the lower animals, for instance this of nest-building, be all under the influence of motives, in other words, *rational*, we must conclude, since they are so invariable, either that their workmanship is perfect beyond the reach of improvement, or so imperfect as not to be capable of degenerating. The former of these conclusions cannot be supported, unless it be contended at the same time, that the lower animals have made more early and greater discoveries and advances in the arts and sciences than we have. Nor will the latter be maintained by any man, who considers the structure of a honey-comb, or who reflects, that all the skill of man has never yet excelled the workmanship even of a wren in the structure of such a nest as he builds. However, if the supposition be admitted, the former seems the better inference. But, if this doctrine be true, we must say, that birds are good judges of climate and circumstances; that they know the dangers and advantages resulting from them, and the best methods for obviating the former and securing the latter. We must say, that reasoning shews them the necessity of equality in the structure of their nests; or when, after having been absent for some time, they turn their eggs so as to heat them properly, and at all times equally, we must think, that they know heat, and even an equal distribution of it, to be necessary for incubation. But as none of these can, we think, be affirmed with the smallest appearance of truth, and since those actions of birds are, without teaching, habit, or experience as perfectly performed by the young as by the old, and always so invariable, we must conclude, that in these instances we discover not the reasoning of animals, pointing to consequences and devising means, but the unerring reason and wisdom of Him who made them, and implanted such principles in their constitutions as guide them unceasingly in the performance of their various natural operations, the complete purposes and utility of which He only knows. Our reasoning is confirmed by that of Addison—"What," says he, "can we call the principle which directs every different kind of bird to observe a particular plan in the structure of its nest, and directs all of the same species to work after the same model? It cannot be imitation; for though you hatch a crow under a hen, and never let it see any of the works of its own kind, the nest it makes shall be the same, to the

laying of a flick, with all the other nests of the same species. It cannot be *reason*; for were animals endued with it to as great a degree as man, their buildings would be as different as our's, according to the different conveniences that they would propose to themselves." Some birds display a wonderful share of sagacity in the process of incubation and in rearing their young. Without attentive and cautious observation, one would be almost positive, that in every step they are guided by reason. But it is easy to show that this is not the case. Let us take a very familiar instance: a hen seeks a silent and an unfrequented place for her nest; when she has laid her eggs and began to cover them, she takes care to turn them frequently, that the vital warmth may be communicated to all parts of them. When she is obliged to leave them, in order to procure food, she is sure to return before they have time to cool, which would render them incapable of producing chickens. In summer she will often stay away for two hours; but in winter, when the cold would destroy the principle of life, she stays away a much shorter time. When the birth approaches, with how much nicety and attention does she help the little ones to break their prison. When brought forth, how cautiously does she cover them from the injuries of the weather, provide them proper nourishment, and teach them to help themselves. It deserves also to be remarked, that she forsakes the nest if, after the usual time of reckoning, the young do not begin to make their appearance. Can any thing have a greater appearance of reason and sagacity than all this. "But, at the same time, the hen that has all this seeming ingenuity (which is indeed absolutely necessary for the propagation of the species), considered in other respects has not the least glimmering of thought or common sense. She mistakes a piece of chalk for an egg; and sits upon it in the same manner; she is infensible of any increase or diminution in the number of those she lays; she does not distinguish between her own and those of another species; and when the birth appears of ever so different a bird will cherish it for her own. In all these circumstances, which do not carry an immediate regard to the subsistence of herself or her species, she is a very idiot." None of these instances justifies the doctrine, "that animals, in all their natural operations, act with a view to consequences." To confirm our reasoning and opinion still farther, out of the numberless examples afforded us by Natural History, we shall content ourselves with one, which, if we mistake not very much, is decisive of this question. This we take from the operations of the bee, as it seems to act with a view to consequences, and to be, as was said of the ant, "*haud ignara et non incauta futuri.*" Let us attend a little to the structure of a honeycomb. The cells of the bees are equal and similar; and of the three possible ways in which this can be effected, they have chosen the best for holding their honey and rearing their young. The cells are built on both sides: they may then be placed exactly opposite one another, so that two would rest upon the same bottom; or they may be so placed, that the bottom of one will rest upon the point where the partitions meet on the opposite side. This latter mode gives them more strength, and they are accordingly built thus. Further, the bottoms of the cells are not planes perpendicular to the sides, but consist of three planes meeting in a solid angle in the centre, exactly where the partitions on the opposite side cross one another. And it has been demonstrated, that this makes the cells similar without loss of room, and considerably spares both labour and materials. Thus, then, it is shewn, that bees build their cells so as as lose no room; to have no useless partitions; in the strongest possible manner; and with the least possible expence of labour

and materials. All this, as far as geometry and mathematics can shew it, has been rigorously demonstrated by Mr. Maclaurin, and proves them, on the supposition that they act with a view to consequences in this instance, more skilled in both the instances than the most philosophical and learned men; and that too from the earliest ages. But as this is a doctrine too improbable to be insisted upon, we must rather conclude, that the bees, although they act geometrically, understand neither the rules nor the principles of the arts which they practise with such accuracy; but that the geometry in this instance is in the Maker of the bee, "that Great Geometer, who made all things in number, weight, and measure." (Reid's Active Powers of Man, and the London Philosophical Transactions.) Were a man to construct so nice a piece of workmanship as a honeycomb, we should immediately conclude, that he worked according to rule, and understood the principles upon which he proceeded. Is it necessary to remark, that we have no reason whatever for thinking, that bees understand one or the other? In the most complicated works of human contrivance, a man of equal knowledge and skill will comprehend the principles and general design of the artist: but to understand the rules and principles, which are so rigorously adhered to in the constructing of a honeycomb, is, and will always be, beyond the comprehension of the far greatest part of mankind. The few instances of animal *instinctive* operations, which we have now briefly detailed, will, we hope, be sufficient for the present; they correspond fully with our notion and explanation of instinct, and serve our purpose, as well as a million of instances crowded together. But it is objected, that this instinct, which we call a simple, original principle, accommodates itself to circumstances; that it is improved by experience and imitation; that no such accommodation to circumstances can take place without reasoning, or a comparison of ideas; and, therefore, that this principle of the constitution of the lower animals is not *instinct*, but *reason*. The instances to prove that instinct accommodates itself to circumstances are numerous. Birds fly away from their eggs longer in warm than cold weather. The oilrich in Senegal, where the heat is great, neglects her eggs during the day, but sits on them during the night; but at the Cape of Good Hope, where the heat is less, she sits on them both night and day. In countries infested with monkeys, birds, which in other climates build in bushes and clefts of trees, suspend their nests upon slender twigs, and thus elude their enemies. The same species of birds build their nests differently, when climate and circumstances require it. We have numberless instances of this accommodation to circumstances in the pairing instincts of animals. None, it has been observed, ever pair, except those whose young require the nursing care of both the parents. The extent and continuance of the parental care are in the proportion of the wants and helplessness of the young. When the wants of the young cease, the mother withdraws her fondness, and leaves them to provide for themselves; but the love of the parent may be lengthened out beyond its usual time, as we see in birds, which continue to feed their young, if they are tied to the nest, or confined within a cage, or by any other means appear to be out of a condition of supplying their own necessities. This last instance, whilst it very nicely exemplifies an accommodating instinct, affords the happiest proof of the guardian care of a kind and parental Providence. In answer to the objection which these facts contain, it may be first observed, that taking instinct, as it is generally defined, to be a principle in the constitution of animals, given them by their Maker, for the purpose of preserving the individuals

Individuals and continuing the kind, in other words, a predisposition to perform certain actions necessary for these ends, when incited by certain feelings or sensations, that its accommodating itself to circumstances and situations is no argument against its existence, nor a good proof, that it is the result of reasoning; since *He*, who made it a part of the constitution of his creatures, knows, that the same ends must be often sought by different means, particularly when times, places, and circumstances are altered; and only manifests his wisdom and goodness the more, by constituting this principle of such a nature, as to vary when requisite, and to change only when such a change is necessary. Let us add to this, that did *He* not impart this accommodating property to instinct, it would not produce the effects for which it seems intended; as we know it to be impossible, that similar means should produce similar effects, when circumstances, climates, and situations, are different. Indeed this accommodating peculiarity, so far from being a good argument against it, is a necessary consequence of instinct. The abettors of this principle do not maintain, that the accommodating variations will take place on every occasion. They will occur only where the disadvantages exist, against which the instinct is intended to provide. Instinctive actions take place when certain sensations exist, and when these do not exist, we cannot wonder that the actions do not occur. In the following remarks we follow the learned author of "Ancient Metaphysics," a work, in which we find a just view of the subject of instinct. Before we positively conclude, that no accommodation to circumstances can take place without reasoning, or a comparison of ideas, it may not be irrelevant to consider some of the appearances which the vegetable and inanimate worlds exhibit. If, because the operations of some animals are so artificial, and because they sometimes accommodate their actions to circumstances, we must say, that they reason and compare ideas, we must contend, that vegetables and inanimate bodies do so likewise: we know, that a vegetable reared in a dark cellar, if some light be admitted, will bend itself towards the light: or, if made to grow in a flower-pot with its head downwards, that it will turn its head upwards, according to the natural position of a plant. Can it be maintained, that the plant in either case does what it does from any judgment or opinion, that it is best, and not from a necessary determination of its nature? The facts taken from the inanimate world are equally in point. How shall we account for the phenomena of elective attractions? when one body unites with another, and then, if a third is presented to it, quits the first and unites itself with the other, shall we say that this is the effect of reasoning and of a comparison of ideas, and suppose, that this preference of the one to the other proceeds from any predilection or opinion, that it is better to cleave to one than to the other? What shall we say of the crystallizations and configurations of salts exhibited to us by the microscope, so various and yet so constant and regular? Must we say, that their minute particles reason and compare ideas, because their operations are so various, and, at the same time, so regular and constant? Or, if nobody affirms this, why should we think, that the actions of animals, not more various and surprising, not more constant or regular, than these motions of the salts, should be the result of reasoning and of a deduction of inferences? Should we not rather affirm, as those inanimate substances arrange themselves so regularly, and yet so variously, upon different occasions, in consequence of an original law of nature, that the benevolent Author of all such laws, intending to display his providence and wisdom still more conspicuously in his animal kingdom, bestowed upon

his creatures this accommodating instinct, without which; (supposing that they act instinctively on any occasion) the great purposes of their propagation and preservation could never be attained? This objection, upon which we have been commenting, is contained in the "System of Natural History" already mentioned in this article. The compilers of that work have been carried much too far in their zeal to do away Mr. Smellie's very unphilosophical notions concerning instinct: and, although we have read over their opinions with much attention, we are still at a loss in some parts to comprehend their meaning. Their dissertation on the subject is but short, and yet, we think, they often contradict themselves. One time you would suppose, that they admit such a principle as instinct in the lower animals; at another they seem to reject it altogether. This latter, indeed, seems to be the fairest account of their opinions. What theory they had in view, when they called instinct a mechanical principle, we know not. It could not be the exploded doctrine of Des Cartes, nor the equally unphilosophical theory of Buffon, which has been so fully and so ably refuted by Condillac. Perhaps they referred to Dr. Reid's, who, as we have already observed, calls instinct a mechanical principle. We are equally at a loss for their allusions, when they call brute *insensible instruments* under the influence of instinct, which they denominate a "myterious influence." None of the advocates for instinct, so far as we know, have ever held this absurd opinion. On the contrary, they all allow them not only *sensibility*, but even *spontaneity*, in their instinctive operations. And, when they are allowed to possess these, we cannot deny them *consciousness*, by which they must know that they are acting. The supporters of instinct assert no more than this, since force of the natural operations of animals are so complicated, and yet so perfect and invariable, that it is irrational, with such evidence as we possess, to suppose them acquainted with the rules of the arts which they practise, or the ends for which they operate. These, however, are known to Him, and perhaps to Him only, who implanted such principles in their constitutions, as direct them unerringly in all their ways. Besides those now mentioned, there are some other mistakes and errors in this work on the subject under discussion. These, however, with one exception, we shall pass unnoticed. The error we mean, and which, indeed, is not peculiar to these writers, is their supposing, that the advocates of instinct deny reason altogether to the brutes. But this opinion is wholly groundless. That some animals display wonderful sagacity and docility, that they even reason on several occasions, is, we think, clear from the most satisfactory evidence. We shall mention a few facts in support of this opinion. On the northern coast of Ireland a friend of Dr. Darwin's saw above a hundred crows at once preying upon mules: each crow took a muscle up into the air twenty or forty yards high, and let it fall upon the stones, and thus, by breaking the shell, got possession of the animal. A few years ago there was slain at Exeter Change, London, an old monkey, who having lost his teeth, used, when nuts were presented to him, to take a stone in his hand, and crack them with it one by one; thus, using means, like the crows in the preceding instance, to accomplish his purposes as well as we do. We are told by Linnaeus, that the martin dwells on the outside of houses in Europe under the eaves; and that, when it has built its nest, the sparrow frequently takes possession of it. The martin, unable to dislodge his intruding enemy, convokes his companions, some of whom guard the captive, whilst others bring clay, completely close up the entrance of the nest, and then fly away, leaving the sparrow to be suffo-

gated, as the punishment due to his injustice and temerity. This fact is mentioned in the "Amusement Philosophique, &c.," of Father Bougeant. There is also an instance of it in the "Gentleman's Magazine;" in which we find also some interlocking particulars concerning a raven kept, some years ago, at the Red Lion at Hungerford. The account is, however, too long to be transcribed, although very much to our present purpose. We recollect seeing, a few years ago, a very sensible cat, which, when out at night, would tap regularly at the windows, if the doors and shutters were closed; knowing by experience, that she was often let in at the windows by day. And what is still a better proof of her reasoning and sagacity, she would always tap at the bed-room windows, when disappointed at the others, or when the night was far advanced. A lady with whom we were acquainted, had a tame bird, which she was in the habit of letting out of its cage about her room every day. One morning as it was picking up some crumbs of bread off the carpet, her cat, who always before showed great kindness for the bird, seized it on a sudden, and ~~seized~~ with it in her mouth, upon a table. The lady, alarmed for the fate of her favourite, on turning about, observed that the door had been left open, and that a strange cat had just come into the room. After turning it out, her own cat came down from her place of safety, and dropped the bird, without injuring, if we may so express it, a hair of its head. Cowper's beautiful little poem on the dog and the water lily, gives an amiable instance of the reasoning of the lower animals, which has been so sweetly, and yet with such elegant simplicity, told in verse, that we cannot think of melting it down into the languid coldness of prose. When we see brutes thus using means to obtain their ends, as well as ourselves, must we not conclude that they reason? When the cat watches for hours in silent expectation of her prey; when the hound traverses a wide extent of country in the chase; when the meaght insect that we tread on, drags its wounded frame to a safe retreat; they shew as much preferring voluntariness as man can boast. No animal manudicates its food, or laps its drink, from the mere pleasure of the motions. It uses them as means for an end; and it hunger and thirst were not felt, they would be considered as labours, and would not be performed. "Animals (says professor Stewart, nearly in the words of Mr. Hume,) are left to make some small acquisitions, by experience, as sufficiently appears in certain tribes, from the sagacity of the old, when contrasted with the ignorance of the young; and from the effects which may be produced on many of them, by discipline and education."—"It seems as evident to me," says Mr. Locke, "that some animals do, in certain instances, reason, as that they have sense; but it is only in particular ideas; just as they receive them from the senses. They are the best of them tied up within those narrow bounds, and have not, as I think, the faculty to enlarge them, by any kind of abstraction." The observations which Mr. Locke makes in this part of his work on the faculties of the brutes, as compared with our's, are in general very just and worthy of perusal. But there are several facts, which our brutes do not allow us to state, from which it is evident that brutes on some occasions exhibit proofs of the power of abstraction. That an animal can be capable of gratitude and affection for its master, without reasoning, can, we think, hardly be maintained. From the master's protection and kindness, it infers that it is under obligations to him, which it owes not to another. Before concluding our remarks on the reasoning of animals, we may quote one instance of the affection of a dog, which we think has never been surpassed. And we do it the more readily, as the circumstance has been very

poetically described by an author, who, with all his great merits, seldom writes better than upon this occasion. The instance to which we allude is very interesting, from the incident to which it relates, the death of an unfortunate young gentleman of promising talents, who perished, by losing his way, in the spring of 1805, on the mountain Helvellyn. His remains were found three months afterwards, guarded still by a terrier bitch, that had long been the companion of his solitary rambles. This last circumstance in particular, is very finely alluded to by Mr. Scott, in his little piece on the subject, to which he has given the name of Helvellyn. As the few instances now related are sufficient, and speak fully for themselves, we shall not add to the number, nor stop to make any comments upon them. But it has been asked, if we allow reason to the lower animals, in what does the difference between them and man consist? Do their faculties and our's differ in degree, or in kind? To this question we have not the vanity of thinking that we are able to give a satisfactory answer; we may, however, offer a few remarks. We see that animals learn much from experience and observation as well as ourselves. It is thus they learn the nature, or the properties, of the objects that surround them, such as heights, depths, distances, &c. "A horse that has been accustomed to the field, becomes acquainted with the proper height which he can leap, and will never attempt what exceeds his force and ability. An old greyhound will trust the more fatiguing part of the chase to the younger, and will place himself to as to meet the hare in her doubles; nor are the conjectures which he forms on this occasion, founded in any thing but his observation and experience." By training and education we can teach our domestic animals much more than they would ever learn, if left to themselves and their own observation. If we put them in new situations, we see that their acquired knowledge is much increased and improved, and that by a proper and strict discipline we can train them up to a mode of acting directly contrary to their instincts, or natural propensities. If these observations be just, (and we cannot see how they can be questioned,) it follows, that in the lower animals instinct is susceptible of very great and striking modifications. To produce these, however, strict culture and discipline are necessary; without which, we do not think, that their own experience and observation would ever teach them to deviate much from the line of acting chalked out to them by their instincts, or original propensities. And accordingly we agree with a remark of Mr. Hume's, "that though animals learn many parts of their knowledge from observation, there are also many parts of it which they derive from the original hand of nature, which much exceed the share of capacity they possess on ordinary occasions, and in which they improve little or nothing, by the longest practice and experience." Yet, notwithstanding this susceptibility of improvement by culture and education in the lower animals, we can never observe in them any thing approaching to the knowledge and sagacity of man. They do not, like him, heap observation upon observation, they do not improve by the experience of the past, nor manifest any indications of a regard to futurity; their manufactures are always stationary, and all their acquisitions of knowledge perish with the individual. They never learn the arts of man; for instance, though often as fond of artificial heat as we are, not one of them has been ever known to lay a piece of coal or of wood upon the fire to keep it from going out. All this may be owing to their want of language; but it seems strange, that they possess not this art, as some of them seem to have organs of articulation, as perfect as our's. They use means, it is true, for obtaining their ends sometimes; but these in general are very simple and obvious. They reason

for too on some occasions; but the want of language, or of general facts, puts it out of their power to reason, but on particular facts. The powers of classifying objects, of abstract reasoning, of using artificial signs as instruments of thought and of mutual communication, seem to be almost altogether peculiar to man. From these considerations, and several others, relating both to the intellectual and moral faculties of man, as contrasted with those of the lower animals, it has been inferred, that the regular chain of being every where else observable on our globe, fails entirely here, and that their faculties differ from ours, not in degree, but in kind.

Thus then we see, that animals perform certain operations that are neither *rational, habitual, nor mechanical*; and although it cannot be doubted but some of them reason in several instances, still, even from the short details now given, we cannot allow, that their natural operations are performed with a view to consequences. Nor ought the effects of instinct, (the labours of birds and bees for instance) appear extraordinary to us, when we consider what astonishing effects *habit*, which has been happily called "a second nature," enables us to produce. For instance, we need go no farther than reading, writing, and playing upon musical instruments, all of which we learn by great attention, pains, and study; and most of all, perhaps, correct and quick extemporary eloquence. And surely, when the effects of an acquired principle are so very uncommon, it cannot be deemed strange, that an original principle of the constitution of animals should perform works still greater or more astonishing.

INSTITA, a word used by the surgical writers, for a fillet or other bandage of that kind; and by medicinal writers, for that sort of flat worms bred in the intestines called by many the tape-worm, or flat worm.

INSTITUTE, NATIONAL, of France, was newly organized in pursuance of a decree of the French government, with the advice of the council of state, as follows: 1. It is now divided into four classes, *viz.* 1. Clafs of physical and mathematical sciences. 2. Clafs of French language and literature. 3. Clafs of history and foreign literature. 4. Clafs of the fine arts.

The actual members and foreign associates of the institute, shall be divided into these four classes.

A committee of five members of the institute, named by the First Consul, shall adjust this division, which shall be submitted to the approbation of government.

II. The first class shall be formed of the ten sections which at present compose the first class of the institute, with a new section of geography and navigation, and eight foreign associates.

The sections shall be composed and called as follows:

Mathematical Sciences.	Geometry	- - - - -	6 members.
	Mathematics	- - - - -	6 ditto.
	Astronomy	- - - - -	6 ditto.
	Geography and Navigation	- - - - -	3 ditto.
	General Physics	- - - - -	6 ditto.
Physical Sciences.	Chemistry	- - - - -	6 members.
	Mineralogy	- - - - -	6 ditto.
	Botany	- - - - -	6 ditto.
	Rural Economy and Veterinary Art	- - - - -	6 ditto.
	Anatomy and Zoology	- - - - -	6 ditto.
Medicine and Surgery	- - - - -	6 ditto.	

The first class shall appoint, with the approbation of the First Consul, two perpetual secretaries, one for the mathematical sciences, the other for the physical sciences. The per-

petual secretaries shall be members of the class, but shall not form a part of any section.

The first class may elect six of its members from the other classes of the institute.

It may name an hundred correspondents selected from the learned men of France and foreign countries.

III. The second class shall be composed of forty members.

It is particularly charged with the composition of the dictionary of the French language. It shall examine, with respect to language, the important works of literature, history, and the sciences. The collection of its critical observations shall be published at least, four times in a year.

It shall name from its own body, and with the approbation of the First Consul, a perpetual secretary, who shall continue to be of the number of the forty members which compose it.

It may elect twelve of its members from the other classes of the institute.

IV. The third class shall be composed of forty members and eight foreign associates.

The object of its researches and labours shall be learned languages; antiquities and monuments; history, and all the moral and political sciences connected with history. It shall particularly apply itself to the enriching of French literature with the works of Greek, Latin, and Oriental authors, which have not yet been translated.

It shall employ itself in the continuation of diplomatic collections.

It shall name from its own body, under the approbation of the First Consul, a perpetual secretary, who shall be of the number of the forty members which compose the class.

It may elect nine of its members from the other classes of the institute.

It may name sixty correspondents, natives or foreigners.

V. The fourth class shall be composed of twenty-eight members and eight foreign associates.

They shall be divided into sections, described and formed as follows:

Painting	- - - - -	10 members.
Sculpture	- - - - -	6 ditto.
Architecture	- - - - -	6 ditto.
Engraving	- - - - -	3 ditto.
Musie (composition)	- - - - -	3 ditto.

It shall appoint, with the approbation of the First Consul, a perpetual secretary, who shall be a member of the class, but shall not be a part of a section.

It may elect six of its members from the other classes of the institute.

It may name thirty-six correspondents, national or foreign.

VI. The foreign associated members shall have a deliberative voice only on subjects of science, literature, and the arts; they shall not form part of any section, nor interfere in any usage.

VII. The present actual national associates of the institute shall form part of the one hundred and ninety-six correspondents attached to the classes of the sciences, belles lettres, and fine arts.

Correspondents may not assume the title of members of the institute.

They shall lose that of correspondent when they shall be domiciliated at Paris.

VIII. Nominations to vacant places shall be made by each class in which the vacancy happens; the persons elected shall be confirmed by the First Consul.

IX. The members of the four classes shall enjoy a reciprocal

cal right to assist at the particular sittings of each class, and may deliver lectures when they are requested.

They shall re-unite four times in a year into one body, to communicate their proceedings.

They shall elect in common the librarian and under librarian of the institute, as well as all those agents who belong to the institute in common.

Each class shall present for the approbation of the government, the particular statutes and regulations of its internal police.

X. Each class shall hold one public sitting every year, at which the other three shall assist.

XI. The institute shall receive annually from the public treasury 1500 fr. for each of its non-associated members, 6000 fr. for each of its perpetual secretaries; and for its expences, a sum which shall be fixed every year, upon the demand of the institute, and comprised in the estimates of the minister of the interior.

XII. There shall be an administrative committee of the institute, composed of five members, two from the first class, and one from each of the others, named by their respective classes.

This committee shall regulate in the general sittings prescribed by art. IX. all that relates to the administration, to the general expences of the institute, and to the division of its funds between the four classes.

Each class shall afterwards regulate the application of the funds assigned to it for its expences, as well as all that concerns the printing and publishing its memoirs.

XIII. Every year the classes shall distribute prizes, the number and value of which shall be regulated as follows:

The first class, a prize of 3000 francs.

The second and third class, each a prize of 1500 francs.

The fourth class, grand prizes of painting, sculpture, architecture, and musical composition. Those who shall have gained one of the grand prizes shall be sent to Rome, and maintained at the expence of government.

The above decree was followed by a second, appointing the members of the different classes, and regulating the days of their meeting.

The sittings of the first class are to be held every Monday; those of the second class every Wednesday; those of the third every Friday, and those of the fourth every Saturday.

These sittings are to be held in the same place, and to last from three o'clock till five.

INSTITUTE, *Institutum*, in the *Civil Law*, a book, containing the elements, or principles of the Roman law; and which constitutes the last part of the *corpus juris civilis*.

The institutes are a compendium, or summary of the whole body of civil law, in four books, composed by Tribonianus, Theophilus, and Dorotheus, by order of the emperor Justinian, for the use of young students; who, having the first elements of the whole profession in this little treatise, might the sooner gain a competent knowledge of it without being discouraged by the bulk of the other books.

These institutes proceed, with no contemptible method, from I. "Persons" to II. "Things;" and from things to III. Actions;" and the article IV. of "Private Wrongs" is terminated by the principles of "Criminal Law." For an abridged account of these institutes, see Gibbon's *Decl. and Fall of the Roman Empire*, vol. vii. See also *CIVIL LAW*.

INSTITUTES likewise denote a system of law, or rules in science.

INSTITUTION, in a general sense, the act of ordaining, founding, or establishing any thing.

Thus we say, Moses instituted the ceremonies of the old law; Jesus Christ instituted the sacraments of the new.

INSTITUTION, in the *Canon and Common Law*, is the act of the bishop, or of one commissioned by him, whereby a clerk, after the patron's presentation has been admitted, is invested with the spiritualities of a rectory, or vicarage: for by institution the care of the souls of the parish is committed to his charge. See **PRESENTATION**.

The clerk kneels down before the bishop, whilst he pronounces these words of institution (*instituo te rectorem ecclesie de A. B. cum cura animarum, & accipe curam tuam & meam*); and the clerk holds the written instrument, with the episcopal seal annexed, in his hand, during the ceremony.

Before the clerk is instituted, he must subscribe the thirtynine articles of religion, in the presence of the ordinary, or his substitute; and this subscription must be without reserve, exception, or qualification; else his institution is, *ipso facto*, void and null, and the church still vacant. 13 Eliz. c. 12.— At the same time the ordinary requires the clerk to subscribe the other two articles mentioned in the 36th canon about the king's supremacy, and the lawfulness and use of the liturgy: the clerk must also, before institution, subscribe to that part of the declaration enjoined by the act of uniformity, 14 Car. II. c. 24, viz. "I will conform to the Liturgy of England, as by law established."— Before institution, he must also take the oaths mentioned in the first statute of William and Mary, c. 8. instead of the former oaths of allegiance and supremacy, required by stat. 1 Eliz. and then he must take the oath against simony, enjoined by the 40th canon, and the oath of canonical obedience; and if it is a vicarage, the oath of personal residence; and he is to have certificates given him of his subscribing the declaration contained in the act of uniformity, in English, in a distinct instrument, under the hand and seal of the bishop; and of his other subscriptions and oaths, in Latin.

The clerk ought by all means to have witnesses of his institution, his taking the oaths, making subscriptions, &c. and therefore he should make some present to write their names on the back of his instruments, and make memorandums who they are, and where they live.

The church, by institution, is full against all persons but the king, but it is not full against the king, till induction; and the clerk by it may enter upon the parsonage house and glebe, and take the tithes; but he cannot let or grant them, nor sue for them, if they be refused to be paid till he be inducted.

After institution, the clerk is to receive a written mandate from the ordinary to the archdeacon, or other proper person, in order to his induction; without which he has not a full right to his temporalities, unless the benefice be a donative. See **INDUCTION**.

INSTITUTION, African, a society formed by the friends of the Abolition of the Slave-trade assembled on the 14th of April 1807, and established on the subsequent 15th of July. The resolutions adopted by the constituent meeting, as the basis of the association, are as follow: 1. That this meeting is deeply impressed with a sense of the enormous wrongs which the natives of Africa have suffered in their intercourse with Europe; and from a desire to repair those wrongs, as well as from general feelings of benevolence, is anxious to adopt such measures as are best calculated to promote their civilization and happiness. 2. That the approaching cessation of the slave-trade, hitherto carried on by Great Britain, America, and Denmark, will, in a considerable degree,

gree, remove the barrier which has so long obstructed the natural course of social improvement in Africa; and that the way will thereby be opened for introducing the comforts and arts of a more civilized state of society. 3. That the happiest effects may be reasonably anticipated from diffusing useful knowledge, and exciting industry among the inhabitants of Africa, and from obtaining and circulating throughout this country more ample and authentic information concerning the agricultural and commercial faculties of that vast continent; and that through the judicious prosecution of these benevolent endeavours, we may ultimately look forward to the establishment, in the room of that traffic, by which Africa has been so long degraded, of a legitimate and far more extended commerce, beneficial alike to the natives of Africa, and to the manufacturers of Great Britain and Ireland. 4. That the present period is eminently fitted for prosecuting these benevolent designs; since the suspension, during the war, of that large share of the Slave-trade, which has commonly been carried on by France, Spain, and Holland, will, when combined with the effect of the Abolition laws of Great Britain, America, and Denmark, produce nearly the entire cessation of that traffic along a line of coast extending between two and three thousand miles in length, and thereby afford a peculiarly favourable opportunity for giving a new direction to the industry and commerce of Africa. 5. That, for these purposes, a society be immediately formed, to be called the "African Institution." See the first report of the society, which proceeds to obviate the difficulties which may appear to lie in the way of the attainment of these interesting objects; and particularly to remove the most specious objection to the design, *viz.* despair of its success. The means by which this laudable association purposed to accomplish its noble and captivating objects are as follow: First of all, this institution, wise by the example of the Sierra Leone company, disclaims in the outset all projects of a colonial or commercial nature. It embarrasses itself with no concerns of government—no mercantile speculations—no factories or forts—not even with the possession of a single ship, or an acre of ground. This clears the way for exertion, not only by removing every suspicion of unworthy or doubtful motives, but by throwing off a thousand clogs which must have hampered an establishment of a different character. For obvious reasons the society also disclaims all schemes of religious mission; and avowing, upon that important subject, not certainly any kind of indifference, but a wise and necessary neutrality, it leaves in other hands the task of propagating the gospel among the Africans, and confines its own exertions to the introduction of that civilization, which is the best preparative for the truths of Christianity. Not to mention other reasons for this salutary caution, it has one most important and beneficial effect. It opens wide the doors of the institution to all sects and denominations of Christians,—whom it thus invites to co-operate for purposes equally subservient to every form of worship, and every modification of religious belief. The means which it is proposed by this society to employ for the purpose of promoting civilization and improvement in Africa, are of the following kind: "1. To collect and diffuse throughout this country accurate information respecting the natural productions of Africa, and, in general, respecting the agricultural and commercial capacities of the African continent, and the intellectual, moral, and political condition of its inhabitants. 2. To promote the instruction of the Africans in letters and in useful knowledge, and to cultivate a friendly connection with the natives of that continent. 3. To endeavour to enlighten the minds of the Africans with respect to their true interests; and to diffuse in-

formation amongst them respecting the means whereby they may improve the present opportunity of substituting a beneficial commerce in place of the slave-trade. 4. To introduce amongst them such of the improvements and useful arts of Europe, as are suited to their condition. 5. To promote the cultivation of the African soil, not only by exciting and directing the industry of the natives, but by furnishing, where it may appear advantageous to do so, useful seeds and plants, and implements of husbandry. 6. To introduce amongst the inhabitants beneficial medical discoveries. 7. To obtain a knowledge of the principal languages of Africa, and, as has already been found to be practicable, to reduce them to writing, with a view to facilitate the diffusion of information among the natives of that country. 8. To employ suitable agents, and to establish correspondences, as shall appear advisable; and to encourage and reward individual enterprise and exertion in promoting any of the purposes of the institution."—First Report. Besides, the society has adopted from the beginning, and since steadily pursued, the resolution of watching over the strict execution of the abolition laws—of procuring all information respecting the evasion or breach of those laws, which daring speculators may attempt—of keeping the attention of the government alive, and quickening the exertions of the crown-officers on those points—of suggesting, from time to time, such improvements in those laws as a practical experience of their imperfections, or the change of circumstances, may point out;—and, finally, of promoting, as far as possible, by communicating information, and other appropriate methods, the abolition of the African Slave-trade in foreign countries. This latter service is quite essential to the improvement of Africa; and it is such as a body, like the African institution, is well adapted to perform. The president of the African Institution is the duke of Gloucester; and of the directors, who chiefly carried on its ordinary business along with this distinguished prince, we shall only mention the names of Messrs. Wilberforce, Thornton, Vanlittart, W. Smith, Brougham, Clarkson, G. Sharp, A. Fen, Stephen, and Macaulay, who, much to the advantage of the society, undertook the laborious and difficult office of secretary, until it could be filled by a permanent arrangement. A respectable subscription of about 3000*l.* was immediately raised. At the end of 1808, this had increased to 4374*l.* of which 531*l.* arose from annual subscriptions. Since that time the funds have been augmented by many donations, and the list of annual contributors soon increased. For a further account of this institution, we refer to its annual reports, and to the Edinburgh Review, No. 30.

INSTITUTIONS, in *Literary Matters*, denote a system of the elements, or rules, of any art or science. Such are institutions of medicine, institutions of rhetoric, &c.

INSTITUTEURS, in *Botany*, that set of authors in this science who have laid down certain settled rules, axioms, and in limitations in it.

INSTRUCTIVE COLUMN. See **COLUMN**.

INSTRUMENT denotes a thing which is subservient to a cause for producing its effect.

A common case of mathematical instruments contains several compasses, a sector, scale, drawing-pen, and protractor. A case of surgeon's instruments for the pocket contains different sized lancets, scissors of several kinds, plain and toothed forceps, straight and crooked incision-knives, a spatula, probes, needles, &c. Astronomical instruments are the telescope, quadrant, &c. Chemical instruments, see **LABORATORY**. For the method of dividing mathematical and astronomical instruments, see **ENGINE** and **GRADUATION**.

INSTRUMENTS of Sacrifice, in the *Antique Architecture*, are ornaments.

ornaments, as vases, pateræ, caudlesticks, knives, &c. where-with the victims were killed, &c. instances of which we see in a Corinthian frieze in the remains of a temple behind the Capitol at Rome, &c.

INSTRUMENT is also used, in *Law*, to signify some public act, or authentic deed, by means whereof any truth is made apparent, or any right or title established, in a court of justice:

INSTRUMENT, primarily denoting writing, charter, or record, is sometimes used by Latin writers for the Old and New Testament. It occurs several times in Tertullian, reckoned the most ancient Latin writer of the church now remaining. He calls the Gospels, or the New Testament in general, the Evangelic Instrument, and says, "how large chafms Marcion has made in the epistle to the Romans, by leaving out what he pleases, may appear from one entire Instrument," or one unaltered copy of the New Testament, particularly of that epistle. Speaking of the shepherd of Hermas, he says, it was not reckoned a part of the Divine Instrument; thereby meaning, as it seems, the New Testament. He calls the law and the prophets the Jewish instruments, that is, writings or scriptures. He speaks of the antiquity of the Jewish instruments, or scriptures. He seems in one place (Apol. cap. 18.) to use the word instrument as equivalent to scriptures, containing the doctrine of revelation, or the revealed will of God. Lardner.

INSTRUMENT, in *Music*, is a general term, under which all artificial bodies, capable of producing and varying musical sounds in imitation of the voice, are comprehended. Every body capable of agitating the air by some shock, and exciting by its vibrations in this agitated state undulations sufficiently frequent, may produce sound; and all bodies capable of accelerating or retarding these undulations may vary their sounds. See SOUNDS.

There are three ways of producing sound by instruments: by the vibration of strings, by the vibration of elastic bodies, and by the collision of air inclosed in pipes. The invention of these instruments will be considered at the word MUSIC.

Instruments are generally classed under the three following heads: stringed-instruments, wind-instruments, and instruments of percussion. The stringed-instruments of the ancients were very numerous. Those most known were the following: the lyra, psalterium, trigonum, sambuca, cithara, pectus, magadis, barbiton, testudo, epigonium, simmicum, epanorion, &c. All these instruments were touched with the fingers or played with a plectrum.

Their principal wind-instruments were the tibia, fistula, tuba, cornu, lituus, hydraulicon, &c.

Their instruments of percussion were the tympanum, cymbalum, crepitaculum, tintinnabulum, crotalum, &c; but many of these are monotonous, and only render one sound.

Of most of these ancient instruments representations on plates have been given (Hist. Mus. vol. i.) from drawings made at Rome under our own eye, and under the guidance of Piranesi, and Messrs. Jenkins, Morrison and Byers, the best antiquaries at Rome in 1770; with a description and authorities for their local situation at the time.

The best books on the subject of ancient musical instruments, and the most worthy of being consulted, are Blanchini de Tribus Generibus Instrumentorum Veterum Organica; Gabinetto Armonica, del Bonanni; Bartolinus de Tibibus Veterum; and Elfaiss sur la Musique par M. Laborde; who has given representations very neatly engraved of the musical instruments during the middle and lower ages, from illuminations in ancient MSS. of the Bibl. Royale at Paris in 1780; which, if the wish to render their delineation picturesque had not a little injured their fidelity, would be invaluable.

INSTRUMENTS, *Musical*, of the Abyssinians, from Mr. Bruce, the authenticity of whose account seems to be no longer doubted, we shall give from his letter inserted in Burrey's General History of Music, vol. i.

"There are six musical instruments known in Abyssinia; the flute, the trumpet, the kettle-drum, the tambourine, the sitrum, and the lyre.

"The four first are used in war, and are by much the most common; the fifth is dedicated to the services of the church; and the sixth is peculiarly an attendant on festivity and rejoicings.

"There are two principal languages in Abyssinia, the Æthiopic, which is the literal, or dead language; and the Amharic, or language of Amhara, spoken by the court.

"The flute, in the Æthiopic, is called *Kcutz*, a word difficult to be written or founded in English; in the Amharic, it is called Agädä: it is about the shape and size of the German flute, but played upon long-ways, with a month-piece resembling that of the clarinet; its tone is not loud, but accompanied with a kind of jar, like a broken hautbois; not owing to any accidental defect, but to construction and design, as it would not be esteemed without it.

"The kettle-drum is called in both languages *Nagareet*, because all proclamations are made by the sound of this drum (these are called *Nägär*), if made by governors, they have the force of laws in their provinces; but if made by the king, they are for all Abyssinia. The kettle-drum is a mark of sovereign power: whenever the king promotes a subject to be governor, or his lieutenant-general in a province, he gives him a kettle-drum, and standard as his investiture. The king has forty-five of these drums always beating before him when he marches. They are in shape and size like our's, only they are braced very disadvantageously; for the skin is strained over the outer rim, or lip of the drum, and brought a third down its outside, which deadens it exceedingly, and deprives it of that clear, metallic sound which our's has. Each man has but a single drum, upon the left side of his mule, and beats it with a crooked stick, about three feet long. Upon the whole, its sound is not disagreeable, and I have heard it at an incredible distance.

"The third instrument is the small drum, called *Käbäro*, in Æthiopic and Amharic; though in some parts of Amhara it is also called *Hätämo*. It is about half the diameter, and twice the length of our common drum; it is just the tambourine of Provence, only rounded to a point at the lower end. This is beaten always with the hand, and carried sometimes on foot, sometimes on horseback, when any inferior officer (not having a *Nagareet*) marches.

"The trumpet is called *Mélékëta*, or *Mélékët*; and *Kenet* in Amharic, but *Keren* in Æthiopic (or horn); which shews of what materials it was anciently formed. It is now made of a cane that has less than half an inch aperture, and about five feet four inches in length. To this long stalk is fixed at the end a round piece of the neck of a gourd, which has just the form of the round end of our trumpet, and is on the outside ornamented with small white shells; it is all covered over with parchment, and is a very neat instrument. This trumpet sounds only one note, E, in a loud, hoarse, and terrible tone. It is played flow when on a march, or before an enemy appears in sight; but afterwards it is repeated very quick, and with great violence, and has the effect upon the Abyssinian soldiers of transporting them absolutely to fury and madness, and of making them so regardless of life, as to throw themselves in the middle of the enemy, which they do with great gallantry. I have often in time of peace tried what effect this charge would

would have upon them, and found that none who heard it could continue seated, but that all rose up and continued the whole time in motion.

“The fifth instrument is the *fitrum*: it is used in the quick measure, or in allegros, in singing psalms of thanksgiving. Each priest has a *fitrum* which he shakes in a very threatening manner at his neighbour, dancing, leaping, and turning round with such an indecent violence, that he resembles rather a priest of paganism, whence this instrument was derived, than a Christian. I have forgot the name of the *fitrum* in Ethiopic, but on looking into my notes I shall find it.

“The sixth and last instrument is the lyre, which is never played solo, but always in accompanying the voice, with which it plays constantly in unison; nor did I ever hear *music in parts*, in any nation, savage or polished, out of Europe: this is the last refinement music received, after it was in possession of complete instruments, and it received it probably in Italy.

“The lyre has sometimes five, sometimes six, but most frequently seven strings, made of the thongs of raw sheep or goat skins, cut extremely fine, and twisted; they rot soon, are very subject to break in dry weather, and have scarce any found in wet. From the idea, however, of this instrument being to accompany and sustain a voice, one would think that it was better mounted formerly.

“The Abyssinians have a tradition, that the *fitrum*, lyre, and tambourine were brought from Egypt into Ethiopia, by Thot, in the very first ages of the world. The flute, kettle-drum, and trumpet, they say, were brought from Palestine with Menelek, the son of their queen of Saba, by Solomon, who was their first Jewish king.

“The lyre in Amharic is called *bēg* (the sheep); in Ethiopic, it is called *mēsīnkō*; the verb *finko* signifies to strike strings with the fingers: no *pletrum* is ever used in Abyssinia, so that *mēsīnkō* being literally interpreted, will signify “the stringed instrument played upon with the fingers.” This would seem as if anciently there was no other stringed instrument in Abyssinia, nor is there any other still.” See THEBAN HARP, with Mr. Bruce’s drawing and account of it, in the same volume.

Modern musical instruments will be described under their first heads as they occur.

In modern times, since harmony has sustained so important a part in music, musical instruments have been divided into *perfect* and *imperfect*, the first of these being such as are capable of executing or sounding as many notes of different pitches within a given compass, as within an octave for instance, as the harmony of the music performed upon it may require, without being forced to introduce notes, which make false or tempered intervals, or *wolves* with the other notes of the piece, founded at the same time; as in the second class necessarily happens, in very numerous instances, where the notes are previously fixed and tuned, as it is called, to some certain scale or system of 12 notes within the octave, and which notes the performer of any one part in a piece of music has not the power of altering and adjusting to the true harmonic relation with the simultaneous notes of the bass, or other principal part: imperfect instruments are not, however, confined to those with 12 strings, pipes, &c. in an octave, but the term applies, though in a less degree, to instruments with 14, 16, or 17 strings, as shewn in our article HAWKE’S *temperament* of the musical scale, where his 17 notes in the octave are proved to be incapable of banishing wolves, or false intervals, even from tempered systems, and which

Dr. Smith’s harpichords with 21 notes in the octave were alike unable to effect, in the numerous passages of modern music where double sharps or double flats occur: but on the improved organs and piano fortes of D. Loefelman, whose scale is extended to 24 notes, all such notes as usually occur can be truly given, according to any assigned system of temperament. The violin, viola, bass-viol or violoncello, and double bass, have held a distinguished rank in modern refined concerts as perfect instruments, and were, indeed, the only instruments that should be admitted to accompany the human voice, which exceeds, in the perfection of its scale, any instrument whatever, since a vocal performer, with a good ear and intonation, can instantly strike a perfect interval to any note whatever, without the least beating or degree of temperament or imperfection in the harmony, and this he does, by attuning the leaps or intervals of the melody (see MELODY, *Temperaments of*): it being absolutely and demonstrably impossible to avoid temperaments, or the use of imperfect intervals, either in the harmony or in the melody, (but they need not be used in both,) on perfect instruments, as on imperfect instruments they necessarily must, as is shewn in our article HARMONY, *Temperaments of*: the late Mr. Maxwell, in the year 1781, in his “*Essay on Tune*,” sketched out the principles of an organ capable, by means of 44 pipes in each octave, of entirely banishing temperaments from the harmony, in 24 keys, 12 major and 12 minor: but we never heard until very lately, that any one had constructed such an instrument. It appears, however, that on the 3d of July 1810 the Rev. Henry Liston took out a patent for his *enharmonic organ*, and in the autumn of the year issued proposals for publishing, by subscription, “*An Essay on perfect Intonation*,” and for exhibiting one of these patent organs in London, which had been completed in Scotland, and tuned, says his prospectus, “perfectly true throughout, without any temperament whatever, and performs every chord, in every key absolutely perfect, nor is there any combination which it is not capable of performing.”—“The decided superiority of the harmony has been acknowledged by the best judges, and the performers have found no serious difficulty in the most sudden and extraneous modulation, or in the widest range of keys:” such were the pretensions of this instrument, and which no musical persons that we conversed or corresponded with seemed disposed to expect would be realised: however, in the beginning of this month (April 1811), Mr. Liston arrived in London with his organ, and had it put up at Flight and Robson’s, organ builders in St. Martin’s lane, and tuned it, and on the 16th politely gave us the opportunity to be the first that heard it performed on in London, and of hearing the effect of some glees sung to it; which proved delightful indeed, and rather exceeded our expectations than otherwise, though they had, as above hinted, been raised above those of most musical persons. The Rev. Mr. Liston also favoured us with the perusal of the manuscript of the first part of his intended work, in which we were delighted to observe, that a good knowledge and a correct application of mathematics is combined with a thorough knowledge of composition, and of the wants of the practical musician: the defect of one of which essential qualifications we have so often had to deplore, and even to reprobate, in our numerous quotations and references to modern writings on temperament, and on the nature and magnitude of musical intervals, in the different articles of our work. Mr. Liston’s work will describe an instrument with 24 pipes in each octave, and to each of which two valves or shades, of different sizes, are adapted, affixed to radii from rolls or axles, that can be

turned by means of pedals, so that each of these pipes can be made to sound one major comma or two major commas flatter than the pitch of the pipe, making in all 72 sounds in each octave, which, by the 12 usual finger keys and the use of twelve pedals, enables the performer to give 33 perfect keys, without any tempered harmonies. The instrument, thrown as above, has not B F, but contains 20 pipes, and gives 60 different sounds within the octave. See the *Philosophical Magazine*, vol. xxxvii. p. 273, and our article *List of Scales of Musical Intervals*.

INSTRUMENT, *Wind*. See WIND.

INSTRUMENTAL ARITHMETIC. See ARITHMETIC.

INSTRUMENTAL Cause. See CAUSE.

INSTRUMENTUM SYNODALE. See SYNODALE.

INSUFFLATIO, a term used by some writers in medicine, to express the blowing into any part, in order to convey the fumes of medicine into it.

INSULATE, or INSULATED, a term applied to a column or other edifice, which stands alone, or free and detached from any contiguous wall, &c. like an island in the sea; whence the denomination is apparently derived.

INSULATED, in *Electricity*, is a term applied to bodies that are supported by electric or non-conductors; so that their communication with the earth, by conducting substances, is interrupted.

INSULT, in *Law*. See ASSAULT.

INSULT, a military term used for the attack of any post with open force: without the apparatus of trenches, saps, or any regular approaches. See ASSAULT.

INSULTUS, a word used by the writers in medicine to signify the access of the paroxysm in intermittent diseases, or sometimes the first invasion of a disease.

INSUMA, in *Geography*, a town of Arabia, in the province of Hedjas; 10 miles S.W. of Mecca.

INSUPER, a word used by the auditors of the Exchequer. In their accounts they say, so much remains *insuper* to such an accountant; that is, so much remains due on his account.

INSURANCE, or ASSURANCE, in *Law and Commerce*, a contract or agreement whereby one party, in consideration of a stipulated sum, undertakes to indemnify the other, against certain perils or risks to which he is exposed, or against the happening of some event. The party, who takes upon himself the risk, is called the "Insurer;" sometimes the "Underwriter," from his subscribing his name at the foot of the policy; the party protected by the insurance is called the "insured;" the sum paid to the insurer, as the price of the risk, is called the "premium;" and the written instrument, in which the contract is set forth and reduced to form, is called a "policy of insurance, or assurance." See POLICY.

The risks against which insurances are made are infinitely various, and many frauds have been practised on the ignorant and credulous, under pretence of insurance, which the legislature has found it necessary, from time to time, to repress. In the reign of queen Anne, several offices were opened for making insurances on marriages, births, christenings, service, &c., and fraudulent practices prevailed to such a degree, that by stat. 9 Ann. c. 6. § 37, a penalty of 500*l.* is imposed on every person setting up such office, and 100*l.* on every person making such assurances in any office already set up. Fraudulent insurances have also occurred among dealers in lottery tickets, the shares and the chances of them,

which, besides the restraints to which they are subject in the annual lottery acts, have occasioned the stat. 27 Geo. III. c. 1, made expressly with a view to this evil, and by which they have been considerably diminished. See LOTTERY.

Insurances of the greatest public utility are, "Marine Insurances," including bottomry and respondentia, which are a species of marine insurance (see each of these articles); "Insurance upon Lives" (see ASSURANCE); and "Insurances against Losses by Fire."

INSURANCES, *Marine*, are made for the protection of persons having an interest in ships, or goods on board, from the loss or damage that may happen to them from the perils of the sea, during a certain voyage, or a fixed period of time. By "peril" is here meant, not danger or hazard, according to the common acceptance of the term; but it signifies the "happening" of the event or misfortune of which danger was apprehended. The utility of this contract consists in the protection it affords to maritime commerce, by dividing losses, when they happen, between many, so as to make them fall less heavily on individuals, who are thus enabled to embark their whole capitals in hazardous enterprises. (See the preamble to the stat. 43 Eliz. c. 12.) As the Turks are unacquainted with insurance, they require for the loan of money 15 or 20 per cent.; and when they lend money to merchants who trade by sea, they charge 30 per cent. Some have ascribed the invention of insurance to the ancient Romans. Accordingly Puffendorf, Barbeyrac, Loccenius, Kulpis, and others, refer to a passage in Livy (l. xxiii c. 44.), who says, that when the Roman army in Spain was distressed for provisions, clothing, and other necessaries, a company engaged to convey to them every thing of which they stood in need, under this stipulation, that the state should make good their loss, in case their vessels should be shipwrecked by storms, or taken by the enemy. This was undoubtedly a promise of indemnification, but by no means an insurance, in which it is always necessary to give a premium. Kulpis, Anderfon, Malync, and others, rely on the authority of Suetonius (l. v. c. 18.) who tells us, that the emperor Claudius promised to indemnify merchants for their losses, if their ships should perish by storms at sea; but neither this passage nor another that has been referred to in Valerius Maximus (l. vi. c. 5.), contains any thing that can be applied to insurance in the modern sense of the term. A passage has also been quoted by Grotius from Cicero's epistles (Epistol. ad Fam. ii. ep. 7.), as a proof that the Romans were acquainted with this contract. But Cicero's words, justly interpreted, seem to bear a much stronger allusion to the practice of remitting money by means of bills of exchange, than to that of insuring against the perils of the sea. In the Pandects we have an observation of Ulpian, which affords greater reason for supposing that the contract of insurance was not altogether unknown to the Romans, than any of the passages already cited. He says (Dig. l. xlv. de verb. oblig.), "Illa stipulatio, decem millia falva fore promittis? valet." This passage, however, shews, as serjeant Marshall has observed, that the contract alluded to, whatever it might have been, was very little known at the time when Ulpian wrote, since he thought it necessary to remark, that "it was not illegal." Malync, Anderfon, &c. affirm, that insurance is mentioned in the marine laws of the isle of Oleron, on the coast of France, which was much celebrated in the 11th, 12th, and following centuries, on account of its trade. But in these laws there is no trace of insurance, as the learned editor, Cleirac, acknowledges. The celebrated maritime laws of the city of Wisby, in the island of Gotland, are equally silent with regard to insurance. Insurance was, undoubtedly,

not known in 1597, when the ordinances of the Hanseatic league were framed, nor in 1614, when several new regulations were added; because, though the contract of bot-tomy is mentioned in these regulations, there is not a word on the subject of insurance, nor does any thing certain occur in the collection of maritime laws, intitled "Il Confolato del Mare," written in the Catalonian dialect, partly framed in the 11th, but for the most part in the 13th century, and published at Leyden in 1704. (See *Marine Law*.) Some have said, without sufficient authority, that the practice of insurance was introduced by the Jews in 1182; and others have sought its origin about the year 1560, in the great woollen commerce that subsisted between England and the Netherlands. But as the maritime commerce of the Italian states appears to have been carried on to a very considerable extent about the end of the 13th century, it is very probable that insurance came into use in Italy about that time. From thence it was transported into all the countries where the Lombards had established their trading companies. One of these companies settled in London, and from them Lombard-street in that capital took its name. According to Malynes insurance was introduced into England by the Lombards somewhat earlier than into the neighbouring countries on the continent; and in proof of this, he says, that even Antwerp, in its meridian glory, borrowed insurance from England; and that, down to the time in which he wrote (1622), there was, in every policy made at Antwerp, and other places in the Low Countries, a clause inserted, that it should be in all things the same as policies made in Lombard-street, in the city of London; the place where the Lombards are known to have first settled, and carried on their commerce in England, and where the merchants of London used to hold their meetings before the Royal Exchange was built. Anderson (*Hist. of Commerce*) says, that the vast commerce carried on about the middle of the 16th century, between England and the Netherlands, introduced the practice of insuring from losses by sea, by a joint contribution. But the preamble to the statute 43 Eliz. c. 12, already cited, which statute was passed in 1601, distinctly states, that it had been an "immemorial usage" among merchants, both English and foreign, when they made any great adventure, to procure insurance to be made on their ships or goods adventured. From this it may be reasonably supposed, that insurance must have been in use in England long before the middle of the preceding century. The law of insurance, says Mr. Marshall (*ubi infra*), is considered as a branch of marine law; and it is also a branch of the law of merchants (see *LAW*); and it may be collected from these two sources in the ordinances of different commercial states, in the treatises of learned authors on the subject of insurance, and in judicial decisions of this country, and also of others professing to follow the general marine law and the law of merchants. The earliest ordinance now extant on the subject of insurances is that of Barcelona, supposed to have been published about the year 1435. The next ordinance on this subject was published at Florence in the beginning of the year 1523. The emperor Charles V. in 1551 published several regulations concerning maritime commerce, called the "Caroline" code, to which his son Philip II. added a number of new ordinances in 1563 and 1565. Magens, in his "Treatise on Insurance, Average, and Bot-tomy," published at Hamburg in 1753, has collected many of these ordinances; but the most complete system of positive law for the regulation of insurances, that has yet appeared in any country, may be found in the celebrated ordinance of the marine of Louis XIV., published in 1681.

The statutes pertaining to this subject, which have been enacted in England, have not been numerous; and, therefore, the practice among us has been found most conformable to the general usage of trade. As to treatises on insurance, the earliest now extant is that entitled "Le Guidon de la Mer," which is found in the collection of marine institutions, published at Rouen in 1671 by Cleirac, under the title of "Les Us et Coutumes de la Mer." This is supposed to have been written about the 15th century. In France, Valin, Potbier, and Emerigon, have written on this subject. The treatise of the latter is, in the judgment of ferjeant Marshall, the most useful to an English lawyer of all the foreign publications on this subject. Roccus, Cafaregis, Locennius, Bynkerf-hock, and Santerna, have also published treatises on this subject. We have also in England detached observations on insurance in the treatises of Malynes, Molloy, Beaves, Postlethwaite, and some others of less note. Mr. Magens, a merchant, in 1735, republished in two volumes 4to. his "Essay on Insurance," which he had before published in German at Hamburg. Mr. Millar, a learned advocate at the Scots bar, published at Edinburgh, in 1787, the "Elements of the Law relating to Insurances;" Mr. Park has also given to the world his excellent "System of the Law of In-surances;" and in 1802 the public was favoured by Samuel Marshall, ferjeant at law, with his "Treatise on the Law of Assurance," in 4 books, containing an ample account of every thing that is essentially necessary to be known on this subject. As to judicial decisions, none of these are considered as binding authorities in our superior courts, except such as have been there determined; and even these may be re-considered and over-ruled. Before the passing of the act of queen Elizabeth, above cited, almost all disputes, arising upon contracts of insurance, were settled by arbitration, and without recurring to any legal proceedings. And there seems to have been a particular tribunal for such arbitrations, established in London, composed of persons annually appointed by the lord mayor. From Malynes we learn that there was an "office of assurances," on the west side of the Royal Exchange, where insurances were made; and to this office belonged certain commissioners, who were annually appointed. The authority of these commissioners was confirmed by act of parliament, in the latter period of the reign of queen Elizabeth. (See *COURT of Policies of Assurance*.) This court gradually sunk into disrepute, and all suits on policies of insurance were preferred in the courts of common law. After some of the decisions of the courts of Westminster, on questions of insurance, came to be generally known, the confidence which the justice, impartiality, and ability of those courts inspired through Europe, soon induced the merchants of all countries to prefer English insurances to those of any other country.

The parties to the contract of insurance are the insured and the insurers. In this country, all persons, whether British subjects or aliens, may, in general, be insured. The principal, if not the only exception to this rule, is the case of an alien enemy. The insurance of the ships and merchandise of France, during a war with that country, is prohibited by 21 Geo. II. c. 4; and by 33 Geo. III. c. 27. § 4, which latter statute not only declares such insurances to be void, but also subjects the parties concerned in them to three months' imprisonment. The policy of this prohibition was however disputed in 1741, by sir John Barnard, and in 1748 by sir Dudley Rider and Mr. Murray, then attorney and solicitor-general. But their objections were over-ruled. Nevertheless, it appears that a neutral, though residing in the enemy's country, and carrying on

trade there, and even in partnership with an alien enemy, may insure his interest in the joint property.

Those who are insurers, or underwriters, should be persons of great prudence and circumspection; and cases may occur, which will require more than ordinary sagacity, penetration, and experience. At common law, any man, or company of men, might be insurers; and individuals, upon their own separate account, have till the same right. But about the beginning of the last century it was thought expedient, partly with a view of counteracting the evil arising from insurance by insufficient persons, and perhaps, principally for enabling government to raise a sum of money by the sale of a monopoly, to erect two companies for making marine insurances, with such funds to answer all demands on their policies as might give confidence to mercantile adventurers, who were unwilling to depend on individual underwriters; still, however, leaving to merchants the option of insuring with such underwriters whom they thought proper. To this end the stat. 6 Geo. I. c. 18, authorized the king to grant charters to two distinct companies or corporations, for the insurance of ships, goods, and merchandize, at sea, or going to sea, and for lending money on bottomry. In pursuance of the powers given by this act, the two proposed companies, the one called the "Royal Exchange Assurance," and the other the "London Assurance," were established by royal charter, bearing date June 23, 1720. The most important privilege granted to these companies was the exclusive right of making marine insurances, and lending money on bottomry, as a "Company" or "Partnership," on a "joint capital."

Insurance is said to be "a contract of indemnity from loss or damage, arising upon an uncertain event." So that the object of insurance is to avoid a possible loss. Hence it appears, that there cannot be an indemnity without a loss, nor a loss without an interest. A policy, therefore, without interest, is not an insurance, but a mere wager. It is not easy to define and ascertain insurable interest. The interests of commerce, and the various rights which different persons may have in the same thing, require that not only those who have an "absolute" property in ships and goods, but those, also, who have a "qualified" property in them, may be at liberty to insure them; and this principle has been so extended, that if a merchant abroad, in order to secure the payment of a debt due to his correspondent in England, mortgage to him his interest in certain goods and freight; the correspondent, after the mortgage becomes absolute, may insure the "legal" interest on his own account, or the "equitable" interest on account of the mortgagor. A reasonable expectation of "profit," or a well-founded expectation of a future interest in the thing insured, is an insurable interest. But a mere hope or expectation of future gain, however well founded, is not an insurable interest, unless accompanied by possession of the subject-matter of the insurance. Of this nature is the interest which the captor acquires in a prize regularly taken in war. It also appears, that persons in the character of "trustees," for the disposal of ships and goods according to such instructions as they might receive from third persons, may insure such ships and goods for the benefit of the persons who may eventually be entitled to the produce of them. Accordingly, commissioners, entitled "The Honourable Commissioners for the Sale of Dutch Property," were appointed by 35 Geo. III. c. 80. § 21, to take into their care all Dutch ships, &c. detained in British ports, and to dispose of them in pursuance of directions from the privy council; and they were authorized to insure, in their own names, such ships, after seizure at sea, and while they were on their

passage to England. At common law, an insurance might have been made without interest; nor is it necessary to aver interest in any case not prohibited by 19 Geo. II. c. 37. An insurable interest can only be founded on a legal or equitable title; but a mere claim, which the law cannot admit to be either legal or equitable, is not an insurable interest. As freight can only be due to the legal owner of a ship, he only can insure it; and no person can have either a legal or equitable title to a ship, unless he be named in the register. Although "respondentia" and "bottomry" are of themselves a species of insurance, yet the lender has an insurable interest in his securities, and therefore may protect himself from the sea-risk by insuring them. However, a policy on bottomry or respondentia cannot be subscribed by the borrower of the money; for if he were to become an insurer, this would be no longer a loan upon bottomry, but a cloak for usury. See *Wager Policy*, and the sequel of this article.

Insurances are of various kinds, as on ships or parts of ships, on merchandize singly, and on ships and goods jointly, on freight, and bottomry loans; and these are again branched out to run either for a time stipulated, or to one single port, or out and home, with liberty to touch at the different places mentioned in the policy.

It is laid down as a general rule, that no insurance can be legally made upon any voyage undertaken contrary to the laws of this kingdom, or to those of its dependencies, or to the law of nations. Nor is it of any importance whether the insurer was or was not informed that the voyage was illegal. Consequently, an insurance upon a voyage undertaken contrary to the navigation laws would be void. The case is the same with regard to a voyage prohibited by the laws made for the protection of the monopoly of the East India company. Under the treaty allowing the Americans to trade to the British colonies in India, concluded in 1795 and confirmed by 37 Geo. III. c. 97, it is not necessary that this trade should be carried on from America to the British settlements in the East Indies "direct;" but it may be carried on "circuitously" by the way of Europe. With respect to the risks or perils against which insurances are usually made, they are expressed in the words of the policy, which are as follow: "Touching the adventures and perils which we the assurers are contented to bear, and do take upon us in this voyage, they are of the seas, men of war, fire, enemies, pirates, rovers, thieves, jettisons, letters of mart and countermart, surprisals, takings at sea, arrests, restraints and detentions of all kings, princes, and people, of what nation, condition, or quality whatsoever; barratry of the master and mariners; and of all other perils, losses, and misfortunes, that have or shall come to the hurt, detriment, or damage of the said goods and merchandize, and ship, &c., or any part thereof, without prejudice to this insurance." But by the agreement of the parties, the general words of the policy may be altered or qualified, and any of the risks may be wholly or in part excluded: and the insurance may be made only against some particular risks, or up to, or beyond certain degrees, or upon particular articles. In the policies of most countries it is stipulated that the insurer shall not be liable for any partial loss under a given rate *per cent.* A clause to this purpose, which was first introduced in 1749, is inserted at the bottom of all English policies. Nevertheless, the insurer is liable for losses, however small, called "general average," and losses occasioned by the "stranding of the ship." In the policies of private underwriters the memorandum is as follows: "corn, (comprehending every sort of grain, and also pease and beans,) fish, salt (not including salt-petre), fruit, flour and feed, are warranted free from average

INSURANCE.

average, unless general (denoting losses arising from any cause affecting the general safety of the ship and cargo), or the ship be stranded: sugar, tobacco, hemp, flax, hides and skins are warranted free from average, under 5 per cent., and all other goods, also the ship and freight, are warranted free from average, under 3 per cent. unless general, or the ship be stranded." In 1754 the two companies, viz. those of the London and Royal Exchange assurance left out of the words, "or the ship be stranded;" but private underwriters have continued them. If any loss or damage happen to the goods, from any fault or defect of the ship, the owner has his remedy against the proprietors of the ship, and the insurer is not liable; but, in every contract of insurance, there is an implied warranty, that the ship is sea-worthy: if otherwise, the contract is void. In many cases the master also is liable. The marine law, which agrees the common law of England, considers the owners, as well as the master, as common carriers, and answerable for all losses, except such as arise from the act of God, the king's enemies, or the perils of the sea. In order to charge the insurer, the loss must happen in the course of the voyage, and during the continuance of the risk. In our policies the words usually employed to express the commencement and end of the risks on goods are these: "Beginning the adventure upon the said goods and merchandize from the loading thereof aboard the said ship, and so shall continue and endure until the said ship with the said goods shall be arrived at ——— (her port of delivery), and until the same be discharged and safely landed." This rule, however, admits of some exceptions, which our limits will not allow us to enumerate. The duration of the risk on the ship varies with us in almost every case. In outward-bound voyages it is generally made to commence from her beginning to load at her port of departure. Ships engaged in the coaling-trade, or in short voyages, are insured for a limited period of time; and in such cases, the risk commences and ends with the term, wherever the ship may then happen to be. If a ship be insured from the port of London to any other port, and before the breaks ground, an accident happen to her, the insurers are not answerable; for the risk does not commence till the sets sail on her departure from the port of London: but if the insurance be "at and from" the port of London, the insurers are liable for any accident that may happen to her, "from the time of subscribing the policy." When a ship, in homeward voyages, expected to arrive at a certain place abroad, is insured "at and from" that place, or from her arrival there, the risk begins from the first moment of her arrival at the place specified; and the words "first arrival" are implied, and always understood in policies so worded. As to the termination of the risk on English policies, it is usually made to continue only "until the ship hath moored at anchor 24 hours in good safety." The risk on the furniture, the rigging and tackle, and provisions of the ship, may continue even when put on shore. With insurers, a liberty to touch and stay at any ports and places, means ports and places in the usual course of the voyage. This liberty to touch and stay at any ports or places, does not authorize the insured to break bulk and trade. Although a ship, through necessity, change the order of the places at which she is to touch, yet if she do not abandon the original voyage, the risk continues. In an insurance upon freight, the risk generally begins from the time the goods are put on board. If an accident happen to the ship before any goods are put on board, which prevents her from sailing, the insured cannot recover for the loss of freight, which the ship might have earned if the accident had not happened. But if part of the cargo be put on

board, and the rest be ready to be shipped, the insured may recover for the whole freight, upon a valued policy. (See POLICY.) If a ship be lost in her way to her port of loading, the insurer is liable for the whole freight.

If, after the insurance is effected, any thing be done by the insured to alter the nature of the risk, this must be done with the consent of the insurer, otherwise it will avoid the contract.

Insurances may likewise be made on goods sent by land, or by hoys, &c. on rivers; and this is frequently done, more especially on jewels, and other things of great value. They may likewise be made on ships and goods, lost or not lost, which is commonly done when a ship has been long missing; and those words being inserted in the policy, oblige the underwriters to pay, though the ship was lost at the time of making such insurance, except the assured had then certain knowledge of the ship's being wrecked; in which case the subscription shall not oblige, as this is accounted a mere fraud. So likewise if a person get more insured than the ship is worth, with a villainous design to destroy her, this fraudulent act will not obligate the insurers, but expose the proprietors to suffer death for their knavery. An insurance made on prohibited goods is illegal and void, unless they were not prohibited till after the insurance was made. The insurance of seamen's wages is prohibited in all maritime countries; and by the law of England such insurance is unquestionably illegal. But they may insure goods purchased abroad with their wages; and the captain is allowed to insure goods which he has on board, or his share in the ship, if he be a part-owner. By the law of France, the insurance of freight, not actually earned, is prohibited; but in England the freight, as well as the ship, may be legally insured. To entitle the owner, however, to recover for a loss on a policy for freight, it must appear, that, before the loss, the owner's right to freight had commenced; that is, that the ship had actually begun to earn freight, for till that time the risk on freight does not commence. Although it is not unusual in England to insure profit, the question whether this be a proper subject of insurance has never yet come under solemn discussion. Where the policy expressly mentions that the ship is to depart with convoy, it is intended that she shall, if possible, keep with the convoy during the voyage, and if she depart wilfully from the convoy, it is a fraud; but if having departed with the convoy, she by stress of weather loses the convoy, and is taken, the insurers are liable. (See WARRANTY.) If there be thieves on board among themselves, the master of the ship is to answer for that, and not the insurers; for though the words of the policy insure against losses by thieves, yet assailing or external thieves are only here intended, and for external theft the insurer as well as the owner of the ship is liable; but the proprietor of the goods, or the insurers in his name, may recover against the owners. An insurance made in a foreign country, may be sued in England by the common law, if the insurers come here. Where the policy is against restraint of princes, that does not extend to a navigation carried on against the law of nations, or where there shall be a seizure for not paying of customs or the like. If goods be insured as the goods of an ally, when they are the goods of an enemy, it is a fraud, and the insurance not good. If a man pays money on a policy of insurance, supposing a loss where there was none, this shall be money received for the use of the insurer, for which he may maintain an action. A suppression of the truth, or a false allegation, is sufficient to discharge the policy; for it is a general rule, that the insured ought to

inform

INSURANCE.

inform the insurer of all material circumstances that were come to his knowledge at the time of making the policy, in order that the contract may be fairly adjusted; which being a contract upon chance, cannot be done, if one party knows more than the other; for equality in contracts, by the law-merchant, is essential; but a proof of an intention to make a deviation, will not avoid the policy before the deviation is actually made. See REPRESENTATION.

By an act made in 19 Geo. II. c. 37. it is determined, that after the first day of August, 1746, no insurance shall be made on ships or lading, "interest or no interest," or "without further proof of interest than the policy," or by way of gaming or wagering, or without benefit of salvage to the insurer, and that every such insurance shall be void: that it shall not be lawful to make re-insurance, unless the insurer shall become insolvent, become a bankrupt, or die: in which cases such insurer, or his executors, &c. may make re-insurance to the amount of the sum before insured, provided it be expressed in the policy to be a re-insurance (see REINSURANCE); that all sums of money lent on bottomry or respondentia, upon any ships belonging to his majesty's subjects, bound to or from the East Indies, shall be lent only on the ship or merchandize, laden, or to be laden, on board such ship, and shall be so expressed in the condition of the bond; and the benefit of salvage shall be allowed to the lender, his agent or assigns, who alone shall have a right to make insurance on the money so lent; and no borrower of money on bottomry, &c. shall recover more on any insurance, than the value of his interest in the ship or merchandize, exclusively of the money so borrowed; and in case it shall appear, that the value of his share in the ship and merchandize does not amount to the full sum borrowed, such borrower shall be responsible to the lender for so much of the money borrowed, as he hath not laid out on the ship or merchandize, with lawful interest for the same, together with the insurance and all other charges, to the proportion which the money not laid out shall bear to the whole money lent, notwithstanding the ship and merchandize be totally lost. And, in all actions brought by the insured, the plaintiff, or his attorney or agent, shall, within 15 days after he shall be required so to do, in writing, by the defendant, or his attorney or agent, declare in writing what sum or sums he hath insured or caused to be insured in the whole, and what sums he hath borrowed, at respondentia or bottomry, for the voyage, or any part of the voyage in question.

Whenever advice is received of the loss of a ship or goods insured, application is to be made to the insurers, and the vouchers produced; and if they are satisfied, they will pay the money: but if they have cause to scruple the doing it, the insured must stay till the insurer can obtain a more satisfactory account; but if nothing be heard of the ship in any reasonable time, the insurers will be obliged to pay the money agreed upon.

In adjusting a loss, the quantity of damage for which the underwriters are responsible is first to be ascertained; and the next point to be settled is by what rule this shall be appraised. The adjustment is usually indorsed on the policy and signed by the underwriters. When the loss is admitted to be *total*, and the policy is a valued one, the insured is entitled to receive the whole sum insured, subject to such deductions as may have been agreed by the policy to be made in case of loss. It is merely in respect of total loss that any difference subsists between an open and a valued policy. Upon the latter the value is admitted, and the insured has only to prove, if the insurance was on goods, that

the goods valued were on board. Upon an open policy, it is necessary to prove, not only that the goods were on board, but also the value of them, which the insurers, provided it does not exceed the sum insured, are bound to pay. But in the case of a *partial* loss, the amount of the loss should be ascertained in both kinds of policy. When a part of the goods insured is saved, and this exceeds the amount of the freight, the practice is to deduct the freight from the salvage, and to estimate the loss by the difference; but when the freight exceeds the salvage, then it is a total loss. If the goods insured are damaged in the whole, or in part, it will be necessary to ascertain the *quantity* of such damage, which is done by taking the value of the goods, in their damaged state, from the prime cost, and the remainder will be the amount of the loss. If several articles be insured for one entire sum, but with a distinct valuation to each, and only one be sent in risk, and if that one be lost, the insured shall recover such a proportion of the sum insured as the value of that article bore to the value of the whole. If the policy has a clause, to be free of average from a particular risk, under *fo* much *per cent.* and a loss occasioned by that risk takes place, the proportion which the loss bears to the cargo must be calculated upon the cargo which was on board when the loss happened, not upon that which was on board at any other time. With respect to the valuation of goods insured, there has been a difference of opinion; some contending for the prime cost, others for the current price at the time of loss; some again insisting on the price at the time and place of shipping the goods, others on the price at the port of discharge. In England, if the policy be an open one, it is an invariable rule to estimate a total loss, not by any supposed price which the goods might have been deemed worth at the time of the loss, or for which they might have been sold, if they had reached the market for which they were destined; but according to the prime cost, that is, the invoice price, and all duties and expences till they are put on board, together with the premium of insurance. The value is never affected by the rise or fall of the market, nor by the course of exchange. A ship is valued at the sum she is worth at the time when she sails on the voyage insured, including the expence of repairs, the value of her furniture, provisions and stores, the money advanced to the sailors, and, in general, every expence of the out-fit, to which is added the premium of insurance. A partial loss upon either ship or goods is that proportion of the prime cost, which is equal to the diminution in value occasioned by the damage. An adjustment, being indorsed on the policy and signed by the underwriters, with a promise to pay in a given time, is *prima facie* evidence against them, and amounts to an admission of all the facts necessary to be proved by the insured to entitle him to recover in an action on the policy. It is like a note of hand, and being proved, the insured has no occasion for further proof. An adjustment, however, may be impeached by shewing that the underwriter was induced to sign it by some fraud or concealment, or by some misconception of the law or fact; but this must be done by evidence, and not by doubts or surmises after the time for payment is come.

If it be inquired, under what circumstances the insured shall be entitled to demand a return of premium, the particular cases are as follow. In general, the premium ought to be returned, when the contract is void *ab initio*; that is, either for want of interest in the insured, or because the insurance is illegal, or on account of fraud on the one side or the other. However, upon a wager-policy the insured can-

not recover back the premium, at least after the risk is run. 19 Geo. II. c. 37. But before the risk is run, and while the contract is executory, the insured may recover back the premium. If the contract be void, as being a re-insurance, within the above cited statute, the insured shall not be intitled to a return of premium. If, under any circumstances, the insurer might, at any time, have been called upon to pay the whole sum insured, the premium is earned, and he shall not be obliged to return any part of it. Although an insurance to protect trading with the enemy is void, yet the insured shall not recover back the premium. In the case of fraud likewise on the part of the insurers, the premium shall be returned. However it has been doubted, whether the insurer be bound to return the premium, in a case where fraud has been committed by the insured. The court of chancery, in two instances, ordered a return of premium where the policies were declared void for fraud committed by the insured. The courts now hold a contrary doctrine. As to the commencement of the risk, the rule in England is, that where the risk has not been begun, whether this be owing to the fault, pleasure, or will of the insured; or to any other cause, the premium shall be returned. But if the insurances be upon a voyage, divisible into several distinct risks, or, which amounts to the same, into several distinct voyages, the premium may be apportioned, according to these several risks; and if one or more of these risks should not have been commenced, the proportion of premium applicable to those parts shall be returned. But if the risk be entire and be once commenced, there shall be no return. If part of the premium is to be returned upon the performance of some stipulation agreed upon between the parties, this shall be returned, though the insurer be obliged to pay a partial loss. As the insurer can never, by his own act, discharge himself from the contract, it seems reasonable, that, where the insured thinks proper to put a stop to the adventure, and prevent the risk from ever commencing, he should make some compensation to the insurer for his trouble and disappointment; it is therefore the general custom in all the maritime countries of Europe, to allow him to retain one-half *per cent.*

With regard to actions on policies of insurance, the sole jurisdiction belongs to the courts of common law; and the proper form of action against private underwriters, is special "Assumpsit;" which see. The two insurance companies, being corporations, can do no act but by deed under their common seals. Their policies of insurance, being under seal, no action of "Assumpsit" will lie upon them, but only debt of covenant. See stat. 6 Geo. I. c. 18, and 8 Geo. I. c. 30. The evidence generally adduced on the part of the plaintiff is reducible to the following heads, *viz.* proof of the contract, payment of the premium, interest of the insured, performance of warranties and loss. For a further detail of these and other particulars, relating to matters of insurance, and the determinations of judges and courts of law in illustration and confirmation of them, see "A Treatise on the Law of Insurance," by Samuel Marshall, serjeant at Law, in 2 vols. Lond. 1802. On this subject, see farther under *BAHRATRY, Insurance Brokers, DEVIATION, POLICY, SALVAGE, UNDERWRITERS, and WARRANTY.* See also *BOTTOMRY and RESPONDIENTIA.*

INSURANCE upon Lives, is a contract by which the insurer, in consideration of a certain premium, either in a gross sum or by annual payments, undertakes to pay the person, for whose benefit the insurance is made, a stipulated sum of money, or an equivalent annuity, upon the death of the person whose life is insured, whenever this shall happen,

if the insurance be for the whole life, or in case this shall happen within a certain period, if the insurance be for a limited time. For the principles on which this kind of insurance is made, and other particulars relating to it, see the article *ASSURANCE.* It is generally a condition or warranty, in insurances upon lives, either inserted in the policy, or contained in a declaration or agreement signed by the insured, that the person whose life is meant to be insured has not any disorder which tends to the shortening of life; that he has, or has not, had the small-pox; and that his age does not exceed so many years; that this declaration shall be the basis of the contract between the insurers and the insured; and that if any untrue averment be contained therein, the contract shall be void, and all money paid on account of the insurance forfeited. As this declaration is to be taken as part of the written contract, amounting to a warranty, it behoves every person who makes an insurance upon a life, to be very circumspect in ascertaining the truth of the allegations which it contains; because upon that the validity of the contract must depend. When there is no warranty, the insurer takes the risk upon himself, whatever may be the state of health of the person whose life is insured, unless there be some fraudulent misrepresentation or concealment.

In order to check the spirit of gaming, which is ready to avail itself of insurance upon lives, it is enacted by stat. 14 Geo. III. c. 48. § 1, that no insurance shall be made by any person or persons, bodies politic or corporate, on the life or lives of any person or persons, or on any other event or events whatever, wherein the person or persons, for whose use or benefit, or on whose account, such policy or policies shall be made, shall have no interest, or by way of gaming or wagering; and that every insurance made contrary to the true intent and meaning of this act, shall be null and void to all intents and purposes whatsoever; and that it shall not be lawful to make any policy or policies on the life or lives of any person or persons, or other event or events; without inserting in such policy or policies the name or names of the person or persons interested therein, or for what use or benefit, or on whose account, such policy is so made or underwrote;—and that in all cases where the insured hath an interest in such life or lives, event or events, no greater sum shall be recovered, or received from the insurer or insurers, than the amount or value of the interest of the insured in such life or lives, or other event or events. This act extends to every species of insurance except marine insurances, which are expressly excepted. The different insurance companies annex to the contract certain conditions or exceptions. For those of the "Royal Exchange Assurance" (see *ASSURANCE*) the same exceptions are adopted by the "Wellminster Society." The "Equitable Assurance," and the "Pelican Life-insurance," adopt the same exceptions, only omitting the word "duelling," even where the party insures his own life. Other societies for insurance on lives, such as the "Rock Insurance Society," &c. have been more recently established, and insurances of this kind are made by some of those societies, which will be noticed in the next article.

The societies which restrict themselves to insurance on lives are the following; *viz.* the "Amicable Society," incorporated by royal charter of queen Anne in 1706, sanctioned by the grant of two subsequent charters in 1730 and in 1790, and further improved under the powers conferred by a new charter in 1807. By virtue of this charter, persons are admitted to insure their own lives, or the lives of others, in which they may have an interest, on the following payments:—

The whole of the annual contributions for every share granted previous to the last charter, and seven eighths of the contributions on shares subsequently granted, are to be divided every year amongst the claimants by deaths which happen in that year: a principle of division, which is calculated, in the general course of things, to raise each claim considerably above 18*l.* which sum at least the corporation engages each share shall produce to the claimant. See ASSURANCE.

The "Society for Equitable Assurances on Lives and Survivorships" was established by deed, enrolled in his majesty's court of king's bench, Westminster. For an account of this society, which has acquired high reputation, under the conduct of its present actuary, William Morgan, esq. see ASSURANCE. The "Westminster Life Insurance Office" was established in 1792. The "Pelican Office" for insurance of lives, granting annuities and endowment of children, was established in the year 1797. The "Rock Life Assurance Company" was instituted in 1806, on a principle different from that of any society hitherto established for the assurance of a sum to the representatives of a person assured. The company consists of a number of proprietors, possessing a capital stock of one million; and each proprietor is under the necessity of assuring a sum on his own life, if accepted

by the directors; or on that of an approved nominee, to the amount of one quarter of the stock in his name. Thus by assuring each other's lives, the proprietors have a mutual interest in the support of the society, and are engaged to each other to take care that no improper life, with their knowledge, be admitted into it. By the mode of assuring property in this society, the representatives of the assured receive a certain sum at his decease, and whatever addition may have been assigned to that sum by the previous resolution of the society, agreeably to its deed of settlement. The persons who assure in this office are not all partners; they are not all responsible for the payment of the sum assured to each individual. The assured are either proprietors or non-proprietors. The proprietors are answerable each to a certain amount; they lay down a certain sum, and form a determinate capital to answer all contingencies, and by thus forming a capital, they are enabled to make a due assignment of the sum to be added at different periods to various policies of assurance. The assured non-proprietors have no share in the risk: they pay down definite premiums, which assure to the representatives the sum assured, and who partake equally with proprietors in the addition which may be made at different periods to each policy. The security for the payment of that sum is the capital stock of the company and the amount of all the premiums, with the interest upon them. Such a security, it is said, may be deemed as a "rock," whence we apprehend the company derives its appellation; for the transfer of shares will produce a continual renovation of policies, which, with the capital of the company, and the amount of annual payments from assurances, will form an increasing fund, adequate to every purpose of profit and security. The character of William Friend, esq. the actuary of this society, as a mathematician, is well known. The "Provident Life Institution" was established in 1806. In the same year was also established the "Philanthropic Annuity Institution;" the object of which is to enable those, who wish to raise an immediate sum of money by the grant of annuities, or to invest money for the purpose of accumulation, to do it on the most advantageous terms fitted to the various circumstances and contingencies of life; and also to provide endowments for children, &c. The investment of money in this institution may be made in three different ways: 1st, by paying a certain sum of money down, to receive an annuity, to commence immediately; 2dly, by paying down a certain sum of money, to receive an annuity, to commence at a future time: and, 3dly, by paying a sum of money at particular periods, to receive back a sum, or an annuity when the investor requires it. The "London Life Association" for the assurance of lives, consists of persons insuring their respective lives for the whole term of life; and the members become, to the amount of their policies, mutual assurers to one another. The society also undertakes every description of assurance on the lives of persons, not members; and it is part of its plan to make endowments, and to grant and purchase annuities, by virtue of an act of parliament of the 47th Geo. III. c. 32. The distinguishing principle of this society is, that the benefits resulting from its transactions shall be enjoyed by the members, during life, so as to render life assurance as easy to the assured, as a due regard to security will admit. The "Royal Exchange Assurance Annuity Company" has been already mentioned under the article ASSURANCE: but in May 1803, the following table of rates was formed;

N. B. The foregoing annuities are receivable in quarterly Payments.

INSURANCES *against Fire*, are founded on a contract, by which the insurer, in consideration of a certain premium, received by him, either in a gross sum, or by annual payments, undertakes to indemnify the insured against all loss or damage which he may sustain in his houses or other buildings, goods, and merchandize, by fire, during a limited period of time. Although the precise time of the introduction of this kind of insurance into England cannot be ascertained, it has certainly been in use here considerably more than a century. Of late years, notwithstanding a very heavy, and we may add impolitic, stamp-duty imposed on these insurances, they have very generally, not to say universally, prevailed in this country: particularly in London, and other cities and large towns. In other countries they have been less general, and more recently introduced. The

fire-office at Paris is said to have been established in 1745. In Holland, though insurance against fire is not altogether unknown, yet few people seek its protection; because they rely on their own caution, and do not chuse to incur the expence of any greater security. It has, indeed, been confidently asserted, by persons well acquainted with the cities both of London and Amsterdam, that after making all fair allowances, there is, upon an average, more property destroyed by fire in the former in one year than in the latter in seven years. Some persons have charged many of the fires that occur in London and its vicinity on insurance: but though negligence and fraud may in some instances deserve encouragement from this establishment, the benefits must be allowed far to overbalance the mischiefs of which it is, directly or indirectly, productive. In London and other parts

INSURANCE.

parts of the kingdom, companies or societies for insurances against fire have been very numerous; and their number has possibly been augmented by the emoluments that accrue to those who establish and conduct them. Some of these are called "Contribution Societies," in which every person insured becomes a member or proprietor, participating in profit and loss. Such are the "Hand in Hand," and the "Welfminster" fire-offices, for the insurance of houses and other buildings; and the "Union" fire-office, for insurance of goods. The other companies insure both houses and goods at their own risk. Of these the principal are the "London" and "Royal-Exchange" Assurance Corporations, the "Sun," the "Phoenix," and the "Britannic" fire-offices.

As to the duties to which this contract is liable, the stat. 37 Geo. III. c. 90. § 23. repeals all the former stamp-duties imposed on policies of insurance against fire; and (by § 24.) imposes on every policy, in lieu thereof, a new duty of *three shillings*, where the sum insured is under 1000*l.*, and of *six shillings* where the sum insured amounts to 1000*l.* or upwards. And by the stat. 44 Geo. III. a duty of *two shillings and sixpence per cent. per annum* is to be levied on property insured against fire. It is much to be regretted, that insurances against fire are often made to a large amount upon property of very small value; this can only be done with a fraudulent view, and a premeditated fire must be the necessary consequence. Such practices require caution in the insurers, ought to be restrained, and when they occur severely punished. If there be several insurances on the same property in different offices, each office should have notice, that the same may be allowed by indorsement on the policy; in order that each office may bear its rateable proportion of any loss that may happen. But unless such notice be given to the office where another insurance is made on the same effects, the insurance made without such notice will be void. In general, the risk commences from the signing of the policy, unless some other time be specified; and it will of course end with the term for which it is made. Insurances against fire are, in general, either annual or for a term of seven years, at an annual premium; and the offices, as an indulgence to the insured, generally allow fifteen days from the expiration of each year for the payment of the premium for the next succeeding year. But the insured has always been considered as being under the protection of the policy till the expiration of the fifteen days, provided the premium were paid within that time. Several offices now hold themselves liable for any loss during the fifteen days that are allowed for the payment of the renewed premium upon annual policies, and others for a longer period; but every policy for a shorter period than a year ceases at six o'clock in the evening of the day that is mentioned in it. A policy of insurance, being a chose in action, is, in strictness, not assignable at law; but it may be assigned in equity. However, the mere assignment of the policy would be of little avail without an assignment of the subject-matter of the insurance also. In the printed proposals of all the offices, it is declared, that, upon the death of an insured, his interest in the policy shall be continued to his representative to whom the property insured belongs, provided that such representative, before any new payment be made, procure his right to be indorsed on the policy at the office. The policies of the Contribution Societies, viz. the "Hand in Hand," "Union," and "Welfminster," may be assigned, without any express permission from the respective offices for that purpose; and it is sufficient if the assignment be brought to the respective offices to be entered. But the other offices give notice,

generally upon the policy, that it shall be of no force if assigned, unless such assignment be allowed by an entry in the books of the office, or indorsed on the policy; and hence it seems to be a settled rule in all the offices, not to allow any transfer of any policy without the consent of the managers. If an assignor of the property insured undertake to get the policy transferred to the assignee, he will be liable to an action for neglecting to do it; even though his undertaking was merely gratuitous. For the proof and recovering of loss, the following article is found in the proposals of several of the offices, importing, "that persons insured sustaining any loss or damage by fire, are forthwith to give notice thereof at the office, and, as soon as possible afterwards, deliver in as particular an account of their loss and damage as the nature of the case will admit of; and make proof of the same by their oath or affirmation, according to the form practised in the said office; and by their books of accounts, or other proper vouchers, as shall be reasonably required; and procure a certificate under the hands of the minister and churchwardens, together with some other reputable inhabitants of the parish not concerned in such loss, importing, that they are well acquainted with the character and circumstances of the person or persons insured, and do know, or verily believe, that he, she, or they, really and by misfortune, without any fraud or evil practice, have sustained by such fire the loss and damage, as his, her, or their loss, to the value therein mentioned. But till such affidavit or certificate of such insured's loss shall be made and produced, the loss-money shall not be payable. And if there appears any fraud or false swearing, such sufferers shall be excluded all benefit by their policies." In the policies of these offices the insurers undertake to pay the loss, not exceeding the sum insured, "according to the exact tenor of their printed proposals," describing their proposals by their respective dates.

Insurances against fire are described in the plans and proposals of the different societies, with little variation, as *common, hazardous, and doubly hazardous*; and they comprehend buildings and goods. Buildings subject to common insurances are those of brick or stone, standing alone, or separated by partition walls, and covered with slate, tile, copper, lead, or iron, with brick chimneys; in which no hazardous trades are carried on, or hazardous goods deposited. Goods are household goods, in private dwellings, merchandize and stock, not hazardous, in brick or stone buildings as above described, and in which no hazardous trades are carried on, nor hazardous goods deposited. *Hazardous* insurances comprehend buildings of timber or plaster, brick and timber, or brick and stone, not having party walls of brick or stone, wherein no hazardous trades are carried on, or hazardous goods deposited, brick or stone buildings in which hazardous trades are carried on, or hazardous goods deposited; also thatched barns and out-houses (having no chimneys, or adjoining to any building having a chimney), containing farmer's stock or implements of husbandry; likewise all shops and warehouses which have German or metal stoves with pipes. Goods subject to the same kind of insurance are the stock and goods of bread-bakers, brewers, vinegar and sweet-makers, printers, hot-pressers and calenderers, carpenters, chemists, coach-makers, colour-men, coopers, hemp and flax-dressers, iron-holders, maithouses, oil leather-dressers, ship and tallow-chandlers, stable-keepers, pawn-brokers, hemp, flax, pitch, tar, turpentine, rosin, tallow, hay, straw, and all manner of fodder, and corn unthraffed, apothecaries' stock; also, oil and spirituous liquors, as merchandize and the stock in timber-yards. *Doubly hazardous* insurances comprehend buildings

INSURANCE.

which are thatched, also timber or plaster buildings, in which hazardous goods are deposited, or hazardous trades carried on; and *goods* or *stock* in thatched dwellings; also salt-petre, working-perfumers, tallow-melters, wax-chandlers, spermaceti candle-makers, and rope-makers in brick and tiled buildings, boat-builders, china, glass, or earthen wares.

The "Hand in Hand Fire-office" was instituted in the year 1696; and its terms are, for *common* insurances, 300*l.* or under, 2*s.* per cent. per annum; for *hazardous* insurances, 300*l.* or under, 3*s.* per cent. per annum; for *doubly hazardous* insurances, 300*l.* or under, 5*s.* per cent. per annum. If insurances are desired for any larger sums than are specified in the table of premiums, a special agreement may be made for the same, and also for particular buildings, goods, &c. not included in the second and third articles above

enumerated. Persons insuring in this office are allowed one year's premium and duty, and must pay the requisite premiums and deposit according to the nature of the risk. They become joint proprietors and members of the society, and are entitled to a proportionate share of the profits.

The "Union Fire-office" was instituted in 1714, for insuring houses and buildings, goods, merchandize, and ships in harbour, in dock, or while building, from loss or damage by fire. The septennial insurances are allowed one year's premium and duty, and become proprietors, partaking of the profits of the society. The annual or short period insurances are completely protected from any loss or damage by fire, or from any call or contribution towards any loss or damage happening to others, by a very ample fund which has been raised for that purpose.

TABLE OF ANNUAL PREMIUMS.

(Exclusive of Government Duty.)

	Common.	Hazardous.	Doubly Hazardous.
On sums not exceeding $\begin{matrix} \text{£.} \\ 3000 \\ \hline 6000 \end{matrix}$	$\begin{matrix} \text{£.} & \text{s.} & \text{d.} \\ 0 & 2 & 0 \\ \hline 0 & 2 & 6 \end{matrix}$ } per cent.	$\begin{matrix} \text{£.} & \text{s.} & \text{d.} \\ 0 & 3 & 0 \\ \hline 0 & 4 & 0 \end{matrix}$ } per cent.	$\begin{matrix} \text{£.} & \text{s.} & \text{d.} \\ 0 & 5 & 0 \\ \hline 0 & 6 & 0 \end{matrix}$ } per cent.
Larger Sums may be insured by special Agreement.			

No charge is made for policies of 300*l.* and upwards. Farming stock may be insured at 2*s.* per cent.. The "Royal Exchange Assurance," of which we have given an account, as far as it is a life-insurance office, under ASSURANCE, insures also from loss or damage by fire.

TABLE OF ANNUAL PREMIUMS.

(Not including Duty.)

Common Assurances.	Hazardous Assurances.	Doubly Hazardous Assurances.
Not exceeding } 2 <i>s.</i> per cent. 300 <i>l.</i>	Not exceeding } 3 <i>s.</i> per cent. 200 <i>l.</i>	Not exceeding } 5 <i>s.</i> per cent. 200 <i>l.</i>
Larger Sums may be assured by special Agreement; and Farming Stock at 2 <i>s.</i> per cent.		

The corporation of the "London Assurance" insures houses and goods from fire, and also insures lives. (See ASSURANCE.) The premiums are as follows:

Common Assurances.	Hazardous Assurances.	Doubly Hazardous.
Sums not exceeding } 2 <i>s.</i> per cent. 10,000 <i>l.</i> — above 10,000 <i>l.</i> 2 <i>s.</i> 6 <i>d.</i>	Sums not exceeding 3000 <i>l.</i> 3 <i>s.</i> 0 <i>d.</i> per cent. Above 3000 <i>l.</i> and not exceeding 5000 <i>l.</i> 3 <i>s.</i> 6 <i>d.</i> Above 5000 <i>l.</i> 4 <i>s.</i> 0 <i>d.</i> 5 <i>s.</i> per cent. Farming Stock, 2 <i>s.</i> with average clause.

INSURANCE.

Persons assuring for seven years, will be allowed one year's premium, and duty; for six years, 10 per cent. on the premium; for five years, 8 per cent.; for four years, 6 per cent.; for three years, 4 per cent.; for two years, 2 per cent.

Premiums of assurance from fire for ships in harbours, building, or repairing, or for cargoes, or for vessels and other craft employed in inland navigation, and goods, &c. laden thereon.

	For one Year.		For six Months.		For three Months.	
	£.	s. d.	s. d.	s. d.	s. d.	per cent.
Sums not exceeding 10,000	10,000	3 0	2 6	2 0	2 0	
Above 10,000	10,000	4 0	3 0	2 6	2 6	

Five per cent. discount allowed on premium. The premium on goods, hazardous or not hazardous, in any of the warehouses or sheds, or on the open wharfs, or in any part of the port of London, within five miles of the Royal Exchange (the West India docks excepted), with the average clause, 5s. per cent.; on goods not hazardous, similarly situated, 3s. per cent. The average clause, so often referred to, is as follows: It is agreed, that if the goods assured shall be of greater value than the sum assured, and the same shall not be

totally consumed, the insurer shall only be liable to pay such a proportion of the loss as the sum assured shall bear to the whole value of the goods at the time of the breaking out of any fire. On sums of 300*l.* and upward, the policy and mark are allowed gratis.

The "Sun Fire-office" was established in the year 1710, and insures against loss or damage by fire, upon the following terms.

Table of Rates.

Annual Premiums to be paid for Insurances.		
Sums not exceeding 10,000	Common	2s. per Cent. } Sums above may be insured by Special Agreement.
6,000	Hazardous	3s. Ditto. }
3,000	Doubly Hazardous	5s. Ditto. }
<p>Farming Stock, on any Part of the Farm, insured under General Policies, without the Average-Clause, at 2s. per Cent.</p> <p>N. B. Any barn, or other out-building, and the farming stock therein, may be insured under one sum:—premium 3s.</p>		

Persons may insure for more years than one, not exceeding seven; and, in such case, there will be an abatement of six-pence in the pound per annum, on the premiums agreed for, for every year except the first: In a common insurance of 1000*l.* for seven years, the premium to be paid, by the table, will be seven pounds, in which the six-pence in the pound per annum is to be deducted for the last six years, that is, three shillings and six-pence per annum, which amounts to one pound one shilling, and reduces the sum to be paid to five pounds nineteen shillings, and the same in proportion for any other sum or number of years; and persons insuring can never be subject to any calls or contributions to make good losses.

The "Sun Life Assurance Society" grants annuities, makes assurances on lives and survivors, and provides for the endowment of children; on the terms, and in the manner of other offices for insuring lives.

The "Westminster Fire-office" was established in the year 1717. The terms are, in the first class of common insurances, for any sum not exceeding 10,000*l.*, 2s. per cent. per annum; in the second class of hazardous insurances, for any sum not exceeding 6000*l.*, 3s. per cent. per annum; in the third class of doubly hazardous insurances, for any sum not exceeding 3000*l.*, 5s. per cent. per annum. The fourth class includes insurances by special agreement. Every septennial insurer becomes a member of the society, and shall be allowed one year's premium; he will also have a propor-

tionable share of the profits, and be liable to contribute to losses, but not to exceed 10s. per cent. on the first; 15s. on the second; and 20s. on the third class of insurances.

The "Phœnix Fire-office" was established in 1782; and its premiums are for common insurances, for sums not exceeding 3000*l.*, 2s. per cent. per annum; for hazardous insurances, for similar sums, 3s. per cent. per annum; and for double hazardous insurances, the sums being the same, 5s. per cent. per annum. Hay and corn in barns or stacks, and other farming stock, may be insured at 2s. per cent. per annum. Ships, barges, and all kinds of water-craft; also, cargo on board may be insured at 3s. per cent. per annum, for sums not exceeding 3000*l.* Insurances on larger sums, and on goods, &c. particularly hazardous, may be effected by special agreement. Persons chusing to insure for seven years, will be charged for six years only; and for any number of years, more or less than seven, will be allowed a reasonable discount both on the premium and the insurance tax.

"The Globe Insurance" was established in 1803, and comprehends the granting insurances against loss or damage by fire, on lives and survivorships, the endowment of children, and immediate, deferred, and progressive annuities. This office makes common insurances at an annual premium of 2s. per cent.; hazardous insurances at 3s. per cent.; and doubly hazardous insurances at the annual premium of 5s. per cent. Farming stock is insured at 2s. per cent.; and this may be insured for three, six, or nine calendar months at certain stipulated rates.

INSURANCE.

rates. Policies are allowed in all cases where the annual premium amounts to *6s.* Insurances for seven years are charged only six years premiums; and a considerable reduction is made on country insurance. The insurances on lives and on survivorship are made at the rates of other offices; nor does the company require entrance money, or admission fees, from persons effecting life insurances. The capital of the company is stated to be one million sterling, the whole of which has been invested in government or real securities, and it is stipulated that no members of the company shall be liable to pay any sum beyond the amount of his subscription or share in the said capital of one million.

The "Imperial Fire-office" was established in 1803. Its capital, of one million two hundred thousand pounds sterling, has been subscribed in shares of 500*l.* each; and no member is a subscriber for more than 5000*l.* Each member has deposited 10*l.* per cent. on the amount of his subscription, amounting in the whole to 120,000*l.* which sum is invested, and to accumulate for five years, without dividends to the members of the company. In case the current premiums on insurances, with the deposit of 120,000*l.* and all its accumulations, shall prove inadequate to satisfy the losses which may arise, the members of the company are, from time to time, to be called upon for farther sums, in proportion to their subscriptions, and even to their full extent, if necessary. If the current premiums shall be more than sufficient to answer losses, and the expenses of management, the surplus is, from time to time, to be invested; but such profits are in no event to be divided, but are to be applied for augmentation of the capital stock; and the dividends and interest of the profits only are to be divided, after the expiration of five years. The premium in common insurances is 2*l.* per cent. per annum for 3000*l.* and under; in hazardous insurances, 3*l.* per cent. per annum, for 1000*l.* or under; and in double hazardous insurances, 5*l.* per cent. per annum, for 1000*l.* or under. Persons desiring to insure for seven years will be charged for six years only; and for any number of years, less than seven, will be allowed a reasonable discount, both on the premium and duty.

The "Albion Fire and Life Insurance Company" was instituted in the year 1805; and is stated to possess a capital of one million sterling. Its insurance against loss or damage by fire is in the first class of common insurances 2*l.* per cent. per annum, to the amount of 3000*l.*; in the second class of hazardous insurances, 3*l.* per cent. annually; and in the third class of doubly hazardous insurances, 5*l.* per cent. per annum both to the same amount. Insurances are taken to a larger amount than that above stated; and policies are granted at suitable premiums for less than 12 months. On insurances for seven years, or for any greater or less term, exceeding one year, a considerable allowance is made, both on the premium and duty. The following abatements are made on the premiums of fire insurances of the first class, out of London; viz. 25 per cent. per annum on policies for single years; 30 per cent. on policies for three years; 35 per cent. on policies for five years; 40 per cent. on policies for seven years; and in the like proportion for policies for other periods. Insurances on lives are conducted on the same terms with those of other offices of a similar kind. No admission fee is charged on life insurance.

The "British Fire Office" insures houses and goods in the three classes above specified at 2*l.*, 3*l.*, and 5*l.* per cent. per annum respectively.

The "Hope Fire and Life Insurance Company" was instituted in 1807. Its annual rates of insurance on the three classes above recited are, 2*l.* per cent., 3*l.* per cent., and 5*l.* per cent. on sums not exceeding 10,000*l.*, 6000*l.*, and 3000*l.*,

respectively. Farming stock is insured at 2*l.* per cent. on a sum not exceeding 10,000*l.* Special risks may be insured on terms corresponding to them. The following abatements are made upon country assurances, viz. 10 per cent. on policies for a single year; 15 for three years; 20 for five years; 25 for seven years. Every person not being a proprietor of a share or shares in the company, and who shall insure or procure to be insured, property to the amount of 1000*l.*, shall, upon the payment of 5*l.* beyond the premium of insurance, be entitled, out of the profits (arising from fire insurance only) to such interest or dividend as may arise and become payable on one 50*l.* share in the capital stock of the company; and so on in like manner for every additional 1000*l.* so insured; and such interest or dividend shall continue to be paid to such person or persons, or to his or their legal representative or representatives, during such period as such insurances shall continue to be effected, and in the event of the same being discontinued, all dividends and interest, which may be then due or payable, together with the sum of 5*l.* so paid for every 1000*l.* so insured as aforesaid, shall be forfeited and become the property of the company. Life insurances are effected by this company on the same terms with those of other offices. Persons not being proprietors, who insure, or procure to be insured, 500*l.* upon their own lives, or lives of others, will, upon the payment of ten shillings per cent. (on the admission of the party) beyond the premium paid for the insurance, be entitled, out of the profits of the life fund, to such interest or dividend as may be paid on a 50*l.* share to the several proprietors thereof, and so on in like manner for every 500*l.* so insured; but in no case whatever are they to be responsible for any claims which the life fund may be called upon to pay, the capital of the company being of a sufficient magnitude for that purpose.

The "Eagle Insurance Company" was instituted in 1807, for fire and life insurance, and for granting annuities. Its capital is stated at two millions sterling. The annual rates of insurance against fire are as follows:

Annual Rates of Insurance.

	s.	d.	
Common Insurance, not exceeding 10,000 <i>l.</i>	2	0	per cent.
Above	2	6	
Hazardous ditto, not exceeding 6000 <i>l.</i>	3	0	
Ditto, above	4	0	
Doubly hazardous, not exceeding 3000 <i>l.</i>	5	0	
Ditto, above 3000 <i>l.</i> and not exceeding 4000 <i>l.</i>	6	0	
Ditto, above 4000 <i>l.</i> and not exceeding 5000 <i>l.</i>	7	6	

Farming Stock.

	s.	d.	
Without average clause, for three months	1	3	per cent.
for six months	1	6	
for any longer period, not exceeding 12 months	2	0	

The building and stock of sugar refiners, sugar grinders, sea biscuit bakers, distillers, musical instrument makers, cotton-spinners, calico printers, flax dressers, and other extraordinary risks, may be insured by special agreement.

Policies for short periods, or less than a year, may be effected at considerably reduced premiums, and will pay only a proportionable part of the duty. The insurance on lives is conducted as in other offices.

The "County Fire Office" was established in 1807, for the express benefit of country residents. The distinguishing principles

INSURANCE.

principles of this institution are, that its business consists of a selection of the best risks; that the persons insured become members; that all the members share the profits equally, according to the sums which they respectively contribute during seven years (whether their policies be taken out originally for seven years, or be renewed annually), and with the important advantage of not being liable to make good the losses of others, as a surplus capital of 400,000*l.* has been provided to meet any excess of losses that may occur. In common insurances of 5000*l.* and under, in one risk, the annual premium is 2*s.* per cent.; in hazardous insurances, of 3000*l.* and under, in one risk, 3*s.* per cent., above 3000*l.* and under 5000*l.*, 4*s.* per cent.; in doubly hazardous insurances, 3000*l.* and under, in one risk, 5*s.* per cent., above 3000*l.* and under 5000*l.*, 7*s.* per cent. Larger insurances, according to the above description of risks, may be made by special agreement: and other insurances against more hazardous risks may be settled in the same manner. Hay, corn, and other agricultural stock, of whatever description, on any part of a farm, may be insured in one general sum, at the

reduced rate of 2*s.* per cent. without the average clause. Persons insuring for seven years will be charged only for six; and for any number of years more or less than seven, discount will be allowed both on the premium and duty. All the offices insure against fire by lightning. It will be remembered, that a duty of 2*s.* 6*d.* per cent. per annum, on all property insured from fire, is payable to government, under an act of the 44th of George III.

The "Atlas Assurance Company" was established in 1808, and undertakes to assure the proprietors of buildings, merchandize, furniture, farming stock, goods and effects, and also of craft and shipping upon canals and in harbour, against loss by fire; and also grant assurance upon lives. The capital is stated at one million two hundred thousand pounds, of which the sum of 120,000*l.* invested in government or real securities, will be applicable to the immediate purposes of the institution; and the remainder guaranteed under a deed of settlement by a numerous and respectable proprietary.

Rates of Assurance per Annum.

Risks.	Quality.	Per Cent.		On Sums not exceeding—					
		<i>s.</i>	<i>d.</i>	<i>£.</i>					
First	Not Hazardous	2	0	}	5000				
Second	Hazardous	3	0						
Third	Doubly Hazardous	5	0			}	3000		
Fourth	Farming Stock	2	0					}	500
Fifth	Risks, to which none of the above rates will apply.—These may be assured by Special Agreement, on Terms as moderate as the nature of them will permit.								

N. B. An additional premium of Sixpence per cent. will be required on buildings or goods within the Water-Side District, for extra risk.

No charge is made for policies or indorsements on them: and for the encouragement of persons making assurance for seven years by one payment, a deduction of one-seventh part of the premium and duty will be made; and if at the end

of that period a further assurance of seven years be effected on the same property, a deduction of one-fifth part of the premium, and so on for succeeding years. The terms of life-assurances are much the same as those of other offices.

A Table, exhibiting the Amount of the Duty on Insurances for the Year 1810.

INTACTÆ, right lines to which curves do continually approach, and yet can never meet with them; more usually called *asymptotes*.

INTAGLIOS, precious stones, having the heads of great men, inscriptions, and the like, engraven on them; such as we frequently fee set in rings, seals, &c.

IN-TAKER, a name anciently given to certain banditti, or free-booters, who inhabited part of the North of England, and made frequent incursions into the very middle of Scotland; plundering the inhabitants wherever they came.

Those who made the expeditions, were called *out-parters*; and those who were left behind to receive the booty, *in-takers*. 9 Hen. V. c. 7.

INTAVOLARE, *Ital.* to write music for the lute and guitar in tablature, instead of musical characters. See **TAB-LATURE** and **TIME-TABLE**.

INTAWA, in *Geography*, a town of Hindoostan, in Bundelcund; 15 miles E. of Pannah.

INTEGERS, in *Arithmetic*, denote whole numbers; in contradistinction to fractions.

Integers may be defined to be, numbers which refer to unity, as a whole to a part.

INTEGRAL, or **INTEGRANT**, is applied by the schoolmen to those parts which are necessary to the integrity of a whole. In which sense they stand contradistinguished from *essential* parts.

Thus the arms, legs, &c. are integral parts; body and soul, essential parts of a man.

INTEGRAL Calculus, in the *New Analysis*, is the counter part to the differential calculus.

This last has been completely explained by the marquis De l'Hospital; but the other still remains imperfect, having been yet but little cultivated.

The integral calculus of Leibnitz, and other foreigners, answers to what the English call *inverse method of fluxions*. See **FLUXIONS**, and **CALCULUS**.

INTEGRANT PARTS, in *Philosophy*, the similar parts of a body, or parts of the same nature with the whole; as filings of iron are the integrant parts of iron, and have the same nature and properties with the bar they were filed off from. The chemists distinguish, in their resolutions of bodies, between the dividing and resolving them into integrant parts like these, and what they call constituent parts; that is, dissimilar parts, or the principles of the bodies they work upon. Thus when crude mercury is dissolved in aquafortis, though held imperceptibly in the menstruum; yet when that menstruum is diluted with water, and a copper-plate is suspended in it, the menstruum leaves the mercury, to work upon the copper, and the mercury subfides unaltered and in its own natural form; the mercury, therefore, in this operation, was only divided into its integrant parts, or small parcels of the same nature and properties of the whole; but when artificial cinnabar is resolved or divided into crude mercury and sulphur, neither of these are of the same nature and properties with the cinnabar, and are not its integrant but its constituent parts. This therefore is the dividing a body into its constituent parts or principles.

INTEGRITY of the *Action*. See **ACTION**.

INTEGRUM FOLIUM, among *Botanists*. See **LEAF**.

INTEGRUM, in *resistitio*. See **RESTITUTION**.

INTEGUMENTS, in *Anatomy*, the coverings of the body; the word is generally employed with the epithet *common*, as they are of the same nature and number in all parts of the frame. They consist of the cuticle or epidermis, with its appendages the nails, of the rete mucosum, and of the true skin, cutis, or dermis. The hair in its

nature seems to resemble the cuticle; but it grows from the cutis. To these three layers a fourth is sometimes added, under the name of the *adiposus membrana*. In truth, the skin is always connected to the subjacent organs by cellular tissue, the interstices of which in most cases contain fat, but not invariably so. This connecting stratum belongs entirely to the cellular organ. See **CELLULAR Substance**.

To the technical expression of common integuments, the word *skin* corresponds in common language; but this term is often used by anatomists to denote the cutis, in opposition to the cuticula.

The three parts composing the integuments of the body are so different in their organization and functions, that we cannot approve the common arrangement, by which they are all considered together as forming one organic system. We prefer the method of Bichat, who describes the cutis, with the mucous layer on its surface, under the name of the *dermoid system*; the cuticle with the nails under that of *epidermoid system*; and the hairs under that of *hairy system* (*systeme pileux*). We shall employ this division, and derive our account of the subject chiefly from the *Anatomic Generale* of that writer.

Dermoid System.—The surface of the body is covered in all animals by a more or less dense membrane, generally proportioned in its thickness to the volume of the body, and serving the purpose of protecting the subjacent organs, of separating a considerable portion of the residue of nutrition and digestion, and establishing the relations between us and surrounding objects. In man it is the sensitive limit of his frame, placed at the extremity of his sentient powers, incessantly exposed to external impulses, thus giving rise to the relations of his animal life, and connecting his existence to that of external objects. This covering is the skin or cutis.

Being every where proportioned to the external parts over which it is applied, it follows their chief inequalities, rendering the large projections very sensible, but concealing a great number of the smaller; hence the different appearance of the body in its entire and flayed states. It is continuous throughout, and reflected at the different openings into the interior of the body, giving origin to the mucous system. The limits of the two systems are constantly marked by a reddish line, the mucous being within, and the dermoid on the outside of that boundary. The demarcation, however, is not so decided in the organization as in the colour; they appear to be insensibly blended. The dermoid system becomes thinner in the neighbourhood of these openings, particularly about the face. At their commencement the mucous organ borrows more or less of the characters of the dermoid.

The external surface of the dermoid system is every where contiguous to the epidermis, and is remarkable on account of the hairs implanted in it, of the oily matter which habitually covers it, of the sweat which is deposited on it, and of the sense of touch residing in it. We shall disregard these points at present, and confine ourselves to the consideration of the external forms of the system.

Various kinds of folds are seen on the external surface.

1. Some depend on certain superficial muscles, which, adhering closely to the dermis, and almost consolidated to its substance, throw it into wrinkles when they contract. Such are the wrinkles of the forehead produced by the epicranium; the radiated folds round the eyelids formed by the orbicularis; those of the cheeks by the zygomatici and levator a guli oris; those round the mouth when the lips are contracted by the orbicularis oris, &c. These folds arise from the circumstance that the skin cannot contract

INTEGUMENTS.

Organization of the Dermoid System.

as the muscles do; and they are of the same nature with what we observe in mucous surfaces, particularly in the stomach, when the contiguous muscular plane is contracted. Hence their direction is always perpendicular to that of the subjacent muscles, whose fibres they cut at right angles. As the motions of these parts in the human countenance are much influenced by the passions, the wrinkles and irregularities in the face are highly important in a physiognomical point of view. The repeated actions of particular muscles, under the habitual impression of particular passions, produce permanent lines, which give the character of the individual.

2. Other wrinkles arise from the motions of parts, but not from those of the subjacent muscles: such are those of the palm and sole. Here there is no sub-cutaneous muscle adhering to the skin, except the palmaris brevis, which has no share in producing the folds, where the skin is habitually modified by the flexion of the organ. To this class belong the impressions at the articulations of the phalanges. In the palm there are three principal ones: at the basis of the thumb, produced by the motion of opposition of that organ, at the front of the palm, by the flexion of the fingers, and in the middle of the palm. The cutis forms folds in these depressed lines when the palm is rendered hollow. Numerous other small folds, corresponding to less marked and frequent motions, cut the former at various angles.

In the back of the foot and hand we observe numerous wrinkles at each articulation of the phalanges, when they are extended: they disappear on flexion, and arise from the skin being looser and more copious in these parts to accommodate the motions. There are analogous folds at the joints of the articulations, but they are less strongly marked, because the skin is less adherent to the neighbouring organs. Over the whole trunk, on the arm and fore-arm, the leg and thigh, no depressions are observed except those produced by muscular prominences.

3. A third kind of wrinkles, or rather of cutaneous impressions, which are very inconsiderable, occurs particularly in the sole and palm, where they are easily distinguished from the foregoing. They indicate the rows of papillæ: and nothing of the kind occurs on the surface of the trunk.

4. Lastly, there are the wrinkles of old age, the nature of which is quite different. When the sub-cutaneous fat has begun to disappear, the skin is too large for the parts which it covers: it loses its contractility by age, and cannot therefore accommodate itself to the altered bulk of parts. Thus, where there was moist fat, as in the face, the wrinkles are most strongly marked. When young persons are suddenly emaciated, the skin contracts, and no wrinkles ensue.

The internal surface of the skin corresponds every where to the cellular tissue, which is loose on the trunk, the thighs, arms, &c. and more dense on the cranium, hand, &c. In most animals, a muscular plane, named panniculus carnosus, and analogous in its form to that which is every where connected to the mucous membranes in man, separates the skin from the other organs, and imparts to it various motions. Traces of such a structure occur in a few instances in man, as in the latissimus colli, the epicranii, and the muscles of the face.

The cellular tissue connects the cutis to muscles almost universally in the trunk; but it has nothing to do with the motions of these muscles, and receives from them no sensible influence. It is separated from the muscles in the limbs by aponeuroses. Many vessels pursue their course under it: large veins may be observed through its substance; numerous arterial ramifications are distributed on its surface; and nerves are found among these.

1. *Proper Tissue of this System.*—This comprehends, 1st, the corion; 2dly, the rete mucosum; and, 3dly, the papillæ or villi. The corion is the essential part, which determines the thickness and form of the skin: the rete mucosum is not very distinct from it; and the papillæ manifestly grow out of it.

The corion is always white in the human subject. Its thickness varies considerably. In the head it possesses opposite characters on the cranium and the face: in the former it is very thick and dense in its texture, in consequence of the numerous hairs which traverse it: in the latter it is every where thin and delicate, but more particularly in the eyelids and lips. On the posterior part of the trunk, and especially along the back, its thickness is nearly double that which it has in front, where it is nearly uniform in the neck, chest, and abdomen. We must except, however, the penis, scrotum, labia, and breasts, where its texture is much thinner. The corion is nearly of equal thickness in the shoulder, arm, and fore-arm; in the hand its thickness is rather increased, and more so in the palm than on the back. It is generally much thicker on the thigh and leg, where there are more bulky muscles than in the arm and fore-arm. It grows thicker in the foot, but less so in the dorsal than in the plantar region, which is the thickest part of the system. The relation of its functions to the various degrees of thickness observed in the hand, foot, and cranium, may be easily understood; but in other parts we do not clearly see the reason of these differences.

It is generally thinner in women than in men, so as to present a sensible difference when the two are contrasted in any region of the body.

In order to examine the interior structure of the corion, it should be carefully separated from the cellular and adipous tissue, to which the inner surface adheres more or less closely: we shall then find that surface differently disposed in the different regions.

1. In the sole and palm we see an infinite number of whitish fibres, thinning like those of an aponeurotic nature, detached from the inner surface of the skin, decussating each other in every direction, leaving, particularly towards the heel, numerous areolæ of different sizes filled with fat, and gradually less in the sub-cutaneous tissue. Hence there is not the same mobility of the skin over the covered parts, on these surfaces, as in most other situations; an arrangement well suited to the functions of prehension and support belonging to these parts.

2. The cutis of other parts of the body has these fibres much less distinct, not interwoven with the cellular tissue, and separated by smaller areolæ: hence it is much looser, and more easily dissected from the subjacent parts. The areolæ represent a vast number of openings placed irregularly by the side of each other, and lodging small masses of fat: when these are carefully removed very sensible vacuities are left. The fibres, which form them, are sufficiently close to give the appearance of an uniform structure perforated by numerous apertures. These areolæ are very favourable to the action of the tanning principle, which is introduced through them to the corion much more effectually than it can penetrate on the opposite side. Bichat ascertained this point by a direct experiment on the human skin. Chaptal has observed that the epidermis is a real obstacle to the action of tanning, and that its removal, with that of the hair, is an essential preliminary for this reason: but that the hide, even when thus prepared, is affected much more easily on the inner than on the outer side.

INTEGUMENTS.

3. On the back of the hand and foot, as well as on the forehead, the corion does not exhibit these numerous openings on its inner surface; it is smooth and whitish, particularly after being macerated a little: the same observation may be made concerning that of the scrotum, prepuce, and labia. Its tissue is more compact, and exhibits no intervals; so that although it is thinner than on the limbs and trunk, it contains nearly as much substance. In that, which corresponds to the hair and beard, we observe only the openings necessary for the transmissibility of those parts.

The three great modifications in the organization of the skin, which we have just described, are merely differences of form, and not in the essential nature of the organ. The areolæ may be seen in all parts, where they exist at all, by means of maceration, which is a very good method of examining the structure of the skin. Immersion in water softens the skin by separating the fibres of its corion, and rendering their intervals more distinct; we then find that the areolæ are not confined to the internal surface, but are prolonged into its substance, which is penetrated by them in its whole thickness. These areolæ do not terminate in cul-de-sacs towards the external surface, but they open on that surface by numerous holes very apparent in skin, which has been macerated for a month or two. The epidermis must be removed in order to render them sensible: they penetrate the skin obliquely, and admit in some parts and some subjects the introduction of a pin's head. They are simple communications from the interior to the exterior for the passage of hairs, exhalants, and absorbents, as they come to the surface; thus the subjacent areolæ are merely cells containing the blood-vessels, and the tissue of the skin altogether is a true cellular net-work, of which the interstices are very distinct on the inside, but less obvious externally. Thus the corion constitutes the basis or skeleton of the cutaneous organ, lodging in its areolæ all the other parts of the organ, and giving to them their proper form.

Bichat considers that the areolar tissue, which composes the corion of the skin, has much analogy with that of the fibrous system. Its density and resistance are nearly the same in the heel: it becomes yellowish and transparent by boiling; it resists maceration for a long time; and it receives in some situations the insertion of muscular fibres. Yet the sensibility and the diseases of the two systems differ altogether.

The acute sensibility of this organ does not reside in the areolar tissue of its inner surface, but in the part containing the papillæ. And we find that the same part is the seat of most cutaneous eruptions. The external surface only is coloured by the blood in erysipelas; and hence slight pressure, by driving this fluid into the deeper vessels, removes the red colour. In measles, scarlet-fever, &c. the redness is also superficial. Injections occasion much greater redness of the external than of the internal surface; as the arterial trunks are found in the latter, and the numerous exhalants in the former. These considerations prove clearly that the cellular tissue of the skin has much less vital activity than its outer surface; that this tissue is foreign to almost all the great phenomena occurring in the skin, particularly those of sensation and circulation, which take place in the papillæ and the reticular body. Its functions, like those of the fibrous system, suppose it almost always in a passive state, as they consist merely in shielding the body, and protecting it against external agents. Its properties are well suited to this office of a general protecting medium. Very large weights are supported by slender strips of skin, and dragging in any direction tears them with great difficulty. Yet this resistance

is still much less than when the corion has been submitted to the action of the tanning principle. After such preparation it offers the strongest connecting medium which we have in the arts: no other tissue in the animal economy, except the fibrous, unites in so remarkable a degree pliability and resistance.

Haller, who regarded cellular substance as the principal component part of most organs of the human body, and particularly as forming the basis of membranes, describes the cutis as being made up of this tissue in a condensed form. "Its structure," says he, "is on the whole the same as that of membranes; viz. made of short, intricate, and closely-adhering threads and laminae. Its external surface is dense; the internal is gradually resolved into the cellular texture, so that there are no accurate limits between the two parts. Under maceration it swells and becomes loosened, and separates into its component laminae and fibres, both in man and animals." Elements Physiolog. t. v. p. 3.

The *rete muc. firm.* or reticular body of the skin, is so called from its tupeped perforations by the papillæ and the hairs, and because it appears of a soft mucous nature. It was first noticed by Malpighi, after whom it is sometimes named *rete Malpighii*. The colour of the surface of the body seems to reside entirely in this membrane: Riolan said that the cause of the black colour in the negro is in the epidermis, and does not go so deep as the true skin. Malpighi, by shewing the distinction between the cuticle and *rete mucosum*, demonstrated the true seat of the colour of the body. "Ex quo," says he, "deduco non incongruam forte nigredinis Æthiopicum causam: certum enim ipsi cutem albam esse sicuti et cuticulam, unde tota nigredo a subjecto mucoso et reticulari corpore ortum trahit."

The *rete mucosum* in the negro is a thin black layer, about as thick as the cuticle itself. Putrefaction easily detaches it with the cuticle from the cutis; but it can hardly be separated from the former. It dissolves in water, and communicates a turbid cloud to it, like that produced by the pigmentum nigrum. Mr. Cruikshank describes it as being "double, and consisting of a grey transparent membrane, and of a black web, very much resembling the nigrum pigmentum of the eye." The demonstration of this reticular body is much less easy in the white races than in the negro; and indeed very little seems to be known concerning its anatomy in the former. "Most authors," says Bichat, "represent the *rete mucosum* as a mucous stratum interposed between the cutis and epidermis, and pierced by a large number of openings for the passage of papillæ: but I do not understand how this can be demonstrated on detaching the cuticle, if it be fluid according to the usual description. I have employed, for discovering it, several means, none of which has succeeded. So closely does the cuticle adhere to the cutis, that they cannot be separated without injuring one or the other in the recent state. Yet, if we succeed in an attempt of this kind, there is no appearance of mucus on the corion. After a longitudinal section, particularly in the foot, where the epidermis is very thick, the line of distinction between it and the corion is very manifest: but nothing escapes from between them. When the cuticle has been removed, after boiling the skin, nothing remains on either of the surfaces. Maceration and putrefaction, but particularly the latter, produce a kind of viscid covering on the skin, very obvious when the epidermis is detached: but this is produced by decomposition, and nothing of the kind is seen under ordinary circumstances. I believe, from all these considerations, that there is no substance deposited by the vessels on the surface of the cutis, and forming an exterior covering in the sense in which Malpighi has represented the matter.

matter. I think we should understand, by the reticular body, an inter-texture of extremely fine vessels, the trunks of which, already very minute, after passing through the numerous perforations of the corion, are ramified on its surface, and contain different kinds of fluids. The existence of this vascular net-work is placed out of all doubt by minute injections, which entirely change the colour of the skin on the outside, without altering it much internally. This is the principal feat of the various eruptive disorders, most of which are altogether foreign to the corion.

"We may then conceive the reticular body as a general capillary system, surrounding the cutaneous organ, and forming, with the papillæ, a stratum intermedium to the corion and epidermis. In the white part of the human race this system contains only white fluids; in the negro they are black, and of various tints in the other varieties of our species. The enumeration of the different shades of this organ, and the consideration of the causes of these varieties, belong to the natural history of man. Hitherto we have very few data concerning this substance: it does not seem to circulate in the part. We see that the negro's skin is black, and we know very little more. The rete sometimes adheres to the cutis, but generally to the cuticle, when they are separated after maceration. It is manifestly foreign to both, since they have the same colour in the dark as the white races."

It seems really to be a matter of doubt, whether in the white races there be any colouring-matter in the exterior capillary system analogous to the black substance of the negro, or whether the colour of their surface arise merely from that of the cutis and cuticle. That there is some colouring-matter is rendered probable by the singular anomaly exhibited in the *albinos*; which see. We can demonstrate in that case the absence of the pigmentum nigrum of the eye, and we see clearly the deficiency of colour in the hair. The peculiar dead white of the skin is referred, by analogy, to the want of the colouring principle in that organ. There is generally a connection between the colour of the skin, hair, and eyes, which is remarkably evinced in this instance. A dark complexion is accompanied with black hair and dark eyes; and the light irides, as the blue and grey, occur in individuals with red, flaxen, or other light shades of the hair and light skin. All these circumstances lead us to conclude that the skin, hair, and eyes have their colour dependent on some peculiar matter, the tint of which follows a general law in all these parts.

Even in the white races certain portions of the skin sometimes exhibit a dark colour. The areola round the nipple becomes black or dark brown in women who are somewhat advanced in pregnancy, and affords a very sure mark that they are pregnant. Haller says that he saw the skin of the pubes in a woman approaching nearly to that of the negro in blackness; and Albinus mentions a similar circumstance in a man.

The colour of the skin is transmitted to the offspring, and is surprisingly altered by intermarriages of the different races. Where a black and a white individual copulate, the offspring has the middle tint between those of its parents. If the child of a black man should intermarry with a white person, and their child with another white individual, and so on, the offspring will be white in the fourth generation; or *vice versa*. But the detailed consideration of this subject belongs, more properly, to natural history.

The colour of the cutaneous organ in the white races of the human species is much modified by accidental circumstances. Exposure to the sun's rays produces various shades of a reddish-brown colour, which effect is commonly

called tanning: this alteration is very rapidly produced by going much on the water, in consequence of the reflection of the light from its surface. That this is the consequence of the cause just assigned, and that the effect is not produced by heat, is rendered obvious by the difference of colour in the face and hands, and on those parts of the body which are habitually covered: also by the brown tint of the face produced by a summer's sun, which offers a remarkable contrast to that of the forehead, where it is protected by the hat. Our clothes do not prevent the action of heat upon the skin, but will intercept the luminous rays. The pale and fallow tints of the inhabitants of large towns, compared to the florid countenances of country people, arise from the same cause. Men are blanched like plants when shut out from the influence of the sun. Tanning takes place much more quickly in individuals of light complexion, than in those of an opposite character. The effect in all cases is temporary, and goes off when the cause no longer acts. It is produced in a greater and more permanent degree in white individuals who move into warm climates: but neither here nor in any other instance is it transmitted to the offspring. Physiologists have chosen to represent this as a change occurring in the rete mucosum; on what authority we do not know. The light brown spots, called freckles, which occur about the head and neck when exposed to sun and air, seem to be of the same nature with the tanning. The colours impressed on the skin in the operation of tattooing, reside in the cutis, and consequently remain when the cuticle and rete mucosum have been destroyed by maceration. These colours are permanent: they remain through life, and the marks can only be destroyed by removing the skin which contains them; a circumstance which is hardly reconcilable to our notions of the constant changes of decomposition and composition in all parts of the frame.

Mr. Cruikshank describes a vascular membrane as existing between the rete mucosum and cutis; and apparently it is the same as the vascular net-work of Bichat. He injected this in the skin of persons who had died of small-pox; and was led to investigate the matter from a conversation with a gentleman who conceived that he had injected vessels in the rete mucosum. He macerated in putrid water, during the summer, portions of small-pox skin, which had been kept for some time in spirits. "Cuticle and rete mucosum were already turned down; and upon the eighth or ninth day I found I could now separate a vascular membrane from the cutis, in which were also situated the injected small-pox pustules. These last consisted of circles of long-floating villi at the circumference, but of a white un.injected substance in the centre. This central part Mr. Hunter had previously said was a slough formed by the irritation of the viruliferous matter. The surface of the skin, from whence this membrane was separated, was elegantly porous. The pores now appeared exceedingly more numerous, and this surface of the skin was still tough and shining. I macerated the same skin for four or five days more, and separated another membrane, more delicate than the former, but also vascular. The former I easily preserved; the latter, attracted by the instrument that separated it, or unable to bear the agitation of the water or spirits in which it was separated, constantly broke down. But the corresponding surface of the skin was still tough and shining; the pores were now much larger and more distinct than before, and convinced me that the appearance was natural, and that the skin had sustained no real injury in the process." Experiments on the insensible Perspiration of the Human Body, &c. p. 38.

It has generally been stated that the rete mucosum is not regenerated when it has been destroyed in ulcers; and conse-

quently that the cicatrices of blacks are always white. We believe that this point is not clearly proved.

Whatever opinion we may form concerning the different strata described above, as intervening between the cuticle and cutis, whether we regard them as distinct membranes, or as portions detached by art from the cutis, they are of importance, as containing an extensive distribution of capillary vessels. Independently of the colouring matter, these vessels seem ordinarily to be filled with white fluids; the exhaling pores, which furnish the matter of perspiration, arise from them, and the same vascular network is the seat of erysipelas, and of all the cutaneous eruptions which do not affect the corion.

"The blood," says Bichat, "does not penetrate this capillary system in the ordinary state; but numerous causes will lead to its being suddenly distended. Rub the skin a little roughly, and it is instantly reddened. Irritate it mechanically or chemically, its sensibility is immediately awakened, it becomes filled with blood, which could not enter before, and is reddened in a surface proportioned to the extent of the irritation. The cheeks exhibit an analogous phenomenon in blushing; and all rubefacient membranes shew the great tendency of the superficial capillary system to admit, under circumstances of excitation, that blood which it rejects in its natural state. Blisters, and fire, applied to a degree short of destroying the surface, act in the same way: they cause a sudden species of erysipelas, which is followed by an abundant serous exhalation under the cuticle.

"Irritation of the skin is not the only cause which determines an influx of blood into the exterior capillary system. Whenever the action of the heart is accelerated, and the motion of the blood consequently precipitated, there is a tendency to this passage, as we see clearly after violent exercise, or on the access of the hot stage in fevers.

"The capillary system of the face is more subject to this sudden influx of blood than that of any other part. This is seen in the two cases just mentioned, of exercise and fever, where the action of the heart is accelerated. In various diseases of internal organs the facial capillaries are sympathetically affected, and produce redness or paleness of the countenance; and their distention always gives to the face in asphyxia a livid tint, which is confined to that part. In deaths resembling asphyxia, where the circulation becomes embarrassed in the lungs, and in apoplexy, the head is equally remarkable for its lividity. Three circumstances may be noticed, in explanation of this great susceptibility of the facial capillary system for the admission of blood; 1st, the ordinary redness of the cheeks shews that blood is habitually contained in these capillaries in a certain quantity, which is not the case in other parts; 2dly, anatomical injections shew us that the arteries communicate here more freely with the capillaries; fine injections colour the face much more deeply than other parts; and, 3dly, there is a more acute sensibility in the face; a slight blow will bring the blood into the cheeks in an instant, although it would produce no redness in the arm.

"The blood quits the capillaries of the face as quickly as it enters them; the passions produce here, almost in instantaneous succession, the lively red of a febrile attack, the deadly paleness of syncope, or any intermediate shades. Thus the face becomes well adapted to serve as a kind of scene, painted successively by the passions with numerous shades, which are effaced, return, and undergo a thousand modifications according to the state of the mind.

Let us observe further on this subject, that the passions have a threefold mode of expression in the countenance; 1st, by the capillaries which, being altogether involuntary, often

betrays what we should be inclined to conceal; 2dly, the muscular motions, which contract or expand the features to express the fad or the joyful affections, and thus produce the wrinkles already noticed; and, 3dly, the eye, which, as Buffon observes, not only receives sensitive impressions, but also expresses mental emotion. The two latter are in some degree voluntary; we can feign them, although we cannot deceive with the first.

"The tendency of the facial capillaries to become distended with blood, disposes them to numerous morbid affections. Erysipelas frequently attacks this part; venolous pustules are particularly active here; and several eruptions occur more frequently in the face than in other situations.

"We must therefore distinguish two parts in the capillary system exterior to the corion. One contains habitually the colouring matter of the skin, which is at rest, or experiences at least no other motion, than the slow and almost insensible one of composition and decomposition, and which therefore never exhibits such sudden changes as we have just described. Though the other fluids are habitually circulated, and are constantly escaping by transpiration; their place is often supplied by blood. We know of no communication between these; they appear to be absolutely independent. Some white fluids remain in the latter part at the time of death, as the following experiment will prove. Immerse a piece of skin in boiling water for a short time; and the epidermis will be elevated into numerous small vesicles containing a serous fluid."

The papillae of the skin are small eminences of its external surface, supposed to perforate the reticular body, and consequently to be contiguous by their extremities to the epidermis; they differ in form in various situations, and are called villi where they are small and fine. Malpighi first observed in animals, and particularly in the foot of the pig, that the external surface of the skin is not level, but elevated into certain prominences under the cuticle. This structure does not belong to the whole surface of the cutaneous organ, which, although rather unequal in consequence of small risings about the hairs, has no regularly arranged parts deserving to be called papillae. Thus Ruysch could find nothing of this kind on the back of the foot, and acknowledges that they are obscure in other parts, and only to be seen after injections; and other anatomists have experienced considerable difficulty in detecting these parts, even with the assistance of glasses.

"Neither," says Bichat, "are we to mistake for papillae the numerous and very sensible tubercles, which make the skin of certain subjects very rough. These consist of small cellular and vascular fasciculi, or of sebaceous glands found at the openings of the corion under the epidermis, through which the hairs are transmitted; elevate the external surface, and thus cause projections. Maceration for two or three months converts these bodies, which always contain a little fat, into the firm, whitish, unctuous and spermaceti-like substance always produced from adipous matter by maceration; the skin at the same time becomes soft and pulpy, and is loosened round these tubercles, which are clearly seen to be continuous with the subjacent fat. These prominences are more frequent on the limbs and back than on the front of the trunk; and they are more numerous in the former, on the aspect of extension than of flexion. The absence of these risings, and a consequent smoothness of the outer surface of the corion, belong to our notion of a beautiful skin; and this character belongs much more to the cutaneous organ of women than of men. The epidermis covering these prominences is often detached in scales, particularly by any rather strong rubbing; and this contributes still more to the

roughness and harshness of the skin; it might lead us to suppose that the epidermis forms them, although it is only accessory. Where the latter is thick, as in the palms and soles, these cutaneous tubercles are never seen."

The proper papillæ of the skin are very visible in the hands and feet, and may be seen when the cuticle has been carefully removed after simple maceration for a sufficient time; but still more plainly when the cutis has been minutely injected previous to the macerating process. We observe narrow, longitudinal, and slightly prominent lines in the cutis, distributed spirally at the ends of the fingers and toes. From these ridges arise very small conical processes like fine threads or hairs, slightly inclined towards the nail, shorter and more imperfect in the smaller toes and fingers; they give a rough villous appearance to the surface, which is represented in the seventh figure of Mr. Cruikshank's work on the insensible perspiration. They are very distinct in the red part of the lips, where they are numerous and long, and produce a villous appearance; Ruysch has figured them in his eighth *Theaurus*. The soft and spongy skin of the glans penis is remarkable for a similar structure, which is well represented by Albinus in the *Annot. Acad. lib. iii. tab. 4*. They are more obtuse in the female mammæ. The minuteness of these organs renders it difficult to ascertain their internal structure satisfactorily. They receive numerous blood-vessels, so as to become much more deeply tinged by coloured injections than the surrounding skin. They receive numerous nerves, and have generally been regarded by anatomists in a particular manner as organs of a nervous structure. That a considerable supply of nerves is bestowed on those parts of the skin which have these papillæ is very clear; but, that the minute filaments can be traced into the very prominences, and that they lay aside their coverings, so that the nervous pulp is bare in them, must be regarded as inferences from analogy rather than from direct observation. The density of the corion, and the extreme tenderness of the nervous threads, are almost insuperable obstacles to our tracing the nerves into the papillæ.

We can scarcely doubt, says Haller, that these bodies are the organs of touch, when we observe them larger, more distinct, and receiving a greater supply of nerves where this sense exists in the most acute degree, hardly discernible in other situations; and particularly calculated by their prominence to be impressed by external objects. Perhaps their existence in the sole of the foot, where they are covered by so thick a cuticle, is hardly reconcilable with this opinion.

That the vessels, which they contain, contribute to the separation of the matter of perspiration, is so conformable to general analogy, that we can easily admit it. Mr. Cruikshank was disposed to regard them as the organs of cutaneous absorption from their resemblance to the intestinal villi, on which he discovered the orifices of the lacteals.

Effect of various Agents on the Dermoid Tissue.—We have noticed already, under the head of the rete mucosum, the action of light upon the living skin.

The action of caloric on the living integuments presents different phenomena, according to the degree in which it is applied. A warm atmosphere relaxes its tissue, increases its action, and promotes the evacuation by the exhalants of the residual fluid of nutrition and digestion. It is contracted and corrugated by cold, and refuses to admit these fluids, which then go off chiefly by urine. The gradual change from one to the other of these states does not produce any unpleasant effect; but sudden vicissitudes are not so free from danger. The cold produced by the evaporation of the cutaneous exhalation, enables the human subject to preserve his ordinary temperature in air, heated above the degree of

boiling water. See the very curious facts on this subject detailed in the article *HEAT, Animal*. The interruption of the cutaneous discharge on the corrugation produced by cold suspends this evaporation, and thereby prevents the temperature from being lowered beyond the natural standard.

When more considerable heat is applied to the skin, it produces first a sensible redness, which is followed by vesications. If it be increased in degree, the texture of the organ is destroyed; it is hardened and curled up, like any other animal tissue when burnt; beyond this point it is blackened and converted into a coal. The first operation is on the vital powers of the organ, and consequently can take place only during life: the latter effects are produced on the tissue, and may be exhibited in dead skin. The latter, when heated, contracts, and then swells, exhales a fetid odour, and leaves a dense charcoal, difficult to incinerate. On distillation it yields the same products as fibrine. Intense cold produces in the first place a redness of the organ, as in the nose, ears, fingers, &c. of individuals exposed in a very cold climate: inflammatory action and mortification ensue. The latter occurs immediately on the application of high temperature, but after some interval in the opposite case.

The air evaporates and carries off habitually the matters secreted from the skin; and when this effect is not produced, they are accumulated on the surface, and render it moist. This evaporation is a physical phenomenon entirely distinct from the vital action of transpiration. The latter takes place in a warm bath, as well as in the air; but in the former case the fluid is dissolved by the water. Does free exposure of the skin to air increase or diminish the amount of its exhalation? The common opinion seems to be that the latter effect is produced; the exhaling pores are supposed to be obstructed by the impression of cold on the skin. Dr. Stark, however, proved by direct experiment in his own person, that the body lost more weight in a given time when naked, than when covered by the ordinary clothing.

Moisture of the skin may be produced in two perfectly distinct ways; 1st, by increased exhalation, which may arise from accelerated action of the heart, as in violent exercise or fever; from relaxation of the organ by the warmth of the air, or by baths; or from sympathy, as in consumption, fear, &c. Under all these circumstances the increased discharge will keep the skin moist. 2dly. The same effect will be produced by insufficient dissolution of the perspiration when it is produced, as in bed, or in damp weather.

When the air has access to dead skin on all sides, it is dried, and becomes transparent, unless it should contain blood; it is then firm, but admits of being bent. In this state it yields very little to external agents, does not readily absorb moisture, and has no disagreeable smell. Hence skins simply dried are of great use in the arts, and afford serviceable and pleasant coverings; hence, too, probably the great durability of the mummies.

If the skin be left on the body, or exposed in moist air, it putrefies, assuming successively a brown, a greenish, and lastly somewhat black colour. It exhales a most fetid odour, and becomes swollen by the liberation of gas. A fluid mucus appears on its surface, from which the epidermis is then separated. When all the fluids are evaporated, a blackish substance remains.

Water removes from the living skin those parts of the perspired matter which are not dissolved by the air; and the use of bathing, which is much neglected in these days, must be regarded as an efficacious means of preserving the surface free from acrid and irritating matters, and consequently in a state of health. We cannot state precisely what action baths have on the living skin; we are told indeed that they relax and

INTEGUMENTS.

and soften, or constrict and brace; but no precise meaning is attached to these vague expressions. They seem to affect the vital powers of the part, to augment or diminish them, but we know of no influence on the tissue.

After macerating the skin for some hours in water, with agitation and pressure, evaporation of the fluid yields a little gelatine. When macerated longer it becomes softened, and sensibly whiter, swells a little, and remains for a long time without undergoing any other alteration than a degree of putrefaction, much less than what occurs in the muscular, glandular, and other tissues. This putrefaction is more marked on the surface in contact with the cuticle, but at the end of two months the skin has lost but little of its confidence; it begins to be reduced into a fetid pulp at the end of three or four months. According to Fourcroy, spontaneous decomposition in water or milk earth converts it into a fatty matter, and into ammonia, which compose a kind of soap. It produces very little froth when boiled. Just before ebullition commences, so as always to be convex on the side covered by the epidermis, and concave on the opposite; the fibres are contracted and condensed at this time, and the contraction is greater on the inner surface, where the intervals are the largest. At the same period small vesications are observed. This crispation of the skin renders it dense, hard, and elastic, but reduces its dimensions. It soon acquires a semi-transparency and yellowish colour, like that of the fibrous organs when boiled. The hardness which it had acquired at the instant of crispation is now gradually lost; the skin is softened, yields much gelatine to the water in which it is boiled, but instead of diminishing, is rather increased in thickness. All appearance of fibres is lost in this stage; a semi-transparent, gelatinous, and homogeneous mass remains; still it does not lose its elasticity; probably the large quantity of gelatine, which it contains, occasions it to retain this property. The slightest motion excites in it a general vibration as in the different animal jellies. By a continuance of the boiling nearly the whole gelatine is dissolved, constituting a viscid liquor, which by proper evaporation is converted into glue; and a small membranous residue only, which is dissolved with great difficulty, remains; a long time is required to reduce the skin to this state. From this solubility in water, the cutis of animals is mostly employed in the manufacture of glue.

Sulphuric, nitric, and muriatic acids act on the skin, as on any other animal substances, but much more slowly, particularly on the surface covered by the epidermis. The first reduces it quickly to a blackish pulp; the two others, even in a concentrated state, bring it less readily into a pulp: the oxymuriatic acid produces very little effect on it. Nitric acid converts it into oxalic acid and fat, while, at the same time, azotic gas and prussic acid are emitted. Acids do not act in this way during life: they never produce this pulpy state of the organ. A piece of caustic, enveloped in a portion of skin, is reduced to a yellowish-red thick fluid in the course of a day: the skin is crisped and contracted, but not penetrated; its tissue does not even appear injured on the surface. Alkalies have different effects, according to circumstances, in the living state; they destroy some granulations much more readily than others. An alkaline lixivium, applied to the surface of the body, causes an unctuous and slippery feel, as its combination with the unctuous matter produces a soap. Concentrated alkalies dissolve the dead skin, converting it into oil and ammonia.

"The cutis," says Dr. Thomson, "appears to be a peculiar modification of gelatine enabled to resist the action of water, partly by the compactness of its texture, and partly by the viscosity of the gelatine, of which it is formed; for

those skins which dissolve the most readily in boiling water, afford the worst glue. Mr Hatchett has observed that the viscosity of the gelatine obtained from skins is nearly inversely as their flexibility, the supplest hides always yielding the weakest glue; but this glue is very soon obtained from them by hot water." *Système de Chimie*, v. 5. p. 575.

The production of leather, by the action of the tanning principle of vegetables upon the skin, is a subject of such importance, that it would be useless for us to enter on it here: it will be considered separately in the articles of the dictionary relating to tanning: further information on the chemical properties of the skin may also be derived under the heads GELATIN, GLUE, &c.

Very little is known of the chemical constitution of the rete mucosum. Oxymuriatic acid deprives it of the black colour, and renders it yellow in the negro. Beddoes states that immersion for some time in water, impregnated with that acid, will discharge the colour in the living subject. (*On Fætidious Airs*, p. 45.) Fourcroy mentions that the foot of a negro, after a familiar exposure, nearly lost its colour, but that the original black hue returned in a few days. *Système des Connoissances Chimiques*, t. ix. p. 259.

Common Parts belonging to the Tissue of the Dermoid System.—The skin contains a large proportion of cellular substance. Numerous prolongations of the subcutaneous cellular stratum penetrate the contiguous areolæ of the corion, then pass into the more exterior ones, and end at the numerous pores which transmit the vessels, nerves, and hairs. Thus, if the cellular tissue could be completely separated, the cutaneous organ would represent a piece of sponge, being perforated in every direction. According to Bichat, boils perform this dissection, destroy the cellular organ, and leave the skin in this cribriform state. He adds, that the corion itself is not the seat of any acute affection: that all diseases of this nature either affect its surface, or the cellular tissue of its areolæ. But it may be altered by chronic diseases; and is manifestly disorganized in elephantiasis.

In anasarca of long continuance the subcutaneous serosity gradually penetrates the cellular substance of the dermoid areolæ, separates its fibres, and sometimes arrives even at the epidermis, which it bursts; through these openings it escapes.

Probably, says Bichat, the cellular tissue does not extend so far as the external surface, under the epidermis: for when that covering is removed, no granulations are formed, although there are always produced whenever cellular tissue is exposed.

The arteries, running in the subcutaneous cellular substance, furnish an infinite number of small branches, which enter the areolæ of the skin with the cellular prolongations, anastomose at every point in the areolæ of the organ, and penetrate at last through the pores of the external surface to produce the capillary network already described, which, in the ordinary state, contains very little red blood. In this passage, through the areolæ of the skin, very few branches seem to terminate on the fibres of the corion itself.

After penetrating the skin in the opposite direction, the veins open into the large subcutaneous trunks, which in many parts may be so clearly seen through the integuments. The venous ramifications of the areolæ are nearly insensible in the natural state, but are considerably dilated over cancerous tumours, so that the skin is marked by numerous blueish serpentine lines. All gradual extensions of the cutaneous organ, as in aneurisms, pregnancy, dropsy, &c. are attended with the same phenomenon, which is never exhibited in acute cases.

Numerous and considerable branches of nerves form a kind

INTEGUMENTS.

of lubricaneous nervous system, producing the filaments which enter the skin. They communicate with each other in traversing the areolæ of the organ, and probably terminate on the papillæ. In the hand, where these prominences are very numerous and clearly marked, there are more subcutaneous nerves, in proportion to the surface, than in any other part.

A great number of absorbing vessels is found under the skin; inasmuch, indeed, that this is the most favourable situation for investigating them. The veins are surrounded by them, and several fasciculi are observed in the intervals of these vessels; so that we may represent the skin and aponeuroses as being separated, in the limbs, by a continuous stratum of these vessels. We must refer the origin of many of them to the corion, from the areolæ of which they carry into the blood the fat and cellular lymph, as well as the nutritive matter of its fibres. But is there, moreover, a particular order of branches opening on the epidermis, for the purpose of absorbing substances from the surface of the body under certain circumstances? Anatomical investigations do not enable us to decide this question directly: the absorbing pores cannot be demonstrated: we must therefore inquire whether the phenomena of the cutaneous functions indicate their existence. We may observe, previously, that the superficial absorbents are very numerous, and seem to be in greater number than would be required for absorbing the contents of the cellular substance.

It had long been received as an established truth, that the skin is an inhaling or absorbing, as well as an exhaling organ; that though the loss by perspiration commonly greatly exceeds what the system gains by absorption, yet sometimes, according to the varying circumstances of external relations and conditions of the body itself, the inhalation balanced, and even surpassed the exhalation. Of late this doctrine of inhalation has been called in question, and, in the opinion of many, has been completely overturned.

The most direct argument in favour of absorption from the skin, is the action of various substances upon the body, when applied to this organ. This is shewn in a particularly clear view in the instances of opium and mercury. Dr. Currie (Medical Reports, chap. 19) considers, that in all such cases the article absorbed is forced through the epidermis by mechanical pressure; or that the epidermis has been previously destroyed by injury or disease; or if found, that the article applied to it is of an acrid nature, which first irritates and erodes this tegument; and then coming into contact with the mouths of the lymphatics under it, is of course absorbed. This explanation is quite unsatisfactory. The firm adhesion of the cuticle and cutis is well known: on the supposition just mentioned they ought to be separated, which is not the fact, we ought to see the ointment under the cuticle, which is equally untrue, and the ointment should penetrate equally in the dead subject, which is not the case. However, the action of mercurial fumigations, where no friction is employed, affords a case of absorption from the surface of the found cuticle, which cannot be denied.

On the same side of the question, it has been asserted, that water is taken up by the skin in various cases. Many instances have been known of persons at sea, with no fresh water, having their thirst much allayed by wetting their cloths with the salt water. Haller affirms, too, on the authority of Desault, that the body acquires an increase of weight in the warm bath: "deique vapor aquæ calidæ in manum resorbetur, et homini in balneo constituto cutis tumet et rubet, corpus pondere augetur, fitis sedatur, et omnia signa eduntur aquæ resorbæ et sanguini admittit." t. v. p. 84. Experiments have since been made with every

necessary care, which seem to contradict this position, and to prove that the body acquires no additional weight in the warm bath. Seguin, from a great many experiments of this description, concludes that there is no inhalation, because the body, so far from gaining, always lost some part of its weight during immersion, although much less than in the air in equal times. Thus, in a bath heated from 10° to 12° of Reaumur, the loss of weight was so that it failed during the same time in air as 6.5 to 17; at the temperatures from 15° to 18°, as 7.5 to 21.7; and from 26° to 28°, as 13 to 23. *La Médecine éclairée par les Sciences Physiques*, tom. iii.

In other experiments, again, as in those of Drs. Gerard and Currie, there was no increase of weight; but neither was the body in general observed to have suffered any loss during immersion in the warm bath. "When I was at Buxton," says Dr. Currie, "in 1788, I made an experiment on the effects of bathing on the weight of my body, and after half an hour's immersion, I found it rather diminished than increased. This experiment had, I believe, been made before by Dr. Pearson with the same result; it has since been repeated with great care, and it is ascertained, as a fact, that no increase in the weight of the body is produced by immersion in water at the temperature of 82°. In the year 1790, I had a patient in diabetes, whose cuticle, as is usual in that disease, was in a morbid state; and being desirous of trying how far the inordinate action of the kidneys might be affected by a gentle stimulus applied to the skin, I immersed him in a bath of the temperature of 95°, weighing him before and after immersion. There was no sensible variation in the weight. This experiment has since been made by Dr. Gerard in another case of diabetes, an account of which is given in the publication of Dr. Rollo; and as it was repeated a great number of times with the utmost care and accuracy, it may be considered as established, that immersion in the warm bath in diabetes produces no increase in weight. I have made five different experiments of the same kind on myself, varying the heat of the bath from 87° to 95°, but never in any instance found my weight augmented." (Medical Reports, vol. i. p. 302.) The doctor then details a case of strictured œsophagus, where the patient gradually wasted, and ultimately died of inanition, although he was immersed daily in a tepid milk and water bath.

We may observe, concerning the facts just quoted, that they by no means warrant a decisive negative inference. We have every reason to suppose that the action of the skin goes not uninterruptedly in the bath, and that the pulmonary exhalation proceeds as usual. Yet the weight either continued unchanged, or, if any loss was observed, this was constantly less, much less, than is experienced during the same interval in air: hence we may argue, that there must have been absorption. Dr. Currie's case of strictured œsophagus merits further consideration: no experiment could be more unfavourable for an opponent of cutaneous absorption. The patient, it is true, gained no weight while in the warm bath, but the loss continually going on in the air, was, as in other trials, suspended during the immersions. "It is worthy of observation, that there was neither increase nor decrease of weight in the bath; yet Mr. M. was at this time wasting twenty ounces in 24 hours, and consequently, if there was no absorption in the bath, it might be supposed that he would have lost five-sixths of an ounce during the hour of immersion. It is the more remarkable that there was no decrease, because in the bath the skin always softened, and the forehead became covered with a gentle moisture." Besides, "he always expressed great comfort from the bath, with abatement of thirst."

INTEGUMENTS.

thirst," and "subsequent to the daily use of it, the urine flowed more plentifully, and became less pungent." An observation precisely similar is made by Mr. Cruikshank: "a patient of mine, with a stricture of the œsophagus, received nothing, either solid or liquid, into the stomach for two months; he was exceedingly thirsty, and complained of making no water. I ordered him the warm bath for an hour, evening and morning, for a month; his thirst vanished, and he made water in the same manner as when he used to drink by the mouth." Anatomy of the Absorbing Vessels, p. 101.

Dr. Currie states further, concerning his patient, that the discharge by urine alone exceeded much in weight the waste of his whole body; and it cannot be doubted, he adds, that the discharge by stool and perspiration exceeded the weight of the cylinders. Thus it appears that the egesta exceeded the ingesta in a proportion much greater than the waste of the body will explain. That cutaneous absorption affords the only adequate solution of this phenomenon is an irreducible conclusion. Still, however, this is denied. When forced to confess that there are cases where the egesta exceed the ingesta, and which can only be accounted for by absorption, the opponents of the cutaneous inhalation deny this function to the skin, and bellow it most gratuitously on the lungs.

Many other examples might be cited, in which the body evidently acquired weight from some other quarter than by the food or drink. Haller has many such instances. Rye and Linings gained several ounces by exposure in a moist atmosphere; and Fontana experienced a similar occurrence.

Some facts, which oppose the notion of inhalation by the surface of the skin, have been observed in the applications of medicated substances to the body. Seguin made numerous experiments of this kind, with solutions of muriate of mercury on syphilitic patients; we are informed, that in cases where the epidermis was perfectly found, neither the known effects of mercury on the body, nor any amelioration of the venereal symptoms, was ever observed. He also immersed his own arm in a solution of two drachms of the mercurial muriate in ten pounds of water. At the temperature of 10° and 28° of Reaumur, no part of the salt was missing at the end of the experiment; but when the bath was at 18° of the same scale, there was a loss of one or two grains of the muriate in the hour, though the quantity of fluid was not diminished. It appears to us that the experiments on the whole shew that the muriate of mercury was not absorbed; we can hardly admit that two grains were taken up as stated in this account. The entrance of so large a quantity of this very active preparation into the system, must have been attended with very unpleasant effects on the subject of the experiment, which do not seem to have occurred.

The effects produced on the odorous properties of the urine, by exposure of the body to oil of turpentine, are well known. By inhaling the vapour of this fluid, the violet smell is imparted to the urine very speedily: even a single full inspiration is sufficient to produce the effect. Walking in a room where it has been spilled will operate in the same way. It has been proved by experiment that the lungs are the organs by which the absorption takes place, and that the fluid is not taken up by the skin. Dr. Rouleau, of Philadelphia, exposed his body freely to the turpentine vapour, breathing through a pipe, which communicated with the external air, and had no connection with the air of the room. No effect was produced on the urine. He immersed his arm in spirit of turpentine for two hours, luting the vessel containing it to the arm, so that no vapour could escape; no change was perceptible in the properties of the urine. He smeared his body all over several times with the spirits of

turpentine, guarding against the inhalation of the vapour of the lungs, by breathing the external air through a tube. He continued this for some time, until the surface was irritated, and the pulse quickened; the result was the same. These experiments were frequently repeated, and with the same result, whether the spirit of turpentine was employed, or camphor, garlic, or malk. *Carrie's Med. Rep.* v. 1. chap. 19.

The exhalant vessels of the skin arise in the exterior capillary system, which surrounds the corion, and which affords the point of termination of the cutaneous arteries. They draw from this source the fluid which they pour out on the epidermis. We are entirely ignorant of their form, length, course and direction: but the phenomena of the cutaneous discharge, and of injections prove their existence. They do not seem to be equally abundant in all parts: in the face and chest they are numerous, so that we sweat easily in those parts; the number is smaller in the back and limbs. Sweat is very seldom observed in the palms and soles: but there is great variety in these respects in different individuals.

It appears from experiments, that a considerable discharge takes place from the skin habitually, although not in a form cognizable by our senses. This is called insensible perspiration, or tranpiration. Under particular circumstances, the cutaneous discharge consists of fluids possessing very sensible properties: this is called sweat. The epithet insensible is applied to the former, to distinguish it from the sweat, but under certain circumstances it may be rendered obvious to the senses. It has been often asserted that a vapour may be observed to arise from the body, and may be recognized by its shadow against a white wall in the summer. This is observed more readily in a dense atmosphere. Haller saw a kind of cloud or smoke arising from the face, hands, and indeed every part of the naked body in the subterraneous excavations of Clauthal and Rammelberg. A still more obvious demonstration of the tranpiration is yielded by holding a finely polished metallic surface near the skin; the watery vapour is condensed by the metal, and clouds it. Under ordinary circumstances, the whole discharge is evaporated as it is produced, and passes off in this invisible form. As all bodies absorb heat in changing from a fluid to a gaseous form, this evaporation must have a very powerful effect in regulating the temperature of the animal frame. When the nature of our clothing confines the perspiration, and prevents its evaporation, an unpleasant feeling of heat is produced; this is particularly observed when the body is covered with oiled silk. On the other hand, exposure of the skin in a naked state, particularly in the wind, has a very rapid and powerful cooling effect. The importance of this function in regulating our heat did not escape the notice of that sagacious observer Benj. Franklin: "during the hot Sunday at Philadelphia, says he, in June 1750, when the thermometer was up at 100° in the shade, I sat in my chamber without exercise, only reading and writing, with no other clothes on than a shirt, and pair of long linnen drawers, the windows all open, and a brisk wind blowing through the house. The sweat ran off the backs of my hands, and my shirt was often so wet as to induce me to call for dry ones to put on. My body, however, never grew too hot as the air, or as the inanimate bodies immersed in the air." (*Letters and Papers*, p. 365.) It does not appear that Franklin actually measured his heat; but he makes the inference of his comparative coolness from remembering that all the bodies about him, even the shirt out of his drawer, felt warm to the touch; and he concludes that he was kept cool "by the continued sweating, and by the evaporation of that sweat."

Probably sweat is only an increased quantity of the same kind.

INTEGUMENTS.

kind of fluid with that of the transpiration: very small particles of fluid are observed on the skin, and they unite into larger and larger drops. Heat is the most common cause of sweating, as it is a very powerful means of exciting the action of the heart, on which this phenomenon depends in many cases: hence warm air and the warm bath are powerful causes. Strong bodily exertion, and warm food, by stimulating the vascular system, produce the same effect. Fear, and other affections of the mind, fainting, and various morbid states of the frame, also produce sweating. We cannot name any particular degree of heat at which sweating is certainly produced: and the pulse is often very greatly accelerated in disease without this consequence. Sometimes a particular part of the body only sweats: sometimes one side, as Haller has noticed in his own person.

Dichat enquires whether the nerves have any influence on the cutaneous discharge. He observes, that in palsied patients sweat takes place on the diseased as well as on the sound side. "I lately," says he, "attended at the Hôtel Dieu a patient, in whom the left side of the body was rendered perfectly paralytic, in consequence of an apoplectic attack: yet he sweated only on this side. Examples of the opposite phenomenon are adduced; but they cannot invalidate the common observation that the discharge is equal on both sides. Is it not well known, that when the nervous action is entirely annihilated in a paralytic limb, blisters affect it in the usual manner? Do convulsions, in which the nervous action is increased, augment the cutaneous exhalation? Have the states of acute sensibility, where there is in the cutaneous nerves too great a susceptibility of impressions, any known influence on perspiration? Let us then confess, that in cutaneous exhalation, as well as in secretion, we are entirely ignorant of the nature of the nervous influence, if any such exist."

The discharges by the skin and the kidney seem to be regarded by physiologists as the principal means by which the residuary matter of nutrition and digestion is expelled from the body; and they have attempted to shew the ratio which these bear to each other, to the pulmonary exhalation, and to the feces. We have not derived much information from these labours, which merely prove, in a general manner, that the discharge is effected through the internal organs in cold climates and seasons, and through the skin under opposite circumstances. In this respect, the kidney and the skin are always in opposite states in relation to each other: in winter the urine is much loaded with substances, and in summer the perspiration has a salt taste and other peculiar characters, arising from matters which it does not contain in the former season. Every individual must have observed in his own person that while he sweats freely no urine is collected in the bladder; and that when the cutaneous discharge is interrupted, the secretion of the kidney goes on very actively.

We do not know much about the pulmonary exhalation, either as to its quantity, its nature, or its relations to the cutaneous discharge: but that the two organs very powerfully influence each other, is rendered very obvious by the phenomena of disease. The effect of exposure to cold and moisture in exciting pulmonary affections, and the disposition to such disorders in the winter, when the cutaneous exhalants are less active, are well known.

We often have occasion to observe a manifest connection between the perspiration and the alvine discharges.

When the extent of the exhaling organ, the innumerable tubes by which it is penetrated, the quackknives with which we can even fee the perspiration produced, are regarded, we shall expect to find that the quantity of the discharge is very considerable. Although it was known to the ancients, who

had noticed its influence on the health, and introduced it into their pathology, we find little detailed information concerning this function before the seventeenth century, about the beginning of which it became the subject of the most patient research, and of the most extensive experiments perhaps ever undertaken. Sanctorius, a Venetian physician, dedicated thirty years to his experiments, which consisted chiefly in weighing whatever he ate and drank, as well as what he discharged by urine and stool. From him the inflexible perspiration has sometimes received the epithet of Sanctorian. His example was followed by several persons in different countries; by Dodart in France; by Keil, Robinson, Rye, and Home in this country; and by Linings, in South Carolina. Even our gay monarch, Charles II. amused himself with some experiments on this subject. Something must be taken from the numbers expressing the quantity of perspiration, on account of the pulmonary exhalation, the mucus of the air passages and nose, and spitting. For, in the experiments now alluded to, all the difference between the ingesta and the egesta is set down as lost by inflexible inspiration.

In the experiments of Home, in Scotland, the food amounted to 4 lb. 3 oz.; the feces to 3½ oz.; the urine to 2½ lb., or 3½ lb.; the perspiration, in the course of an hour, varied from two-thirds of an ounce to 4 oz., and even six under exposure in the sun. In the twelve hours of night, the perspiration varied from 12 to 18 oz.; and in 23½ hours the discharge amounted to 3 lb. 3½ oz.; and on another occasion, to 2 lb. 6½ oz.

Rye, who lived at Cork, in Ireland, found the urine in the winter season to amount in one day to 42½ oz.; the perspiration to 53 oz. in spring, the urine was 40 oz.; the perspiration 60; in summer the numbers were 37 and 63. The average daily quantity of urine, therefore, was rather less than 40 oz., and that of the perspiration 56½ oz. The average daily amount of the feces was 4½ oz.; that of the food 96 oz. The large quantity of perspiration in the winter is chiefly made up of what is produced during the night.

Keil found the medium quantity of perspiration to be 31 oz.; of urine 38; of feces 5; food 78.

Robinson allows that the urine is diminished, and the perspiration increased in a very sensible manner in the summer, so that the average number of ounces of the former is in summer 27, in winter above 30. In the summer months the perspiration and urine are as 5 and 3, in the winter as 2 and 3; in April, May, October, November, and December, they are nearly equal. In a young person he eliminates the ratio of the perspiration to the urine as 1340 to 1000; in an old one as 967 to 1000. He makes the average quantity of food 86 oz., and 58 when he was old; the urine 35 and 28; the perspiration 46 and 27½; the feces 5½ and 3½. Thus the food and all the excretions are diminished as age advances.

Hartman, in Germany, found the food to be 8 oz.; the urine 28; feces 6 or 7; and perspiration 45 or 46.

Dodart, in France, found that the perspiration was to the feces as 7 to 1. He eliminates the discharge in summer at 40 oz. 3 dr. 26 gr.; in winter at 26 oz. 46 gr.

Sanctorius, in the warm and humid air of Venice, took 8 lb. of food; the perspiration amounted to 5 lb.; the feces to 4 oz.; and the urine in the night to 16 oz.; in the twenty-four hours to 44 oz.

Linings has given us very accurate accounts of his experiments, which were performed in South Carolina. From his labours, as well as from those of Robinson, in Ireland, it appears that the perspiration is most abundant in the warm months

months, and the urine in the cold: the former was in greater quantity during five months, and the latter during seven. The largest proportion of urine was 143 oz. which occurred in the month of December; and of the perspiration 130 oz. in September. The average daily amount of the food, on a mean of experiments continued for a year, was 27,18 oz.; of the drink 102,17; of the urine 64,84; of the perspiration 60,10; of the feces 4,35. The ingesta were to the urine, throughout the whole year, as 2,02 to 1; but at many particular times they were as 3 to 2; their ratio to the perspiration as 2,18 to 1; to the fecal discharge as 30,13 to 1; and the perspiration of the whole year to the urine as 1 to 1,08. These experiments differ from those of Sanctörinus and of Rye, in shewing that the urine exceeds the perspiration even in a hot climate.

It appears doubtful, says Haller, on comparing together the results of the trials made by individuals of different ages in various climates and seasons, whether the discharge by the skin exceeds that by the urine. On such a comparison we must set down the cutaneous exhalation much below the quantity assigned by Sanctörinus, as it did not exceed 60 oz. in a very hot climate, and in colder countries was 56, 45, or even 30 oz.

It will be readily perceived, as we have already observed, that these calculations do not give the measure of the perspiration alone, but of the cutaneous and pulmonary discharges together. To separate these, and to determine the quantity of each, still remained an important problem, the solution of which has been attempted only of late years.

Mr. Cruikshank introduced his hand into a glass jar, and tied a bladder, fixed to the mouth of the jar, round his wrist. In less than a minute the inside of the bottle was rendered dim, as if it had been held over the steam of warm water: small drops appeared in less than ten minutes, and a tea-spoonful of transparent and perfectly insipid fluid, weighing 30 gr., was collected in an hour. Assuming that the hand is to the whole body as 1 to 60, and that the whole surface perspires equally, the exhalation at this rate would be 7 lb. 6 oz. in 24 hours. When the experiment was repeated after taking exercise, 48 gr. were collected in an hour, which is at the rate of 12 lb. in 24 hours. By breathing into a bottle for an hour, this gentleman collected 124 gr. of insipid transparent fluid: the produce in 24 hours at this rate would be 6 oz. 1 dr. 36 gr. If this be added to the former statement of the cutaneous exhalation, the sum will be 8 lb. 1 dr. 36 gr.; and the evaporation from the lungs will be little more than $\frac{1}{4}$ th of the whole. Bichat says that he collected 2 oz. of fluid by breathing for an hour into a vessel. *Anat. Gener. t. 2, p. 701.*

Mr. Abernethy collected from his hand and wrist, inclosed in a glass jar for six hours, about 3 dr. of fluid. He estimated the surface from which this was collected at $\frac{1}{4}$ th of the whole body: hence, if the perspiration be equal at all times and in all parts, the produce in one day would be about 2½ lb. This result is so different from that of Mr. Cruikshank, that there must be some signal error in the data on one side or the other.

The method adopted by Lavoisier and Seguin seems calculated to afford results more worthy of our confidence. The whole body was inclosed in a silk bag, varnished with elastic gum, impenetrable by air or moisture, having a small opening carefully cemented round the mouth through which the person might breathe; so that whatever came from the lungs escaped, while the whole of the cutaneous discharge was confined within the bag. By weighing the body, there-

fore, before putting on this dress, and immediately after leaving it, the total loss by the pulmonary and cutaneous discharges was ascertained. The amount of the loss by the lungs was known by weighing the subject of experiment full before he put on the dress, and again immediately before he removed it. When the latter quantity was subtracted from the total loss, the remainder gave the value of the cutaneous discharge. From repeated trials performed in this manner, Seguin and Lavoisier found the mean loss by the cutaneous and pulmonary exhalations, to be about 12 gr. in the minute, or 2 lb. 12 oz. in 24 hours. The pulmonary discharge amounted to 15 oz. so that the mean quantity is 14 oz. as the mean quantity of water perspired.

The greatest quantity of water retained in a minute was 26,25 gr. Troy; and the minimum 9 gr. The quantity perspired is increased by drink, but not by solid food. Perspiration is at its minimum during meals, and immediately after it reaches its maximum during digestion. *Mém. de l'Acad. des Sciences, 1790; or in Fourcroy, Syst. des Connoiss. Chimiques, sect. 8, ord. 3.*

Our next object of inquiry is into the composition and properties of the cutaneous exhalation. As it escapes from the surface insensibly, there is a difficulty in collecting it in sufficient quantity for examination: hence its nature and composition are very imperfectly known. Lister, who collected it by placing his hand in a glass, found it to be water with a salish or urinous taste.

The fluid collected by Mr. Cruikshank appeared to possess all the properties of pure water. When Mr. Abernethy had procured 3 dr. of fluid, he evaporated one half: there remained on the glass a small residuum, which had a very slight taste of salt. The other half was suffered to stand many days, in which time no change appeared. It did not alter the colour of vegetable blue; no coagulation or precipitation of animal matter was produced by muriatic acid, neither was any change caused by the addition of pure alkali. It appeared, therefore, to Mr. Abernethy, that the water of perspiration contains little of any thing, except a very small portion of salt.

We cannot reasonably doubt that the greater part of the matter of perspiration is water; but it certainly contains other matters, of which the nature is not well ascertained. Its sensible properties are often very perceptible: it causes the peculiar odour of the body, which is very remarkable in particular individuals, and possesses peculiar characters in whole races of mankind. Its smell is often four; and it is said, under such circumstances, to change the vegetable blue colours to red. Berthollet thought he had detected the presence of the phosphoric acid; he observed that a blue paper, applied to a part labouring under a gouty paroxysm, became red; but Fourcroy remarks, that if this acid were constantly deposited, it must accumulate on the skin, as it is too fixed to be volatilized with the aqueous vapour of perspiration.

From the strong odour of the perspiration when profuse, and from the tinge which it communicates to linen, there is reason to suppose that it contains a particular animal matter. In the perspiration of the horse, an animal substance of the nature of urica has been detected by Fourcroy and Vauquelin, who have also discovered that the phosphate of lime is left in considerable quantity by the evaporation of the perspired matter on the skin of the same animal. It seems to crystallize on the surface, and forms the branny matter detached by friction of the surface. The above-mentioned chemists observe that the urine of this animal contains no calcareous phosphate.

INTEGUMENTS.

Mr. Cruikshank's experiments prove clearly that there is an oily matter secreted by the skin: indeed the familiar appearance of the repulsion of water, so as to cause it to run into globules, sufficiently evinces the fact. Mr. Cruikshank wore the same veil of fleecy hoisery night and day during the hottest part of the summer. At the end of this time he always found an oily substance accumulated in considerable masses on the nap of the inner surface of the veil, in the form of black tears. When rubbed on paper, it makes it transparent, and hardens on it like grease. It burns with a white flame, leaving behind a chisry residuum.

Besides the condensable vapour which is exhaled from the skin, it has been asserted that gaseous fluids are also separated. Many philosophers have laboured on this subject, but the results of their experiments are so contradictory, that we cannot deduce from them any very satisfactory conclusion.

The count De Milly seems to have been the first who called the attention of philosophers to this subject. He had often remarked the accumulation of small air-bubbles on the surface of his body, when immersed in the warm bath. At length, by means of a funnel and inverted glass jar he collected, in a few hours, half a French pint of the gas, which was examined by Lavoisier. It was incapable of supporting combustion, produced a precipitation in lime water, and suffered no change from the admixture of nitrous gas. Acad. Roy. des Sciences de Berlin, 1777.

Mr. Cruikshank found that a lighted taper, introduced into a bottle in which his hand or foot had been confined for some time, burned dimly; and lime water agitated in it was rendered turbid.

Ingenhous could not procure the air from the skin in the warm bath in such quantity as the Count de Milly did. What he collected seemed to be azotic gas. *Expériences sur les Vegetaux*, t. 1.

Priestley denies that any gas is perspired by the skin. He repeated the experiments of Ingenhous, and never could observe the appearance of gas arising from the body when he employed boiled rain water, from which the air had been completely expelled, and detached the adhering bubbles from his arm. He observes that the air obtained by Ingenhous "was just that mixture of fixed air and partially phlogisticated air, that pump-water, which he recommends for the purpose, generally abounds with." *Experiments and Observations*, vol. v. p. 103.

Fontana arrived at the same conclusion from his researches.

Such also was the result of Mr Jurine's experience, who, after remaining in the bath at different temperatures from 18° to 30° of Reaumur for hours together, never could procure a single bubble of air from his skin. He obtained the same result from observations on several individuals in water of various temperatures. *Histoire de la Société Royale de Médecine*, tom. 10.

Mr. Cruikshank's experiments seemed to prove that air, which has been confined for some time in contact with the skin, becomes changed; though Dr. Priestley maintained that the perspirable matter has no such effect on the air, but leaves it as wholesome as ever.

A very extensive set of experiments performed by Mr. Jurine, of Geneva, and published in the volume already quoted of the *Memoirs of the Royal Society of Médecine*, seems to confirm the observation of Mr. Cruikshank. Although Mr. Jurine could not collect any air from his skin, when immersed in the warm bath, he always found the air

confined about the skin much vitiated. He fixed well-dried bottles under his arm-pits, and round his waist, and having left them there for an hour, accurately corked and removed them, that the contained air might be examined by the usual tests. In these experiments he always employed the mercurial trough. This air was found, on different occasions, to contain .7, .7½, .6, .4½ of carbonic acid gas. He next inclosed his arm in a glass cylinder containing 68½ cubic inches of air. One extremity of this vessel closely embraced his arm, round which it was cemented. To the other extremity was fixed a bent tube, which, during the experiment, was plunged under water in the pneumatic trough. After two hours, the air of the cylinder was found to contain .8 of carbonic acid gas. In another experiment the same quantity was obtained after one hour; but the proportion of carbonic acid gas was not greater at the end of two, three, or four hours. Being thus fatished that carbonic acid gas is formed by the skin when in contact with the air of the atmosphere; he concluded, that he should find the same gas under the bed clothes which confine the air round the body during sleep; and in experiments on different individuals he found that this air contained .4, .6, .7, .8 of carbonic acid gas.

In the same volume are some experiments by Gattoni, which do not lead to the same conclusions with those of Jurine; but they do not seem to have been very accurately performed, and the test of lime water was not employed.

We come in the next place to the researches of Mr. Abernethy. From the hand, introduced into a glass jar filled with mercury and inverted, he collected, in the space of sixteen hours, one half-ounce measure of air, which had escaped in small bubbles from every point of the surface of the immersed hand. Two-thirds of this gas were absorbed by lime water; and the remainder suffered no diminution from the admixture of nitrous gas. When the experiment was repeated under water, a small quantity of azotic gas only was obtained, the carbonic acid having been, in the opinion of Mr. Abernethy, absorbed by the water. The hand was exposed five hours, in a jar containing seven ounces of atmospheric air, which was diminished about half an ounce. One ounce of the remainder was absorbed by lime water, with precipitation of the lime. By the test of nitrous gas the air was found to contain nearly ¼th less of oxygenous gas than it did before the experiment. When a similar experiment was performed with seven ounces of azotic gas, rather more than one ounce measure of carbonic acid gas was produced in two hours. The trials were repeated with hydrogenous, nitrous, and oxygenous gases, and in every instance nearly the same quantity of carbonic acid gas was obtained.

In the 45th vol. of the *Annales de Chimie*, there is a short paper by Dr. Troustet, who had noticed, like Milly, the appearance of bubbles on the skin in the warm bath. He seems to have seen this only in two individuals, and found the air to be perfectly pure nitrogen. In his own person, and in many others, he could observe nothing of the kind.

Spallanzani is the last experimental philosopher who has paid particular attention to this subject. The detail of his experiments has not been published, but the results are preserved in a letter to Senecber, introductory to the *Memoirs on Respiration*. He appears to have been completely fatished that air in contact with the skin is changed exactly in the same manner as by respiration. When atmospheric air was employed, oxygen disappeared, and carbonic acid gas was produced: he was of opinion, that the oxygen of

the atmosphere had no share in the production of the carbonic acid gas, because it was equally great when the animal was confined in gases containing no oxygen; and he therefore concludes, that the carbonic acid gas was exhaled, and the oxygen absorbed.

On a review of these very contradictory evidences we do not seem to be warranted in believing that any gas is separated from the skin; but perhaps we may conclude that the air in contact with the organ undergoes a peculiar modification.

Sweat Glands of the Skin.—This organ is habitually covered with an oily substance, which occasions water to run into globules on the surface of the body, which imparts a greasy stain to linen, when it is worn for a long time, and which occasions dirt, &c. to adhere to the skin. This unctuous substance is more abundant in some parts of the body than in others. About the face it is observed in considerable quantities, and on the hairy scalp. Hence, when personal cleanliness is not sufficiently attended to, the hair becomes quite greasy and shining. It is abundant in situations exposed to friction, as the axilla, perineum, &c.; and when confined in such parts causes a very disagreeable odour. It is found in very small quantity, so that it can hardly be observed, in the palms and soles. Certain races of mankind, as the negroes, have it in great abundance. Probably the sensible qualities of the cutaneous discharge depend in great measure on this matter, the particular nature of which is but little understood. It does not seem to undergo those changes of augmentation and diminution which are observable in the perspiration. Its obvious utility seems to be that of protecting the skin from the agency of external causes, and keeping it in a state of softness.

Is this matter simply an exhalation from the cutaneous vessels, or is it produced by glandular apparatus? In some parts of the skin, as about the nose, and in other situations of the face, the external ear, &c. there are very manifest small rounded bodies, with a simple aperture, from which a sebaceous matter may be sometimes expressed like a fine thread. Morgagni also admits their existence in the neck, back, perineum, buttocks, &c. Haller does not conceive that they are proved to exist in all parts, and we certainly do not find them: yet this oily matter is formed over the whole body. The examples of the fat of the cellular interstices and of the medullary fluid of bones shew us that the exhalants can produce matters of this kind.

Properties of the Dermoid System.

1. *Properties resulting from Organization.*—These are found to exist in the skin in a very striking degree: the changes of size, in which different parts, particularly the limbs, swell to twice or three times their natural bulk, and then recover their former state, prove these properties; and the various tumours, external aneurisms, sudden distentions from great bruises, collections of fluid in the abdomen, pregnancy, enlargements of the testicle, &c. afford additional proof. In all these cases the skin is first expanded, and then is restored when the distending cause ceases to act. A square inch of integument has been found able to sustain a weight of 200lb.

The contractility of the skin occasions the retraction of its edges when it is cut: and this occurs in the dead subject; but it seems to be heightened by the vital powers as it occurs to a much greater degree during life.

The extensibility of the skin is less in many cases than it would appear to be on first sight, as the neighbouring integuments are drawn over a tumour. Thus in large swell-

ings in the scrotum, the skin of the penis covers part of the tumour, &c.: in extensive cicatrizes the skin of the surrounding parts is drawn towards the centre of the ulcer.

In most extensive the thickness of the dermoid tissue is diminished. When it is distended by the infiltration of water in its interstices, as in anasarca, its thickness increases, while the density is diminished. It seems to lose the power of extension, so as to burst under the action of a distending cause, from chronic inflammation. Most of the chronic affections, which alter the tissue of this organ, destroy its contractile power.

Vital Properties.

2. *Properties of the Animal Life.*—Animal sensibility exists in this organ in a very high degree: it partakes over the general sense of feeling, which is more acute in this than in other tissues, and also that of touch, which is very distinct from the former. The general sense, called by the French tact, is the power of perceiving the impressions of surrounding objects: in this signification it seems to mean the same as the English word feeling, which is the office of a nerve in general; as those organs only are so affected by external bodies as to produce some change by which the mind is rendered conscious that the bodily organ has been modified. Thus heat and cold, roughness and smoothness, hardness and softness, moisture and dryness; pressure causing pain; acid qualities; titillation producing itching, &c. are all perceived by the nerves. This kind of tact belongs to the whole body; and does not suppose any peculiar arrangement of the organ; it is merely the animal sensibility considered in a state of exercise. Thus, when the particular modifications of this sensibility belonging to the other senses have been destroyed; when the eye is insensible to light, the ear to sounds, &c. the organs still retain the power of perceiving the presence of bodies and their general attributes.

The sense of touch is the power belonging to the skin alone, of examining more minutely and accurately those properties of bodies, which we have just named. For this purpose we employ chiefly the ends of the fingers; those of the toes seem to be organized exactly in the same way, and are incapable of being turned to this use by the hardness of their coverings. These parts are conspicuous for the size of their nerves, and for the number and prominence of the papillae. This organization gives to them a more exquisite sensibility of the same kind with that belonging to the skin in general. The form of the organ in the human subject, where it is composed of several movable parts, adapts it particularly to serve as an instrument of touch, by facilitating its application to external objects; and this advantage may be more particularly seen in bodies of a rounded figure. We rub the fingers gently against the object, so as to apply the papillae successively to the different points of its surface. Whether any physical change takes place in the organ, whether the papillae for example are erected or no, is entirely unknown.

The distinction of colours by blind persons, if such a power has really existed in any instance, must have arisen from modifications in the surface produced by the colouring matter. We know that the touch in all cases of blindness acquires great acuteness, as it must be so much more exercised and depended on, than in individuals who can see.

The temperature of bodies is estimated by a comparison; those are called cold, which are of a lower temperature than what we had felt immediately before; and *vice versa*. Or we refer to the state of our own surface, and call the objects, from which heat passes to us, warm, and those of the opposite kind cold. The same fluid will appear cold to one hand

INTEGUMENTS.

and warm to the other, if we have previously immersed one in a warmer, and the other in a colder medium.

It has been conceived that the sense of touch is of great use to us in correcting the errors of the other senses, and particularly of the sight. This peculiarity belongs to it certainly, that the organ is modified by the very body whose properties we are examining; while, in the case of vision for example, the eye is affected not by the object itself, but by the rays of light. Perhaps we are less deceived by the other senses, and by that of sight itself, than has been commonly imagined. Without any assistance from the sense of touch, for which his organization entirely disqualifies him, the horse measures the hedge or ditch with his eye most accurately, and clears the distance with great exactness. Newly born animals seem to commit no errors in seeking their food or their parents, &c. On the other hand, the touch is not free from error. The experiment of rolling a round body under two fingers decussated, which give us the sensation of two bodies, shews this. Moreover, the touch no more informs us of the real nature of things, than any other sense; we acquire a knowledge of their properties through certain interposed media, and alterations in them very much modify the perception. When the epidermis is removed, external bodies cause pain, and do not excite the impressions, which inform us of tangible properties; again, when the cuticle is preternaturally thick, as in the hands of labouring men, no sensation takes place.

This sense is also subject to various morbid conditions. In hypochondriacs there is sometimes a feeling as of cold air; and the slightest contact of air is intolerable. Ann of Austria found the finest linen manufactures unpleasantly rough; and some have not been able to endure the touch of silk, or of the down of a peach.

Habit, too, has a powerful influence in modifying the impressions which we receive from the touch. The heat of a glass-house, which is sustained without any unpleasant feeling by the workmen for several hours, is intolerable to a person unaccustomed to it.

The touch differs from the other senses in not requiring a peculiar mode of sensibility for its exercise; the hand is rather more sensible than the rest of the skin, but we can touch with other parts of our surface. In the other senses there are peculiar kinds of sensibility disposing the organs to be acted on by particular objects, and rendering them unsusceptible of other impressions. The exercise of the touch is determined by volition, and is generally consequent on the employment of the other senses.

Most of the other senses require an express organic arrangement, as well as a peculiar sensibility in the organ; the touch, on the contrary, requires only a particular form in its organs. If they have the animal sensibility, and can embrace objects by several points, they can distinguish the tangible properties. The touch will be imperfect, if the organ is in contact with the body only in one or two points; yet it will take place. Thus we can touch with the hollow of the axilla, at the bend of the elbow, or the knee. But the sense is exerted more advantageously when the points of contact are multiplied. The structure of the human hand is particularly well contrived in this point of view; it shews it that man is calculated, much more than the animals, for communication with surrounding objects; that the contain of his animal life is therefore much more extensive; that his sensations are more precise, as the possessors of additional means of perfection; that his intellectual structure is capable of filling an infinitely greater sphere, because they are grounded on the exertion of a much more perfect organ.

The sensibility of the hand seems to reside essentially in the papillae, which be the part of the integuments truly belonging to the animal life, as the vascular plexus, composing the reticular body; it is connected with the organic functions. Its very acute sensibility requires a protection from too strong impressions; and this is afforded by the epidermis. When that is removed, even the impression of the air is painful, and causes a sensation, which we call smarting, which belongs perhaps exclusively to the dermoid system. It is felt in burns, blisters, erysipelas, and in all the inflammations affecting the reticular body of the skin. Itching is another mode of sensation peculiar to this system.

Besides the impressions, which teach us the properties of bodies, the exercise of this organ produces feelings of pleasure and pain. So far as the sense of touch is concerned, pleasure may be considered as that condition of the body, which we should wish to have continued. The more exquisite feelings of this kind are produced by friction of the papillae. Without referring to venereal sensations, we may mention a practice of the Chinese, of introducing a small pencil into the ear and moving it round so as to excite a very acute pleasurable feeling. Tickling must be something of this kind; it is peculiar to the skin, and in many individuals excites sensations which are almost intolerable. Great differences in this respect are observed in different persons. Pain is the very reverse of pleasure; and, in the skin, is the most acute, when the naked organ, where it possesses many papillae, is irritated.

The animal sensibility of the skin, like that of the mucous surfaces, is under the powerful influence of habit, which transforms successively into indifference, and into pleasure what was at first painful. The air in the successions of the seasons, heat in the various states of the atmosphere, water in the bath, or in the humid vapours with which it loads the medium in which we live, our clothes, of which the woollen are at first very unpleasant, in short, every thing which acts on the skin by simple contact, produces sensations which are incessantly modified by habit. Observe the varieties of dress in different countries; sometimes the upper limbs are uncovered, sometimes the lower; in some instances more or less of the trunk is exposed to the air; often the savage is entirely naked. The parts which are left naked in each people, support the contact of the air without any painful sensation. Expose, on the contrary, the parts which are habitually covered, particularly if the atmosphere be cool, a painful sensation will be produced at first, but, as the parts become gradually habituated to the contact, they are at last insensible to it.

But habit has no power over that heightened state of the cutaneous sensibility, which results from an organic affection, as inflammation for example. The slightest contact of a foreign body is extremely painful in this case; and consequently the skin can no longer exert its function of touch. Even the tact, or the power of distinguishing general sensations, is destroyed. The impression of all bodies is uniform; it is that of pain.

The animal sensibility of the skin may be diminished or destroyed, as in palsy; but the whole organ is never affected; and in this respect there is very seldom even hemiplegia. These cases afford a further proof that the cutaneous exhalation and capillary circulation are not influenced by the nerves, since both go on very well as they do in the paralysis of the moving organs.

Properties of the Organic Life.—The organic sensibility and the insensible contractility exist in the skin in a very high degree, and reside particularly in the exterior capillary system, which
forms

forms the reticular body. On these properties depend immediately, 1, the capillary circulation; 2, the cutaneous exhalation; 3, the absorption; 4, the nutrition of the dermoid system; and 5, the secretion of the cutaneous oil, where sebaceous glands exist. Besides these numerous functions, we must reflect that the skin is constantly exposed to the action of external causes, which keep it in a state of habitual excitation, as the contents of mucous surfaces act on those surfaces.

The skin does not seem to possess the sensible organic contractility; irritating applications act only on the capillaries, and therefore produce an effect, which is not obvious to the eye. Yet the corrugation of the integuments under the strong action of cold, resembles in some respects the sensible organic contractility; this, which takes place in the corion, seems to hold the middle between the two kinds of organic contractility.

Passive Sympathies.—The animal sensibility is often brought into action sympathetically in the skin, by the affections of other systems. There are various examples of itching, &c. without any derangement of the part, to which the sensation is referred.

Very often the feeling of heat or cold occurs in the skin, when there is no cause affecting the organ to produce such sensations; there seems to be an erroneous reference of the unpleasant feeling to its source as in the case of pains felt in amputated limbs. The shiverings which occur at the commencement of most acute local diseases are of this kind: there is often a sudden and sympathetic sensation of cold on the skin at the moment of the expulsion of the semen; the shivering of fear, and the sweat which often accompanies it, seem to be of the same nature. A species of sympathetic cold is also often referred to the skin at the commencement of digestion.

The feeling of heat often occurs sympathetically in the skin. The flushings, which occur so often and irregularly in different fevers, are well known, and are not attended with any disengagement of caloric. These feelings of heat and cold are produced without any alteration of temperature, as sympathetic pains occur without the action of those obvious causes, which give rise to them under other circumstances. In fact, the sympathies of the animal sensibility call into action, in each system, the feeling which is habitual to it. The same cause which produces the sensation of heat or cold in the skin, would have given rise to that of lassitude in the muscles, &c.

The organic properties of the skin are frequently called into action by sympathies: thus cold drinks suppresses perspiration. Augmented cutaneous exhalation follows almost immediately the introduction of warm fluids into the stomach. The sweat of fear and that of consumption are of the same nature. Diseases exhibit to us innumerable varieties of dryness and moisture of the organ, phenomena which are generally sympathetic.

Active Sympathies.—The irritation of the skin in tickling, in very sensible individuals, excites various organs sympathetically; as the heart, producing fainting; the stomach, vomiting; and the brain, convulsions. Affections of the cutaneous exhalant, or of the capillary system, from which they arise, act sympathetically on various organs. Thus the skin when bathed disturbs the process of digestion; while its disease in many cases alays disorders of the stomach. The action of cold on the surface, particularly during sweating, produces several sympathetic effects. We express what occurs more accurately, when we refer to the translation or reflection of the perspiratory matter. The organic sensibility

of the pleura is sympathetically affected by the application of cold to the skin; just as an uterine or nasal hemorrhage may be stopped. The suppression of transpiration is an accessory circumstance completely foreign to the internal inflammation. If there were no perspiration at the time that the cold is applied, the inflammation would still come on.

The shaking of the muscles, and the concentration of the pulse, produced by the weakened action of the heart, are phenomena caused entirely by the action of cold on the skin.

The numerous phenomena occasioned by the sudden disappearance of cutaneous eruptions should be referred to modifications of the vital properties of the organs, and not to any morbid matter repelled from the skin.

The serous surfaces and the cellular substance on one side, and the skin on the other, are often in opposition in diseases. Patients never sweat during the formation of dropries; and this dryness of the skin is often more remarkable than the small quantity of urine.

Character of the vital Properties.—1. They vary in the different regions of the body. The palms and soles are the most distinguished for their animal sensibility: the hypochondria are so sensible in some individuals, that tickling will produce convulsions: the anterior and lateral parts of the trunk are more sensible than the back. The organic properties do not differ less; of which the great susceptibility of the face to the influx of blood is a proof. Particular parts are subject to particular cutaneous diseases, &c.

2. Intermittion of action in one respect, uninterrupted continuance in another. The former character belongs to this system, as to all the senses, in its animal sensibility. Immediately before sleep comes on, external objects produce but an obscure sensation, which is entirely lost in that state, in which animals seem to part with half their existence. Yet the touch seems to be exerted occasionally while the other senses are in repose; pinch the limb of a person sleeping, and he will move it without waking, or retaining any recollection of the occurrence. In its organic sensibility the life of the cutaneous system is uninterrupted; consequently the functions, over which this property presides, have an opposite character to the preceding. The insensible transpiration goes on continually, although it is more active at some times than at others.

3. Influence of sex. The animal sensibility is more acute in women, in whom every thing belonging to the senses is more developed, while the power of the muscles predominates in man. No very sensible difference can be remarked in the organic properties.

4. Influence of temperament. The colour and other sensible properties of the skin vary in individuals, and these variations even constitute characters of the different temperaments. When we see these differences of organization, can we be surprised at finding that the sense of touch is acute in some, dull in others; that some persons are very susceptible of tickling, and others almost insensible to it? That the organic sensibility admits a great quantity of blood into the capillaries of the face in some, and rejects it in others; that some have a moist and others a dry skin; that there are dispositions in individuals to particular cutaneous affections, chronic or acute? &c. &c.

Development of the dermoid System.—The skin, in the earliest times of conception, appears as a viscid coating, which is gradually condensed into a transparent layer, then by the slightest violence, and allowing the subjacent organs to

ticularly the blood-vessels, to be easily seen through it. Its confidence increases until it acquires the appearance exhibited at the time of birth. In its mucous state cellular substance and vessels compose it entirely: when the fibres of the corion are added, it becomes firmer. The external surface exhibits but few of the wrinkles described above; they are prevented from appearing by the large quantity of subjacent fat. The inner surface adheres but slightly to the cellular layer under it. It contains more blood than at any other period of life. The animal sensibility is not yet called into exercise; there are no causes to excite it. Is the organic sensibility in action at this time? It must be so in a certain degree to produce the unctuous secretion, by which the surface is covered.

This system undergoes a sudden revolution at the infant of birth. Hitherto it has received only black blood, and is consequently more or less livid at birth. This colour gives place to red, produced by the arterial blood now first formed; and the state of the skin in this respect may be considered as an index of what is passing in the lungs. All parts of the organ are penetrated uniformly by the red colour. A sudden excitation is thus communicated to the organ, exalting its vital properties, and rendering it more susceptible of the impressions of surrounding objects. The surrounding temperature, the air, clothes, the water used in washing it, communicate to the skin an excitation, which is the more sensible in proportion to its novelty. The sympathies connecting the skin to the other organs now become necessary: thus the internal organs quickly feel the excitations applied externally.

The organic sensibility is augmented at the same time; transpiration is established; various substances are separated by it; others perhaps absorbed; and various diseased affections shew themselves.

The organ still continues soft for some time after birth; and melts entirely into jelly very easily by ebullition. Its density increases gradually, but has not arrived at its greatest state till towards the thirtieth year. As this augmentation proceeds, the fibrous substance is increased in proportion to the gelatinous. At the same time the adhesion of the internal surface to the cellular substance becomes stronger, and the wrinkles of the face are gradually formed. No remarkable change is produced in this organ at puberty; sweats are more abundant after this time; in children the residue of nutrition passes off by the kidneys rather than by the skin.

The organ still retains a great activity after the age of growth, and very easily influences other parts of the frame: hence the peripneumonies, pleuritis, &c. produced by the action of cold.

The increase of the fibrous substance renders it more firm: less blood seems to be sent into its vessels, and it is less subject to those eruptions so common in infancy and youth.

In declining age the dermoid system becomes more and more dense: it resists ebullition for a long time, but yields a firmer and more consistent, though less abundant jelly. It is stronger but less pliant. The blood penetrates it in smaller and smaller quantity: the redness of the cheeks disappears. The adhesion to the cellular substance is much more close. All the wrinkles are more strongly marked, and several are now perceptible for the first time.

The vital powers of the skin are more weakened than those of other systems in the old man, because it has been more excited by external objects during life: the habit of feeling has blunted its sensibility. The touch is now exer-

cised but rarely; as this sense is employed in a great measure in subservience to those of sight, hearing, &c. to rectify or confirm our other sensations, the old man, being acquainted with what surrounds him, has no motive for the use of his organ of touch. Contrast, in this point of view, the two extremes of life. The infant, to whom every impression on the sight, hearing, &c. is new, wishes to touch, to seize every thing; his hands are in constant motion. Touching is a great pleasure to him, because all new sensations are agreeable. If an old man were placed in the midst of objects, which had never before impressed his senses, he would exercise his touch more frequently; but, among the things to which he is habituated, there is nothing to excite him. Hence old age is no longer the time of enjoyment. Almost all our pleasures are relative; as habit renders these less lively, they cease in consequence of having existed; thus the advance of years, by leaving us few new sensations, diminishes the sources of our happiness. For the contrary reason the happiest age is that of infancy; because the whole domain of sensation lies before us unexplored; at every step of his advancement man leaves behind him a source of enjoyment. This career ends in indifference, a state very suitable to that period, as it diminishes the interval between life and death.

The following phenomena shew that the organic, as well as the animal sensibility, is remarkably diminished in the old man. Contusions are less easily absorbed. The sweat is less abundant, and hardly ever exhibits those augmentations which are so frequent in the adult. The greatly covering it less copious, and hence the surface is drier. The various morbid affections, such as erysipelas, and the various eruptions, are less common and much slower. The power of resisting cold is sensibly diminished.

Epidermoid or cuticular System.—The slightest examination is sufficient to shew very striking differences between this and the preceding system, although physiologists have generally described this merely as a dependance of the former. The organization, properties, functions, mode of growth, in short, every circumstance is different in the two cases.

Under this head we consider the exterior epidermis; that which covers a part of the mucous system; and the nails. Many characters approximate the latter to the epidermis, although the external appearance is very different.

The exterior epidermis is a transparent layer, differing in thickness in different parts, every where covering the skin, and immediately exposed to the excitation of external bodies.

It has the same inequalities as the cutis, since they are every where exactly contiguous. Various pores penetrate it, and terminate on its surface: the more conspicuous ones transmit the hairs; others give passage to exhalants. The latter are not easily seen; but it, when the skin is dry, we suddenly begin to sweat, we can distinguish them by the small points of moisture then exhibited over the whole cutaneous surface. We cannot actually see the pores in the dead cuticle, even with the assistance of the microscope; and the fluid under a blifter does not escape through them; but the phenomena exhibited during life leave no doubt of their existence. The internal surface adheres most closely to the outer surface of the cutis. We conceive the union to be by means of the exhaling and absorbing vessels and the hairs. Dr. Hunter thought that the vessels could be demonstrated. On separating the cuticle after long maceration, particularly in the sole of the foot, a vast number of extremely fine and soft threads are seen passing between it and the cutis: they break after being extended to about

INTEGUMENTS.

one-eighth of an inch. These may be vessels; but it is only a conjecture. On examining the surface of the separated cuticle, numerous prolongations of various lengths are observed, appearing like small ends of fine threads, or as more inequalities, and disposed obliquely. These may be absorbents and exhalants. Whatever the medium of connection may be, the adhesion of the parts to each other is very strong.

Various causes destroy this adhesion of the epidermis, and occasion its separation. Acute inflammations, as erysipelas, phlegmon, &c. are followed by its detachment; and various eruptions, not of an inflammatory nature, cause its detachment in a dry scaly form; which has given rise to the notion that it is made up of scales in its natural state. When the skin is unequal on the surface, friction detaches it in small scales, which give a very rough appearance to the part. Fevers are not unfrequently followed by desquamation of skin. The action of veniferous is familiarly known. In the dead subject, putrefaction, maceration, and desiccation are the most effectual means of accomplishing the separation.

The thickness of the epidermis is in general very uniform; it does not seem to follow those varieties which we observe in the cutis of the trunk, limbs, &c. It is thickest in the palms and soles, and on the corresponding surfaces of the fingers and toes, that its thickness is increased; and here the augmentation is so considerable, that there is no proportion between these and other parts of the body.

There seem to be in this part several additional laminae; and the inner surface, after separation, does not exhibit those processes already spoken of. This excessive thickness prevents the action of blisters. In repeated trials Bichat found that they produced no effect. The transparency of the epidermis is destroyed by this thickness: it is here whitish, and even opaque. Hence, in the negro, it conceals the black colour of the reticular body; which, however, is, at the same time, less black here than in other parts. The epidermis in these situations is manifestly composed of successive laminae, adhering with such force, as to be very difficultly separated: in all other parts we can discern only a simple layer. No fluid can be noticed in this tissue: when cut in various directions, either in the living or dead subject, nothing exudes. Its scales are always perfectly dry: the absorbents and exhalants merely traverse it. No blood in the living state, nor injection after death, enter it in any case. It never participates in the diseases of the subjacent organs, except by being elevated when that is swollen, and then detached. Nerves and cellular tissue are completely foreign to it. Thus we see that none of the general systems, common to all organs, enter into the composition of the epidermis: it has not the common basis of all organized parts; and in this point of view may be regarded as inorganic. It seems to contain no fibre in its composition; it possesses very little power of resistance, breaking under a slight distention, except in the soles and palms, &c. where it is so thick.

The action of air produces hardly any effect on it. When a large piece is exposed, it becomes rather harder, and more consistent, and is torn more difficultly. Next to the hair and nails, it is the tissue least changed by desiccation. It is rendered a little more transparent, but immersion in water restores it to its former state. When the skin passes into a state of putrefaction, the cuticle is not at all changed. It is separated from the cutis, but is not rendered at all putrid; if it be thoroughly washed, it has no bad odour. When preserved in moist air, it is not changed; and it may be regarded as the most incorruptible of animal substances, after the hair and nails.

Moulture applied for a long time whitens the living cuti-

cle, and throws it into numerous wrinkles. This effect is observed in the application of poultices, and seems to arise from the tissue becoming permeated with the fluid; it takes place to the greatest degree in the feet and hands, and often is hardly sensible in other parts. The sensibility of the skin is rendered more obtuse by this change in the cuticle. The water imbued by the parts of the epidermis evaporates, the wrinkles disappear, and the article recovers its former state. When separated from the body, and immersed in water, it is whitened: it undergoes no putrefaction, but is covered by a whitish pellicle formed of separate molecules. At the end of two or three months it is softened, and may be torn very easily, but does not swell: it is never reduced to a completely analogous to that of other organs when macerated. Boiling water produces crispation or contraction of the tissue: prolonged ebullition renders it less resistant, so that it may be torn very easily, but never reduces it to gelatine, nor gives it a yellow colour. The laminae which compose it in the hands and feet are easily separated after long boiling. The tanning principle has no action on it; nor has alcohol.

When well dried in the air, and exposed to the flame of a candle, it undergoes no crispation, as a piece of skin does when treated in the same way: it exhales a fetid odour analogous to that of burnt horn. It burns with great facility, so that if it be lighted at one end, it will often be entirely consumed. A blackish fluid is observed in the flame, like that of burnt feathers. This is clearly of an oily nature, keeps up the combustion by its great abundance, and is found in so large a quantity only in the hair and nails: this produces a disagreeable odour. A blackish coal remains after combustion. Light does not seem to affect the epidermis, which is not changed when exposure to the sun has altered the appearance of the skin.

Nitric acid turns it yellow, but dissolves it with great difficulty. Sulphuric, on the contrary, when not much diluted, acts very powerfully on it, rendering it very thin and transparent, or dissolving it entirely by long immersion. Alkaline solutions dissolve it, but with difficulty: pure alkali acts on it rapidly; as also does lime, according to Chlapal.

If, says Dr. Thomson, the cuticle be mixed with nitric acid, the application of ammonia to it will be known to give it instantaneously a deep orange colour. Now, as Hatchett has shewn that this change is also produced upon coagulated albumen in the same circumstance, and as the epidermis resembles that substance in all the properties above detailed, it can scarcely be doubted that it is any thing else than a peculiar modification of coagulated albumen. *Syll. of Chemistry*, v. 5, p. 574.

Properties.—It has very little extensibility, as the smallest cutaneous tumour causes it to crack, and be detached in scales. Yet it is not entirely destitute of this property, as its elevation in blisters proves. It has no contractility; when no longer distended, the portion elevated in a blister collapses in wrinkles, and does not regain its original size. It has no animal sensibility in any part: it may be nicked, cut, torn, or injured in all parts without exciting any sensation. It differs from other organs, as cartilages, tendons, &c. which also have no animal sensibility, in being altogether insensible of that property, which they often acquire under certain kinds of excitement. The epidermis is equally destitute of the organic sensibility, and organic insensible contractility: it possesses no circulation, and is susceptible of no diseases, which depend on the organic properties. We have no proof, in short, that it enjoys any vital powers at all; so that we may consider the whole superficies of the body as composed of dead matter. "Its life," says Bichat, "is extremely ob-

INTEGUMENTS.

ferre; I even doubt whether it can be said to possess life. I am inclined to regard it as a semi-organized, or rather inorganic body, placed by nature at the point of communication between external dead matter and the living skin, and serving as a gradation between them."

The action of external bodies wears it away, and it is constantly reproduced. Scrape the surface with the blade of a knife, and an abundant greyish dust will be detached. This matter accumulates in greater quantity, when the skin is not frequently washed; under such circumstances there is often a considerable layer.

It is reproduced very completely after being removed; and differs in that circumstance from most other tissues. How this is effected has been a point greatly disputed by physiologists; but the explanations have been entirely mechanical and unsatisfactory. That it is deposited by the vessels of the skin cannot be doubted; and we shall probably understand how the process is effected, when we understand how the vessels make bone, muscle, nerve, &c. This reproduction only takes place on the skin: the thin pellicle covering the cavities of other tissues has a completely different texture. The different excrescences arising on the cuticle, as corns, &c. result from the exercise of this reproductive power. They are all insensible, have no vessels nor nerves, and possess the same consistence and colour as the epidermis. External pressure seems to promote their formation very powerfully; tight shoes produce corns; and much handling of heavy instruments in hard work produces the thick cuticular covering of the hand in blacksmiths and other mechanics.

The cuticle of the palms and soles is however originally thicker than that of other parts; this may be seen in the fœtus.

In the dead body the cuticle has a remarkable effect in preventing the evaporation of the fluids; none of which are dissipated so long as this covering remains entire. If the body be exposed in a high temperature, as of 100 or 120°, it does not seem to become dried; and where the limbs are distended in anasarca, if it has not cracked, none of the fluid escapes. Remove the cuticle, and the cutis quickly becomes dry, transparent, and horny, and the subjacent parts are subsequently affected in the same way.

The epidermis is seen very clearly in the fœtus, where its development is greater in proportion than that of other systems. It may be recognized when the skin leaves that pulpy state which we have spoken of. At the end of the fifth month it is thicker in the palms and soles than in other parts. It appears to undergo no change at birth; but grows rather thicker afterwards as age advances. In the old subject it differs from that of the adult only in being subject to scale and crack, and thereby appearing dry and rough.

Internal Epidermis.—Most authors have admitted an epidermis on the mucous surfaces; and they have generally supposed that this is the only part of the integuments that lines the mucous cavities. But a little examination will show us that this expansion forms only a superficial stratum, and that if it be detached by hot water from the tongue, palate, &c. an organ analogous to the corion is left behind.

1. *Epidermis at the Origin of the mucous Surfaces.*—It is very distinct at all the origins of the mucous system, at the glans, urethra, anus, nasal cavities, mouth, &c. It may be demonstrated in these situations by the excoaritions which sometimes affect them, by detaching it with a fine lancet, by the action of hot water, by maceration, &c. It is much more delicate in these situations than where it covers skin, and becomes more and more so as it penetrates deeper. In these parts it

is easily reproduced. It is destitute, like the exterior epidermis, of vital properties; and its nature seems to be in all respects the same; it yields the same results, when exposed to the same agents.

2. *Epidermis of the more deeply seated mucous Surfaces.*—As we advance further into these organs, the epidermis becomes gradually thinner, and soon is no longer perceptible. The most delicate instruments and methods do not enable us to demonstrate it in the stomach, intestines, urinary and gall-bladders, vesiculae seminales, and the various excretory passages. No epidermis is elevated on the surface of these organs by boiling or maceration; nor by blisters: nor is there any thing like a separation of such a covering in any diseases. We shall be disposed to conclude, from these considerations, that there is no cuticle on the deeply seated mucous surfaces, and that the large quantity of mucous fluids poured out in these situations supplies its place by protecting the corion from the impressions of noxious matters. The only circumstance that could induce us to hesitate, is the occasional separation of substances like membranes, which might be regarded as exfoliations of an epidermis. Numerous examples occur in medical writers of such matters being voided from the bladder, stomach, and intestines. On this subject we possess no very precise data.

The Nail.—We connect the history of these organs with that of the epidermis, as they adhere to it very strongly, and come away with it in maceration. Their form in the human subject differs very much from that which they have in animals: they are generally thick and conical in the latter, thin and flattened in the former. They consist of hard, transparent, and elastic plates, of a substance resembling that of the horns of animals, covering the extremities of the fingers and toes on the aspect of extension. Thus they are not adapted to purposes of offence, but are better suited to the support of the broad ends of these members, which confer on the human subject a more perfect power of touch. Their length is limited by the universal practice of cutting them to a level with the end of the finger or toe: if left to themselves, they are prolonged, and at the same time bent so as to cover the ends of those parts. The natural limit of their growth seems to be that period at which they acquire a sharp cutting edge: for they are then gradually worn away at the margin.

Three parts may be very easily distinguished in the nail: a posterior portion, covered on both sides by integuments: a middle part, which is the most considerable, adhering by its concave, and unattached on its convex surface; and an anterior, free from adhesion in both respects.

The posterior division is about one-sixth of the whole: it ends behind in a very thin serrated edge, by which the nail seems to grow out of the skin. This part is soft and flexible, and of a white colour: it is bounded by a straight line, which, with the two margins, give to the organ a square figure. The convex surface adheres intimately to the epidermis, which covers it in the following manner. The cutis terminates over the root of the nail in a semilunar edge, in front of which is a small cavity adapted to, and filled by, the white part of the nail. Along the concavity of this crescent the cuticle forms a small and distinct fold, which may be cut without any feeling of pain, and which is reproduced. It adheres closely to the root of the nail, and is produced anteriorly for some length on its surface, unless it be cut away. Many describe it as being continued over the whole convex surface. Behind it appears to be lost in the soft and thin posterior margin. Without the adhesion, which connects the semilunar border of skin

INTEGUMENTS.

to the nail, there would be a species of cul-de-sac between these parts. Some have conceived that the extensor tendon reaches to the posterior edge; but its termination at the tubercle of the last phalanx is very distinct; and there is a space of two or three lines between this and the nail. The concave surface of this posterior division adheres in the same way as that of the middle part.

The convex unconnected surface of the middle division is smooth, whitish behind for a small space terminated by a semicircular edge, and red in the rest of its extent in consequence of the colour of the subjacent parts. On the sides it is covered a little by the skin, which is continuous with the femoral projection already described. The fold of cuticle is also continued, and adheres to the margin of the nail. The concave surface of this part is laminated longitudinally, and the plates end in very thin and membrane-like edges; but this laminated texture does not extend to the white part. The organization may be well seen in the hoof of an animal, as the horse; where the plates are of considerable breadth and number.

The edge of this concave adhering portion is fixed in front by the epidermis, which, after covering the extremity of the finger, is attached to the surface of the nail at the front end of its laminated portion, in a curved line; here again it seems to be confounded with the substance of the nail.

The loose anterior portion, the length of which is limited by cutting, is manifestly thicker than the middle and posterior parts. Indeed the thickness, hardness, and resistance of the organ increase gradually from behind forwards.

At the attachment of the nail, the skin is marked by a deep parabolical groove, in which the former is received; the fold, which bounds this groove behind, overlaps the white part of the nail, covers a considerable portion of it, and adheres firmly to the posterior thin edge. From this hollow the cutis is produced over the posterior surface of the last phalanx to the end of the finger, between the nail and the bone, and adheres closely to the periosteum. At the sides and in front it is continuous with the common skin. In this situation it has a peculiar organization; it becomes softer and redder, has more numerous vessels, and is distributed in longitudinal laminae, corresponding to, and received between, those of the nail. But the portion of skin corresponding to the white part of the nail, is also different in its colour, and not laminated on its surface. From this part numerous fine and long papillae or villi arise, and are received into corresponding hollows of the nail: the same structure exists more or less over the whole surface covered by the nail. It appears that the organ grows principally from the white part: at least, if a mark be made towards the root, it gradually advances to the loose edge, coming more and more forwards until it entirely disappears. The papillae of this part give to the organ a very exquisite sensibility: hence the acute pain of paronychia, and of that barbarous practice of tearing off the nails.

Organization and Properties of the Nails.—These can be most advantageously observed in the larger ones, as those of the thumb or great toe. A single lamina occupies the whole convex surface; this exists alone at the posterior edge, and hence the thinness of that part. New plates are successively added on the concave surface towards the front, so that the organ becomes successively thicker and thicker; they may be easily removed in separate strata, and are shorter and shorter as they are placed more and more towards the front.

These laminae, composing the nails, seem to be in their nature nearly identical with the epidermis. The most superficial is manifestly continuous with that organ by its edges. The nails may be detached and are regenerated exactly as the cuticle is. Their vitality is as obscure as that of the cuticle; they exhibit no trace of animal sensibility, nor of any organic property. When burnt they cause a disagreeable odour like that of the epidermis, and exhibit altogether the same phenomena. Mr. Hatchett conceives that they consist, like the cuticle, of coagulated albumen. They contain a little phosphate of lime. Maceration and coction do not, however, produce in these organs the same want of consistence or kind of brittleness which they do in the epidermis, on account of their greater solidity. The action of acids presents nearly the same phenomena. Thus, on the whole, the composition, organization, and properties of the nails and epidermis seem to be perfectly analogous; they make up together a perfect insensible covering to the cutis, a structure void of vital properties, and therefore exercising no vital functions. The only differences between them seem to be modifications of form and arrangement arising from the uses of the parts which they cover. Physiologists assign to the nails the office of supporting the soft ends of the fingers by which the sense of touch is exercised, affording to the papillae a point of resistance, and protecting them from external violence. They are so supposed to enable us to grasp objects more firmly, and to take up minute bodies more conveniently.

Development of the Nails.—While the skin is still pulpy in the fetus, the nails possess considerable firmness, but are very thin. Their length at the time of birth is not proportionate to what they acquire afterwards; they do not exceed, and frequently do not reach the ends of the fingers. At this time their transparency enables us to observe the livid colour of the venous blood circulating before respiration, and to observe how it is succeeded by the redder arterial fluid. After birth they increase as the epidermis does; and they become extremely thick in old persons.

Of the Hair, (Système Plexus of Bichat).—The human frame possesses much less of this covering than that of animals: the contact of external bodies with the skin being in great measure intercepted in the latter, the animal sensibility of the cutaneous organ must have much fewer external relations in them, and consequently perform a much less important part. In animals the reproductive and digestive functions seem to be the principal sources of pleasure.

1. *Hairs of the Head.*—The system predominates in this part, covering the cranium nearly as the bodies of animals are covered. For this reason, as well as on account of its convex form, which allows it to come in contact with bodies by a small surface only, it is very little capable of acting as an organ of touch. The face is less generally covered, excepting one part in the male sex. This portion of the body, in which most of our means of communication with external objects, as the organs of sight, smell, and taste are assembled, is not favourable in its form to the exercise of touch. The elongated snout of most quadrupeds enables them to touch external objects, to turn and move them in various directions, as well as to seize them for food; in man the former functions are exercised by the hands.

The boundary of the hair towards the front is very variable in different individuals; and these varieties influence the breadth and apparent height of the forehead; the direction of this part is dependent entirely on the bony structure. Hence the hair influences but slightly the expression

INTEGUMENTS.

of the figure: we attach the ideas of majesty and grandeur less to the breadth of the forehead, than to its perpendicular direction. The number of the hairs in a given surface is singularly variable: they may be so close as to touch in every point, or may leave intervals in which the skin of the cranium is visible. We hardly know the natural extent of their growth. They will sometimes become so long as to touch the thighs or even legs; and this circumstance, like a crowd of others, tends to prove the destination of the human subject to the erect attitude. It has been questioned whether the practice of cutting them produces any physiological effect; whether the constant growth, rendered necessary by this practice, be performed at the expence of any other parts or functions.

The strength of the hair is very considerable in proportion to its slender bulk: no part in the animal economy, not even the fibrous system, will support such considerable weights. Ropes made of hair would therefore be very useful, if they could be procured of sufficient length.

Smooth and straight hair grows to the greatest length; in proportion as it is curly it is shorter, of which the woolly kind in the negro is a remarkable example. The colour varies in the different races of mankind, and thus becomes a characteristic attribute in the natural history of the species. But it varies no less in the different individuals of the same species; and these varieties follow the same general rule with that which regulates the colour of the skin and eyes. Hence these differences are to be considered in enumerating the characters of the different temperaments.

The eyebrows and eyelashes are described under the article EYE. The hair composing the beard, which we have alluded to in the article GENERATION, as one of the sexual distinctions of the male, is shorter than the covering of the head, and longer than any other hairs in the body: it is always more or less disposed to curl, is stronger and less greasy than the hairs of the head. It generally follows their colour; but very often deviates into the red tint. Its quantity varies singularly in different individuals: common opinion associates the idea of strength to its abundance, particularly if it be black. For some remarks on the effects of cutting it, see HAIR.

2. *Hairs of the Trunk.*—Their quantity is exposed to very great variations; some being almost covered, while others have the surface perfectly smooth. They are much more numerous in front than behind; and in the former situation abound chiefly on the chest; and in the course of the linea alba in men. There are none on the thorax in women, who have altogether but few on the trunk. A considerable collection, resembling the beard in its nature, is found about the generative organs in both sexes. These are very seldom light in colour, frequently approaching to red, and very commonly black. This increase of the hairy system is almost peculiar to the human subject. Its quantity varies very greatly.

3. *Hairs of the Extremities.*—These organs are for the most part covered: the number of their hairs is nearly uniform in most individuals, but the length differs greatly. In the hollow of the axilla, a small collection occurs resembling those of the genital organs: but there is nothing like this in the lower limbs. The inner surface of the arm and forearm has none of this covering in most men: but the lower limbs are more uniformly covered; the back of the foot and hand are constantly covered, but the palms and soles, and corresponding surfaces of the fingers and toes, are always perfectly smooth. The latter circumstance seems to contribute to the perfection of the organ of touch.

On the organization and mode of growth of the hair, the reader is referred to that article.

Properties of the Hair.—It experiences but a slight corrugation from the action of heat, but it is twisted or curled in various directions: moisture makes it straight again. It hardly possesses any extensibility or contractility. Whether they have any vital properties is a subject of dispute: at all events they are exceedingly obscure. We are disposed to deny their existence in this system, as well as in the epidermis and nails. Bichat, who, for some of the reasons explained in the article HAIR, conceives that they are the seat of vital processes, adds, "we cannot however deny, that in the natural state these organs come next to the epidermis and nails in possessing the least active life, and having the fewest relations to other organs. While all other systems are deranged by disease, this is generally unaffected; the hair grows as usual, and seems not to experience the slightest disturbance; its mode of existence is, therefore, quite different from that of other structures."

Mr. Hatchett concludes, from his experiments, that hair contains gelatine, and owes its suppleness and toughness to that matter. This may be separated by boiling it in water, after which it is much more brittle. If the process be continued for a long time, the hair crumbles in pieces between the fingers. The portion insoluble in water possesses the properties of coagulated albumen. Vauquelin obtained a solution of human hair in water, by raising the temperature of the fluid in Papin's digester. When the heat was too great, it was decomposed, and ammonia, carbonic acid, and an empyreumatic oil formed. Sulphuretted hydrogen is always evolved, and its quantity increases with the heat. The solution of hair effected in this way contains a kind of bituminous oil, which is deposited very slowly. The colour of this oil corresponds with that of the hair. Filtration allows a colourless fluid, in which copious precipitates are formed by infusion of galls and oxymuriatic acid, to pass through. Silver is blackened by it, and acetate of lead precipitated brown. Though very much concentrated by evaporation, it does not concrete into a jelly. Water, containing four per cent. of potash, dissolves hair with an evolution of hydrofluorure of ammonia. A thick oil, differing in colour according to that of the hair, with some sulphur and iron, remains undissolved. Sulphuric, muriatic, and nitric acids dissolve it: with the latter an oil is separated. Oxymuriatic whitens, and then reduces it to a substance of the consistence of turpentine. Alcohol, digested on hair, extracts from it two kinds of oil: the first is white, and subsides in white shining scales as the liquor cools; the second varies according to the hair employed: it is greyish-green when black hair is used, and as red as blood when red is employed. When incinerated it yields iron and manganese, phosphate, sulphate and carbonate of lime, muriate of soda, and a considerable portion of silica. The ashes of red hair contain less iron and manganese; those of white hair still less, but they contain magnesia. The ashes do not exceed 0.015 of the hair. According to the above experiments, performed by Vauquelin, black hair is composed of the nine following substances; 1, an animal matter, which constitutes the greatest part; 2, a white solid oil, in small quantity; 3, a greyish-green oil in greater abundance; 4, iron in an unknown state; 5, oxyd of manganese; 6, phosphate of lime; 7, carbonate of lime, in very small quantity; 8, silica; and 9, sulphur. Thomson's System of Chemistry, book v. chap. 2. sect. 7.

Development of the Hair.—In the first months none can be perceived. When the fibrous part of the cutis begins

to be perceptible, we see a slight down on the head, concealed, in great measure, by the white unctuous matter. The colourless down begins to assume something of the tint which the hair will have after birth, but it is in all cases pale till birth, when it may be half an inch long on the head, although it is only in the state of down in any other part. It grows much more rapidly after birth than before; but is always comparatively lighter in colour in proportion as the subject is younger. The age of puberty witnesses a remarkable change in this system in the development of the beard, of the hair about the organs of generation, and in the axillæ. It undergoes very little change in the following years; but is said to grow more rapidly in summer than in winter. Towards the end of life the hairs feel that general obliteration which affects all the exterior vessels: it ceases to receive colouring matter, and becomes grey. On the subject of this change, see HAIR. After remaining grey for some time they fall off, and the bulbs shrink and disappear. Bichat found no traces of the latter parts in the integuments of perfectly bald old men: but they were entire in the case of a man who had lost his hair from a putrid fever.

It has been very generally supposed that the hair, nails, and epidermis continue to grow after death: but we have no very accurate observations on this subject. Bichat saw the fact in a closely shaven head macerated for eight days: and there is no greater difficulty in admitting this than in allowing that the absorbing vessels can continue their action at the same time. The growth of the hair does not seem to go on at a rate proportioned to the degree of living power: it is as rapid in cases of prostration as in those where these forces are augmented.

Bichat, *Anatomic Generale*, tom. 4. Haller, *Elementa Physiologie*, lib. 12. Cruikshank on the Insensible Perspiration.

INTEGUMENT is also extended to the particular membranes which invest certain parts of the body; as the coats or tunics of the eye.

INTELLECT, a term used among philosophers, to signify that faculty of the soul usually called the *understanding*.

The Peripatetics make two kinds of intellect; *active* and *passive*. See IDEA.

INTELLECTUAL EDUCATION, is that branch of education which respects the understanding, considered in distinction from the affections and dispositions. By intellectual education we understand that series of means by which the various powers, which may be called the intellectual powers, are cultivated; by which those habitual qualities of mind are produced, which immediately respect the acquisition of knowledge, or are essentially auxiliary to it; and by which the mind is stored with those ideas which are subservient to scientific acquirements, or to the arts and pursuits of life.

The full consideration of these objects would lead to three primary divisions of this branch of education: first, the cultivation of the several intellectual powers and qualities; secondly, the value and mode of cultivation of the different branches of knowledge; and thirdly, the peculiar culture of mind and intellectual acquisitions requisite for the different sexes, classes, and professions. In a field so wide, it is necessary to make some selection. In our present article we shall chiefly confine ourselves to a brief consideration of the culture of the leading intellectual powers and qualities. The last of the three divisions (which will include some remarks clashing under the second), would in some measure lead us to anticipate what more properly comes under the head of MORAL Education; and we shall therefore leave the consi-

deration of it to that article, for which also we shall, for the same reason, defer a comparative view of the advantages of public and private education.

Though it is not our business, in this department, to enter into the subject of mental philosophy, yet, as in a work so extensive as the present, the same arrangement, views, and employment of terms cannot be expected throughout, we shall find it at least expedient to say more respecting the several powers of the mind than might be in any way requisite, if we were possessed of what will be brought forwards in a more direct form, under its appropriate head; independently of which consideration, we should be induced to give such general views of the intellectual powers as are necessary, in order to understand the principles of education, by the hope that thus we might be the means of exciting the attention of some of our readers to a branch of knowledge which is of peculiar importance, not only in the education of others, but in the cultivation of our own minds.

The first of the intellectual powers in the order of development is of course sensation (or less ambiguously the sensitive power); by which is meant that power or capacity of the mind, by whose operation it receives sensations from things which affect the organs of sense. Proceeding in the same order, we next find the retentive power, without which sensations would be of no avail: this is the power or capacity of the mind, by which it retains reliefs of sensations or ideas. Next succeeds the associative power, which is that power or capacity of the mind by which it connects and compounds ideas. This last principle, if not the sole cause of all our mental phenomena (except the origin of sensations, and the retention of the simple uncompounded reliefs of them), has some effect in the origin and modification of all of them. It is owing to this important principle that sensations become the signs of thoughts and feelings, by which means man becomes a social being; that the whole mental furniture of perceptions, notions, affections, passions, sentiments, emotions, &c. is formed from the simple reliefs of sensation; that man, from mere sensation, rises to intellect. In short, whatever mental operation we attend to, except at the very earliest period of mental culture, we find association the cause of its productions, or intimately concerned in it.

These three powers may be considered as the elementary powers of the mind, to the operation of which all intellectual phenomena may be referred; but as it is under peculiar modifications and combinations that we see them act, this summary division would be insufficient for our purpose. We shall therefore follow in the order which we find most convenient, a somewhat more minute division of our intellectual principles, according to the combinations, or peculiar modes of operation, of the simple powers; *viz.* sensation, perception, observation, attention, abstraction considered both as a habit and as a power, memory, understanding, and imagination.

1. *Sensations* are the rudiments or elements of all our ideas, that is, of all our thoughts and feelings. When an infant enters into the world, there is no appearance whatever which can authorize any one to assert that there are ideas in its mind; and no one can reasonably doubt, that if a human being could be deprived of all his organs of sensation, before any sensations had been received, that he could never have ideas. In the earliest exercise of the capacity of sensation, sensations are simple, uncompounded with the reliefs of former corresponding sensations; but the sensations very soon become perceptions, that is, they immediately recall the reliefs of other corresponding sensations. That sensa-

tions, in a somewhat advanced state of mental culture, are usually perceptions, any person may satisfy himself, by considering that sensations are usually accompanied either with an idea of an external object causing them, or (if they are merely the effect of the state of the bodily system) with an idea of the sensation being in that part of the body, in which the cause of the sensation exists; both of which are complex ideas, formed from a great number of impressions, and which could in no instance be produced by any exertion of the sensitive power alone, but necessarily require the exercise of the retentive and associative powers.

Considering man as an intellectual being, the correctness and extent of his perceptions are of the first moment. They are, in fact, the materials of all knowledge respecting external objects; and in the early stages of mental culture are the only objects of the understanding. Now, the correctness and extent of the perception depend upon the vividness and efficaciousness of the component sensations, and the number of them received from the same or similar objects in different situations, and through the medium of different senses. One leading object, therefore, in the education of the human being, should be to invigorate and exercise the organs of sense. Independently of the effects of the general healthiness of the system, it appears decidedly probable that the organs of sense are capable of being improved by proper exercise. It is a grand law of our frame, that moderate exertion increases the power of exertion; and there are facts which lead to the same conclusion in this particular case. But this may be safely left to the natural effect of varied exercise. What is principally to be done is, to afford children the opportunity of exercising their senses on a variety of objects, and in a variety of situations. We should think it desirable to proceed a little farther on the cultivation of the organs of sensation; but some observations on this subject will properly form a part of what we shall have to say under the head of *PHYSICAL Education*.

II. By the law of association, many ideas, received directly from sensible objects, through the medium of different senses, become connected, and at last blended together, so as to form one very complex, though apparently uncompounded, idea; and this complex idea is often recalled to the mind by a corresponding sensation; and by association it becomes so connected with that sensation, that the complex idea itself is often mistaken for a part of the sensation. For instance, the sensation produced by the impression made by a globe on the sense of sight, is, as can be proved, nothing more than that produced by a circle, with certain variations of light and shade; yet, immediately on the sensation being received, the ideas of the solidity of the object, of its hardness, of its magnitude, and of its being something external to oneself, (all of which have been derived from the sense of touch, in connection with this object, or others in some respect similar,) immediately rise up in the mind in one blended form; by their complete coalescence they appear to be one, and by their immediate and constant connection with the sensation, they appear to the mind as a part of the sensation. The sensation thus connected with the complex idea is the perception: and by the faculty of perception we understand that compound power (or rather combination of powers) by which perceptions are received from external objects. The accuracy and vividness of the sensation depend upon the sensitive power and its organs: the accuracy and vividness of the perception depend partly upon the accuracy and vividness of the component sensations, and partly upon the activity of the retentive and as-

sociative powers. Supposing the powers of sensation to be in a sound and vigorous state, yet it is obvious that the perceptions will vary very greatly in different individuals, and in the same individual, at different periods. The perception is in fact the sum total of all the notions which the individual has of the object. How much the perceptions of the same object vary in different individuals, may be understood from a simple instance. Suppose a watch to be subjected to the observation of three persons, whose organs of sense are alike healthy and vigorous, the one a very ignorant person, totally unacquainted with its purposes and movements; the second a well-informed person, not however possessed of any acquaintance with the particular mechanism; the third an artist, minutely and completely acquainted with it: the sensation may be precisely the same in all instances; the picture upon the retina may convey to the mind an equally impressive notice of the object; but how different the perception! The first sees a number of minute objects, which attract his attention perhaps by their beauty and regularity; but nothing more: he has no idea of their subserviency to each other or of their general use; there is little more in his case than sensation, indeed we may say, nothing more than sensation besides those associated perceptions which so soon become connected with every impression from external objects, and to which we have already referred. The second, from his general knowledge of mechanism, has some ideas excited by the sensation of use and connection, but he cannot discern the specific kind of connection, nor how each part tends to answer the end of the whole. If he sets about to study the mechanism, he subjects each part to minute examination in its structure and connections; and by degrees may acquire an acquaintance with the whole, which, on a subsequent inspection, would give him an immediate, distinct perception of the parts and purposes. What he thus acquires by laborious and patient examination, the third saw at once. His perceptions have long been cultivated by daily attention to the movements and their dependencies, by studying their defects and excellencies, by the actual formation of various parts, and the construction of the whole: and a great number of the ideas produced by such observations and operations, become so intimately united with the sensation, that at last this at once excites them, and thus he sees (or, more correctly, perceives) what lies totally out of the reach of the observation of others.

From this brief account of the perceptive power, we may readily derive the most essential considerations as to its cultivation. To render the sensations efficacious in forming distinct ideas, and to connect these ideas already derived from any object with the new impressions, depends principally upon the degree of attention (or fixed direction of the mind) which the sensations receive. Hence those who have the care of infants and young children, should give them every opportunity to keep their attention directed to the objects of their senses; and every means should be employed to lead them to such attention. An infant, intently gazing upon an object, or examining it with its little hands and lips, is as usefully employed in the cultivation of intellect as the fondlest parent can wish. In the early periods of mental culture there is, however, more to be done in this connection by allowing a child full scope for its own efforts, than by any direct exertions which can be made by others. When its attention is fixed upon any object, let it remain so: if possible let the objects of sense be brought into view under different aspects, and exposed to the examination of different senses. Before words become to a child the signs of vo-

INTELLECTUAL EDUCATION.

luntary action, all that can be done is to expose it to sensations, and to allow them to fix the attention; but afterwards more direct efforts may be made, and the attention may be fixed by various other means beside the mere action of the sensations themselves.

Children of quick sensations, for the proper cultivation of the perception, require to be frequently induced to observe minutely the objects of perception. We do not venture to go so far as to assert, that it is of no consequence what they observe, provided that they do carefully observe it; but there can be no hesitation in saying, that when the sensations are constitutionally vivid, every instance of close observation given to objects which are within the scope of the comprehension, is cultivating the perception, and contributing to the stock of materials on which the highest efforts of the understanding are to be exercised; and however trifling, in common estimation, those objects may be, yet the mind is receiving a useful employment, and every thing is going on as effectually as could be wished. It is a most erroneous idea in education, that nothing is done except when children are engaged in the usual rudiments of instruction. A child watching the motions of objects around, observing their figure and sounds, examining their structure, is employed in a work which it should be our aim as much as possible to aid and encourage, and from which we may expect very valuable results both on the faculties and furniture of the mind.

The leading point with respect to those whose physical sensibilities are lively, is to engage them to steady observation of the objects of perception; with respect to those whose sensations are by their constitution dull, our efforts must be directed to the awakening of the perceptive power. Whatever is found to stimulate the mind to the exercise of the power, must there be employed. It does not much signify in this case whether, in the first instance, we succeed in producing ideas which will be permanently useful; if the perception is exercised, it will become more vigorous, and by degrees the original dulness of sensation may be in some measure remedied, by the influence of associated feelings. But, in general, dulness of perception does not arise from dulness, and still less from deficiency, in sensation; but from the inefficient employment of the organs of sense. Many lively children are found to be dull in their perceptions; and on the other hand, children whose physical sensibilities are far from vivid, see what their companions see not, and hear what they hear not: the former glance over, and see at a glance, the most impressive objects, or features of an object, but the more minute parts, or the less prominent, and brilliant objects, they do not stay to notice, and though these affect the organs of sense, they make no impression on the mind; the latter more readily dwell on the objects of their sensations, which allows the various parts to call up associated ideas, and in other ways to affect the mind, and thus to make their sensations efficacious.

III. The habit of accurate *observation* depends, in a great degree for its foundation, upon the manner in which the perceptive power has been early cultivated, while at the same time it invigorates the perceptions: indeed, in some points of view, it may be regarded simply as the employment of the perceptive power. This habit depends also, especially for its utility, upon the cultivation of the judgment, and upon the associations which become connected with the objects of sense. A child observes, in the first instance, because the notice of the mind is excited by the pleasure or pain accompanying the sensation; afterwards also, through the influence of external motives, that is, associated pleasures or pains.

When the understanding is so far developed as to perceive the uses of different objects, this again increases the motives to observation, and makes it subservient to much valuable cultivation of the intellect. Every fact which is intelligible and interesting to a child respecting the objects of perception, excites the notice of the mind to those objects, at the same time that the communication, reception of it in the mind, and repetition of the *idea*, increases the stock of knowledge, and exercises the memory and judgment, and often the reasoning powers.

Yet here, as in every branch of education, by aiming to do too much, we may make our best directed exertions ineffectual. To observe with effect, requires patient and frequently repeated attention. To observe is not merely to see, but to see so as to perceive *that*, whatever it be, of which the ever active principle of association has made the visual sensation the symbol or index; and the more the observation is well employed, the more will be brought into the view of the mind by those sensations which to another would not lead on one link in the chain of thought. To force the observation is therefore impossible. We may make our children parrots, by giving them words; but the growth of ideas must be gradual. The observation must first be employed upon directly sensible qualities alone; the more these are noticed, and the ideas of them associated together, (in other words, the clearer the perceptions,) the better foundation is laid for future knowledge. By degrees, and as it is perceived that the mind will bear it, those circumstances and qualities which imply some of the simplest exercises of the understanding, should be brought into view; and from these the skillful instructor (or rather instructress, for we presume that in general the early intellectual education is chiefly conducted, as it will be best conducted, by the female sex) will proceed to others which are still more remote from mere sensation. It will usually be found that children who have been educated in the country, or have had continual opportunities of being in fields and gardens, (other things being equal,) acquire much more completely the habit of observation than those who have been bred up in large towns. In the works of nature there is much more than in the works of art to excite the observation of children, much more in general than can be made the subjects of pleasing instruction; but the judicious parent will not be at a loss to find numerous objects within doors to excite the observation and exercise the perceptive powers; and provided that the observation is actively employed, and correct perceptions are acquired, the mental culture in this essential point is successfully going on.

The habit of observation depends in part upon the general culture of the mind, especially upon the associated thoughts and feelings connected with external objects. The poor plough-boy, with all the advantages that his rustic employments afford him for the excitement of his observation, will often be found extremely deficient in that habit; his perceptions are dull, and his mind is scarcely awakened. Sensations often repeated, without any associations being formed with them, cease to excite the notice of the mind; and where the work of instruction has been totally neglected, as unhappily it so often is among the poor in country situations, the noble powers of the mind lie dormant; there is nothing to rouse its capabilities separate from the narrow round of the daily employments; these soon become mechanical and cease to excite its exertion; and as far as intellect is concerned, the situation is surely less favourable than that of the untutored savage, whose ingenuity and observation are stimulated by the necessities of life.—As the mind, therefore, is capable of receiving them, such ideas should be communicated in con-

INTELLECTUAL EDUCATION.

nection with the objects of sensation as are calculated to keep up the interest which the mere sensations at first excite; and thus to continue that attention to them which may gradually render the observation habitual.

It will not be supposed that we would wish the observation to be cultivated, to the exclusion of reflection; the two habits of mind are not in any respect in opposition, in the early periods of education; but, on the contrary, the one materially aids the other. The reflection may be well and successfully exercised upon the ideas which have been left by the absent objects of sense; and indeed it is only upon these that, at first, it can be properly exercised. If this be done, the interest by which the observation is stimulated will be kept up; and, what is not less important, the employment of the observation will be rendered effectual, and will afford materials for after-reflection. The exercise of thought respecting the occurrences of the day, respecting those things which have been the subject of direct observation, in short respecting any object of sensation, is in various points of view of great value; and the more this is employed, the more the mind is prepared for farther observation.

Nevertheless, the period of childhood is more the period of observation than of reflection (or steady attention to our own thoughts and feelings); and it is the former that, in the preparatory parts of education, we should make the primary object. It is of essential value in every branch of education, and in every department of life. The successful acquisition of every science depending upon experiment; indeed the acquisition of knowledge of every kind which depends upon the exercise of the perceptive power, the cultivation of the taste, the common concerns of life, the intercourses of civility, and the efforts of benevolence, require the constant exercise of the habit of observation; and so long as the observation of a child does not rest merely with the immediate objects of perception, but continues to connect with them that information which the instructor communicates, or which has been derived from past observation, it is very usefully employed. Whatever method is found to invigorate and correct the observation, should be frequently made use of; till the understanding has made considerable progress, this should be a leading object in the intellectual culture; and in every period of it, the habit should be frequently brought into exercise. By a proper cultivation of it, the memory and judgment are directly cultivated; and while it strengthens and rouses the energy of the mind, it furnishes it with some of the most serviceable materials for the understanding and imagination.

Those who have been at all engaged in the business of education, will know in what different degrees accuracy and quickness of observation are found, and how important it is for the progress in intellectual acquirements, and often for the moral culture, that the habit should be early and steadily cultivated; and we here wish to express our decided opinion, that the character of the intellect and affections, however much it may be modified by future cultivation, receives its stamp from the employment of the first few years of life; that the education of the nursery is of almost incalculable moment in the mental and moral culture; that by the neglect of it, years of labour may be rendered requisite to compensate in some degree for it; and that by a proper attention to it, a foundation is laid for a clear and vigorous understanding, and lively and pure affections.

IV. *Attention* is an essential constituent part of the habit of observation, and is necessary to every observation of the mind in its first stage. Many corporeal, and even mental opera-

tions may, when become thoroughly habitual, go on without exciting the attention of the mind; and thus we have no hesitation in saying, notwithstanding the great authority of Dugald Stewart to the contrary: but this is not the place for the discussion of this point; and what more immediately concerns our purpose is, that before any operation of mind is become habitual, the exercise of it requires the direct notice of the mind, that attention is requisite to render sensations efficacious, that every exercise of the understanding requires it, and that the habitual power of employing it in the direction which the judgment points out, may be regarded as what is most necessary for the attainment of the highest degrees of intellectual culture. In this perfect state it is very rarely to be met with; but in a considerable degree it is frequently acquired; and some good portion of it is so important in every stage of the mental progress, that the formation of the habit cannot be begun too early, nor the cultivation of it made too steady an object.

Attention is now not unfrequently spoken of as a distinct faculty of the mind; and the philosopher to whom we referred in the preceding paragraph has greatly contributed to this change of nomenclature, if he did not begin it. It may perhaps be regarded as a mere verbal distinction if we deny it the appellation; but, in fact, it appears to be, in its simple state, merely the notice of the mind, which in various instances is involuntary, but which by degrees may be connected with volition, and directed by habitual tendency, or direct motives, even in opposition to the strongest impressions from external objects. We may very correctly speak of the power of the mind over its attention, and, by abbreviation, of the power of attention; but the true point of view in which the attention is to be regarded, both when it can be fixed by stimuli of different kinds without the direct intervention of volition, and when it is capable of being produced by direct volition, is as a state or habit, which we would in the one case speak of simply as a state or habit of attention, in the other as the habit of voluntary attention. In very young children the attention is entirely involuntary; the sensible excitements of various kinds which we employ attract the notice of the mind; and the attention is directed to the most impressive excitement. This is very much the case in every stage of education; but under judicious management the state of mind which we call attention may be early produced by the influence of motives without sensible stimulus; and the foundation is then begun for the habit of voluntary attention.

The attention produced by sensible stimulus begins even with the very first sensation which is received. It is a beautiful provision of Providence, that sensations which give pain, while they are the most impressive, are of rare occurrence; and that those which are of most frequent occurrence, or which it is important for the mind to seek for, are attended with pleasure. It is probable that no sensation is at first indifferent; and therefore in the commencement of the growth of intellect, every sensation will excite all the attention which is requisite to give it the degree of efficacy which is necessary for the period. All we then have to do, is to allow the attention to remain where the sensation calls for it. "It is unfortunately in the power of a foolish nurse," says Miss Hamilton, (vol. ii. p. 47.) "to retard the natural progress of the mind, by perpetually interrupting its attention. A child that is much danced about, and much talked to, by a very lively nurse, has many more ideas than one that is kept by a silent and indolent person. A nurse should be able to talk nonsense in abundance; but then she should be able to know when to stop." And the same very respectable writer

INTELLECTUAL EDUCATION.

adds in a note, from the observation of a judicious friend, that nothing more effectually tends to retard the progress of the infant faculties than a custom prevalent with nurses, of keeping the child in a continual trut upon the knees; and this especially in cases where its attention is most closely, and therefore most usefully engaged.

But it will not be long before the impressions which have often been received zeal, by the diminution of their vividness, to produce the same effect on the mind. When a child has had some cultivation of memory and association, the repetition of a former impression is often much more pleasant than the first reception of a new one; because, if the impression itself is less lively, and in itself considered less pleasant, the associated circumstances often communicate a still more interesting pleasure: the child remembers the pleasure before derived from it; and the repetition of it sets his little faculties to work in connection with his former sensation, and the ideas to which it led, and the moderate exercise of the faculties is generally pleasant; and there is often a positive pleasure in the mere repetition of past impressions, even when the disposition of a child is very active, arising from the increased power of fully comprehending the objects causing the impressions. But before the associative power has been much exercised, new sensations are very commonly more attractive than old ones; and here begins that restless desire of novelty, which, while it operates as a most powerful stimulus to the pursuit of knowledge, requires to be carefully watched in every period of education, lest the attention should be completely dissipated, and no knowledge acquired; for there is no principle in education more certain, than that knowledge (clear, correct ideas respecting the objects of sense and intellect) cannot be gained by wandering, hasty attention. At this point the efforts of the parent should be given to lead the little mind to the examination and re-examination of the objects of sensation; not indeed so much by direct influence, as by those little contrivances which a judicious mother soon learns by experience, and to aid her in which she may consult Miss Edgeworth's excellent observations on the subject, which, though they more immediately refer to a later period of education, suggest many important hints respecting the best methods to be pursued here.

Though we perceive that we shall swell this division of our article beyond what may be thought its due proportion, yet the subject of attention is so important, that we shall select some of Miss Edgeworth's leading observations on the cultivation of the habit, and subjoin our own remarks in addition. In doing this we wish to lead our readers, if they have not already engaged in it, to the study of a work, the value of which we rank higher in proportion to our own experience and observation, and by no means to prevent it. Though in several of her positions we cannot agree, though we think her work essentially deficient, and are by no means satisfied as to the probable result of her plans on the whole, and though to follow them in detail to any considerable extent requires a degree of mental cultivation, and a combination of circumstances, which are very rare in those walks of life where the subject is likely to receive the most attention, yet we cannot hesitate in strongly recommending her work, as containing a fund of very important observations, the result of varied and long-continued experience, guided by sound judgment and good sense, and generally correct moral views, as exhibiting a number of very important phenomena and principles subservient to mental philosophy, and as furnishing to the "practical" parent very valuable aids, even where her plans cannot be minutely followed. Her elementary works ("Early Lessons," "Parents' Assistant," &c.) are incomparable; and if their striking and much-to-be-lau-

mented deficiency in every thing like religious principle were suitably supplied, they would have scarcely a wish ungratified. If any female writer should hereafter come forward to the public, possessing the clearness, simplicity, correctness, and well-flored understanding of an Edgeworth, the brilliant yet chaste imagination and "devotional taste" of a Barbauld, and the energy and high-toned moral principle of a More, divested of bigotry, and founded upon genuine Christian theology, in the scale of utility he will probably stand unrivalled among her contemporaries, however eminent her age may be in every thing great and good. But to return to spher realities.

The three principles which are laid down by Miss Edgeworth in her concluding Summary, as of universal application, are, that the attention of young people should at first be exercised for very short periods; that they should never be urged to the point of fatigue; and that pleasure, especially the pleasure of success, should be associated with the exertions of children. With respect to the first of these points we shall extract the following remarks from her chapter on Attention: "Besides distinctness and accuracy in the language which we use, besides care to produce but few ideas or terms that are new in our first lessons, we must exercise attention but during very short periods. In the beginning of every science pupils have much laborious work, we should therefore allow them time; we should repress our own impatience when they appear to be slow in comprehending reasons, or in furnishing analogies. We often expect that those whom we are teaching should know some things intuitively, because they may have been so long known to us that we forget how we learned them."—"A reasonable preceptor will not expect from his pupil two efforts of attention at the same time; he will not require them at once to learn terms by heart, and to compare the objects which those terms represent; he will repeat his terms till they are thoroughly fixed in the memory; he will repeat his reasoning till the chain of ideas is completely formed. Repetition makes all operations easy; even the fatigue of thinking diminishes by habit. That we should not increase the labour of the mind unreasonably, we should watch for the moment when habit has made one lesson easy, and then we may go forwards a new step."

Respecting the third point, Miss Edgeworth urges, that the stimuli which we employ to excite attention should be proportioned in degree and duration to the mental character of the individual, and the circumstances of the case. "It is not prudent early to use violent or continual stimulus, either of a painful or a pleasurable nature, to excite children to application, because we should, by an intemperate use of these, weaken the mind, and because we may with a very little patience obtain all we wish without these expedients." Besides which, violent motives frequently disturb and dissipate the very attention which they attempt to fix. Regularly recurring motives, which interest, but do not distract the mind, are evidently the best. In proportion as the attention becomes habitual, the excitements producing it should be withdrawn. Success is a great pleasure, and when children have sometimes tasted it, they will exert their attention merely with the hope of succeeding. "Instead of increasing excitements to produce attention, we may vary them, which will have just the same effect. When sympathy fails try curiosity; when curiosity fails, try praise; when praise begins to lose its effect, try blame; and when you go back again to sympathy, you will find that after this interval it will have recovered its original power." At the conclusion of her remarks on this head, Miss E. justly urges the cultivation of the affections of children as a most important means of acquiring

quiring power over their minds, and exciting them to the noblest exertions. "When once this generous desire of affection and esteem is raised in the mind, their exertions seem to be universal and spontaneous: children are then no longer like machines, which require to be wound up regularly to perform certain revolutions; they are animated with a living principle, which directs all that it inspires."

"With *timid* tempers we should begin with expecting but little from each effort, but whatever is attempted should be certainly within their attainment; success will encourage the most timid humility. It should be carefully pointed out to diffident children, that attentive patience can do as much as quickness of intellect: if they perceive that time makes all the difference between the quick and the slow, they will be induced to persevere."

"It is more difficult to manage with those who have *sluggish*, than with those who have *timid* attention;" and with respect to that class of the indolent "who saunter at play and every thing," Miss Edgeworth does not appear to have discovered any remedy. If a child's mind is capable of active exertion in any thing there is hope: the object is to gain the direction of that exertion to the acquisition of knowledge; but the other case she seems to consider as hopeless. Locke's proposal of presenting them (among other stimuli) with fine clothes, eating, &c. she regards as inadequate, but does not suggest any plan by which the love of knowledge may be produced. We doubt whether instances are at all common of such complete want of physical sensibility as she seems to attribute to the *sluggish*; but "the pain of attention," if it be not excited to something which is beyond the powers of the mind, cannot be so great as to render it preferable to undergo shame and punishment, if judiciously administered. It is probable that a moderate degree of exertion of the faculties is always attended with some pleasure. There are employments which engage the attention, without requiring great effort of mind. The simple operations of arithmetic, the copying of passages from a printed book, &c. are of this kind. If the performance of some of these is steadily made necessary; if temporary abstinence, for instance, or the loss of every thing which is not necessary in diet, be made the regular consequence of determined *sluggishness*, and the remissions of attention be constantly followed with the trouble of rectifying errors, &c.; in short, if the pain of attention be constantly rewarded by the avoidance of some greater pain, and the comfort of indolence be constantly followed by that greater pain, it cannot be but that in process of time the attention will be less irksome, the mind awakened, and the idea of mental employment accompanied even with satisfaction. If once this state is reached, nothing more is wanting, than to make the attention habitual, to employ it gradually on more difficult objects, and as uniformly as possible to make remissions the source of inconvenience naturally following from it; and to reward exertion by whatever suitable consequence of it is found to gratify the now awakened mind. The most difficult case is, where indolence is united with that quiet amiableness of disposition, and that tolerable degree of good sense, which, united, make those who do not know how to appreciate the ill effects of the baneful quality, yield their affection and approbation, and give the appearance of injustice and harshness to every measure of pain or privation which is employed to excite to exertion.

"*Vivacious* children are peculiarly susceptible of blame and praise; we have therefore great power over their attachment, if we manage these excitements properly. These children should not be praised for their happy hits; their first glances should not be extolled: on the contrary, they

should be rewarded with universal approbation when they give proofs of patient industry, when they bring any thing to perfection."—"To win the attention of vivacious children, we must sometimes follow them in their zig-zag course, and even press them to the end of their train of thought. They will be content when they have obtained a full hearing; then they will have leisure to discover that what they were in such haste to utter was not so well worth saying as they imagined; that their bright ideas often, when steadily examined, fade into absurdities." With respect to children of this character, we think Miss Edgeworth's remarks peculiarly happy; and from many which we might with advantage select, we will transcribe the following: "We should not humour the attention of young people, by teaching them always in the mode which we know suits their temper best. Vivacious pupils should from time to time be accustomed to an exact enumeration of particulars; and we should take opportunities to convince them, that an orderly connection of proofs, and a minute observance of apparent trifles, are requisite to produce the lively descriptions, great discoveries, and happy inventions, which pupils of this disposition are ever prone to admire with enthusiasm. They will learn not to pass over *old* things, when they perceive that these may lead to something *new*; and they will even submit to sober attention, when they feel that this is necessary to the rapidity of genius."

Judicious and useful as these observations are, we are of opinion that Miss Edgeworth has, in her system of education, too much left out of view the actual condition of human nature, that, in every department of life, circumstances are continually occurring in which it is necessary that the attention should be given to objects not in themselves pleasant, from their subserviency to others which are of importance, and that exertions, in like manner, must often be made, to which nothing but a sense of duty would prompt. With respect to the observations which we have extracted, they have all their value, and may be applied, with modifications, not only to the earliest periods of education, but to every succeeding stage; yet her plans strike us as deficient. They are principally calculated for those cases in which, from early example and cultivation, there is a desire of knowledge excited, in which it is imbibed without direct effort on the part of the parent or early instructor, in which, from the habits and pursuits of those around, its advantages are at once felt, and the acquisition of it regarded as of the first importance. In the hands of such teachers as Miss Edgeworth, so well suited to the task by enlightened judgment, steady perseverance, and the ready command of much varied knowledge, with children whose early habits they have themselves formed, whose understandings they have cultivated and furnished with ideas, the processes which she has pointed out may be all which are sufficient: but we doubt whether the ends proposed can, in general, be answered by such means alone; and still more, whether they are, in general, calculated to produce that strength and energy of mind which, with a view to an object fixed upon as important, can steadily pursue a course of arduous exertion.

The habit of attention must be gained in order to make any progress in intellectual culture; that is of course a point decided. It cannot be acquired too early, because thus the utmost efficacy will be given to all the other operations of the mind, and especially to the acquisition of clear, impressive, and serviceable perceptions; that is also a point indisputable. It must, too, be associated with volition as early as possible, and then the foundation is laid for every degree of mental culture to which circumstances may direct.

We are of opinion, that, after this point, Miss Edgeworth's plans are defective. Her pupils are to be *allured* on too much. The path of knowledge is often a difficult one, and sometimes requires painful efforts; so also the path of duty; and the culture to which her system is chiefly confined, is scarcely calculated to produce that hardy vigour of mind, which, whether the possessor is called to engage in the highest pursuits of science, or in the narrower sphere of social employment and duties, cannot be otherwise than valuable. When the power of voluntary attention is acquired, then the various motives of confidence in the judgment of the teacher, of habitual submission to authority, of affection, and perhaps occasionally of fear, should be employed as circumstances direct, in order to give it strength and activity, to excite the pupil to such employment of it as may make it a hardy vigorous principle, capable of employment, even where the employment may have no intrinsic attraction, and may even be at first positively painful.

If a pursuit can be made attractive to a pupil at the outset, it is well; but if he have acquired that hardness of attention of which we speak, which will enable him to struggle through first difficulties, and perhaps by degrees to take some delight in them, he is then fitted for the acquisition of any branch of knowledge to which his objects in life, or the bent of his own inclination and cultivation of his understanding, may induce his instructor to direct him. If he have not acquired that strength or activity of attention, difficulties which must meet him in the higher departments of literature and science, will often be found to stop him; and however judiciously his attention may have been early cultivated, if it have not acquired this firmness, the attractions of less arduous pursuits, which will still gratify his taste for knowledge, will effectually check all progress.

There are few points in which the cultivation of the intellectual powers is concerned, in which we do not find the importance of the moral habits, particularly of diffidence, of submission, and the desire of doing what is right; where these are suitably produced in the mind by previous education, the culture of the attention very greatly depends upon the instructor. The attention may be restless, or it may be sluggish; but the more suitable efforts are made to render it voluntary, the more it comes under the command. These efforts will be made, if the dispositions are right; and when the attention is once become to a considerable degree voluntary, the direction of it may be obtained (by the influence of those views and motives, which the above-mentioned moral habits put in the power of the instructor,) to whatever object it is thought right to direct it. Thus influenced and directed the way will be comparatively clear. Where the attention is fairly given, the mere employment of the mind becomes itself pleasant. Difficulties will then be overcome, and the pleasure of success will aid every other motive. By degrees the utility of the object begins to be distinctly seen, and the purposes of the different steps which are taken to gain it are also discerned, and then if the habit of patient industry have been formed, or the continued direction of the attention be kept up by the influence of the moral habits, the judgment will aid and encourage every exertion, and at the same time the foundation of a most valuable habit will be laid, of pursuing definite important ends, by the steady use of suitable means.

The habit of attention, or at least the direction of the attention to any object, must sometimes be produced by compulsion, wholly or in part. What kind of compulsion should be employed, and especially whether or not corporal pain is in any instance expedient for this purpose, and in other departments of education, will be considered

under the head of *MORAL Education*: but we here have only to state the fact, that unless every impression could be regulated by a judicious parent, from the very birth, compulsion must sometimes be employed, even in the best symptoms of education, that education in which compulsion has not been employed, might probably produce amiable characters, but seldom such as will be great in intellectual or moral worth,—that as early education has long been, and it is to be feared long will be, too generally conducted without any steady cultivation of the habits of industry and attention, and of ready submission to authority, the instructor to whom children are committed, whether at home or at school, will commonly find some degree of compulsion necessary, in order to produce that degree of attention which is requisite for any valuable improvement. With respect to this period, and these cases of much neglected mental and moral culture, the chief points appear to be, to proportion the exertion required, as much as possible to the degree, not of actual capacity, but of habits possessed; to abstract as much as possible all causes of inattention, and to generate the impression that the effort must be made. By whatever means the habit of attention is produced and rendered voluntary, and the more frequently and regularly it is produced by volition, the more it becomes at the command of the will, the easier, and consequently the more pleasant it becomes, and the more therefore it can be excited when the motives are sufficiently strong to produce it. It is not, then, “the attention of circumstances,” but the attention of volition: and will then be subject in a great measure to the judgment, guided by a sense of the importance of the object either in itself or to the individual, or to those strong motives which arise from the pleasures of activity, from the gratification of curiosity, the influence of prevailing fashions, the desire of obtaining the approbation of those we love, &c.

When the early training of the mind has made its perceptions distinct and efficacious, and has given it the habit of steady attention, the grand points in intellectual culture are secured; and the rest will proceed, with tolerable care, in the direction which found views may dictate.

V. When the attention is directed to some particular object of thought, so as to prevent its being diverted to any other object of thought, or to any external impression, it is denominated *Abstraction*. This state of mind has been seldom dignified with the name of abstraction, except when directed to objects out of the common sphere of thought; but Miss Edgeworth has shewn, by her usual happy method of illustration, that it is the same habit or exercise of mind, whether it be devoted to the highest flights of philosophic pursuit, or to the usual concerns of life. “Persons of ordinary abilities,” she justly remarks, “tradesmen and shopkeepers, in the midst of the tumult of a public city, in the noise of rumbling carts and rattling carriages, amidst the voice of a multitude of people talking upon various subjects, amidst the provoking interruptions of continual questions and answers, and in the broad glare of a hot sun, can command and abstract their attention, so far as to calculate yards, ells, and nails, to cast up long sums in addition right to a farthing, and to make multifarious bills with quick and unerring precision.”

The habit of abstraction is dependent upon various causes; but every person to whom the attainment of it is necessary, finds it susceptible of culture. It much depends upon the familiarity of the impressions which are otherwise most likely to affect the mind: novel impressions from external objects, by their novelty attract the notice of the mind and tend to distract the attention: sensations which have been

long and closely connected with trains of thought or feeling, are calculated to divert the attention: objects to which we have been accustomed to attend, in like manner solicit the notice of the mind from those to which we may otherwise wish to attend. In situations, therefore, where we receive novel sensations, unless there is a proportionate devotion of the mind to the object of its attention, there will at first distract the attention; and so on in the other cases. Abstraction depends, too, in part, upon the physical state of the system. If the nervous system is in a strong degree of excitement, external impressions proportionally affect the mind, and, of course, tend the more to distract the attention. Abstraction is likewise seriously impaired by a general tendency to dwell upon the directly selfish feelings, whether pleasurable or painful; because as these are constantly present to the mind, and constitute the most powerful agents, in their immediate effects, upon the mental system, the habitual tendency to give attention to them, puts an almost total stop to any valuable degree of abstraction in favour of those objects, which are not immediately connected with self; and this, by the way, furnishes us with another instance of the influence of moral upon intellectual education. This habit also depends for its vigour, upon the degree in which the interest of the mind can be excited towards an object. With minds of ardour and activity, if the mind be engaged, it is abstracted from every impression and thought, not immediately connected with the object; and if the interest of the mind is strongly excited from any other cause, the same effect will happen. The vigour of abstraction also, depends, in part, upon the degree in which the habit of observation is possessed; indeed they are so much in opposition to each other, that to any considerable degree they are seldom found united in the same individual. The habit of observation implies habitual attention to the objects of sense; the habit of abstraction to the objects of intellect. The habit of abstraction is not therefore to be expected, and indeed ought not to be directly cultivated in the earliest periods of intellectual education. Nevertheless, both qualities depending upon the general habit of close attention, the cultivation of the observation is indirectly laying a good foundation for the subsequent cultivation of the abstraction.

As two objects cannot engross the attention of the mind at the same time, abstraction may be cultivated by rendering the mind habitually inattentive to those objects which are not to occupy it, or by making it habitually attentive to those which are from any cause the objects of preference. The former plan should be adopted, if at all, with great caution. It may generally be left to the efficacy of habit in lessening the efficacy of impressions; and the habitual neglect of any commonly occurring objects of observation or reflection, is inconsistent with the pursuits of life. The second plan is in every point of view preferable; and every instance in which the attention is fixed, whether through direct volition, or by means of excitement without the exercise of volition, is essentially contributing to the cultivation of abstraction; still more so, every instance in which the attention is engaged upon the objects of thought, in situations in which there are frequent impressions from external objects which, if the attention were not so engaged, would then excite the observation. Hence it is desirable to accustom the young to mental exertion where there are causes tending to distract their attention, provided however that from their novelty or their power they are not calculated to force it. Whatever tends to make the objects of the mind interesting, and to give ardour in the pursuit of them, also tends to cultivate the habit of abstraction; for that which deeply interests

the mind, fixes the attention, and of course prevents every other object from sharing the notice of the mind.

The power of directing the mind to objects which afford no impression upon the senses, and even in opposition to such as do, is of extreme importance in the later periods of mental culture, and at the same time, with the assistance of previous culture, is much easier than would, with any cultivation, be possible at an early period. In childhood and youth sensations more affect the mind, than the sensations themselves can do as we advance farther in life; and though associated thoughts and feelings assist to keep up the influence of the sensations themselves, yet if the mind have been accustomed early to think of what are not the direct objects of sensation, the power of its own thoughts and feelings easily overbalances the effect of at least customary sensations. Carried to an undue extent, the habit of abstraction is unsuitable to our situation as social beings; but there is scarcely any plan of life in which it is not in some measure requisite; and in the pursuits of science, whether physical or mental, it is continually required, and continually strengthened by exercise. It is even very important in the events of life. The power of directing the attention to some specific objects of thought, to the exclusion of others, and to the exclusion of external impressions, constitutes (as Miss Edgeworth well observes) the leading feature of that quality which we call presence of mind, and which is so often of signal service to our welfare, and even to the preservation of our lives. And this habit is essentially requisite in our moral and religious culture; the acquisition of religious knowledge constantly implies the employment of abstraction; in the exercise of religious affections it is absolutely necessary; and in the discharge of duty, in opposition to powerful temptations, the power of fixing the attention upon those views and principles which ought to guide us, is of the utmost importance.

The habit of abstraction is in general to be cultivated rather indirectly than directly, in the earlier periods of education; and it is one advantage of the pursuit of knowledge, that it frequently requires fixed attention upon the objects of thought, without aid from the sensations. Perhaps it would be beneficial to extend the occasions for this, in literary and scientific education. An easy demonstration carried on without a figure, an operation in arithmetic suited to the progress of the pupil performed without the aid of the pen or pencil, the description of some former object of observation, the contriving or parsing of sentences from the classics without book, and similar exercises of mind, are all calculated to cultivate this habit; and wherever the point can be gained, it greatly increases the power of the mind over its attention. These mental operations may usually be begun early; a child of three or four years of age, can easily be brought to make a little addition in *his head*; and while he does so, his mind must necessarily be occupied to the exclusion of other thoughts and of sensations. If he thinks closely of what he has seen, for the time he is exercising his abstraction. If he is led to think on some of the simple truths of religion, he is exercising his abstraction; indeed these constitute some of the earliest and most powerful exercises of abstraction. It is very important that these and similar mental operations should not be made too frequent, nor continued too long. They should not be continued too long, lest the fatigue of mind experienced should lessen the wish to think, and in reality check the power over the attention; they should not be made too frequent, because, as we have already observed, childhood is the period of observation rather than of abstraction. If the young mind is too much accustomed to think about its own thoughts, the imagination will gain too much power, and that habit of inattention to external

ternal impressions will be formed, which, in most cases, is always injurious, and which in the early period of life is sufficient to stop its progress in intellectual improvement. In this, however, as in every branch of education, our efforts should often be regulated by the prevailing mental habits of the individual. A child of lively conceptions should be directed as much as practicable to accurate observation; where the conceptions are dull, abstraction should be encouraged; and it is encouraged by every instance in which it is exercised with pleasure, by every instance in short, in which the mind is pleasantly engaged upon the objects of thought without the assistance of sensation, and especially if in opposition to sensations. These the intelligent parent has greatly at her command; an account of a walk requiring the recollection of little circumstances and objects which occurred during it, the retracing of ideas on any interesting subject, and various other exercises of a similar kind, contribute to cultivate the abstraction. But after all, it is rather by indirect means, than directly, that we are in the early periods of intellectual culture, to aim to produce and exercise this habit. By early giving a decided bias for intellectual pursuits, and exciting a lively interest in them, and by forming the habit of steady attention to the objects of knowledge as they are presented to the mind, we do in reality prepare it for the cultivation of the habit of abstraction, whenever it may be called for by the higher pursuits of knowledge.

Absence of mind sometimes arises from the mind's being fully occupied with its own trains of thought, but it should not be confounded with abstraction. The latter implies, at least in the commencement of the particular exercise of it, a voluntary direction of the mind: the former, even where it is really caused by mental operations, commonly supposes a want of power over the attention; but it very often arises from a more sluggish inattention to external impressions. Absence of mind, proceeding from this last cause, should be steadily and constantly checked; not so much, however, directly, as by rousing the attention to the objects of sensation, by making the neglect of them unpleasant, &c.: and it should by every means be discouraged in the early periods of education, because it will by degrees induce a tendency to reverie which must almost inevitably give the imagination undue power, and which is more than any quality of mind calculated to destroy all the valuable effects of the habit of well regulated abstraction. In the external appearances, absence of mind proceeding from reverie, differs little, if at all, from the fixed intentional devotement of the mind to some object of thought; but those who have experienced both, and who have watched their characteristics in the young, know that the difference is very important, and deserving of the careful attention of the early instructor. In fact, the habit of reverie is the most baneful possible to the influence of the mind over its trains of thought; and totally destroys, if too much indulged, all power of steadily directing the attention to specific objects of mental pursuit.

VI. We have hitherto spoken of the *habit* of abstraction, by which we understand (agreeably, we believe, to the common acceptance of the term) the devotement of the attention to some objects of thought, to the exclusion of others, and also of impressions from external objects; but it is well known, that the word is also used by some writers on logic and mental philosophy, to denote the *power* which the understanding has (or rather, is supposed to have) of separating the combinations which are presented by it. We introduce the qualifying clause, 'is supposed to have,' because in many cases the understanding has no such power; it is impossible, for instance, to form a conception of extension, without some idea of colour, or of length without breadth;

but in reality, the *abstractive power* is, after all, nothing more or less, than the power of separate attention, the power of attending to one idea distinct from the combination in which it occurs,—of attending to one part of a conception distinct from the rest, and perhaps, by degrees, forming a conception of that part detached from the rest, of attending to one quality or circumstance separate from other qualities or circumstances with which it is really connected, or connected in the mind.

The habit of abstraction, or fixed attention to the objects of thought, is essential to any high degree of mental progress, and is requisite in various circumstances in life; the power of abstraction, or of separate attention to some object of the mind distinct from the combinations in which it is presented, is necessary in almost every process of reasoning, and is the foundation of an accurate, discriminating judgment. The power of abstraction, in this sense, may obviously be cultivated without the exercise of the habit of abstraction; except indeed where the object is purely mental. A child attending to one part of a prospect, to one part of a flower, to one of the sensations which an object presents, (to the colour of a substance, for instance, instead of its smell or shape, or size or weight, or to any one of these without attending to the colours,) is exercising the power of abstraction; and in these very useful exercises of the power of abstraction, the habit of abstraction is not called for; all that is wanting is that of observation. On the other hand, the habit of abstraction may have been cultivated even to excess, without the individual possessing the power of attending to one of a combination of objects, or to a part of a conception, so as not to allow the rest to influence his reasonings and judgment.

The involuntary exercise of the power of abstraction, is very often produced by the mere influence of the associative power, without any effort on the part of the individual, and sometimes by the influence of the sensations themselves. Instances of the latter continually occur. That impression from any object which is the most vivid, attracts the notice of a child; and while the attention is directed to this, the other impressions from it remain unnoticed. But the exercise of the abstractive power is often, in a great measure, voluntary; and though that degree of this power which shall completely separate at once the combinations which are presented to it, is probably altogether chimerical, yet it is in our power to acquire it to such a degree that the parts which we wish to exclude from the attention shall not affect our reasonings, and but little even our feelings. We do not mean that in all cases we have such power; but the more the mind is trained to it, the more it is to be acquired. And here again we perceive the advantage of the pursuits of literature and still more of science. The abstractive power is continually brought into exercise in most of the leading objects of mental occupation. The young are thereby continually led to leave out of view some circumstance or quality, and to direct their attention to the essential points. Every definition that is understood and made the foundation of reasoning, every exercise of classification of words or natural objects according to some system, brings into play this important faculty. It is necessary to every correct judgment, and at the same time the cultivation of the judgment serves as its guide and brings it into exercise.

The abstractive power should be early exercised, but most commonly upon the objects of sensation. Still however not without caution; because, though separate, select attention is of great consequence in the later periods of education, yet in the earlier periods, the first point is correct and extensive observation in order to lay up a fund of ideas for the future operations of the understanding.

With respect to the operations of the abstractive power, as necessary in the processes of the imagination, they may be very much left to themselves. We have no wish that the imagination should be sacrificed; for it is of great importance in the conduct of life, in the pursuits of science, and in spiritualizing the mind; but where there is that call of mind which will lead to form new combinations from its conceptions; all that is necessary is, to give the observation frequent opportunities of exercise, in various situations, upon the objects of sensation, that they may be seen under different aspects, and in different combinations. It is in our own power, at any time, to see only parts of an object; and by dwelling upon these parts, we can form conceptions of them detached from others with which they are connected. Hence, the visual conceptions are very easily subjected to the abstractive power; and as to the objects of hearing and smell, they have so little necessary connection with the objects of sight, the sensations can be received, and the conceptions reproduced, so completely independent of visual impressions or conceptions, that there is still less difficulty in exercising the abstractive power upon them. Where, therefore, the imagination has any considerable strength and activity, the abstractive power may be expected to be sufficiently at its command without direct cultivation. Where, however, the imagination is weak or sluggish, it may be admissible, by leading the attention to separate sensations, and to parts of objects distinct from the whole, and by directing the observation to the same objects under different points of view, to cultivate the abstractive power with specific reference to the conceptions as materials of the imagination. And this should occasionally be done with a still higher aim, to accustom the mind to separate the combinations presented to it, in order that those hasty, casual, and erroneous associations may be weakened, which so often completely mislead the judgment, and which, where they do not directly and obviously affect it, imperceptibly warp it, and materially increase the difficulties which obstruct the reception of truth.

VII. By the *Memory* we understand that power which retains ideas, and which can bring them back again to the view of the mind. The latter act is generally known by the name of recollection; the former, as Mr. Stewart has observed, has not yet received any appropriate appellation. It might be called retention; but it appears decidedly preferable to appropriate this appellation to that capacity, or power of the mind, by which reliefs of sensations are retained, by which, in fact, sensations produce ideas.

It is totally unnecessary that we should dwell upon the importance of this power of the mind. Were it not for the capacity of retaining ideas from sensations, man would be a being of mere sensation. But without going to this extent, if the retaining power of the memory were greatly impaired, past impressions, past reasonings, past conclusions, past experience, would be of no service to the mind in the conduct of life, or in the pursuits of science; and without the power of recalling them to the view of the mind when required by circumstances, they would in a great measure lose their efficacy and advantage. To make the memory, however, duly subservient to the usual objects of life, and to the acquisition of knowledge, it must be placed under the regulation of the judgment; and an accurately retentive memory, united with facility of recollection, accompanied with, and guided by, a sound judgment, may be considered as the summit of excellence in this branch of the mental faculties.

To enter into the proper discipline of the memory, when the individual is so far advanced in the cultivation of the

understanding, as to be able to regulate the culture of his own mind, is not our province: and if it were, we should be able to add little to those very excellent and important remarks which our readers will find in Dugald Stewart's elegant and scientific treatise on the culture of the memory. The question which we have to consider is, what cultivation of the memory is most suited to those periods which are usually devoted to education.

We cultivate the memory indirectly by every instance in which the attention is directed to the objects of sensation; for the vigour and correctness of the memory, so far as it respects external objects, must greatly depend upon the accuracy of the perception. In some points of view it may be considered as the only object at which we need aim with respect to the memory in the earliest periods of education; for where the sensations are duly made the objects of attention, the structure of every mind probably is such, that ideas will be received from them; and the first point is, to gain ideas, which may become the rudiments of perceptions, conceptions, notions, and feelings.

The mere formation of ideas from sensation, is, however, seldom referred to the memory; and though this is a most important object, and serves as the basis for every future operation of the mind, it is so closely connected with the act of sensation, that it can scarcely be distinguished from it. In all probability every impression and every thought which has the notice of the mind, have some effect in modifying or strengthening the corresponding ideas which were previously formed, if they do not form new ideas; and often without our observing the process: but we do not usually speak of such retention as an act of memory, confining the operation of this power to cases in which we can bring again into the view of the mind the objects of observation and reflection. If the ideas produced by observation or reflection have been so much impressed upon the mind, that by active or passive recollection they can be brought again into its view as they were at first produced, the retention and recollection of them are considered as operations of the memory.

As the mere retention of ideas without the power of recalling them, would be of little consequence, and as the recollection of ideas serves greatly to strengthen the retention of them, it appears that one leading object of our aim in the early culture of the memory, should be, to produce the habit of ready, distinct, and accurate recollection. This must of course, in the commencement of intellectual culture, be employed merely upon the objects of sensation, of which the first will be words. When a comparatively small number of words have been acquired, the recollection should occasionally be exercised respecting past sensations; chiefly those of sight, which are in the first instance most easily retained and recalled. By degrees, those which have been received by the sense of hearing, should also be made the subject of recollection; partly with a view to strengthen the power of recollection, but still more the habit of observation, and of attention to those directions which in the early periods of childhood are so essential to well-being, and sometimes even to existence. For several years, from birth, it appears to us scarcely desirable to exercise the memory much upon a connected series of words; the power of recollecting words is of great importance in a later period of the mental progress, but in the earlier, the first object is ideas; and young children should seldom (if ever) be required to repeat words without having a clear idea of the meaning of them. Such ideas must necessarily be deficient; but they should be correct as far as they go, and at any rate should be such as the little mind can grasp. If the habit of remembering

INTELLECTUAL EDUCATION.

membering words, and of recollecting them, without understanding them, is once begun, there is afterwards a very great difficulty in cultivating the understanding, and in making the memory, what it ought always to be, however important in itself, a subservient faculty.

In the early exercises of the recollection, we are to be fully satisfied with correctness, however deficient it may be in fulness. Correctness (we of course do not mean in the repetition of words, but in the recollection of ideas) should always be aimed at. The imagination will not lose by this; for the correct recollection of conceptions and notions tends to fix them more upon the mind; and these are the materials upon which the imagination is to be employed. Most certainly the understanding will be a gainer; for the object of the understanding is truth; and truth cannot be found by that mind which has been trained up to falsehood by early habit of inaccuracy. We have no objection for the little imagination early to work upon the conceptions which have already been treasured up in the mind, under those limits which continual attention will necessarily set upon the operations of the imagination; only let a child be habituated, in detailing its inventions, to detail them as fact; and when recollecting the past objects of observation, to give a faithful outline of them, however imperfect it may necessarily be. We have known an instance in which a child not above four or five years of age, whose imagination was lively, and whose recollection (and perhaps observation also) had unhappily not been trained to accuracy, frequently told his friends circumstances which had no existence except in his own mind, with the regularity, and much of the consistency of real facts, and, probably, by degrees did not know whether he was speaking of the creations of his fancy, or of things which he had actually seen and heard. Such cases must excite our regret for the past, and our apprehension for the future.

Great difficulty often exists, especially in the minds of persons whose conceptions are vigorous, and who have not been habitually careful to cultivate accuracy of perception and correctness in the relation of recollections, to know whether the trains of ideas presented by the associative power are to be referred to the memory or to the imagination. Such persons, seizing only the outline of a fact or series of occurrences, owing to habitual inattention to their sensations, are, from readiness of association, able to fill up the transcript, so as to make it appear plausible to themselves; and by once or twice detailing it without minute regard to accuracy, except in those leading features, they give a degree of vigour to the ideas, and of closeness to the association of them, which at last leads to the full conviction that the whole is recollectcd. Cases of this sort are very frequent; and they often leave upon the minds of others, the belief that such persons intentionally depart from truth; whereas the fact sometimes is, that part of their error arises from a desire to give the whole truth when they have materials for only a portion of it in their minds. However, the fault is one which should be carefully guarded against, particularly in the early part of life, by making young persons of lively imagination habitually attentive to the minute as well as to the leading parts of their impressions.

Recollection should often be exercised directly: but the main object, after all, is, to acquire the power of bringing forward our ideas when they are wanted; and it should therefore be often exercised indirectly, by leading to it for those various purposes of life, in which the young are sometimes capable of being useful, and still more, by encouraging the statement of past ideas as they are called up by present objects, especially when the connection is natural and of

a kind likely to be serviceable. This species of recollection obviously depends upon the manner in which the associative power is exercised; and in fact it is itself an exercise of that power, to which the young should be led in every practicable way; in the period of childhood by free communication with their friends on their various pursuits and occupations, and afterwards, in addition to these means, by composition. Continual opportunities occur in almost every department of instruction, for the advantageous recollection of related ideas which have been before received; and it is only by their being brought into employment, and associated with other ideas and trains of thought, that they can be expected to be permanently retained in the mind, or, if retained, to be at its command.

The recollection of ideas is greatly aided by the connection of words both with them, and with the original impressions; for words being, from the constant use of language, familiar to persons of moderate mental culture, even in various combinations, they are easily retained, and most materially assist in producing the recurrence of the corresponding ideas. And thus, when a person is relating a past fact, the ideas in some cases suggest the words, and in others the words suggest the ideas. Hence illiterate persons, other things being equal, do not remember nearly so well as others. Hence also the importance of teaching the young to remember words as well as things; for in most cases, as words serve as the bond of ideas, ideas will be loose and floating in the mind unless connected with words.

After what we have said respecting the memory, we shall not be misunderstood when we say, that the cultivation of it should constitute a very essential object in the early periods of intellectual education. Without a doubt there are original diversities in the capabilities of the mind; and it should be one grand object in mental culture, to excite those which are weak, and to curb and regulate those which are excessive. With respect to the memory, some young persons appear to retain words, and even ideas, with a degree of facility which astonishes and perhaps delights the partial friend, while at the same time it furnishes some ground for alarm, lest that which ought always to be made subservient should have the ascendancy, and prevent due attention to the cultivation of the judgment and reasoning powers. Others are slow in acquiring, but retain for a long time. Others again are distinguished by the readiness with which they recollect, and the ease and aptitude with which they bring forwards what their memory has stored up; and if the memory has been judiciously employed, and the principles of association have been such as are advantageous to the judgment, this is all which can be wished for. With respect to those who possess great facility of retention, it should be the aim of the instructor to encourage, as much as possible, the sound exercise of the judgment, and the long retention and suitable recollection of ideas, rather than the easy acquisition of words, even if properly understood. Durability of retention depends in a great measure upon the manner in which ideas are associated in the mind, and upon the cast of the ideas which have already been received and retained; but this facility of retention, though depending in part upon exercise, seems to arise in no small degree from corporal organization. It is valuable only as made the foundation of a good memory; it often leads to neglect those exercises of the understanding, to which it should only be auxiliary, because they are more difficult; and the consequence, in innumerable instances, has been, that while apparently the mental progress is going on very rapidly, the judgment, and the reasoning powers, are almost dormant, and the whole of the mental store of the individual consists in the words, or at most

INTELLECTUAL EDUCATION.

the ideas of others, without any real acquisitions of thought, and even without that new-modelling and arranging of them, which would give a degree of appropriation to the possession. We have known an individual arrived almost at the age of manhood, who found it so much easier to learn Euclid's Elements by rote, than to understand them, that he actually went through several of the early propositions without any suspicion being excited that he had not fully mastered them; till on an accidental change in the lettering of the figure, or in the construction itself, it was discovered that memory, not understanding, had been exercised throughout. Where, however, facility in retention is not possessed, though it is by no means the most important feature of the memory, yet it should be cultivated, directly by actual exercise, but still more by well storing the mind with those really valuable ideas which will serve as connecting bonds for new ones. That kind or degree of retention which arises from affection, not from original organization, is of the greatest value; and this may be improved to almost any valuable extent, where there is good sense to work upon.

Where the pursuits are directed to the acquisition of literature and science, there is no danger of a want of objects on which to exercise the memory in all its usual qualities. Indeed the danger principally is, of doing too much; and still more, of cultivating the memory almost exclusively. The apprehension of this has led many ingenious persons who have been concerned in education, to do too little. They consider it unnecessary to exercise the memory more than they think will be probably useful in life, or to burden it with things which, if they should be useful, may be easily acquired when they are wanting. They see the memory often made almost the only object of education, facts stored up without any judicious link of connection, and words, in themselves considered almost unintelligible, and which at any rate convey no ideas to the mind of the learner, committed to memory without explanation; and they go into the opposite extreme, and suppose that the cultivation of the judgment is all which they need attend to. Truth, as in many other instances, lies between the extremes. The cultivation of the memory ought, most assuredly, never to supersede that of the judgment; but, on the contrary, should be kept in subordination to it, and be regulated by it: but when it is considered how many of the purposes of life require accuracy and facility of recollection, how necessary the memory is to the pursuits of science and literature, and even to the cultivation and exercise of the moral sense, can we doubt that as a subservient faculty, and, with a view to its subserviency, we can scarcely cultivate it too much.

Without a doubt, the recollection of ideas is the object of the greatest consequence; but as we have already stated, the memory should often be exercised on *words*, both as an aid to the remembrance of *ideas*, and on account of the great importance of an accurate recollection of words in the usual, as well as in the more peculiar concerns of life. We shall never forget, that, in all probability, the reputed murderers of Steele lost their lives by the definite article being introduced, we doubt not unintentionally, by the reporter of their words: if they said, "We must have had gin there," (not as we believe was stated in evidence, "We must have had the gin there,") their words, so far from being a strong, indeed preponderating argument against them, were plainly consistent, and indeed most consistent, with their reiterated assertions: they were discussing the testimony of the king's evidence; and what they probably said, was designed to account to one another for his representations. We are often led to repeat the statements of others; and it very frequently happens that it is not sufficient to give what we think their ideas.

If we can give their words, every one may judge for himself as to the import of them: if we give merely our own ideas of their import, we preclude all correction of mistake, if from our peculiar prepossessions, or any other circumstances, we have erred. We have ourselves known instances, and probably our readers can at once recollect others for themselves, where very serious consequences have followed from persons detailing their own apprehensions of the meaning of others, instead of what they actually said: and from a regard to truth, and from the consideration of such painful occurrences, we feel persuaded that the habit of the correct recollection of words should be early made an object, and should not be lost sight of in any part of education.

But besides the directly mental effect of the correct recollection of words, and the importance of it in the concerns of life, we do not perceive how the necessity of it can be doubted in the various employments of a literary and scientific education. We have no wish that the memory should be burdened with a number of rules and facts which are of no direct subserviency to the objects of rational instruction; nor that it should be called upon to acquire the principles of grammar, and still less of philosophy, without the continual exercise of the understanding; but though the judgment will afford material aid to the memory, even in the rudiments of the languages, and is of indispensable utility to its exercise in every department of science, yet the ready and accurate recollection of fundamental rules, of the flexions of words, of elementary principles, definitions, &c. is of such signal, and almost essential, advantage, in the progress of education, that we cannot but suppose, either that those who object so much to the frequent exercise of the memory on words, would not wish to be understood to the full extent of their own representations, or otherwise, that they labour under a most material error, arising from ignorance as to what exercise of memory even a rational education requires, or from forgetfulness of those processes by which they have themselves made acquisitions which could not have been made without them.

The exertions of the memory may be classed in three divisions, (as respects our present considerations,) those in which it merely supplies materials for the judgment; those in which it furnishes the results of previous exercises of the understanding, (or at least what have before been the objects of the understanding,) and in which the understanding should still be concerned; and those in which the processes of the memory are become habitual from constant employment, and go on "without our stopping to think." The last class is probably much more extensive than is generally supposed; facility in arithmetic, and in the subordinate exercises in the languages, continually require such an exertion of the memory, and where the memory has not been trained to it, the difficulties in these elementary acquisitions are constantly felt. All the power which we wish the judgment to exercise in such case, is a controlling power; to suggest errors and omissions, but not to direct what is right; and if the readiness and accuracy of memory have not been early cultivated, say before the age of twelve or thirteen, it will often prove up-hill work to acquire facility in those branches of knowledge which, from being of practical value, are of very frequent occurrence. One case has occurred to our own observation, in which the excessive fear of making the memory paramount instead of subordinate, led to such a degree of slowness in every operation in which the judgment is not principally concerned, that the individual found ten-fold difficulties, where the memory of much younger companions (without blindfolding the judgment) succeeded at once every thing that the circumstances might require, and will doubtless enable

ble them to succeed best in the usual employments of life. Of course we should prefer the cultivated judgment, with great hesitation of memory, to the most fluent memory without judgment; but fluency in memory may be acquired without sacrificing the judgment; and who would then despise it? One leading object of the work of instruction, in the middle period of it, (perhaps from the age of eight to twelve or farther,) is to give by practice that facility of recollection which, if not acquired before the understanding is become somewhat mature, will seldom be acquired at all; and which, though always to be regarded as a subservient quality, is of almost indispensable utility in the concerns of life, and even in the employments and researches of science.

The remarks in the last paragraph were suggested by what we are advancing on the memory of words, and chiefly refer to it. Words continually stand for many thoughts; and short combinations of them frequently imply trains of reasoning; but it is often sufficient, for the purposes of education, and indeed all that is desirable, that the memory should suggest such combinations, and afford the impression of their accuracy, without the exercise of the understanding to shew the truth of them. Two instances will illustrate our meaning. The common rule of algebraic multiplication, "Like signs give plus, and unlike signs give minus," is in itself considered almost without meaning, and understood literally involves an absurdity; and we would never teach it to a boy, without first shewing him that it is a convenient abridgment of a number of operations in algebraic multiplication, all of which are well-founded: but when he has once seen the universality of its application, we would then lead him to employ it without hesitation, and even without thought as to its meaning: of course, however, recommending that he should never reason from it, but refer to the facts themselves as the foundation of inferences respecting the nature and combinations of algebraic quantities. But to take a more familiar instance; in common multiplication, where the multiplier consists of several digits, we are directed to place the first figure of each product under the digit by which we multiply. Nothing can be easier, when the effect of multiplication by 10, 100, &c., and the nature of our numeration are well understood, than to understand the reason and meaning of the direction; but we should not wish that the pupil should continually revert to this explanation; it is sufficient if he remember the fact distinctly, and at the time when it is wanted; and it would only serve to embarrass, if the rationale were to be constantly brought into view.

Leaving out of consideration all the intercourses of life, in which the ready recollection of words is often the source of so much interest and delight, there is still another point of view in which we feel the importance of the habit of recollecting words readily and accurately. Ideas fade from the memory much sooner when they are not connected with words. In sickness, and often in old age, the reasoning powers become languid; and the vigour of the mind, which would supply a succession of interesting thoughts, is lost under the pressure of disease or gradual decay. In such circumstances the mind dwells upon the present impressions of pain, or weakness, and can scarcely raise itself above them; but if the memory have been well stored, in the early part of life, with useful and interesting combinations of words, they will often recur, at such periods, without an effort, and without fatigue, and furnish objects of thoughts which will sooth and even cheer. Those who are subject to any degree of mental depression, disabling them from active efforts, to point out a channel for their thoughts, often find such sug-

gestions of the memory an important relief to them. And we need not say to those of our readers who have a religious turn of mind, that these remarks are peculiarly applicable to those devotional compositions and expressions, which, where they have been early and deeply impressed on the mind, occur at the call of affliction to support, to strengthen, and to comfort; and which, thus suggested by the memory, have in innumerable instances allayed the emotions of passion and desire, or poured balm into the wounded heart.

Whether the memory should ever be exercised on words which convey no idea to the mind, we do not venture to determine; but as far as our own experience goes, we should be led to conclude that such a cultivation of the memory can be of little service in a rational memory of words. We have at least observed, that where a boy has possessed great facility in committing to memory passages from the classics, without finding it necessary fully to understand them, (so that the recital of them went on with little if any aid from the understanding, but was effected by the mere dint of verbal recollection,) he has usually found it much more difficult to remember passages from English writers, in which the meaning is obvious, though the modes of expression are out of the common rounds. It appears to us, therefore, that exercises of the memory, in which the memory alone is employed, should seldom be resorted to, since it does not tend to produce that recollection of words which is subservient to, and indeed accompanied with a recollection of notions and feelings. The first stage of recollection should be accompanied with the direct exercise of the understanding; the formula of words may, by habit, cease explicitly to excite the ideas which on reflection it would convey; but it should not be attended with a feeling of unmeaningness or unintelligibility.

The only case (separate indeed from the rudiments of language) in which it appears particularly expedient to exercise the memory upon words alone, is where, though they have no usual connection with certain facts or truths, they serve, by an artificial connection, to bring those facts or truths to recollection; and even here there is the feeling in the mind that they are merely abbreviated representations of a more full combination of words, which is itself at once intelligible. We refer principally to such contrivances as those in Grey's *Memoria Technica*. Of course we would by no means recommend the employment of his method to any thing like the extent which he proposes; but if it be of importance (as we are persuaded it is) in the reading of history, that a few leading dates should be well fixed in the mind, his method will be found of great utility by furnishing an additional aid to the memory; and the mere translation of his technical words, affords materially in the permanency of the recollection. Cases may occur, though not very frequently, in which it will be very serviceable to bear in mind with minute exactness the latitude and longitude of places; and here also, the *Memoria Technica* may be found of considerable service: but for the general purposes of geographical knowledge, there can be no doubt that much more benefit will be derived from forming in the mind a clear idea of the relative situation of places, by means of a familiar acquaintance with the globe, or even with maps. Little advantage can be expected from the extension of this method to astronomy, and other branches of physical science; but if any circumstances render it desirable to retain with accuracy the size of the planets, their distances from the sun, &c. or the specific gravity of different bodies, Grey's contrivance will be found a useful aid, though we can never recommend the employment of it in science, without a full previous acquaintance with the facts to which it relates, and a frequent explicit reference to them: in short it should always be employed merely to aid

INTELLECTUAL EDUCATION.

the remembrance of knowledge, not to enable the young to prate about objects of which they are really ignorant. It is well known to our mathematical readers that there are formulæ of eminent utility, in the remembrance of which the judgment can have little share, and in which readiness and accuracy of recollection are the chief objects; for instance, Napier's celebrated canons for the solution of right-angled spherical triangles. Here the short sentence, "the rectangle of the radius and the sine of the middle part, is equal to the rectangle of the tangents of the extremes conjunct, or, of the sines of the extremes disjunct," enables the calculator to solve with the greatest ease every case of right-angled spherical trigonometry; but in the recollection of this comprehensive canon, the understanding affords little, if any assistance; it is a technical formula, in which there is no opportunity of exercising the perception of truth, except by observing the truth of every class of proportions which may be derived from the application of it; when the truth of these has been demonstrated, all we have to do is to remember the canon. In this and many other instances in the mathematical sciences, a ready and accurate recollection of signs of ideas is of great service; and we cannot have hesitation in maintaining, even from such cases alone, that it is desirable to train the memory, among other objects, to the recollection of words, always indeed as signs of ideas, or abbreviated signs of those which are immediately signs of ideas, and, as such as circumstances will allow, with an explicit exercise of the understanding, but still so as to make the exercise of the memory in these instances the primary consideration. The occasional utility of the recollection of such abbreviations we have already sufficiently adverted to; and we will only add one specimen of the advantage even of the abbreviated statement of these abbreviations. The formula of Napier is readily suggested to the mind by the memorial words *Tan con, Cos-Dia*; and when these are well fixed in the memory, and connected with the more expanded statement of the canon, it is almost impossible that the mind should ever be at any loss in the recollection of the canon itself, or at least of the import of it.

In cases where verbal recollection is found to be an object of importance, the simplest and most correct modes of expression should be employed; and, when they are repeated, it should constantly be done without variation in the order or selection of words. If we can refer to the understanding to check or suggest the words, this is not of so much consequence; but wherever the ready recollection of words is desirable, for purposes of dispatch and accuracy, this precaution will be found of great moment.

We do not mean to charge the later writers on education with being the sole cause of that neglect of the exercise of verbal recollection, which, a few years ago, was prevalent and fashionable at least in domestic education, and which made its way into schools beyond what experience has shewn to be useful; but the unqualified language which has been used by persons of intellectual eminence, aimed, perhaps in some cases exclusively, against burdening the memory with fouds unmeaning to the learner, and almost useless if they were understood, has in many instances been extended to all cases of exact verbal recollection, and has caused great difficulties in the subsequent periods of education as well as in the pursuits of life. We think that Miss Edgeworth stands chargeable with contributing to and supporting this error, not perhaps directly, but by the low estimation in which she teaches us to hold the memory, and by the too unqualified manner of her generally excellent observations on the culture of it, and the subjection of it to the judgment; and we will not deny that we have been led much

farther than we otherwise intended, by our opinion as to the impression which many have derived from her chapter on the subject. Her own writings shew that she herself possesses a judicious memory; but without more attention to the cultivation of the recollection of words than she encourages, we feel persuaded that few will obtain one so serviceable. There is in that chapter a great deficiency in precision and clearness; and it has consequently been the source of much error, or at least countenanced it: and the principle is often obvious, that exertion should be exacted only by being made interesting. Her conclusion, "that memory is chiefly useful as it furnishes materials for invention," is one of those extraordinary positions which can only mislead persons who can implicitly bow to authority, and who prefer quiet acquiescence to the trouble of thinking. It has not infrequently occurred to us, that it is happy for mankind that the human intellect is not generally to be moulded by the oracles; and we have no doubt that in the common walks of life great numbers, not absolutely illiterate, may be found, who, though they possess a tolerable share of good sense and judgment, never have had the merit of forming one new combination of ideas for themselves, and who yet, by the aid of memory, guided, we allow, by the understanding, contrive to pass through life with credit and utility. Viewing Miss Edgeworth's position as limited to science and literature, the subserviency of the memory to invention is only one, and that not the most important department of its exertions; taken as we find it, without any restriction or explanation, the position is as unfounded as it is injudicious.

It is difficult, in education, to lay down any generally applicable rules, especially if they require the specification of ages; but we should be inclined to divide the course of intellectual education into three periods, the first extending to about seven or eight; the second to about twelve or thirteen; and the third to the time when direct instruction ceases. In the first, the exercises of the memory should be constantly and directly subservient to the culture of the understanding, and should not be employed but where they can be made intelligible. In this period the chief object is to produce ideas, and to connect them with words, to cultivate the observation and the judgment, and to store the memory with ideas without much regard to philosophical principles of arrangement. Some notion of causation, however, begins very early in children; and where it can be brought into exercise judiciously, there appears no reason why it should be neglected; but the common bond of union will be connection in time and place, and it is by these links of association principally that recollection will be first produced. In the second period, though the exercise and culture of the judgment should go on as ever, and even become a more prominent object of attention, yet the memory of words should now be particularly cultivated. In the third period, the exercise of verbal recollection should, we imagine, constitute a very subordinate object. The primary aim must then be, to strengthen the judgment, to exercise the operations of reasoning, to cultivate habits of correct generalization and classification; and, as the mind expands, to lay the foundation of that judicious selection and arrangement of the objects of the memory, which will make this faculty of the utmost utility in every valuable employment of the understanding, and indeed make every operation of the memory itself an important exercise of the judgment.

VIII. We now proceed to a few remarks on the cultivation of the *Understanding*. We employ this general term (though in reality it may truly be said to comprehend all the

the preceding intellectual habits or faculties, principally with a view to those operations, which are usually referred to the heads of judgment and reasoning, and to those operations of the associative power by which ideas are combined and associated with words.

The foundation of an accurate, discriminating judgment, can only be laid in the acquisition of clear perceptions. During the period of infancy (that is, before the use of words is understood), this is almost the sole object of intellectual education; and where this is properly attended to, unless in very unfavourable circumstances, the development of the understanding will afterwards go on with success. Where this has been neglected, the injurious effects are seldom completely remedied. The acquisition of clear perceptions does not, however, necessarily introduce the operations of comparison, discrimination, and judgment; but when these are exercised, the perception is thereby rendered more acute and active. The perceptive powers are necessarily improved in proportion to the attention of the mind to the objects of perception; and whatever excites the operations of the mind, is productive of that pleasure which attends every natural and gentle exercise of the mental faculties, more or less in every period of life, but particularly in those to which education is chiefly directed. Every such exercise of the mental faculties in connection with the objects of perception, tends to excite the attention to those objects, and consequently to improve the perception. And thus it is, as in every period of the intellectual culture, that the proper exercise of one faculty tends to the general improvement of the mind. But to compare, to discriminate, and to judge, does not necessarily follow from the exercise of the perception. In the more complicated perceptions, numerous judgments are often included; but for the formation of those simple ones which are the first exercise of the mind, nothing more is requisite than retention of ideas, and that elementary exercise of the associative power by which two or more ideas, derived from the same or similar objects, are connected with the appearance, &c. of the object, so as to be at once recalled by it, and by degrees combined with it: nevertheless, where the mind is active, and suitable opportunities are given, it very early begins to employ those faculties of the mind on the notions presented by the senses. We have observed, even at the age of twelve months, instances of the most decided nature, proving the attentive examination and accurate discrimination of the objects of sensation. Among others, we recollect to mind a little circumstance which we observed with great satisfaction, where parental partiality was not concerned. A boy, of a fine intelligent cast of countenance, but not at all able to speak, had a strawberry with its stalk on, and a red garden daisy not fully opened, and which very much resembled the strawberry, placed before him. He had several times before eaten strawberries, and of course had an infantine motive for discrimination. He looked first at one, and then at the other; at last he took up the daisy, but without putting it to his nose or mouth, he continued observing it, and after some time he put it down and took up the strawberry, which he almost immediately ate. Hence it might be supposed, on the one hand, that there was an operation of reasoning; and, on the other, that it was simply a judgment, formed by comparison of the sensations.

The truth appears to lie between the two suppositions. As far as we can form an idea of the operation of the infant mind, the case was this. There certainly was considerable resemblance between the two objects, or the child (whose discriminative powers were obviously clear) would have at once chosen the right one; but having taken up the

daisy, it did not, on minute observation, present those appearances which excited the connected pleasurable feelings, already associated with the conception and name of the strawberry, and consequently did not excite the disposition to eat it. The judgment was not a direct intentional one, and consequently differed from those which we employ by the use of words; but the process was the same with that which continually takes place in our own minds. The rejection of the daisy was in consequence of the perception of diversity, or at least the want of perception of complete similarity between the sensation and the conception which had been produced by the frequent sight of the fruit. In this instance we have no doubt that words were employed to set the comparison in motion. Children often understand many words before they can at all utter articulate sounds. The child was probably told that one was a strawberry and the other a daisy, and that he might eat the strawberry.

Such comparisons should often be produced, but at first the objects should, as much as possible, be such, that the comparison may be suggested by the wants of the case; and it should, consequently, be always employed on objects which are completely within the grasp of the mind, at least in the view which we wish to have taken of them. It would be absurd, for instance, to lead a child to compare any of the qualities of a guinea and a shilling, but those which are obvious to the sight or the touch. Instances will be continually occurring (where proper room is given for the exercise of the faculties), in which comparison will take place without any effort on the part of the parent; but it will usually be found expedient sometimes to bring about the employment of the judgment directly; and provided we take care never to make it painful, by displeasure at inaccuracy, or by too much sollicitude as to the result, it may be done with great advantage. We never can be without objects to exercise comparison, when children understand the meaning of common words, even if they cannot themselves properly employ them. The size of things, their colour, shape, smoothness, weight, &c. (according to the degree in which the understanding is developed, and the meaning of words understood), furnish constant means for leading to observe resemblances and differences in their various combinations; and the perception of these constitutes discrimination.

These things would doubtless appear trifling to many of our readers; but in all probability those who may consult this article will view things in a different light. Discrimination of judgment is a quality than which no one is more essential in the pursuit of truth; the ready perception of resemblances among diversities, and still more the quick and accurate perception of diversity in the midst of resemblances, constitute some of the most important operations of the understanding. And such discrimination will usually be produced, where the mind is awakened by having sufficient scope and exercise of its faculties. We may often leave it to its own silent progress; and if we encourage accurate and attentive observation, and the correct use of words, discrimination will, in all probability, be found to follow as a natural consequence. But it must also be our endeavour, to awaken and exercise the mind by direct attention on our part; and provided we measure our efforts by the degree in which the understanding is developed, and do not attempt to force it, but only to guide and employ it, we may reasonably indulge the confidence that the work of education is going on successfully, and that we are beginning a progress of intellect, from which the most satisfactory results may be expected.

This quality of accurate discrimination should be kept in view and exercised in every part of education. It is, indeed,

the foundation of clear ideas; and the acquisition of whatever can be truly called knowledge depends most materially on the possession of it. It is exercised by various objects of instruction; and in fact it often is this exercise which gives those objects their leading value. Now, if we wish our children to think clearly, and to reason accurately, the works of thought and reasoning must be attended to early. Those who learn to think and reason comparatively late in life, have difficulties to overcome which can scarcely be appreciated by those whose intellectual qualities have been early cultivated. And no sensible parent need despair on this point. The object to which we would urge, is not to communicate extensive information; that will be gained, and beneficially gained, if the desire of knowledge have been produced, and the qualities of mind, on which the acquisition of knowledge depends, have been properly trained; we only wish that on those objects which properly fall within the sphere of capacity, during the early part of childhood, the observation should be so exercised, that the power of discrimination should be acquired. A few simple play-things, which a child has the opportunity of observing in every situation, the natural objects which surround us, and which usually strike the attention of a child, if he be allowed to observe, pictures of different kinds of animals, the letters of the alphabet, the dissected map, &c. furnish abundant opportunities for that discrimination, the cultivation of which we strongly recommend, as lying at the foundation of every thing which is valuable in the most serviceable exercises of the judgment. All that is requisite is, that we should ourselves be capable of discrimination; that we watch the opportunity, when the mind is alive, to encourage the observation, and to produce distinct and accurate perceptions. Our business is not to be continually making direct efforts, as in the later period of education, but to employ those occasions which so often present themselves to the attentive parent, to lead to the exercise of those qualities of mind which he knows to be of high importance. It scarcely matters what it is on which we do thus exercise them; provided always that we attend to the actual state of the mental progress; circumstances which, to uninterested spectators, appear of the slightest possible moment, often to the judicious parent indicate the operation of some useful quality, and enable him to discover, more than any specific directions can do, what will enable him to promote those qualities of mind which he wishes to see possessed. The grand point to be kept in view is, that we do not aim, on any occasion, to force the faculties, but to employ them as they advance in strength and accuracy suitably to their progress, and to furnish them with appropriate objects of exercise: and we may feel assured, that so long as those qualities are exercised, the business of education is going on much better than if we were endeavouring to store the memory with words to which indistinct ideas, or no ideas at all, are attached, or even to store it with facts, however in themselves considered useful and interesting. We ought never to think the work of education going on, unless the operations of the understanding are in some way or other brought into exercise: and when they are, we may rest fully satisfied. If the development of the intellectual faculties is properly begun, it will go on by the mere influence of external impressions. Our business is to regulate and employ those external impressions, so that their influence may be suited to the state of the mind, and really productive of a suitable exercise of the understanding.

We should aim not only to produce discrimination, but to lead to the habit of observing the grounds of discrimination, the particular qualities or circumstances in which

objects resemble one another, and those in which they differ. This is by no means a necessary effect of the perception of resemblance or difference; and it is often but partially acquired; yet it is certainly essential to correct reasoning, and may be properly included under the head of discrimination. Children very early acquire the power of finding out the grounds of difference and agreement; and the questions, In what are these two things alike? In what are they unlike? often serve, at the age of three or four years, to bring into exercise some of the most useful operations of the understanding. Every thing, in fact, which lets children to think upon the objects of their sensations, and upon their ideas, is a most serviceable employment; and the more they are early led to think correctly, the more easy in the later periods of education will correct thought become.

It would often serve as an important guide, if parents would themselves consider what qualities, or faculties of mind, are brought into exercise by the different circumstances which occur, by their own words to their children, and the modes of expression which they encourage them to use. We should always wish that intellectual education should be made subservient to moral education; but attention to the one would in no way interfere with attention to the other. A sound, comprehensive, vigorous, discriminating judgment, is surely of the first importance, both in a moral and in an intellectual point of view. There can be no doubt that much might be done towards the acquisition of it, if parents kept it in sight as the chief mental object, and regulated their direct efforts, and as much as might be controlled accidental impressions, with a view to the cultivation of it, using their own good sense and patient observation as the best guides to the probable effect of each upon the mind.

IX. *Reasoning*, or the drawing of inferences, is a process which may be expected to go on successfully where the judgment has been cultivated. It begins very early; indeed the mental process is often independent of words. The direct exercise of it does not appear to be desirable, till the mind has acquired some vigour; more especially till the judgment has been tolerably cultivated, and a considerable acquaintance with words acquired: and this is the less necessary, because in every part of early education, circumstances of constant occurrence will continually bring the reasoning faculty into exercise, and give it a right direction, if we avail ourselves of the opportunities which they present. "Scarcely a day passes," says Miss Edgeworth, "in which children do not make some attempt to reason about the little events which interest them, and upon these occasions a mother who joins in conversation with her children may instruct them in the art of reasoning without the parade of logical disquisitions."

As the mind expands, the objects of the reasoning faculty, of course, increase in number and frequency of occurrence. And the judicious parent, without making it a formidable object, may exercise it effectually. Two points, which are of universal application, should, however, be always kept in view; that the premises should be thoroughly understood, and this previously to the employment of them in the act of reasoning; and that the assent of a child to the conclusion should never be exacted, when there is any hesitation. It is too much to expect from a child, that the conclusion should be admitted, if the understanding is to be exercised upon the premises also: and as we cannot force the reasoning powers, and cannot compel a child to see the justness of our reasonings, we shall either lead him to falsehood by too great eagerness, or to assent upon our authority and not upon the effect of the premises; or, we shall

INTELLECTUAL EDUCATION.

shall confuse his understanding, and really prevent that effect which would otherwise have readily followed.

Single acts only of reasoning should be exercised in the early periods of education. We do not mean that one inference should never be made to follow another, after the understanding had previously acquired some strength and clearness: but that, if ever a train of reasoning be employed, it should, in fact, be made to consist of single unconnected reasonings in the first place. The links should be all comprehended separately before they are fastened together. When a child is so far advanced as to be able to pursue a train of premises and conclusions, there can be no loss for subjects on which to exercise the reasoning faculty: the fields of mathematical science will by that time be opening, and they will exercise it, and, at the same time, guide it.

It appears that, in general, the true method of teaching to reason accurately, is to accustom children to accurate reasoning. Long before they can form inferences for themselves, they can understand the inferences of others; and the grand point is, that the reasonings which we employ to them shall be fully intelligible and thoroughly just. If we are sophistical with them, it is too much to expect that they will grow up in habits of clear and correct reasoning. If we make a point of going no farther in our conclusion than our premises will warrant, they will gradually acquire a kind of tact, which may be considered as forming a part of good sense, which will effectually prevent them from being satisfied with false reasoning, even though they could not detect the grounds of the sophistry.

Parents must often require the assent of their children on the score of authority. They will naturally believe implicitly, if the truth is always spoken to them; and it is sometimes impossible to give them any reason which would be intelligible and satisfactory to themselves in reply to their question, Why? or, Why not? We prefer that children should be troublesome sometimes with these enquiries, rather than that they should not themselves be accustomed to think; and if a parent has, by judicious management, acquired the confidence of his children, it will generally be sufficient for him to say, "It is not always necessary that I should tell you the reason of what I desire you to do; I wish you to do it:" and in some cases, indeed, not infrequently, it may be expedient to state what is often the matter of fact, "You are not old enough to understand the reason, if I were to tell it to you: when you have more knowledge and understanding, I shall be able to tell you the reasons of those things better than I can now." But after all, if assent, or obedience, be required on the ground of authority and confidence, let the ground of reasoning be kept out of view. If we once make any thing depend upon our reasoning being understood, let it be kept to that point. We may often assent to the conclusion as an insulated truth; but we never can assent to it as an inference, unless the reasoning is properly understood.

It may be doubted whether it is desirable to give specimens of sophistry to children, before they are really capable of entering into the ground of the sophistry. But if ever we find them drawing false conclusions, then is the time to shew them, if possible, how and why they are false. And it is highly desirable that we should accustom them to caution in their inferences. It is better that they should sometimes reason very erroneously, and draw very erroneous conclusions, than that they should never reason at all; and it is by no means to be expected, or even wished, that their inferences should be always accurate: it is not to be wished, because we should then have reason to apprehend, that the

inference was an act of memory rather than of the understanding; and it cannot reasonably be expected, because the power of reasoning justly depends upon the degree in which the terms of the premises are clearly and fully understood, and also requires, for the acquisition of it, a long course of exercise. Nevertheless, the habit should be early produced of caution in receiving or in drawing inferences. We would never have children suspect the accuracy of their parents; but we should shew them in what they hear (if it can be done with prudence), and still more in their own little reasonings, those defects which their minds are sufficiently cultivated to perceive. And without giving rise to a habit of indecision, (which sometimes is as injurious as a habit of presumption,) we should aim to lead them to take as many circumstances as possible into account, and not to be too decided with respect to inferences which may be drawn from them. If a child once sees that he has inferred too much, it will effectually keep him, for a time at least, from presumption, especially in opposition to the inferences of others.

In order to acquire that freedom from the influence of authority which is often necessary to success in the pursuit after truth, it is requisite that children be accustomed, and encouraged, to state their difficulties and objections against any reasoning or assertion which they hear or meet with in books. We have no wish to see the habit of objecting for the sake of objecting; but those are the most likely to acquire it, who have been accustomed to think but little when young, and to take every thing upon trust. Having believed every thing upon authority, when their minds acquire some degree of independence and activity, they usually find, or think they find, that many of those things which they have believed are inconsistent with truth, and they feel a kind of general suspicion, with respect to all which they have been accustomed to believe; and the consequences often are highly injurious both with respect to the understanding and the conduct. Though we wish to see an unbounded confidence in parental declarations, and unlimited submission to parental authority, yet a parent should employ each only for the good of his children. It will not excite suspicion, if he sometimes lead them to perceive, that he is not equally sure of every thing that he tells them; that when they grow older they will perhaps understand some things better even than himself; and that at any rate they must learn to think for themselves, since he shall not always be at hand to instruct and guide them. He will always point out, or, what is better, lead them to find out, errors in reasoning, &c. in the books which they read, especially though the writers were men of great eminence. He will accustom them to think for themselves; but at the same time he will make them understand that they are not to reject every thing because they see that some things are erroneous. If the mind have been rightly trained, while its education is principally conducted by others, things will go on well when the individual has, as it were, to educate himself. If by early discipline, followed up by the well regulated pursuit of useful knowledge, he have been brought into that invaluable state of mind, in which freedom of thought is united with caution, and a tendency to suspect one's own conclusions, at least as much as those of others, it may reasonably be expected that the acquisition of truth will be an easy task, and that the judgment will have that clearness, activity, and correctness, which will enable the possessor to choose important objects, and to pursue them by suitable and judicious means.

X. After all, perhaps, the most important object in early intellectual education, next to the cultivation of the pri-

INTELLECTUAL EDUCATION.

ception, is that which respects *Words*: at least, this is of essential importance. A clear and correct understanding of the force of words, is of the utmost consequence in every period of the intellectual progress. On the care which is early taken in furthering this object, depend, in a great measure, the future development of the understanding and the acquisition of knowledge. A well-educated child will always hesitate to use words which he does not so far understand as to be able to feel their force in the particular connection: and in many instances this is all which can be understood by a child. The names of external objects, are, of course, the first words which are acquired and understood; and here all is plain. Either the things themselves can be shewn, and the words connected with them; or pictures can be employed to represent to the mind what cannot be directly made the subject of perception. In like manner, names denoting the actions of animated objects, and the changes which take place among inanimate objects, the sensible qualities of the different substances around, and, in short, any thing which can be made the subject of direct sensation, or can be represented to the sight, are calculated for the early exercise of the associative power. And it is in the application of these, that the earliest efforts of classification are employed. The same name is unavoidably given to a variety of things or animals agreeing in some particulars; and indeed this circumstance is of the utmost consequence to the progress of intellect. It may be truly said, that without general terms little knowledge could be acquired, that there would be almost a total stop to every process of mind not immediately depending upon sensation. In the first periods of language the business of classification, and the application of general terms, went on together; the processes of classification are now, however, in innumerable instances, directed by the customary mode of applying the terms. Still the application of them is accompanied with classification; and when the mind is, in some instances, a little familiarized with the operation, it acquires, with great ease, the mode of applying general terms in others. This is an excellent and important exercise of the judgment; and it leads to notice circumstances of agreement and circumstances of difference, which is in itself a highly useful employment of the understanding. In some instances children cannot but be puzzled, either by the unavoidable irregularities of language, or by the application of terms depending upon little niceties which cannot be expected to lie within the sphere of their observation; but wherever the grounds of the application can be shewn, it will always furnish a useful exercise of the mind to be led to observe them as such.

We have already referred to the great importance of the mathematical sciences in training the mind to habits of correct reasoning; and indeed it is by the various acquisitions of knowledge, that the different mental faculties are developed and cultivated; and we fully expect the concurrence of our readers when we say, that an early and accurate acquaintance with our arithmetical notation and numeration, is peculiarly calculated to lay the foundation of habits of precision, of arrangement and classification. Our notation took its rise in the necessities of circumstances, operating upon those powers and qualities of mind which are possessed by every human being; but it is an object worthy of the attentive examination of the philosopher, while, at the same time, from its distinctness and simplicity, it serves as a most important exercise to the juvenile understanding. A child, early made familiar with the simple operations of arithmetic, (taught, not technically, but by a constant reference to the principles on which they are founded, and particularly to

those of the notation, on which in short the whole depends,) can scarcely fail to form some precise ideas, and to acquire a tendency to arrangement and method, which will almost inevitably lead on to a similar employment of the understanding in other circumstances. It may not perhaps be known to all our readers, that there is an excellent posthumous work of Condorcet, which will furnish some highly valuable information to the intelligent parent, on the best means of communicating an acquaintance with the first principles of arithmetic. It is entitled, "Moyens d'apprendre à compter avec facilité." If it were more the object of early education to cultivate the faculties of the mind, rather than to store the memory with words, or with ideas, which are of little importance except so far as they are made an exercise of the understanding, this little tract would not have been so long left inaccessible to the mere English reader. The French editor justly remarks, that the first thing which distinguishes these elements of arithmetic, is, that they are at the same time the elements of the art of reasoning. The usual formulæ of arithmetic are founded upon principles and processes which can generally be made intelligible to those who are capable of employing them; but the formulæ do not of themselves sufficiently exercise the understanding: they are a species of machinery with which we operate almost mechanically. But in so far as those principles and processes are made intelligible and familiar, the judgment is cultivated, the reasoning powers are exercised, distinct ideas are gained, and the commencement made of those intellectual operations and habits, which are subservient to the highest pursuits of knowledge, and to the best conduct of life.

While we thus recommend the early employment of the understanding upon numbers, we ought not in justice to ourselves to omit mentioning, that natural history furnishes ample scope for the exercise of the intellect on things, on words, and in classification; and in some respects it is a more useful object of early mental culture; it brings into exercise the habit of observation, while it equally requires and more rewards the attention; it gives more room for the exercise of the memory, and is more calculated to set the mind at work, and supplies more numerous and interesting subjects for its operations. "The art of forming a sound and active understanding," says Miss Edgeworth, "consists in a due mixture of facts and reflection. Dr. Reid has, in his Essay on the Intellectual Powers of Man, p. 297, pointed out, with great ingenuity, the admirable economy of nature in limiting the powers of reasoning during the first years of infancy. This is the season for cultivating the senses, and whoever, at this early age, endeavours to force the tender shoots of reason, will repent of his rashness." We have not yet been able to meet with the passage to which Miss Edgeworth refers in our 8vo. edition of Reid; but we are fully convinced that she cannot go the whole lengths of that philosopher, respecting the degree in which the reasoning faculty is naturally developed, or rather lies undeveloped, during *childhood*: as we have already remarked, children reason much more than is usually supposed: and provided we are cautious in giving due vigour to the observation and judgment, we may sometimes directly employ the reasoning faculty, under the restrictions which we have already pointed out. It happens, however, it is better to be satisfied with those processes of reasoning, which, where the mind is healthy, will almost inevitably follow the exercises of the observation and recollection, and make no direct effort to cultivate the reasoning faculty, than to aim to bring it forwards prematurely; and it was with a view to this principle, that we have thought it desirable to subjoin the foregoing remarks to what we have said on attention to numbers.

INTELLECTUAL EDUCATION.

In many cases the force of words can only be learnt gradually, by their use in various connections: to attempt to explain connectives, for instance, by assigning their abstract force, would be utterly useless to a child; the force of them must be shewn in particular cases, and from these the mode of applying them, and the force of them will be learnt in others. Similar remarks may be made with respect to all abstract terms: and provided we are careful ourselves to employ them properly, and to take every opportunity of shewing the force of them when level to the capacity or progress of the individual, we do all which is necessary, and probably do better than by attempting to do more.

Though we fully calculate on our readers going along with us, respecting the absolute necessity of early accustoming the mind to seek for, and to acquire, clear ideas in connection with the signs of ideas, the following remarks of Mr. Locke may serve to corroborate their opinions; and, together with what we shall also quote from Miss More, may lead them to make it an object of daily, indeed constant, aim in the business of education, not merely as of great moment in intellectual cultures, and to smoothe the way for intellectual acquisitions, but as incumbent on every one who has in view the moral welfare of his child. "Persons having been accustom'd from their cradles," says our great philosopher, "to learn words before they knew the ideas for which they stand, usually continue to do so all their lives, never taking the pains to settle in their minds the determin'd ideas which belong to them. This want of a precise signification in their words, when they come to reason, especially in moral matters, is the cause of very obscure and uncertain notions. They use these undetermined words confidently, without much troubling their heads about a certain fixed meaning, whereby, besides the ease of it, they obtain this advantage, that as in such discourse they are seldom in the right, so they are as seldom to be convinc'd that they are in the wrong, it being just the same to go about to draw those persons out of their mistakes, who have no settled notions, as to dispossess a vagrant of his habitation who has no settled abode. The chief end of language being to be understood, words serve not for that end when they do not excite in the hearer the same idea which they stand for in the mind of the speaker."

"I have chosen," adds Miss More, after making the foregoing extract, "to shelter myself under the broad sanction of the great author here quoted; with a view to apply this rule in philology to a moral purpose; for it applies to the vivacity of conversation as much as to its correctness; and as strongly recommends unequivocal and simple truth, as accurate and just expression. Scarcely any one perhaps has an adequate conception, how much clear and correct expression favours the elucidation of truth; and the slide of truth is obviously the slide of morals; it is in fact one and the same cause; and it is of course the same cause with that of true religion also.

"It is therefore no worthless part of education, even in a religious view, to study the precise meaning of words, and the appropriate signification of language. To this end, I know no better method, than to accustom young persons very early to a habit of defining common words and things; for, as definition seems to lie at the root of correctness, to be accustomed to define English words in English, would improve the understanding more than barely to know what those words are called in French, Italian, or Latin. Or rather, one use of learning other languages is, because definition is often involved in etymology; that is, since many English words take their derivation from foreign or ancient languages, they cannot be so accurately understood without

some knowledge of those languages; but precision of any kind, either moral or philological, too seldom finds its way into the education of women."

If any of our readers wish for an exemplification of the method of teaching to define, we refer them, with complete satisfaction, to the excellent little work called "Evenings at Home;" the attentive perusal of which must furnish to the judicious parent, many useful reflections and hints calculated to facilitate his views in intellectual education. We may mention in passing, that we cannot but consider it as a duty which the respectable author owes to the public, to make those alterations in the chemical articles which may adapt it more to the present state of the science; and we are persuaded that he could not render a more useful service to the rising generation, than by some supplementary volumes on other points of natural history and physiology, and natural philosophy, calculated, as those preceding eminently are, to convey clear ideas, and to exercise the understanding. We need scarcely add, that the mathematical sciences furnish most important lessons in the art of defining, and some of the finest and most useful specimens of it.

With respect, however, to the plan of definitions, we must again observe, that in a great variety of instances we must rest satisfied with perceiving that the force of a word is clearly understood in the particular case; and we must sometimes require even less than this. Words which are the most forcible to our minds, in consequence of numerous associated thoughts and feelings, often can scarcely affect the mind of a child. The force of those which represent very complex ideas (as most general terms do), must generally be acquired slowly, by the impressions derived from the manner of their employment, and the instances of their application. But wherever the force of a word can be explained, so as to be made intelligible, this should be done; and there can be no doubt that the habit should be formed as early as possible, of never resting satisfied without some ideas connected with the words which occur in books on conversation. We have ourselves had an opportunity of observing the great value and force of this habit. A young person, who, in the course of his reading aloud with his early instructor, had uniformly been called upon to try to explain the meanings of words, and in case of failure had as uniformly been sent to search for a suitable explanation in a good dictionary which was always at hand, by degrees became so much accustomed to this exercise of the understanding, that, when arrived at years of maturity, he felt a kind of internal compulsion to resort to the same means of information, when he could not otherwise ascertain to his satisfaction the force of a word in a given situation, which feeling generally overcame the reluctance of indolence, and even the egotisms which so often urges on the ardent mind towards that which is yet unexplored. The effect of such discipline upon the habit of discrimination and clearness of intellect need not be pointed out. It can scarcely fail to bring the mind into the right state for the search after truth; and even if only defective ideas are thus acquired, yet if correct as far they go, the grand point is gained. After such habitual culture of the mind, the want of something upon which the understanding may rest with satisfaction is constantly felt; and if the whole truth is not grasped, the acquisitions actually made will usually be on the side of truth.

It appears highly inexpedient to attempt, in the early periods of the mental progress, to give the most comprehensive meanings of words. The first business in the early acquisition of knowledge, is to begin with individuals, and after a suitable acquaintance has been gained with them, to

go on to general facts and statements. In like manner with respect to words, it is sufficient if we can give a clear idea of the signification of a word as it occurs: it will afterwards be an excellent employment of the understanding to combine these meanings together, so as to generalize the term; and where the mind has been well cultivated, this will be done almost without our direct efforts. But it should not unfrequently constitute a direct exercise in the more advanced periods of education, to trace out that common signification which a word has throughout all its varieties of signification; and previously to this, it is desirable to accustom the young to expect that the particular force of a word which they have acquired is by no means the only one, and to be ready to receive the change of meaning which the circumstances of the connection may require, or which the writer may, by his definitions, endeavour to communicate to his readers.

The wrong application of words is one of the chief obstacles in the acquisition of knowledge, and constitutes the cause of some of our earliest and strongest prejudices. By the magic power of association, not only do the connections of ideas suggest combinations of words, but combinations of words, in innumerable instances, produce connections of ideas. And this ought to furnish to the early instructor, a powerful motive to caution in the employment of words; so that, in his communications with his pupils, he may avoid, not only those modes of expression which are in themselves calculated to convey wrong ideas, but those also which must convey wrong ideas in consequence of the partial knowledge possessed by those who hear them. It should be a leading object, in every department of education, since it is totally impossible to give full and complete ideas, to render those which we can communicate clear and correct. Where this object is steadily pursued, the understanding may be expected for itself to seek, and will, in all probability, acquire all which is necessary beyond.

But notwithstanding all the care and self-culture of parents and instructors, numerous erroneous associations will be formed or imbibed, which will warp the judgment from the perception of truth, and sometimes obscure it. A large proportion of them operate through the medium of the affections; and some attention will be paid to these under the head of *Moral Education*; but still many remain which arise from the ambiguities of language, from partial observation, from accidental combinations of external objects, &c. These will often give way to the gradual development of the mental faculties, and the acquisition of knowledge; but sometimes these irregular associations will continue for a long period to perplex and mislead the understanding. It is highly desirable, therefore, to watch for them, and, where they are discovered, to take suitable means for destroying them. When we perceive a want of readiness to admit obvious truths which are level to the progress of the intellect, we may usually conclude that some incorrect idea has been connected with the words employed. Sometimes the immediate end may be gained by a change of words; but it is, perhaps, generally preferable to endeavour to enter into the little mind and trace its errors and their sources. We remember once discovering that a child had formed the preposterous idea, that the dust which flies about in the road is in part composed of the particles of the human body; an idea derived (by some process of reasoning, which we do not now recollect, aided no doubt by an effort of the imagination,) from impressions received from the words in the burial service, "dust to dust." Here, and in similar cases, to discover the link and to separate it, are almost the same thing. It is one great advantage of

domestic education, that it enables the parent or instructor to watch over the early associations, and to prevent the formation, or effect the disunion, of many which are injurious to the acquisition of knowledge, and what is still more important, unfriendly to the moral judgment, and to the happiness of the individual. To have the power of availing themselves of this advantage, however, parents must accustom their children to view them as friends, to open their little minds to them with the utmost confidence; they must treat their erroneous judgments with mildness, and be habitually careful in their own modes of expression in their presence, and especially in their direct communications with them.

Before quitting the subject of words we would add, that it is very desirable to accustom children to the peculiar terms of science and art, as soon as they can understand their meaning. In very many instances this can be done with ease, not as a formal object, but in the course of conversation, or while explaining what is met with in books. When the terms are become familiar, and are pretty well understood, the difficulties attending the acquisition of any science are greatly lessened. Even familiarity with the mere words employed, is of some service when we begin a new branch of knowledge; but in many cases even clear ideas may be early obtained in connection with scientific language, which will effectually prepare the way for future progress. Suppose, for instance, the leading terms of geometry are early explained, by means of figures or models, not only will the understanding receive some exercise by the acquisition of distinct ideas in connection with words, but it will be ready whenever the reasoning powers are sufficiently matured to be directed to geometry, to enter upon the field without that perplexity which is so often produced by the multitude of new words as well of new ideas. The utmost care should, however, be taken to make our explanations correct as far they go. If possible, children should have nothing to unlearn; and though we cannot effect this completely, yet more depends than is usually supposed upon those who have to guide the early associations and mould the habit; and the less error enters the mind, the more readily will truth find admittance.

XI. "It is more likely," says Miss Edgeworth, "that *wit* should be engrafted upon judgment, than that judgment should be engrafted upon wit." Numerous excellent observations may be found in her *Practical Education* respecting the cultivation of the understanding; we shall conclude what we have advanced on the subject, by quoting her very judicious remarks on the subject of the early cultivation of wit.

"We have advised, that the judgment of children should be exercised upon the objects of their senses. It is scarcely possible that they should reason upon the subjects which are sometimes proposed to them: with respect to manners and society, they have had no experience, consequently they *can* form no judgment. By imprudently endeavouring to turn the attention of children to conversation that is uninteresting to them, people may give the appearance of early intelligence, and a certain readiness of repartee and fluency of expression; but these are transient advantages. Smart, witty children amuse the circle for a few hours, and are forgotten; and we may observe, that almost all children who are praised and admired for sprightliness and wit, reason absurdly, and continue ignorant. Wit and judgment depend upon different and opposite habits of mind. Wit searches for remote resemblances between objects or thoughts apparently dissimilar. Judgment compares the objects placed before it, in order to find out their differences rather than their resemblances.

INTELLECTUAL EDUCATION.

stances. The comparisons of judgment may be slow; those of wit must be rapid. The same power of attention in children may produce either wit or judgment. Parents must decide in which faculty, or rather, in which of these habits of the mind, they wish their pupils to excel; and they must conduct their education accordingly. Those who are desirous to make their pupils witty, must sacrifice some portion of their judgment to the acquisition of the talent for wit; they must allow their children to talk frequently at random. Amongst a multitude of hazarded observations, a happy hit is now and then made: for these happy hits children who are to be made wits should be praised; and they must acquire sufficient courage to speak from a curious view of things; therefore the mistakes they make from superficial examination must not be pointed out to them; their attention must be turned to the comic rather than to the serious side of objects; they must study the different meanings and powers of words; they should hear witty conversation, read epigrams and comedies; and in all company they should be exercised before numbers in smart dialogue and repartee.

"When we mention the methods of educating a child to be witty, we at the same time point out the dangers of this education: and it is but just to warn parents against expecting inconsistent qualities from their pupils. Those who feebly prefer the solid advantages of judgment to the transient brilliancy of wit, should not be mortified when they see their children, perhaps, deficient at nine or ten years old in the showy talents for general conversation; they must bear to see their pupils appear slow; they must bear the contrast of flippant gaiety and sober simplicity; they must pursue exactly an opposite course to that which has been recommended for the education of wits; they must never praise their pupils for hazarding observations; they must cautiously point out any mistakes that are made from a precipitate survey of objects; they should not harden their pupils against that feeling of shame which arises in the mind from the perception of having uttered an absurdity; they should never encourage their pupils to play upon words; and their admiration of wit should never be vehemently or enthusiastically expressed."

XII. *Imagination* respects the thoughts and the feelings. Considered in reference to the conceptions and trains of thought, it properly falls under the head of Intellectual Education; considered in reference to pleasure and pain, it comes under the head of Moral Education. How the imagination affects the moral judgments, and what influence its pleasures and pains have upon the happiness of life, how they are to be cultivated, and how regulated, will probably be the subject of some remarks in a subsequent article: our business in this will be very brief.

Considered as an intellectual faculty, as assisting to raise the mind above mere sensation, as presenting to the mind conceptions, or trains of conceptions, which are not immediately derived from sensation, (though of course composed of the elements which sensation furnishes,) as forming new combinations of ideas, or as suggesting the grounds of reasoning, the operations of the imagination are very important, and indeed not only powerfully aid the exercise of the judgment, and the pursuits of philosophy, but are even eminently subservient to the cause of morality. Mr. Stewart furnishes us with many admirable observations, which will assist in showing the point to which we should endeavour to raise the imagination, as well as the limits which we should aim to prescribe to it; and from these we shall select the following, as immediately bearing upon our object:

"Point out to two men," says this elegant and interesting

writer, "any object of compassion;—a man, for example, reduced by misfortune from easy circumstances to indigence. The one feels merely in proportion to what he perceives by his senses. The other follows, in imagination, the unfortunate man to his dwelling, and partakes with him and his family in their domestic distresses. He listens to their conversation while they recal to remembrance the flattering prospects they once indulged; the circle of friends they had been forced to leave; the liberal plans of education which were begun and interrupted; and pictures out to himself all the various resources which delicacy and pride suggest, to conceal poverty from the world. As he proceeds in the painting, his sensibility increases, and he weeps, not for what he sees, but for what he imagines. It will be said, that it was his sensibility which originally roused his imagination; and the observation is undoubtedly true; but it is equally evident, on the other hand, that the warmth of his imagination increases and prolongs his sensibility."

"The foregoing observations may account, in part, for the effect which exhibitions of fictitious distress produce on some persons who do not discover much sensibility to the distresses of real life. In a novel or a tragedy, the picture is completely finished in all its parts; and we are made acquainted, not only with every circumstance on which the distress turns, but with the sentiments and feelings of every character with respect to his situation. In real life we see, in general, only detached scenes of the tragedy; and the impression is slight, unless imagination finishes the characters, and supplies the incidents that are wanting."

"It is not only to scenes of distress that imagination increases our sensibility. It gives a double share in the prosperity of others, and enables us to partake, with a more lively interest, in every fortunate incident that occurs either to individuals or to communities. Even from the productions of the earth, and the vicissitudes of the year, it carries forward our thoughts to the enjoyments they bring to the sensitive creation, and by intermingling our benevolent affections in the scenes we behold, lends a new charm to the beauties of nature."

"I have often been inclined to think, that the apparent coldness and selfishness of mankind may be traced, in a great measure, to a want of attention and a want of imagination. In the case of misfortunes which happen to ourselves, or to our near connexions, neither of these powers is necessary to make us acquainted with our situation; so that we feel, of necessity, the correspondent emotions. But without an uncommon degree of both it is impossible for any man to comprehend completely the situation of his neighbour, or to have an idea of a great part of the distress which exists in the world. If we feel therefore more for ourselves than for others, the difference is to be ascribed, at least partly, to this, that, in the former case, the facts, which are the foundation of our feelings, are more fully before us than they possibly can be in the latter."

The power of forming vivid and accurate conceptions is an important acquisition; but the true foundation of it is only to be laid in clear distinct perceptions; and if the imagination early gain such influence as to call off the mind from observation, the most injurious effects may be expected to follow. The exercise of the imagination, (including, as is generally done, what Mr. Stewart denominates the conception,) is necessary to enable us to enter into the reasonings of the philosopher, where these respect individuals, as well as into the pictures of the poet, and the details of history. In reference to this last head, we may be allowed here to mention, that the conception aids the cause even of religious truth: for he who is not able, or who does not take the trouble,

INTELLECTUAL EDUCATION.

trouble, to picture to the mind's eye the statements of the gospel historians, will not have his judgment suitably affected with the reality of the facts which they record, nor will his affections be warmed as they ought to be by the contemplation of the character which, with the most artless simplicity, they portray.

Like the memory, though in a different way, the imagination should be made a subservient faculty; and the early cultivation of it must depend upon the tendency which we perceive to the exercise of it, and the degree in which it is likely to gain ground among the intellectual faculties. If the conceptions are very lively, and we perceive a tendency to dwell upon them instead of the objects of perception, our aim must be to invigorate the observation, to cultivate the judgment, and, as much as possible, to turn the efforts of the imagination into the channel of philosophical invention. If, on the other hand, as is sometimes the case, either from early neglect of the observation, or a want of what may perhaps be properly called philippic sensibility, the conceptions are very dull, and the mind seems unable to enter into any thing which cannot be made the object of perception or abstract reasoning, it is perhaps desirable, with caution, to stimulate the imagination; and in this view the following remarks of Miss More appear to us to deserve the attention of all who are concerned in education.

"I would not however prohibit such works of imagination as suit this early period. When moderately used, they serve to stretch the faculties and expand the mind; but I should prefer works of vigorous genius, and pure, unmix'd fable, to many of those tame and more affected moral stories which are not founded upon Christian principle. I should suggest the use on the one hand of original and acknowledged fictions; and on the other, of accurate and simple facts; so that truth and fable may ever be kept separate and distinct in the mind. There is something that kindles fancy, awakens genius, and excites new ideas in many of the bold fictions of the East. And there is one peculiar merit in the Arabian and some other oriental tales, which is that they exhibit striking, and, in many respects, faithful views, of the manners, habits, customs, and religion of their respective countries; so that some tincture of real local information is acquired by the perusal of the wildest fable, which will not be without its uses in aiding the future associations of the mind in all that relates to Eastern history and literature."

The imagination should early be employed in what is its peculiar field, invention. We do not of course mean, that which has for its object to form combinations with the sole view of pleasing the fancy or gratifying the taste; but that which has in view contrivances to facilitate the purposes of life, and the acquisition of science. We by no means wish to be understood, that in the early part of education, (and still less in the later,) the imagination should never be actively employed on works of fancy and taste; but in a general way it should be laid down as a principle, that the solid and useful qualities of the mind should be cultivated first, the ornamental as a secondary object. The ingenuity and little inventions of children should be encouraged; and where sufficient scope is given for the play of the faculties, and there is no physical cause to prevent activity of mind, not a day will pass, even at a very early age, without some employment in which the inventive power of the imagination is concerned. The inventions of children generally arise, in the first instance, from necessity; but, in their little diversions, they often display, (of course, in a low degree,) the exercise of those qualities by which the most important combinations and inventions have been effected. As they advance

in mental culture, this exercise of the imagination should be more and more submitted to the guidance of the judgment. Many of the literary and scientific pursuits to which the young are directed, have a tendency to cultivate a philosophical imagination; and they furnish numerous opportunities, which a judicious instructor will carefully employ, of calling forth and exercising its most important operations.

Some young persons, we must be contented to allow to pass through life, satisfied if we can make them comprehend the combinations and inventions of others; but it is very seldom, where the mind is active and unshackled, and has been properly stimulated and employed by the usual objects of mental pursuit, that it will rest here. Either in the manner in which it attains to its conclusions, or in which it tries and applies them, or in the conclusions themselves, it will leave the track which may have been beaten by others, and shew the exercise of invention. Novelty ought never to be our object, but truth; but it is pleasant to see any indication of ingenuity; and it should be remembered, that combinations and inventions which are not absolutely new, may be so to the individual.

We shall now finish this head with a few more remarks from Mr. Stewart, which may serve as a restraining check upon the irregular or excessive exercise of the imagination; and may lead the judicious parent to the conclusion with which Miss Edgeworth ends her chapter on the imagination, that it is a good servant but a bad master.

"It was undoubtedly the intention of nature, that the objects of perception should produce much stronger impressions on the mind than its own operations. And, accordingly, they always do so, when proper care has been taken in early life, to exercise the different principles of our constitution. But it is possible, by long habits of solitary reflection, to reverse this order of things, and to weaken the attention to sensible objects to so great a degree, as to leave the conduct almost wholly under the influence of imagination. Removed to a distance from society, and from the pursuits of life, when we have been long accustomed to converse with our own thoughts, and have found our activity gratified by intellectual exertions, which afford scope to all our powers and affections, without exposing us to the inconveniences resulting from the bustle of the world, we are apt to contract an unnatural predilection for meditation, and to lose all interest in external occurrences. In such a situation too, the mind gradually loses that command which education, when properly conducted, gives it over the train of its ideas; till at length the most extravagant dreams of imagination acquire as powerful an influence in exciting all its passions, as if they were realities."

"When such disorders of the imagination have been long confirmed by habit, the evil may perhaps be beyond a remedy; but in their inferior degrees, much may be expected from our own efforts; in particular, from mingling gradually in the business and amusements of the world; or, if we have sufficient force of mind for the exertion, from resolutely plunging into those active and interesting and hazardous scenes, which, by compelling us to attend to external circumstances, may weaken the impressions of imagination and strengthen those produced by realities."

"When a man, under the habitual influence of a warm imagination, is obliged to mingle occasionally in the scenes of real business, he is perpetually in danger of being misled by his own enthusiasm. What we call good sense in the conduct of life, consists chiefly in that temper of mind which enables its possessor to view at all times, with perfect coolness and accuracy, all the various circumstances of his situation; so that each of them may produce its due impression

on him, without any exaggeration arising from his own peculiar habits. But to a man of an ill-regulated imagination, external circumstances only serve as hints to excite his own thoughts, and the conduct he pursues has, in general, far less reference to his real situation, than to some imaginary one, in which he conceives himself to be placed; in consequence of which, while he appears to himself to be acting with the most perfect wisdom and confidence, he may frequently exhibit to others all the appearances of folly."

XIII. In every branch of instruction, and in the mode of conveying it, our first consideration should be, its effect upon the understanding. The mental habits formed, rather than the number of ideas acquired, should be considered as the leading object of attention. We have already intimated, that in a subsequent article we shall have an opportunity of suggesting some observations relative to the manner of communicating knowledge, particularly of the scientific class; and we shall conclude our present article with some remarks which may assist in the appreciation of the value of the common objects of instruction in furthering the cultivation of the intellect, supposing that the best modes of conveying them to the mind have been successfully ascertained. We shall not attempt to follow the natural order of them; but shall be guided by that which appears most suitable to our object.

The acquisition of the *dead languages* forms a leading employment in education; and we trust it will belong before it ceases to be so, though we cannot but regret that it should ever be made an exclusive object. Those who know the intimate connection which subsists between the real command of words, and the noblest exercises of the understanding, will readily allow that the study of language forms a most important auxiliary in intellectual culture. We shall have occasion to specify hereafter to what plans of education the study of the classics should be limited; and this will lead us to enter more at large into the importance of the object. We shall content ourselves therefore, in this place, with stating, that the general advantages of this branch of instruction are, the cultivation of the habits of patience, of attention, of investigation, of accuracy, of discrimination, and of ingenuity; the possession of a key to the ideas contained in those languages; greater power in the use of our own; and the acquisition of numerous data for that branch of mental philosophy which respects language.

Geography exercises the memory, and were it only for its subserviency to history, would be highly valuable; but it has other advantages. It may be made the vehicle for various topics of information, and from these adjuncts, it acquires a rank in the scale of utility, to which, separately considered, it would not be entitled. Independently of this, the habit of associating names with things, and of arrangement, which seems likely to be formed by learning geography, entitle it to a place in the early part of education.

We use the word in its exact though confined sense; and considered as comprehending its adjuncts, the study of it is very important. It leads the mind beyond the narrow sphere of its own observation, enlarges its comprehension, and weakens its prejudices; it forms an interesting link between mere sensation and abstract speculation; it raises the mind above the former, and cultivates and stores it for the latter. Here, however, it obviously borrows its principal utility from what rather comes under the head of civil or natural history, or of natural and mental philosophy.

Natural history, in its various branches, being principally concerned about things, is well adapted for the early stages of mental culture. The study of it forms habits of observation, of attaching distinct conceptions to words (and con-

sequently of using words correctly), of classification, and of attention to objects not connected with itself. In all the stages of mental culture, these ends are answered; it gives additional interest to surrounding objects, and leads us to view them as the works of the great Author of nature. We must add here the words of one of our ablest naturalists, in his introduction to his favourite science. "I would recommend botany for its own sake. I have often alluded to its benefits as a mental exercise, nor can any exceed it in raising curiosity, gratifying a taste for beauty and ingenuity of contrivance, or sharpening the powers of discrimination. What, then, can be better adapted for young persons? The chief use of a great part of our education is no other than what I have just mentioned. The languages and the mathematics, however valuable in themselves when acquired, are even more so as they train the youthful mind to thought and observation. In Sweden, natural history is the study of the schools by which men rise to preferment; and there are no people with more acute or better regulated minds than the Swedes."

Mathematical science forms a higher step in the gradation of mental culture. The lowest branch of it is arithmetic. Learnt merely as an art, it is not without its utility in the culture of the mind. We, however, consider it as more comprehensively studied, or rather as *tought* with further views. The commencement of habits of clear perception, of abstraction, of regularity and correctness in practice, of acuteness, of using definite means in order to obtain definite ends, and of acting upon general rules, may reasonably be expected from the proper mode of learning this science. It then becomes an introduction to scientific investigation; and in this view it is peculiarly valuable, from the exact arrangement of our notation, and the certainty of the results of our operations. Algebra possesses nearly the same advantages, and in addition to them, others more important to a higher degree of mental culture. It generates the power of invention and combination, and it accustoms the mind to general reasoning, at the same time leaving it the power to check and correct that reasoning at every step. Geometry forms a habit of clear and cautious reasoning. It serves as a corrective to the wild flights of imagination, and gives proportional vigour to the judgment. The higher branches of mathematical science resemble, in their effects upon the mind, the one of these elementary branches which they most resemble in their mode of investigation. "If there were nothing valuable in the mathematical sciences for the uses of human life, yet they are well worth our study; for by perpetual examples they teach us to conceive with clearness, to connect our ideas in a train of dependence, to reason with strength and demonstration, and to distinguish between truth and falsehood. Something of these sciences should be studied by every one; and that, as Mr. Locke expresses it, not so much to make us mathematicians, as to make us reasonable creatures."

Another source of the utility of the mathematics, is their subserviency to natural philosophy. To describe the phenomena of the universe, to investigate their causes and the connection of these causes, are the principal objects of this science. To mention these objects, is nearly all which is necessary to indicate its valuable effects on the mind. The habits of accurate and persevering observation, of investigation, of abstraction, and of correct reasoning, are more or less produced and cultivated by the study of the philosophy of nature. It furnishes abundant scope for the most sublime speculations, and calls forth the noblest exercises of the imagination, yet restrains the mind within the limits of reality. It carries us beyond the bounds of sense, and

lessens our interest in self by increasing our concern with every thing around us. It enlarges the comprehension of the soul; for it offers for contemplation the laws of the universe. It prepares the student for an acquaintance with the human mind; for the strictness with which its investigations are conducted, prevents that wildness of theorizing which is the bane of science, and forms the habit of cautiously attending to phenomena, in order to ascertain the general laws which regulate them. It aids the cause of religion; for it accustoms the mind to seek for the causes of observed appearances, and leads it from design and regularity to infer an intelligent First Cause.

History produces or cultivates the habit of pursuing with accuracy a series of connected events or phenomena; of tracing causes from effects, and of observing the operation of causes, either singly, or in their various combinations. The student is concerned about realities, and his judgment is corrected; the web he contemplates is not unfrequently intricate, and his penetration is exercised in unfolding it. He observes the slow operation of moral causes, and he learns patience as to the result of his exertions for the good of others; he sees the efficacy of minute causes operating in conjunction with predisposing circumstances, and he learns prudence in the direction of those exertions. The enlightened study of history prevents the formation, or promotes the eradication of those prejudices which narrow the comprehension of the mind. "There is scarce any folly or vice," says Lord Bolingbroke, "more epidemical among the sons of men, than that ridiculous and hateful vanity, by which the people of each country are apt to prefer themselves to those of any other, and to make their own customs and manners, and opinions, the standard of right and wrong, of true and false." This presents an effectual bar to improvement in the great social concerns of man; and it is apt, perhaps necessarily so, to be accompanied with contracted views of the qualities of those who differ from us in their religious or political sentiments. Now what in one case destroys the illusion tends to dissipate it in the other. He who has learnt to view the qualities and actions of other nations as not to be despised because unlike those of his own, places himself out of his little narrow sphere of self, and gains a comprehensive habit of thought, which will prevent him from refusing to admire those qualities and actions, which can stand the test of reason, in bodies of men, or in individuals who differ from him in their modes of thinking. The study of history is well adapted to the cure of those prejudices. Accustomed to contemplate the history of other nations, to view them in their mutual dependencies and connections, for a time to make their interests our own, we learn to regard the community of which we form a part as itself a part of a still greater community, and without becoming indifferent to its welfare and its excellencies, we acquire the power of discerning the value of opinions and practices which are of foreign growth.

The study of composition derives its value, partly from facilitating our own practice, and partly from putting it in our power, more fully to feel and to appreciate the beauties of the best authors. The practice of composition is highly valuable, because it enables us to benefit others by our mental attainments; to judge of the extent and solidity of those attainments; to command our knowledge; and to make that knowledge clear and substantial. Habits of correct composition are almost necessarily productive of precision in our ideas, of perspicuity in our reasonings; they prevent their possessors from resting satisfied with superficial notions; and they force them to think closely.

The highest scientific object to which the young can

be directed, and what indeed should form the last art of education, is mental philosophy, or the philosophy of the human mind, that science which teaches us the laws of our mental frame, which shews us the origin of our various modes and habits of thought and feeling, how they operate upon one another, and how they are cultivated or repressed. The well directed study of it calls into action and improves the highest intellectual faculties; and while it employs the powers of the mind, it suggests the best means for their culture, and the best mode of their direction. It enables us to trace the intricacies of our own hearts, and points out the proper discipline for their correction. It discovers to us the real excellencies of the mind, and guides us in our efforts for the attainment of them. To success in forming the moral and mental character of others, it is more or less essential; for it discloses the nature of our influence over their minds, and the best mode of exercising it so as to bring their various faculties into the best adjusted and most perfect state. Pursued with proper views, and in a proper manner, it lays the best foundation for the highest degrees of intellectual, moral, and religious improvement. "There are difficulties," to use the words of the great Hartley, "both in the word of God, and in his works; and these difficulties are sometimes so magnified, as to lead to scepticism, infidelity, or atheism. Now the contemplation of our own frame and constitution, appears to me to have a peculiar tendency to lessen these difficulties attending natural and revealed religion, and to improve their evidences, as well as to concur with them in their determination of man's duty and expectations."

The best ground-work for the pursuit of mental science is, an accurate judgment, a discriminating, penetrating intellect, and a habit of correct and cautious reasoning; and therefore the best preparatory culture of mind is the study of the various branches of the mathematics and of natural philosophy. But habits of reflection, and good sense, are all which is essential to the beneficial pursuit of mental science; and with these, it will in all cases lead to results highly important to individual welfare and usefulness. The young in particular will be led, by an acquaintance with the practical laws of the mind, to perceive how their present conduct affects their future character and happiness; to perceive the importance of avoiding a frivolous employment of their time without any end beyond mere amusement; to perceive the impossibility of indulging in vicious gratifications without lessening their means of happiness, and checking their progress towards excellence. They will learn how habits are formed, almost imperceptibly, and, when long exercised, how exceedingly difficult it is to eradicate them; they will learn to consider the formation of habits, as requiring, therefore, their utmost circumspection. They will be enabled to discern what habits of thought and feeling are baneful, what useful; what means of happiness should be regarded as of primary value, what should be regarded as secondary only. In short, there can be no hesitation in affirming, that, next to the immediate pursuits of religion, to which the laws of the mind direct, a judicious acquaintance with those laws is the most important means for the right employment of that period of life in which the happiness of our existence in a great measure depends.

INTELLECTUAL Thinking. See THINKING.

INTELLIGIBLE, any thing capable of being understood, or conceived, by the mind.

Philosophers have invented certain beings which are purely intelligible, and only subsist in the understanding: such are the *entia rationis*, universal ideas, and other chimeras.

The intelligible, or intellectual world, is the idea of the world in the divine mind, frequently spoken of by Malebranche.

INTEMPERIES, in the *Galenical and Humoral Pathology*, the fame with *dyserafy*, *δυσκρασία*, and the oppofite of *temperament*, or *εὐκρασία*, *crasis*. As health was fuppofed to confift in the proper temperament, or proportion of the four qualities of hot and cold, dry and moift; fo the *intemperies*, or difproportionate prevalence of any one or two of thefe qualities, or of the four humours, in which they were fuppofed to be particularly inherent, was deemed the origin of all difeafes: and according to the fuppofed predominance of this or that quality or humour, each morbid intemperies received its name. Thus when heat or bile prevailed, it was called *intemperies calida*, or biliofa; when cold and phlegm, *intemperies frigida*, and pituitofa; and fo on. (See Sennert. Inftit. Medicinæ, lib. ii. cap. 3.) See **HUMORAL Pathology**, and **GALEN**.

INTENDANT, one who has the conduct, infpection, and management of any thing.

This is a title frequent among the French: they have intendants of the *marins*, who are officers in the fea-ports, whofe bufinefs is to take care the ordinances and regulations relating to fea-affairs be obferved; intendants of the *finances*, who have the direction of the revenues; intendants of *provinces*, who are appointed by the king to take care of the administration of juftice, policy, and finances, in the provinces; alfo, intendants of *buildings*, of *houfes*, &c.

INTENDMENT of *Law*, the fenfe, intention, or true meaning of the law.

The judges ought to judge according to the common intendment of the law.

INTENDMENT of Crimes. In cafes of treason, intention proved by circumftances is punifhable as if it were put in execution. So likewife, if a perfon enter the houfe in the night-time, with intent to commit burglary, it is felony; and an affault on the high-way, with an intent to commit burglary, is felony, and punifhed with transportation, 25 Car. II. c. 1. 7 Geo. II. c. 21.

INTENSIO, *Lat.* **INTENSIO**, *Ital.* *Intenfi*, in *Mufic*. Intenfe founds are fuch as are produced with the greateft force, which are loudeft, and heard at the greateft diftance. They are fuch founds likewife, as are produced from ftrings of greateft tenfion, and which, on that account, vibrate more powerfully.

INTENSION is a term frequently ufed by the Greek and other ancient writers on mufic: intenfions of the gravitas, were the major harmonics of the afcent, in the defcending major feale of the gravitas, according to M. Overend's Manuscripts in the library of the Royal Inftitution, vol. vi. p. 7. alfo, vol. ii. p. 213. in which volumes much information on this curious, but almoft obfolete fubject, will be found.

INTENSIONE, in *Law*, a writ which lies againft him who enters after the death of the tenant in dower, or tenant for life, and holds out him in the reverfion, or remainder.

INTENSIONE, *Ital.* as *prima intenfione*, in *Mufic*, as well as painting, implies a *fketch*, a fubject, a firft defign.

INTENSUM DIATONUM. See **DIATONIC** and **GENUS**.

INTENT, in *Civil Law*, fignifies to begin or commence an action, or profecution.

INTENTION, or **INTENSION**, in *Medicine*, that judgment or method of cure, which a phyfician forms to himfelf from a due examination of the fymptoms.

INTENSION, in *Physics*, the increafe of the power, or energy, of any quality; as heat, cold, &c.

By which it ftands oppofed to *remiffion*; which fignifies its decreafe, or diminution.

INTENTION, in *Metaphysics*, denotes an exertion of the intellectual faculties with more than ordinary vigour; when the mind with earneftnefs fixes its view on any idea, confiders it on all fides, and will not be called off by any follicitation.

The fchoolmen alfo fpeak of terms of firft and fecond intention.

INTENTION, a Term of *Firft*, is that which fignifies a thing; the primary defign of men, in eftablifhing words, being to exprefs things, or the ideas they have of things.

INTENTION, a Term of *Second*, is that which does not lignify a thing, but another term, or figu.

This, a tree, a man, &c. are terms of *firft* intention; and the terms in rhetoric, grammar, &c. as figure, kind, &c. are terms of *fecond* intention.

INTENTION, *Intentio*, *πρωταία*, in the *Ancient Mufic*, was ufed to denote the paffage of the voice from grave to acute.

INTENTIONAL QUALITIES. See **QUALITIES**.

INTER CANEM et LUPUM, in *Law*, words ufed formerly in appeals, to fignify that a crime was committed in the twilight, i. e. *inter diem et noctem*, &c. This part of a day has divers other denominations: thus, in fome parts of England, they call it *mock-ffadow*, corruptly *muck-ffade*: and, in the north, *day-light's gate*; others fay, *betwixt hawk and buzzard*.

INTERAMNA, or **INTERAMNIUM**, (*Teramo*), in *Ancient Geography*, a town of Italy, fituated in Latium, very near Campania, on the river Nar, which, from its fource to its mouth, ferved as a boundary between the countries of the Sabines and Umbrians.

INTERCALARY DAY, denotes the odd day inferted in the leap year. See **BISSEXTILE**.

The word is derived from the Latin *intercalaris*, of *calo*, *calare*, which anciently fignified, *to call with a loud voice*: an intercalary day, among the Romans, fignifying a day inferted between two other days; which, for that reafon, was proclaimed by the priefts with a loud voice.

INTERCALATION. See **INTERPOLATION**.

INTERCAPSULARIA, in *Anatomy*, a name given by fome writers to the cavities between the feapula and the vertebra.

INTERCEPTED AXIS, in *Conic Sections*, is the fame with what is otherwife called the *abfeiffa*.

INTERCESSION, **INTERCESSIO**, was ufed in *Ancient Rome*, for the act of a tribune of the people, or other magistrate, by which he inhibited the acts of other magiftrates; or, even, in cafe of the tribunes, the decrees of the fenate. *Veto* was the folemn word ufed by the tribunes when they inhibited any decree of the fenate, or law propofed to the people. The general law of thefe interceffions was, that any magiftrate might inhibit the acts of his equal, or inferior; but the tribunes had the fole prerogative of controlling the acts of every other magiftrate, yet could not be controlled themfelves by any.

INTERCESSOR, from *inter* and *cedo*, *I go between*, a perfon who prays, expoftulates, or intercedes, in behalf of another.

In the Roman law, interceffer was the name of an officer, whom the governors of provinces appointed principally to raife taxes, and other duties.

INTERCESSOR is alfo a term heretofore applied to fuch bifhops as, during the vacancy of a fee, adminiftered the bifhopric, till a fucceffor to the deceafed bifhop had been elected. See **BISHOP**.

The third council of Carthage calls thefe *interventors*.

INTERCIDENT PULSE, a term used by medical writers to express a sort of pulse, in which between two regular strokes there is perceived a third irregular.

INTERCOLUMNIATION, or **INTERCOLUMINATION**, in *Architectura*. Signifies the space between two columns. See the plan of *Boislie*, in *Plata Architecturæ*.

Vitruvius calls it *intercolumnium*; which, according to that author, is of five kinds: *viz.* *pienostyle*, A, one diameter and a half; *stysile*, B, two diameters; *eustyle*, C, two and a quarter diameters, which is the most graceful; *diastyle*, D, three diameters; and *areostyle*, E, four diameters; which fee explained under their proper heads, *PICNOSTYLE*, &c. The intercolumniation, or space between the columns to this arcade F, is seven and a half diameters; and the intercolumniation wherein there is a space, G, of only one half a diameter, is called coupling columns, an invention ascribed to the moderns.

From a medium, some authors have laid down the following proportions; in the Tuscan order, the intercolumniation, is to be four diameters of the body of the column below; in the Doric, three; in the Ionic, two; in the Corinthian, two one quarter; and in the Composite, one and a half.

INTERCOMMONING is when the commons of two manors lie together, and the inhabitants of both have, time out of mind, caused their cattle to feed promiscuously in each.

INTERCOSTALES, in *Anatomy*, the muscles which fill the intervals of the ribs, and are arranged in two strata, distinguished by the epithets of *external* and *internal*. This region of the body includes also the *levatoros costarum* and *triangularis sterni*.

The intercostal muscles (intercostals) consist of two thin muscular planes in each of the intercostal intervals, having their fibres disposed obliquely, and attached to the margins of the ribs, which bound these spaces.

The *external intercostal* muscles are attached by their upper edges to the outer border of the lower margins of the ribs, by means of tendinous and fleshy fibres. Their fibres are directed obliquely downwards and forwards; and they are attached below by an insertion exactly resembling the former to the upper edge of the succeeding ribs. Various blood-vessels and nerves penetrate them in different parts of the trunk. Their origin begins at that part of the rib which is articulated to the transverse process of the vertebra, and is continued towards the front as far as the junction of the bone with the cartilage: beyond this point the intervals of the cartilages are filled with their aponeurotic fibres, which have similar attachments and direction to the external intercostal muscles.

As the fibres of these external intercostal muscles pass from above obliquely downwards and forwards, they form towards the front acute angles with the upper and obtuse angles with the lower ribs. The posterior fibres are more oblique than the anterior. The stratum placed under the first rib, between it and the second, is called the first intercostal muscle; and those of the following intervals, according to the order in which they succeed, the second, third, &c. to the eleventh.

The external intercostal muscles are covered on their outer surfaces by most of the broad muscles of the trunk, as the two pectorals, obliquus externus abdominis, serratus anticus, and the serrati postici; and in some degree behind by the sacrolumbalis and longissimus dorsi. They correspond on the internal surface to the internal intercostals, from which they are partly separated by the intercostal vessels and nerves. Near the vertebral column they are covered by the pleura.

The *internal intercostal* muscles exactly resemble the former

in situation, attachments, and number. They commence behind at the angles of the ribs, and extend in front to the ends of the cartilages. They are attached to the inner borders of the edges of the ribs; and their fibres proceed in an oblique course from above downwards and backwards, so as to decussate those of the external stratum. They form thinner strata than the external intercostals, are more tendinous, have their fibres less oblique and consequently rather shorter. Sometimes a fasciculus of one or two of the internal intercostals passes over one rib to be fixed into the second. These are very irregular in number, size, and situation, and do not require a separate description: they have however been noticed as distinct muscles by the name of *subcosti*.

As the external intercostals only reach to the ends of the bony portions of the ribs, and the internal do not extend beyond the angles, a small part of the intercostal intervals in front and behind is filled only by a single stratum of fibres; but the remaining and largest part is closed by two layers.

The internal intercostal muscles are covered by the external, from which they are partly separated by the vessels and nerves of the same name. Where the former end in front, the latter are covered by the thin aponeurosis already described. They are lined on the inside by the pleura.

The *levatoros costarum* (les transverso-costiens) are small, thin, and flat fasciculi of a radiated form, placed behind the external intercostals, from which they are very distinct. They are twelve in number, as each rib has one. Each of these muscles has an aponeurotic origin from the apex of the transverse process of the corresponding dorsal vertebra, or from the ligament connecting the rib to that process; its fibres pass obliquely downwards and forwards, and, growing broader, are attached to the upper edge of the rib immediately below. The levator of the first rib arises from the transverse process of the seventh cervical vertebra, that of the second from the corresponding process of the first dorsal vertebra, and so on to the twelfth. They increase in size regularly from above downwards.

Besides these, each of the two, three, or four lower ribs has a longer fasciculus, arising from the transverse process of the second vertebra above it. These are called *levatoros longiores*, to distinguish them from the former, which are named *breviares*. They have thin tendinous origins from the transverse processes, pass over the ribs immediately below these processes, and are inserted into the upper borders of the succeeding ribs: thus the first levator longior, arising from the transverse process of the seventh dorsal vertebra, is fixed to the ninth rib.

These muscles are placed between the external intercostals and the sacrolumbalis and longissimus dorsi.

The *triangularis sterni* (sterno-costialis, sterno-costien) is a very thin flattened stratum, of a triangular figure, placed behind the cartilages of the ribs. It is fixed to the posterior part of the edges of the ensiform cartilage, and of the second bone of the sternum, as high as the cartilage of the fourth rib, by aponeurotic fibres, which cover a considerable portion of the muscle. The fleshy fibres, directed outwards and upwards, and more oblique as they are nearer to the upper part, form at first a continuous broad layer, and then divide into separate portions attached by thin aponeuroses to the third, fourth, fifth, and sixth ribs. It is continuous below with the transversus abdominis; corresponds in front to the cartilages of the four last true ribs, to the internal intercostal muscles, and to the mammary vessels; and behind to the pleura, and for a small space to the diaphragm.

The motions produced by the muscles in this region are the elevation and depression of the ribs, which coincide with inspiration and expiration. The agents of elevation are the levatores and intercostal muscles, besides other auxiliary powers. The former, fixed to the transverse processes, which are immovable, can obviously exert their action only on the ribs, which they elevate and carry outwards. Thus they increase the transverse diameter of the chest, particularly at its lower part, where, on one hand, the muscles are much stronger, and on the other, in consequence of the greater mobility of the lower ribs, the resistance to be overcome is much less. The action of the intercostals in elevating the ribs is much favoured by the mode of attachment of the first and second of these bones. They possess but little power of motion, and therefore form a fixed point, to which the others can be elevated. They are moreover still further fixed, particularly in deep inspirations, by the scaleni, which may carry them in a slight degree upwards. Both *frata*, although the directions of their fibres are so different, act equally as elevators: in fact, as the upper part of the chest is fixed, the lower portion must be moved by these powers. In great inspirations, other muscles attached to the chest, as the *pectorales*, *ferrati*, &c. assist the levatores and intercostal muscles in elevating and turning outwards the ribs.

The depression of the ribs, or their restoration from the elevated to their former state, is nearly a passive motion: it depends, in the first place, on the relaxation of the elevating powers, and then on the elasticity of the cartilages connected to the sternum. These are twisted in the act of elevation, and immediately recover themselves when this force ceases to act. When the depression is more considerable, as in coughing, in difficult expectorations, in sneezing, cases in which a strong expiration is required for the purpose of expelling much air from the chest, an active power is exerted for drawing down the ribs. The *triangularis sterni*, which has its fixed point in the sternum, depresses the cartilages of the true ribs. The abdominal muscles fix below the loose edges of the false ribs, which thus become a fixed point to which the other ribs may be depressed by the intercostal muscles. Thus the latter muscles are elevators or depressors, according as the fixed point is above or below. Moreover, the *quadratus lumborum* holds down firmly the last rib; and bears the same relation to that bone in great expirations, which the *scaleni* do to the two first ribs in deep inspirations. The *ferratus inferior pectus* assists the abdominal muscles on these occasions.

The intercostal muscles and the diaphragm seem to form an exception to that general law of the voluntary muscles, by virtue of which, any muscle after long exercise goes into a state of fatigue, requiring for the reparation of its power an intermission of action, which may be particularly observed in sleep. Now the motions of the chest, beginning and ending with life, are never interrupted. This exception is only apparent; each contraction is succeeded by a proportionate relaxation, so that the time of inactivity of the pectoral muscles equals that of their active state. Moreover, the diaphragm and intercostals mutually supply each other's places: both are said to be employed in inspiration, but sometimes one and sometimes the others are more actively concerned; so that we may consider them in some degree as alternately acting and resting. The intercostals appear to be the most concerned during sleep, and the diaphragm in the waking state. Indeed a considerable contraction of the latter, in some measure, opposes that of the lower intercostals, since it tends to contract the lower cir-

cumference of the chest which the others enlarge. The two *frata* of the intercostals may contract separately; thus one may rest while the other is employed. Lastly, the levatores may alternate with the latter muscles: thus, although the motions of the chest are constant, their agent, like all the other muscles of the animal life, may be subjected to the law of intermission of action. Hence, if respiration is considerably hurried, and all the inspiratory muscles are brought into action, they are affected with a real lassitude, and at last cannot contract without difficulty. In running, where the blood is carried in great abundance to the heart, and must pass quickly through the chest, we lose breath; which is merely experiencing a difficulty in contracting the tired muscles of inspiration. Respiration is then interrupted, as locomotion would be by a fatigued state of the muscles of the lower extremities; and this may even go so far as to produce a real immobility of the inspiratory muscles, a state, which though not dangerous in other instances, is in the organs of locomotion for example, is fatal in the respiratory muscles as it suspends breathing. Examples of animals, and even of men falling suddenly dead after great exertions in running, are not extremely rare. Death occurs in these instances, as when the phrenic nerve or the spinal marrow is divided. Those affections of the chest, in which respiration is hurried for a certain time, occasion at last a real lassitude of the pectoral muscles; and the difficulty of breathing produced by this tired state of the moving organs, succeeding to that produced by the disease itself, prolongs the painful sensation of suffocation. We must distinguish, in these cases, what belongs to the lung, from that which arises from the muscles. After certain hysterical attacks, in which the diaphragm and intercostal muscles have been violently agitated, a real sense of fatigue is experienced in the chest, which can only be moved with difficulty, and not to a sufficient extent for the production of loud sounds, a phenomenon which may be observed also after exertion in running. The muscles require rest before they can expel air in a quantity capable of producing strong and distinct sounds.

INTERCOSTALES Arteriae, arteries which run in the intervals of the ribs: the intercostales *venae* are veins corresponding to those. See **ARTERY** and **VEIN**.

INTERCOSTALES Nervi, are the branches of the spinal marrow in the back, which accompany these arteries and veins. The epithet *intercostales* is sometimes also applied to the great sympathetic nerve. See **NERVE**.

INTERCUS, a word used by some medical writers, to express that sort of droopy more usually called an *anasarca*.

INTERDICT, a censure inflicted by a pope, or bishop, suspending the priests from their functions, and depriving the people of the use of sacraments, divine service, and Christian burial.

In common law, interdict is also used in the same sense as in the canon law; where it is defined to be, "censura ecclesiastica prohibens administrationem divinarum."

INTERDICT is most properly understood of a general excommunication of a country, or city, as appears by the Decretals. See **EXCOMMUNICATION**.

There is a *local* and a *personal* interdict: where these two are joined, the interdict is said to be *mixed*.

This punishment, as well as general excommunications, were but little known till the time of pope Gregory VII. In the year 1169, pope Alexander III. put all England under an interdict, forbidding the clergy to perform any part of divine service, except the baptizing of infants, taking confession, and giving absolution to dying penitents.

In excommunicating a prince, all his adherents, that is,

his subjects who retain their allegiance, are excommunicated, and the whole country is put under an interdict. In the reign of king John, the kingdom of England lay under a papal interdict, for above six years together: it began A. D. 1208.

In imitation of the popes, the bishops also soon began to interdict; and it became a common thing for a city, or town, to be excommunicated for the sake of a single person whom they undertook to shelter; but this severity was found to have such ill effects, that they have been obliged to moderate it.

An interdict is denounced, and taken off again, with the same formalities as an excommunication.

INTERDICTS, in the *Roman Law*, certain formulæ of words by which the prator, when the possession of any thing was contended between many, ordered or forbade something to be done with it, till the right or property should be legally determined.

Which formulæ were called interdicts, because they related to the possession of the thing in the interim, or till the right was ascertained.

They had three kinds of interdicts, *prohibitory*, *restitutory*, and *exhibitory*. *Prohibitory*, were those by which the judges forbade any one to vex another in the possession of any thing legally belonging to him. *Restitutory* were those by which the judges appointed any one, who had been expelled out of his estate to be repossessed, before his right was legally ascertained; and this was the same with what they called the *reintegrant*. *Exhibitory* were those by which any thing in dispute was ordered to be exhibited; as a testament, &c.

There was also a second division of interdicts; *viz.* into *adjuvanda*, *retinenda*, and *recuperanda*: the first tending to the acquiring a new possession, as the *interdictum quorum bonorum*, &c., the second to the keeping an old one till it was farther determined, as the *uti possidetis*, &c., the last to the recovering one lost, as *unde vi*, &c.

INTERDICTION of *Water and Fire*, a sentence anciently pronounced against such as, for some crime, were to be banished.

They were not directly adjudged to banishment; but by giving order, that nobody should receive them, but deny them *fire and water*, they were condemned, as it were, to a civil death: and this they called *legitimum exilium*. Livy. See EXILE.

INTEREST, a sum of money reckoned for the loan and forbearance of some other sum, lent for, or due at, a certain time, according to some certain rate.

The sum lent, or forborn, is called the *principal*, because it is the sum that procreates the interest, or from which the interest is reckoned.

Interest is either *simple* or *compound*.

Interest, *simple*, is that counted from the principal only.

Let p represent the principal, n the number of years or parts of a year, r the interest of $1l.$ for a year, and m the amount of the principal p for the time n at the rate r ; and since the amount of $1l.$ for one year is $1 + r$, the amount of $1l.$ for n years, must be $1 + nr$; the interest of the principal p at the rate r in n years must be pnr ; and $1l.$: $1 + nr$:: p : $p + pnr = m$ the amount: from this general theorem we can easily deduce problems for resolving all the cases that occur in simple interest.

Prob. 1.—Having any principal sum, and time, and rate of interest given, to find the amount: as $m = p + pnr = p \times 1 + nr$; we shall have this rule: multiply the interest of $1l.$ for a year by the given number of years. Add unity to the product and multiply the sum by the given principal: this second product will be the amount required. *E.g.*

what sum will $567l. 10s.$ amount to in nine years at 5% per cent. per annum? Here $p = 567.5$, $n = 9$, and $r = .05$; therefore $m = p \times 1 + nr = 567.5 \times 1 + .45 = 822.875 = 822l. 17s. 6d.$ Or if it were required to find the amount of one penny at 5% per cent. simple interest in 1780 years; $p = 1d.$, $n = 1780$, and $r = .05$, therefore $m = 1 \times 1 + 89 = 90d. = 7s. 6d.$

If the time given does not consist of whole years the fractional part may be easily reduced to decimal parts of a year.

Prob. 2.—Having the amount of any principal at a given rate in a given time, to find the principal; it appears,

from the theorem, $m = p \times 1 + nr$, that $p = \frac{m}{1 + nr}$;

i. e. divide the amount by the product of the time and interest of $1l.$ for a year with unity added to it. *E.g.* what principal will amount to $822l. 17s. 6d.$ in nine years at 5% per cent. per annum? Here $m = 822l. 17s. 6d.$ or 822.875 , and n, r as before: therefore $\frac{m}{1 + nr} = \frac{822.875}{1 + .45} = 567.5$, or $567l. 10s.$

Prob. 3.—Having the amount of a given principal at a given rate, to find the number of years. From the theorem we easily deduce, by transposition and division, $n = \frac{m - p}{pr}$, *viz.* subtract the principal from the amount, and divide the remainder by the product of the principal and interest of $1l.$ for a year. *E.g.* in what time will $567l. 10s.$ amount to $822l. 17s. 6d.$ at 5% per cent. per annum? $n = \frac{m - p}{pr} =$

$$\frac{822.875 - 567.5}{28.375} = \frac{255.375}{28.375} = 9.$$

Prob. 4.—Having the amount of a given principal in a given time, to find the rate, and consequently the interest

per cent. From the theorem we easily derive $r = \frac{m - p}{pn}$;

i. e. subtract the principal from the amount, and divide by the product of the principal into the number of years; *e. g.* at what rate per cent. will $567l. 10s.$ amount to $822l. 17s. 6d.$ in nine years? Here $\frac{m - p}{pn} = \frac{822.875 - 567.5}{5107.5} = \frac{255.375}{5107.5} = .05$; and, therefore, the interest is 5% per cent.

Prob. 5.—The annual interest of any principal p at the rate r , is pr ; *i. e.* multiply the principal by the interest of $1l.$ for a year, *e. g.* the interest of $75l.$ for one year at 3% per cent. is $75 \times .03 = 2.25 = 2l. 5s.$ The interest of $157l. 17s. 6d.$ at 5% per cent. is 157.875 (reducing the $17s. 6d.$ to decimals of a pound) $\times .05 = 7.89375 = 7l. 17s. 10\frac{1}{2}d.$ The interest of any principal p at the rate r for n years, is prn ; obtained by multiplying the principal, rate, and number of years.

The daily interest is found by dividing the annual interest by 365 ; thus $.05$, being the interest of one pound for one year at 5% per cent., divided by 365 , the quotient will be $.0001369$, &c. which is the interest of one pound for one day at the same rate. And $\frac{.03}{365} = .0000821$ is the interest of one pound for one day, at 3% per cent. per annum. The interest for one day, at any rate, being thus found, that interest multiplied by $2, 3, 4, 5, 6$, &c. gives the interest of one pound for any number of days; and thus the following table of simple interest for any number of days is easily made.

INTEREST.

A TABLE

Of Simple Interest.—The Interest of One Pound for any Number of Days, &c.

Days	3 per cent.	3½ per cent.	4 per cent.	4½ per cent.	5 per cent.	Days	3 per cent.	3½ per cent.	4 per cent.	4½ per cent.	5 per cent.	Days

and let it be required to find m the amount of the sum p in n years at the rate r . Now, supposing the amount of $1l.$ in one year to be $\overline{1+r}$, the amount of the same sum in two years will be $\overline{1+r}^2$; for $1 : \overline{1+r} = \overline{1+r} : \overline{1+r}^2$. In like manner $1 : \overline{1+r} = \overline{1+r} : \overline{1+r}^2$; the amount of $1l.$ in three years, and the amount of $1l.$ by the same rule in n years will be $\overline{1+r}^n$. Consequently the amount m of the sum p in n years will be $p \cdot \overline{1+r}^n$. From this equation

$$\text{we have } p = \frac{m}{\overline{1+r}^n} \dots n = \frac{\log. m - \log. p}{\log. \overline{1+r}}, \text{ and } r = \left(\frac{m}{p} \right)^{\frac{1}{n}} - 1.$$

Example 1.—Let $p = 50$. . . $\overline{1+r} = 1.04$. . . $n = 30$, then will m (the amount of $50l.$ in 30 years at $4l.$ per cent.) be $50 \times \overline{1.04}^{30} = 162l. 17$.

Ex. 2.—Let $m = 162l. 17$. . . $n = 30$ ($\overline{1+r} = 1.04$), the sum p will then be $= \frac{162.17}{1.04^{30}} = 50$.

Ex. 3.—Let m, p , and r be respectively equal to 162.17 . . . 50 . . . and $.04$, then will n be $= \frac{2.2099705 - 2.16989700}{.0170333} = 30$.

Ex. 4.—Let m, p , and n be respectively equal to 162.17 . . . 50 . . . and 30 , and r will be equal to $\sqrt[30]{\frac{162.17}{50}} - 1 = .04$.

As the amount of $1l.$ in n years is $\overline{1+r}^n$, the amount of the same sum in $n-1$ years will be $\overline{1+r}^{n-1}$, in $n-2$ years $\overline{1+r}^{n-2}$, &c.; therefore, if $1l.$ be the amount at the end of the first year, the series $1 + \overline{1+r} + \overline{1+r}^2 + \dots + \overline{1+r}^{n-1}$ will express the amount of $1l.$ per annum in n years, which may easily be found $= \frac{\overline{1+r}^n - 1}{r}$,

and m (the amount of the annual sum a) will be $= \frac{a \cdot \overline{1+r}^n - a}{r}$, hence a will be $= \frac{m r}{\overline{1+r}^n - 1}$, and $n = \frac{\log. m r + a - \log. a}{\log. \overline{1+r}}$

In order to find the value of r , let the binomial $\overline{1+r}^n$ be expanded, &c., and $\frac{m}{a n}$ will be $1 + \frac{n-1}{2} r + \frac{n-1 \cdot n-2}{2 \cdot 3} r^2 + \dots$ and $\frac{m}{a n} - 1 = \frac{n-1}{2} r + \frac{n-1 \cdot n-2}{2 \cdot 3} r^2$, &c. $\sqrt[n-1]{\frac{m}{a n} - 1} = \overline{1+r} + \frac{n-1}{12} r^2$ nearly. Put $\frac{m}{a n} - 1 = c$, and $\frac{6}{n+1} = b$, then will r be $= \sqrt[3]{b^3 + 2bc} - b$.

Example 1.—If $a = 10$. . . $n = 10$. . . $\overline{1+r} = 1.04$, m will be $= \frac{1.04^{10} - 1}{.04} = 120.06l.$

Ex. 2.—Let n and $\overline{1+r}$ be the same as above, and $m = 120.06$, then will $a = \frac{120.06 \times .04}{1.04^{10} - 1} = 10$.

Ex. 3.—Putting $\overline{1+r}$ and $m = 1.04$ and 120.06 respectively, and $a = 10$, n will be $= \frac{1.170333 - 1}{.0170333} = 10$.

Ex. 4.—Retaining the same values of m and a as in the preceding example, and putting $n = 10$, c ($= \frac{120.06}{100} - 1$)

will be $= .04146$, b ($= \frac{6}{11}$) will be $= .5454$, and r ($= \sqrt[3]{.29751 + .04523} - .5454 = .5854 - .5454$) will be $= .04$.

Since $\overline{1+r}$ is the amount of $1l.$ in one year, the converse of this expression, or $\frac{1}{\overline{1+r}}$ will be the discount of $1l.$ for

the same time; for if $\overline{1+r}$ to be received at the end of a year is of the same value with the present payment of $1l.$ by the rule of proportion $1l.$ to be received at the end of a

year will be of the same value with $\frac{1}{\overline{1+r}}$ now received, that is, $\overline{1+r} : 1 = 1 : \frac{1}{\overline{1+r}}$. By the same reason-

ing $\overline{1+r} : 1 = \frac{1}{\overline{1+r}} : \frac{1}{\overline{1+r}}$; the value of $1l.$ to be received at the end of two years, and hence $\frac{1}{\overline{1+r}^2}$ will be

the present value of $1l.$ to be received at the end of n years, the value of the sum a , therefore, to be received at the end of n years will be $\frac{a}{\overline{1+r}^n} = \pi$; from this equation the value of a will be found $= \pi \cdot \overline{1+r}^n$, the value of $n = \frac{\log. a - \log. \pi}{\log. \overline{1+r}}$, and the value of $r = \sqrt[n]{\frac{a}{\pi}} - 1$.

Example 1.—Let a be $= 20$. . . $n = 40$. . . $\overline{1+r} = 1.06$, and $\pi = \frac{20}{1.06^{40}} = 1.944$.

Ex. 2.—If $\pi = 1.944$, $\overline{1+r} = 1.06$, and $n = 40$, a ($= 1.06^{40} \times 1.944$) will be $= 20$.

Ex. 3.—Retaining the values of π and $\overline{1+r}$, and putting $a = 20$, n will be $= \frac{1.30103 - .2887856}{.0253059} = 40$.

Ex. 4.—If $\pi = 1.944$. . . $a = 20$, and $n = 40$, r ($= \sqrt[40]{\frac{20}{1.944}} - 1$) will be $= .06$.

INTEREST.

The value of $1l$, payable at the end of n years, being $\frac{1}{1+r^n}$, its value at the end of $n-1$ years will be $\frac{1}{1+r^{n-1}}$, at the end of $n-2$ years = $\frac{1}{1+r^{n-2}}$, and so on. It follows, therefore, that the present value of the annual payment of a for n years will be expressed by the series $\frac{a}{1+r} + \frac{a}{(1+r)^2} + \frac{a}{(1+r)^3} + \dots + \frac{a}{(1+r)^n} = \frac{a}{r} - \frac{a}{r \cdot (1+r)^n} = p$; which, therefore, is given when a, n , and r are given. If p, n, r are given, the value of a will be obtained, being = $\frac{p r \cdot (1+r)^n}{1+r^n - 1}$. If a, r, p are given, the value

$\frac{m}{p}$ therefore will be = $\frac{m}{1+r^n}$, and $p = \frac{m}{1+r^n} \cdot a$, from which r will be found = $\frac{m-p \cdot a}{m \cdot p}$.

of n will be obtained, being = $\frac{\log a - \log a - \log p r}{\log 1+r}$. In order to find the value of r , when a, p, n are given, let the binomial $(1+r)^n$ in the equation $\frac{a}{r} - \frac{a}{r \cdot (1+r)^n} = p$,

Case 2.— n, m, p being given to find r . Since $\frac{m}{p} = \frac{1}{1+r^n}$, the log. $1+r$ will be = $\frac{\log m - \log p}{n}$, hence $1+r$, and consequently r , will be known.

be expanded, &c., and we shall have $\frac{p}{na} = 1 - \frac{n+1}{2} r + \frac{n+1 \cdot n+2}{2 \cdot 3} r^2$, &c.; consequently $\frac{p}{na} \frac{1}{1+r} = \frac{na}{p} \left\{ \frac{1}{1+r} - \frac{n+1}{2} r + \frac{n+1 \cdot n+2}{2 \cdot 3} r^2 \right\} \frac{1}{1+r} = 1 + r - \frac{n-1}{12} r^2$ nearly. Let $\frac{na}{p} \frac{1}{1+r} - 1 = d$, and

Case 3.— n, r, p being given to find a . This is derived from the preceding case, being = $\frac{\log m - \log p}{\log 1+r}$.

$\frac{6}{n-1} = b$, then will r be = $b + \sqrt{bb - 2bd}$.

Case 4.— a, m, p being given to find $n \dots \frac{1}{1+r^n}$ being = $\frac{m}{p}$, $\frac{1}{1+r^n} - 1$ will be known; and since r is = $\frac{a \cdot (1+r)^n - 1}{m}$, r will also be known, therefore, since log. $\frac{1}{1+r^n}$ is = $n \times \log. \frac{1}{1+r}$, n will be known, being = $\frac{\log. \frac{1}{1+r^n}}{\log. \frac{1}{1+r}}$.

Example 1.—Supposing a, n, r to be respectively equal to 10, 21, and .05, then will p be = $\frac{10}{.05} - \frac{10}{.05 \times 1.05^{21}} = 200 - 71.79 = 128.21$.

Case 5.— a, r, p being given to find m . By **Case 3**, m may be easily found = $\frac{a p}{a - p r}$.

Example 2.—Let n, r , and p be respectively equal to 21, .05, and 128.21, then will a be = $\frac{.05 \times 105^{21}}{1.05^{21} - 1} = \frac{1393 \times 128.21}{1.78} = 10$.

Case 6.— a, n, p being given to find m . The value of r may be derived from one of the foregoing theorems, in which a, p, n are given (being = $b + \sqrt{bb - 2bd}$), and hence $m = p \cdot (1+r)^n$ will also be given.

Example 3.—The quantities r and p being still the same and a being equal 10, n will be = $\frac{1 - .5150340}{.0211893} = 21$.

Case 7.— n, r, p being given to find m . As r is given, this value is immediately obtained from the preceding case, being = $p \cdot (1+r)^n$.

Example 4.— a, p, n being respectively equal to 10, 128.21, and 21, r will be equal to $\frac{6}{20} - \sqrt{.06246} = .3 - .25 = .05$.

Case 8.— m, r, a being given to find p . By **Case 1**, r is = $\frac{m-p \cdot a}{m \cdot p}$, therefore $p = \frac{a m}{a + m r}$.

Example 5.— m, p, a being given to find r . In the foregoing

Case 9.— n, m, r being given to find p . Since $\frac{m}{p} = \frac{1}{1+r^n}$, p will be = $\frac{m}{1+r^n}$.

Case 10.— n, m, a being given to find p . Let the value of r be found when m, n, a are given by one of the preceding theorems (being = $\sqrt{bb + 2bc - b}$), and $p = \frac{m}{1+r^n}$ will then be given.

Case 11.— n, m, p being given to find a . Since $\frac{m}{p} = \frac{1}{1+r^n}$, r will be = $\frac{m}{p}^{\frac{1}{n}} - 1$, and consequently given; therefore the value of a may be found from the equation $m = \frac{1}{1+r^n} - 1$ to be = $\frac{m r}{1+r^n - 1}$.

Case 12.— m, p, r being given to find a . Let $\frac{m}{p}$ be substituted for its equal $\frac{1}{1+r^n}$ in the expression $\frac{m r}{1+r^n - 1}$, and

cases m being = $\frac{a \cdot (1+r)^n - 1}{r}$, and $p = \frac{a \cdot (1+r)^n - 1}{r \cdot (1+r)^n}$

and

INTEREST.

and a will be = $\frac{m r}{m - 1} = \frac{m p r}{m - p}$.

Dr. Maskelyne, in his introduction to Taylor's logarithms, has, with the view of facilitating these operations, had recourse to the tables of logarithmic sines and tangents, by putting $r = t^2 \cdot A$, $1 + r = \sec^2 \cdot A$, $1 + r^n = \sec^2 \cdot A$, B , &c.; thus, in *Case 1*, the value of r becomes = $\frac{a}{m} \times$

$$t^2 \cdot B; \text{ for } \frac{m}{p} \text{ being } = \frac{1 + r^n}{1 + r} = \sec^2 \cdot B, \text{ and } \frac{m - 1}{r} \times a = \frac{\sec^2 \cdot B - 1}{r} \times a = \frac{t^2 \cdot B}{r} \times a, r \left(= \frac{m - p}{m p} \right) \text{ will be } = \frac{t^2 \cdot B}{m} \times a. \text{ In like manner, in } \textit{Case 12}, a = \frac{m r}{1 + r^n - 1}$$

becomes = $\frac{m r}{\sec^2 \cdot B - 1} = \frac{m r}{t^2 \cdot B} = m r \times c o - t^2 \cdot B$, or $m \cdot t^2 \cdot A \times c o - t^2 \cdot B$. But though the expressions appear more simple, I do not know that in general the operations will be found to be much facilitated by these means.

In the preceding cases money has been supposed to be improved or discounted yearly. But all these different theorems may, however, be applied to the solution of cases which require money to be improved or discounted at shorter intervals. Thus, supposing it were required to determine the amount of 50*l.* when laid out half yearly, to accumulate at 4*l. per cent.* for the term of 30 years: p is = 50, $n = 2 \times 30 = 60$, r the interest of 1*l.* for half a year = .02, and $m = p \frac{1 + r^n}{1 + r}$ becomes = $50 \times \frac{1.02^{60}}{1.01} = 164.05$. If improved quarterly it will be = $50 \times \frac{1.01^{120}}{1.01} = 165$.

Again, if it were required to determine the amount of 5*l.* laid out half yearly, to be improved at 4*l. per cent.* during a term of 10 years. In this case $m = \frac{a \times (1 + r^n - 1)}{r}$ will be = $\frac{5 \times (1.02^{20} - 1)}{0.02} = 121.486$, and if it be improved quarterly, it will be = $\frac{5 \times (1.01^{48} - 1)}{0.01} = 122.2$.

In like manner, if money be discounted at shorter intervals than a year, the present value will be obtained from the expression $\frac{1}{1 + r^n}$; thus, let the present value be required of 20*l.* payable at the end of 40 years, supposing money to be discounted every half year at 6*l. per cent.* Here n becomes = $2 \times 40 = 80$, $r = \frac{0.06}{2} = .03$, and consequently $\pi = \frac{a}{1 + r^n} = \frac{20}{1.03^{80}} = 1.8795$.

Let k be any fraction of a year in which money is to be improved or discounted, and the amount or present value may always be found from the amount or present value when money is improved or discounted yearly, being the same with such amount or value at $\frac{r}{k}$ interest for $k n$ years. Thus, the amount of 50*l.* improved half yearly at 4*l. per cent.* for 30 years is the same with the amount of 50*l.* improved yearly for 60 years at 2*l. per cent.*; the amount of 5*l. per ann.* im-

proved half yearly for 10 years at 4*l. per cent.*, is the same with the amount of 5*l. per ann.* improved yearly for 20 years at 2*l. per cent.*; and 10*l.* discounted half yearly for 40 years at 6*l. per cent.* is the same with 10*l.* discounted yearly for 80 years at 3*l. per cent.* The different values of annuities, when payable yearly, half yearly, quarterly, or at shorter intervals, may in the same manner be deduced from the preceding theorems, but these are explained in the article ANNUITIES.

M. De Moivre, M. D'Alembert, and some others, instead of making the interest of 1*l.* for the k th part of a year = $\frac{r}{k}$,

have chosen to make it = $\frac{r}{1 + r^k} - 1$, and hence the amount of 1*l.* in n years, or its present value at the end of n years, will be the same, whether money be improved or discounted yearly, or at shorter intervals. But the amount of 1*l. per ann.* will be to its amount when improved yearly in the constant ratio of r to $k \times \frac{1 + r^k - 1}{1 + r^k} - 1$, and the value of an annuity of 1*l.* will be to its value, when paid yearly, inversely as r to $k \times \frac{1 + r^k - 1}{1 + r^k} - 1$, whatever the length of the term during which the money is to accumulate, or the annuity is to continue. Now, it is well known that the difference between the values of annuities payable yearly, and their values, when payable half-yearly, quarterly, or at shorter intervals, is always lessened as the term is extended $\&c.$ so that if the annuity be perpetual, the values will be the same, whether the payments are made yearly, or in any fractional part of the year; which can never be the case on the supposition above mentioned. When n is = $\log. \frac{r}{r - k \times \frac{1 + r^k - 1}{1 + r^k} - 1} \div \log. 1 + r$, an annuity pay-

able every k th part of the year, will be equal to the perpetuity, so that an annuity payable half-yearly, at 5*l. per cent.* for 90 $\frac{1}{2}$ years, or quarterly for 80 years, will be equal to the same annuity payable yearly for ever. And at 6*l. per cent.* the annuities will be of equal value if the term be only 72 $\frac{1}{2}$ years in the one case, or 65 $\frac{1}{2}$ years in the other. But while these rules, when the term is very long, give the values of annuities payable at shorter intervals than a year too high, they always, on the contrary, and especially when the term is very long, give the amount of a sum much too low. Thus supposing one penny to be laid out at 5*l. per cent.* compound interest at the birth of our Saviour, or 1810 years ago, it will accumulate, when money is improved yearly, to a sum which is equal to 381,860,000 globes of solid gold, each equal to the earth in magnitude. When improved half-yearly, to a sum which is equal to 1,121,470,000 of such globes, and when improved quarterly, to a sum which is equal to 1,945,680,000 such globes; so that although in this long time the accumulation is nearly three times greater when money is improved half-yearly, and more than five times greater when improved quarterly than it is when money is improved yearly, yet according to the supposition that $\frac{r}{1 + r^k}$ is the amount of 1*l.* in the k th part of a year, or $\frac{r}{1 + r^k} - 1$ = its amount in n years, its accumulation will be the same, whether money is improved yearly, half-yearly, or quarterly. It may easily be shewn that $\frac{r}{1 + r^k} - 1$ is always less than $\frac{r}{k}$, or, in other words, that this expression does not give the full interest of 1*l.* for the k th part of a year. It is no wonder, therefore, that any theorems derived from a principle so erroneous, should, like the preceding, lead to conclusions which are not only incorrect but absurd.

INTEREST.

To the foregoing, a great number of other cases might be added. But it will be sufficient to give only a few of the most curious and important; some of which having occurred in practice, it would perhaps be improper to omit them.

Theorem 1.—To determine the time in which $1l$ will be doubled by compound interest.

Solution.—Since $(1+r)^n$ the amount of $1l$ at the end of n years is in this case $= 2n$, or the required time, will be
$$= \frac{\log. 2}{\log. 1+r}$$
; from which it appears that money doubles

itself at $3l$ per cent. in $23\frac{1}{2}$ years nearly; at $4l$ per cent. in $17\frac{3}{4}$ years; at $5l$ per cent. in $14\frac{1}{2}$ years; at $6l$ per cent. in $11\frac{3}{4}$ years; at $8l$ per cent. in 9 years; at $10l$ per cent. in $7\frac{1}{2}$ years; and at $12l$ per cent. in $6\frac{1}{2}$ years nearly.

Theorem 2.—Supposing money to be doubled by compound interest in n years, required r the rate of interest at which it has been improved.

Solution.—The $\log. 1+r$, by the preceding theorem being given $= \frac{\log. 2}{n}$, the value of r will also be given. Or, if the hyperbolic logarithm of 2 be expressed by h , it will be found $= 1 - \frac{\sqrt{n-2b}}{\sqrt{n}}$.

Theorem 3.—Supposing $1l$ to be doubled in n years at the interest r , and in m years at the interest $2r$, to find the ratio of m to n .

Solution.—Since $(1+r)^n$ and $(1+2r)^m$ are each of them equal to 2, they will be equal to each other, and consequently m will be to n as $\log. 1+r$ to $\log. 1+2r$, or by fluxions and the binomial theorem, as $\frac{1}{2} + \frac{1-r \cdot r}{4}$ to one very nearly, or still more nearly, as $\frac{1}{2} + \frac{1-r \cdot r}{4} + \frac{7-9r \cdot r^2}{24}$ to one.

Examples.—At 3 and 6 per cent. m and n are respectively to each other in the ratio of .50746 to one; at 4 and 8 per cent. of .50934 to one; at 5 and 10 per cent. of .51197 to one; at 6 and 12 per cent. of .51417 to one; at 8 and 16 per cent. of .51889 to one; at 10 and 20 per cent. of .52269 to one; and at 12 and 24 per cent. of .52681 to one. From these examples it appears that the higher the interest the greater will be the ratio of m to n . It follows also from the expression

$$\frac{1}{2} + \frac{1-r \cdot r}{4}, \text{ \&c. that money will not double itself at}$$

$2r$ interest in half the time that it doubles itself at r interest. The truth of this conclusion may perhaps be more satisfactorily proved in the following manner. Since $m : n = \log. 1+r : \log. 1+2r = \log. 1+r : \log. 1+r + \log. 1 + \frac{r}{r+1}$, we shall have $m : n = 1 : 1 + \frac{r}{r+1}$.

But this latter fraction must be less than unity, therefore m will always be to n in a greater ratio than as 1 to 2.

Theorem 4.—To determine the sum to which an annuity a will accumulate at the end of n years, supposing such

annuity to be received annually, and its interest to be improved half-yearly.

Solution.—The series expressing these accumulations is
$$a \left(\left(1 + \frac{r}{2} \right)^2 + 1 + \frac{r}{2} + 1 + \frac{r}{2} \right) \dots \dots \dots + 1 + \frac{r}{2} \Big)^{2n-1} = a \times \frac{\left(1 + \frac{r}{2} \right)^{2n} - 1}{1 + \frac{r}{2} - 1}$$
.

Example.—Let $a = 500$, $n = 30$, and $r = .05$, the foregoing expression will then be
$$\frac{1.025^{60} - 1}{1.025 - 1} \times 500 =$$

$67.1567 \times 500 = 33,578.35$. If the above annuity and its interest be improved yearly, the accumulation will be equal to 33,219.41 and if both principal and interest be improved half-yearly, they will amount to 33,998.84.

Theorem 5.—To determine the sum p which at compound interest will amount in the time n to N , and in the time m to M .

Solution.—In this case $p \cdot (1+r)^n = N$, and $p \cdot (1+r)^m = M$, from which two equations, the $\log.$ of p may be found $= \frac{m \cdot \log. N - n \cdot \log. M}{m - n}$.

Corollary 1.—If the sum p amounts to N in the time n , the $\log.$ of the amount M in the time m will be $= \frac{m \cdot \log. N - m - n \cdot \log. p}{n}$.

Corollary 2.—If the sum p in n years amounts to N , the time m in which it will amount to M , will be $= \frac{n \cdot \log. N - \log. p}{\log. M - \log. p}$.

Theorem 6.—Supposing the sum a to become payable annually for n years, at what time t might all the payments ($n a$) be made at once, so as to be an equivalent to the several annual payments.

Solution.—The present value of the annuity a for n years (see ANNUITIES) being $= \frac{a}{r} - \frac{a}{r \cdot (1+r)^n}$, will in this

case be $= \frac{n a}{1+r}$, from which equation t may be found
$$= \frac{\log. n r + \log. (1+r)^n - \log. (1+r)^t - 1}{\log. 1+r}$$
.

Example.—Let $a = 10$, $n = 15$, and $r = .05$, or, in other words, let an annuity of 10*l.* be payable annually for 15 years at 5*l.* per cent. at what period will the single payment of 150*l.* be an equivalent to this annuity? In this case t will be $= \frac{\log. .5 + \log. 1.05^{15} - \log. 1.05^t - 1}{\log. 1.05} = 7.5$ nearly, or $7\frac{1}{2}$ years. By the same rule, if the annuity were for 30 or 50 years, a single payment made at the end of 13.5 years, or at the end of 20.5 years, will be an equivalent to such annuities respectively.

Corollary.—If the payments, instead of always being a , vary each year, so that in the first, second, and third years they

they are a, b, c, d , &c. respectively, and the whole amount of them be p , the time t will be =

$$\log. p - \log. \left(\frac{a}{1+r} + \frac{b}{1+r_1} + \frac{c}{1+r_2} + \dots \right)$$

Theorem 7.—Supposing the sum b to be now borrowed on condition that the annuity c should be paid in discharge of it, after the expiration of n years; for how many years t should such annuity be continued from that time fo as to be an equivalent to the sum so advanced?

Solution.—The amount of b in n years being $b \cdot (1+r)^n$, and the value of the annuity c for t years being

$$\frac{c \cdot (1+r)^t - c}{r(1+r)}$$

, these two expressions, by the condition of the problem, will be equal to each other. Let

$\frac{c}{r(1+r)}$ be denoted by d , then may t be easily

$$\text{found} = \frac{\log. d}{\log. (1+r)}$$

Thus, if $b = 1032 \dots c = 400$

$\dots n = 37 \dots$ and $r = .05$, d will be =

$$\frac{400}{400 - .05 \times 1032 \times 6.081} = 46.4$$

and $t = \frac{\log. 46.4}{\log. 1.05} = 31.4$, that is, if 1032l. be now borrowed

on condition that the debt should be discharged at the end of 37 years by an annual payment of 400l. such payment, computing at 5l. per cent. should be continued for 31½ years.

Corollary.—If c be = $(1+r)^n \times br$, the annual payment must be continued for ever; if c be less than $br \times (1+r)^n$, the debt can never be repaid.

From any four of the above quantities being given the fifth may be obtained without much difficulty. But it cannot be necessary to pursue this subject further, as the solution of these or any other cases in compound interest may be easily derived from the principles already explained in this article.

See on this subject, Jones's Synopsis Palmariorum Mathematicos, part. i. sect. 3. chap. 10. Gardiner's Tables of Logarithms, p. 13; 3d edition. Philof. Transactions, vol. ix. p. 508. and vol. lxvi. p. 109. Taylor's Tables of Logarithms, p. 30; and Mazere's Scriptorum Logarithmici, vol. v. p. 220. See also ANNUITIES Certain, and DISCOUNT.

A mercantile friend has favoured the editor with the following *universal rule* for finding the interest upon any sum at any rate, for any number of days.

Multiply the *sum* by the *rate* of interest, and multiply that product by the *number* of days; then divide that product by 36500. The quotient will be the answer.

Now suppose the question to be, What is the interest upon 127l. at 3l. per cent. per annum for 254 days?

£. s.	
127	at 3 for 254 days.
3	Rate of interest,
<hr/>	
381	First product.
254	Days.

36500	
<hr/>	
10540	Remainder.

It is evident, that in multiplying 127 by 3, according to the *first* operation of the rule, the amount is *increased* one hundred times too much, for the product 381 is only three, and eighty-one hundredths, or 381l. which is equal to 3l. 16s. 2½d. or the interest of 127l. at 3 per cent. for one year. Therefore, to correct this *first* error, the product 381 must be divided by 100, and it will be right.

But in following the rule, the *first* error is *continued*, and we go on to multiply that product by the number of days, by which it is also evident that the product 96774 includes a *second* error of 365 times too much, being for days instead of for years, and the amount of the *two* errors taken together is 100 times 365 times too much, or 36,500 times too much, therefore, to bring it right, it must be divided by that number.

This explains the principle of the *first universal rule*, which requires *three* operations, because it is adapted to any rate of interest whatever.

To find the interest upon any sum at 5 per cent. for any number of days:

Rule.—Multiply the sum by the number of days, and divide the product by 7300.

Example.

What is the interest upon 2745l. for 365 days?

INTEREST.

Interest at 5 per cent. being the most common rate in Great Britain, may in general be worked as speedily by the above short rule as it can be found by referring to the tables in common use.

The editor's correspondent has never yet met with so short a rule as this, and as 5 per cent. is the general and legal rate of interest in this country, it must be very useful to mercantile persons.

The explanation of the principle of the first rule being understood as above, there can be no difficulty in the last rule, it being derived from it.

When the interest is at any other rate, take the following rule:

Multiply the sum by the number of days; multiply that product by the rate of interest, then divide by 36500.

Example.

What is the interest upon 1612*l.* for 154 days at 4 per cent.?

1612	154	4
248248		
4		
2692	27	4
255500	12

46080	1	
36500		
9580		
4		
38320	1	
36500		
1820		

If the rate of interest is not in even pounds, such as 2½, 3½, or 4½ per cent. take the following rule:

Multiply the sum by the number of days; multiply the product by double the rate of interest, then divide by 73000.

Example:—What is the interest upon 2746*l.* for 328 days at 3½ per cent.?

2746		
328

11840

Any calculation made by the second rule may be proved by the third rule, and *vice versa*. Therefore every calculation of interest at any rate whatever, may be made by either of those rules. When an interest account of considerable length is required to be made out, it may be done as much sooner by this method than it can be done by any interest tables whatever, as there are different lines to be cast.

By the following table of rules, interest upon any sum for any number of days at the several rates of ½, 1, 1½, 2, 2½, 4, 5, and 10 per cent. per annum, may be cast by two operations only, namely, one multiplication and one division.

First, multiply the sum by the number of days, then divide the product by the number standing against the rate of interest, and the quotient will be the answer.

For interest at ½ per cent. divide by 146000

½	-	73000
1	-	36500
1½	-	29200
2	-	18250
2½	-	14600
4	-	9125
5	-	7300
10	-	3650

The above rule may be still further shortened in practice, by cutting off one figure each from the dividend and the divisor, and in that case it will not in any instance make more than one farthing difference.

Interest is the compensation which the borrower pays to the lender, for the profit which he has an opportunity of making by the use of the money. Part of that profit naturally belongs to the borrower, who runs the risk and takes the trouble of employing it; and part to the lender, who affords him the opportunity of making this profit. Interest has been sometimes confounded with usury; and the latter term, the found of which is odious, has been occasionally misapplied and estimated on erroneous principles. (See *USURY*.) Accordingly those who are enemies to interest in general, making no distinction between that and the kind of usury which is criminal, hold any increase of money to be indefinably usurious. This they ground, as well on the prohibition of it by the law of Moses among the Jews, as also upon what is said to be laid down by Aristotle in a passage, (*Polit. l. i. c. 10.*) suspected to be spurious, that money is naturally barren, and that to make it breed money is preposterous, and a perversion of the end of its institution, which was only to serve the purposes of exchange, and not of increase. Hence the school divines have branded the practice of taking interest as contrary to the divine law, both

Both natural and revealed; and the canon law (Decret. l. v. tit. 19.) has proscribed the taking of any, the least, increase for the loan of money as a mortal sin. But it has been observed in reply, that the Mosaic precept was clearly a political, and not a moral precept. It only prohibited the Jews from taking usury of their brethren; but, in expressive words, (Deut. xxiii. 20.) permitted them to take it of a stranger, which proves that the taking of moderate usury, as a reward for the use, for so the word signifies, is not *malum in se*; since it was allowed where any but an Israelite was concerned. As to the reason, deduced from the natural barrenness of money, and ascribed to Aristotle, the same may with equal force be alleged of houses, which never breed houses; and of twenty other things, which nobody doubts it is lawful to make profit of, by letting them to hire. And though money was originally used for the purposes of exchange, yet the laws of any state may be well justified in permitting it to be turned to the purposes of profit, if the convenience of society (the great end for which money was invented) shall require it. That the allowance of moderate interest tends greatly to the benefit of the public, especially in a trading country, will appear from that generally acknowledged principle, that commerce cannot flourish without mutual and extensive credit. Unless money can be borrowed, trade cannot be carried on; and if no premiums were allowed for the hire of money, few persons would care to lend it; or at least the ease of borrowing at a short warning (which is the life of commerce) would be entirely at an end. Thus, in the dark ages of monkish superstition and civil tyranny, when interest was laid under a total interdiction, commerce was also at its lowest ebb, and fell entirely into the hands of the Jews and Lombards: but when men's minds came to be more enlarged, when true religion and real liberty revived, commerce grew again into credit; and again introduced with itself its inseparable companion, the doctrine of loans upon interest. And, as to any scruples of conscience, since all other conveniences may either be bought or hired, but money only can be hired, there seems to be no greater oppression in taking a recompence or price for the hire of this than of any other convenience. To demand an exorbitant price is equally contrary to conscience, for the loan of a horse, or the loan of a sum of money; but a reasonable equivalent for the temporary inconvenience, which the owner may feel by the want of it, and for the hazard of his losing it entirely, is not more immoral in one case than it is in the other. Indeed, the absolute prohibition of lending upon any, even moderate interest, introduces the very inconvenience which it seems meant to remedy. The necessity of individuals will make borrowing unavoidable. Without some profit allowed by law, there will be but few lenders: and those principally bad men, who will break through the law, and take a profit; and then will endeavour to indemnify themselves from the danger of the penalty, by making that profit exorbitant. Accordingly it is well observed by Grotius, (De Jur. Bell. et Pac. l. ii. c. 12. § 22.) "if the compensation allowed by law does not exceed the proportion of the hazard run, or the want felt, by the loan, its allowance is repugnant neither to the revealed nor the natural law: but if it exceeds those bounds, it is then oppressive usury: and though the municipal laws may give it impunity, they never can make it just." The exorbitance or moderation of interest depends upon two circumstances, the inconvenience of parting with it for the present, and the hazard of losing it entirely. The rate of interest will be generally in a compound ratio, formed out of the inconvenience and the hazard.

Mr. Locke, Mr. Law, and Mr. Montefquieu, as well as

many other writers, seem to have imagined that the increase of the quantity of gold and silver, in consequence of the discovery of the Spanish West Indies, was the real cause of the lowering the rate of interest through the greater part of Europe. Those metals, they say, having become of less value than silver, the use of any particular portion of them became necessarily of less value too, and consequently the price which could be paid for it. This notion appears at first sight very plausible; but it has been contested, not to say refuted, by Mr. Hume and Dr. Smith. It is in vain, says the first of these writers, (Essays, vol. i. eff. iv.) to look for the cause of the fall or rise of interest in the greater or less quantity of gold and silver, which is fixed in any nation. High interest arises from three circumstances: A great demand for borrowing; little riches to supply that demand; and great profits arising from commerce; and these circumstances are a clear proof of the small advance of commerce and industry, not of the scarcity of gold and silver. Low interest, on the other hand, proceeds from the three opposite circumstances; a small demand for borrowing; great riches to supply that demand; and small profits arising from commerce: and these circumstances are all connected together, and proceed from the increase of industry and commerce, not of gold and silver. In investigating the causes and effects of a great or small demand for borrowing, Mr. Hume traces the origin and establishment of the *landed* interest; and he observes, after tracing the manner in which some persons become proprietors of land, and the influence of a settled revenue on those who are entirely without occupation, that the prodigals among the landholders will always be more numerous than the misers. In a state, therefore, where there is nothing but a landed interest, as there is little frugality, the borrowers must be very numerous, and the rate of interest must bear proportion to it; the difference depends not on the quantity of money, but on the habits and manners which prevail. By this alone the demand for borrowing is increased or diminished. Were money so plentiful as to make an egg be sold for sixpence; so long as there are only landed gentry and peasants in the state, the borrowers must be numerous, and interest high. The rent for the same farm would be heavier and more bulky; but the same idleness of the landlord, with the higher price of commodities, would dissipate it in the same time, and produce the same necessity and demand for borrowing. The second circumstance, above-mentioned, *viz.* the great or little riches to supply the demand, depends also on the habits and way of living of the people, not on the quantity of gold and silver. In order to have, in any state, a greater number of lenders, it is not sufficient nor requisite that there be great abundance of the precious metals. It is only requisite that the property, or command of that quantity, which is in the state, whether great or small, should be collected in particular hands, so as to form considerable sums, or compose a great *monied* interest; this begets a number of lenders, and sinks the rate of usury; and this, Mr. Hume affirms, depends not on the quantity of specie, but on particular manners and customs, which make the specie gather into separate sums or masses of considerable value. The reduction of interest must proceed from an increase of industry and frugality, of arts and commerce. Besides the peasants and the proprietors of land, there must be another rank of men, who, receiving from the former the rude materials, work them into their proper form, and retain part for their own use and subsistence. As industry increases, and the views of men enlarge, it is found that the most remote parts of the state can afford each other as well as the more contiguous, and that this intercourse of good offices may be carried on to the greatest extent and in-

INTEREST.

tricity. Hence the origin of "Merchants," who serve as agents between different parts of the state; and in all the transactions which this business of connecting agency or merchandize occasions, it is necessary and reasonable that a considerable part of the commodities and labour should belong to the merchant, to whom, in a great measure, they are owing. These commodities he will sometimes prefer in kind, or more commonly convert into money, which is their common representation. If gold and silver have increased in the state, together with the industry, it will require a great quantity of these metals to represent a great quantity of commodities and labour. If industry alone has increased, the prices of every thing must sink, and a small quantity of specie will serve as a representative. Trade, says Mr. Hume, increases frugality, and among merchants there is the same overplus of misers above prodigals, as, among the possessors of land, there is the contrary. Commerce increases industry, as well as frugality. Merchants beget industry, and by their frugality they acquire great power over that industry, and collect a large property in the labour and commodities which they are the chief instruments in producing. Without commerce the state must consist chiefly of landed gentry, whose prodigality and expence make a continual demand for borrowing; and of peasants, who have no funds to supply that demand. The money never gathers into large stocks or sums, which can be lent at interest. Commerce alone assembles it into considerable sums; and this effect it has merely from the industry which it begets, and the frugality which it inspires, independent of that particular quantity of precious metal which may circulate in the state. Thus an increase of commerce necessarily raises a great number of lenders, and by that means produces lowness of interest. The next consideration is, that this increase of commerce diminishes the profits arising from that profession, and gives rise to the *third* circumstance, above-mentioned, requisite to produce lowness of interest. When commerce has become extensive, and employs large stocks, there must arise rivalships among the merchants, which diminish the profits of trade, at the same time that they increase the trade itself. The low profits of merchandize induce the merchants to accept more willingly of a low interest, when they leave off business, and begin to indulge themselves in ease and indolence. Low interest and low profits both arise from an extensive commerce, and mutually forward each other. No man will accept of low profits, where he can have high interest; and no man will accept of low interest, where he can have high profits. An extensive commerce, by producing large stocks, diminishes both interest and profits; and is always assisted, in its diminution of the one, by the proportional sinking of the other. Those, says our author, who have asserted, that the plenty of money was the cause of low interest, seem to have taken a collateral effect for a cause; since the same industry, which sinks the interest, commonly acquires great abundance of the precious metals. But though plenty of money and low interest naturally arise from commerce and industry, they are altogether independent of each other. As to the reduction of interest, which has taken place in England, France, and other kingdoms of Europe, that have no mines, it has been gradual; and has not proceeded, says Mr. Hume, from the increase of money, considered merely in itself; but from that of industry, which is the natural effect of the former increase, in that interval, before it raises the price of labour and provisions. Dr. Smith (*Wealth of Nations*, vol. ii. p. 39.) coincides in opinion with Mr. Hume, and proposes a very short and plain argument, which, he thinks, may serve to explain the fallacy by which those have been misled who ascribe the lowering

of the rate of interest to the increase of the quantity of gold and silver. Before the discovery of the Spanish West Indies, 10 per cent. seems to have been the common rate of interest through the greater part of Europe. It has since that time in different countries sunk to 6, 5, 4, and 3 per cent. Let us suppose that in every particular country the value of silver has sunk precisely in the same proportion as the rate of interest; and that in those countries, for example, where interest has been reduced from 10 to 5 per cent., the same quantity of silver can now purchase just half the quantity of goods which it could have purchased before. This supposition will not, as Dr. Smith believes, be found any where agreeable to the truth, but it is the most favourable to the opinion now examined; and even upon this supposition it is utterly impossible that the lowering of the value of silver could have the smallest tendency to lower the rate of interest. If 100*l.* are in these countries now of no more value than 50*l.* were then, 10*l.* must now be of no more value than 5*l.* were then. Whatever were the causes which lowered the value of the capital, the same must necessarily have lowered that of the interest, and exactly in the same proportion. The proportion between the value of the capital and that of the interest must have remained the same, though the rate had never been altered. By altering the rate, on the contrary, the proportion between these two values is necessarily altered. If 100*l.* now are worth no more than 50*l.* were then, 5*l.* now can be worth no more than 2*l.* 10*s.* were then. By reducing the rate of interest, therefore, from 10 to 5 per cent., we give for the use of a capital, which is supposed to be equal to one-half of its former value, an interest which is equal to one-fourth only of the value of the former interest. Any increase in the quantity of silver, while that of the commodities circulated by means of it remained the same, could have no other effect than to diminish the value of that metal. The nominal value of all sorts of goods would be greater, but their real value would be precisely the same as before. They would be exchanged for a greater number of pieces of silver, but the quantity of labour which they could command, the number of people whom they could maintain and employ, would be precisely the same. The capital of the country would be the same, though a great number of pieces might be requisite for conveying any equal portion of it from one hand to another. The funds for maintaining productive labour being the same, the demand for it would be the same. Its price, or wages, therefore, though nominally greater, would really be the same, they would be paid in a greater number of pieces of silver; but they would purchase only the same quantity of goods. The profits of stock would be the same both nominally and really. The profits of stock are not computed by the number of pieces of silver with which they are paid, but by the proportion which those pieces bear to the whole capital employed. The common proportion between capital and profit would be the same, and consequently the common interest of money; what can commonly be given for the use of money being necessarily regulated by what can commonly be made of it. The interest of money, keeping pace always with the profits of stock, might be greatly diminished, though the value of money, or the quantity of goods which any particular sum could purchase, was greatly augmented.

In countries, says our ingenious author, where interest is permitted, the law, in order to prevent the extension of usury, generally fixes the highest rate which can be taken without incurring a penalty. This rate ought always to be somewhat above the lowest market price, or the price which is commonly paid for the use of money by those who can give the most undoubted security. If this legal rate should

be fixed below the lowest market rate, the effects of this fixation will be nearly the same as those of a total prohibition of interest. The creditor will not lend his money for less than the use of it is worth, and the debtor must pay him for the risk which he runs by accepting the full value of that use. The legal rate, though it ought to be somewhat above, ought not to be much above the lowest market rate. If the legal rate of interest in Great Britain, for example, was fixed so high as 8 or 10 per cent., the greater part of the money which was to be lent, would be lent to prodigals and projectors, who alone would be willing to give this high interest. Where the legal rate of interest is fixed but a very little above the lowest market rate, sober people are universally preferred, as borrowers, to prodigals and projectors. Then a great part of the capital of the country is thrown into the hands in which it is most likely to be employed with advantage. The ordinary market price of land depends every where upon the ordinary market rate of interest. If the rent of land should fall short of the interest of money by a considerable difference, nobody would buy land, which would soon reduce its ordinary price. On the contrary, if the advantage should much more than compensate the difference, every body would buy land, which would soon again raise its ordinary price. When interest was at 10 per cent., land was commonly sold for 10 and 12 years' purchase. As interest sunk to 6, 5, and 4 per cent., the price of land rose to 20, 25, and 30 years' purchase. As to the legal interest in this country, it has varied and decreased for 200 years past according to the accession of trade, the introduction of paper credit, and other circumstances. The stat. 37 Hen. VIII. c. 9. confined interest to 10 per cent. In the reign of Edward VI. religious zeal prohibited all interest. The statute of Henry VIII. was revived by the 13th of Elizabeth, cap. 8. and 10 per cent. continued the legal rate of interest till the 21st of James I., when it was restricted to 8 per cent. It was reduced to 6 per cent. soon after the restoration, and by the 12th of Ann. stat. 2. cap. 16. it was brought down to 5 per cent. yearly, which is now the greatest legal interest that can be taken. But yet, if a contract which carries interest be made in a foreign country, our courts will direct the payment of interest according to the law of that country, in which the contract was made.

INTEREST, Inter-esse, in Law, is commonly taken for a chattel real, as a lease for years, &c. and more particularly for a future term; in which sense it is said in pleading, that one is possessed of *interesse termini*: therefore an estate in lands is better than a right or interest in them. But in legal understanding, an interest extends to estates, rights, and titles, that a man hath in or out of lands, &c. so as by grant of his whole interest in such lands, a reversion therein, as well as possession, in fee-simple, shall pass.

INTEREST on legacies. In case of a vested legacy, due immediately, and charged on land or money in the funds, which yield an immediate profit, interest shall be payable thereon from the testator's death; but if charged only on the personal estate, which cannot be immediately got in, it shall carry interest only from the end of the year, after the death of the testator. If a legacy be devised, and no certain time of payment mentioned, and the legatee be of full age, he shall have interest for the legacy from the expiration of one year after the testator's death; but if the legatee be of full age, he shall have no interest but from the time of the demand of the legacy. Where a legacy is payable at a day certain, it must be paid with interest from that day.

INTEREST, Punitory. See PUNITORY.

INTEREST of no Interest, a denomination applied to insurances made without having any property on board the

ships, in which large sums were insured. The statute 19 Geo. II. c. 37. enacted that all such insurances should be null and void. See *Marine Insurance*.

INTERESTED WITNESS. See WITNESS.

INTERESTING, in the Suppl. to the folio Encyclopædie, has been made an article for the *Beaux Arts*, without the least allusion to music. But dull and uninteresting music is, perhaps, more tiresome than the same degree of insipidity in painting and poetry. You can quit a picture or a book whenever you please; but at a public performance of music, you have no escape from the bad composition or performance. A young composer, ambitious of fame, and of endearing himself to the public, should never write for writing sake; he should not seize his pen without ideas, without a subject. There is no art which has more alluring means of obtaining attention. Grace, pathos, fire, fancy, hilarity, rich harmony, and learned modulation, cannot all have admission in the same piece; yet it is absolutely necessary that at least some one of these excellencies should predominate throughout a regular movement. And where a composer, not certain of his fertility and powers of pleasing, has hastily committed his thoughts to paper, he should shut it up in his desk for at least nine days, if not nine years; at the end of which he should perform it as the production of a stranger; then ask himself what *interest* he thinks his piece would excite in an intelligent and impartial audience; and if self-love is not the blindest of all loves, he will perceive where he is dull, and where genius and abilities are wanting.

INTERFERE, a word used by some to express the periculum.

INTERFERE, in the *Manege*. A horse interferences, when the sides of one of his flanks strikes against and hurts one of the fetlocks. See *Cutting*.

INTERJECTION, in *Grammar*, an expression used to denote some sudden motion or passion of the mind; as *ah! ah!* These exclamations, uttered in a strong and passionate manner, are considered by some writers as the first elements or beginnings of speech.

As the greatest part of the expressions used on these occasions are taken from nature alone, the real interjections in most languages are monosyllables; and as all nations agree in those natural passions, so do they agree in the signs and indications of them; as of love, mirth, &c.

Some deny the interjections to be words, or any part of speech; and make them mere natural signs of the motions or passions of the mind, expressed by these articulate sounds, several whereof brutes have in common with us; but as these are passions, and must be represented in discourse, the interjection has a good foundation in nature, and is a necessary part of speech.

Mr. Harris observes, that interjections coincide with no part of speech, but are either uttered alone, or else thrown into a sentence, without altering its form, either in syntax or signification; and that they are not so properly parts of speech, as adverbial sounds; certain voices of nature, rather than voices of art, expressing those passions and natural emotions, which spontaneously arise in the human soul, upon the view or narration of interesting events. *Hermes*, p. 287.

Mr. H. Tooke, in his "Diversions of Purley," excludes interjections from the parts of speech; and asserts, that "the dominion of speech is erected upon the downfall of interjections." See *GRAMMAR*.

The Greeks confound their interjections with adverbs, and the Hebrews confound them with their adverbs and prepositions; calling them all by the general name particle.

INTERIM, a term borrowed from the Latin, signifying *in the mean time*. It was first brought into popular use by Charles V in 1548, in order to compose the disturbances of Germany.

The interim of that prince was a kind of ordinance, or regulation, to be observed in the empire with regard to the articles of religion then controverted, till such time as they should be determined by a council; and therefore was called interim.

When it was laid before the diet, the archbishop of Mentz, president of the electoral college, thanked the emperor for his unwearied endeavours to restore peace to the church, and in the name of the diet, signified their approbation of the system of doctrine which he had prepared, together with their resolution of conforming to it in every particular. Although the whole diet was amazed at a declaration so unprecedented and unconstitutional, as well as at the presumption of the archbishop, in pretending to deliver the sense of the diet, on a point which had not been the subject of consultation or debate; none had the courage to contradict what he had said. The emperor held the archbishop's declaration to be a full constitutional ratification of the interim, and prepared to enforce the observance of it, as a decree of the empire.

It was said to have been drawn up by two Catholics and a Protestant; but as it retained most of the doctrines and ceremonies of the Romanists, though expressed for the most part in the softest words, or in scriptural phrases, or in terms of studied ambiguity, excepting that of marriage, which was allowed to priests, and communion, which was administered to the laity under both kinds, most of the Protestants rejected it. Those who admitted it were nick-named Interimists, or Adiaphorists. Indeed the interim equally disgusted the generality of both parties, the Protestants and Catholics.

Besides this, there were two other interims made: the one called the interim of Leipzig, the other by the divines of Franconia, who, refusing to accept the two former, made another for themselves.

INTERIOR. See INTERNAL.

INTERIOR Figure, Angle of. See ANGLE.

INTERIOR Polygon. See POLYGON.

INTERIOR Talus. See TALUS.

INTERLACKEN, in *Geography*, a town of Switzerland, and capital of a considerable bailiwick, in the canton of Berne: deriving its name from an abbey, situated between the lakes of Brienz and Thun, and secularized in the year 1528; 32 miles S.E. of Berne.

INTERLINEATION, something inserted between two lines. See DEED.

INTERLOCUTORY DECREE. In a suit in equity, if any matter of fact be strongly controverted, the fact is usually directed to be tried at the bar of the court of king's bench, or at the assizes upon a feigned issue. If a question of mere law arises in the course of a cause, it is the practice of the court of chancery to refer it to the opinion of the judges of the court of king's bench, upon a case stated for that purpose.

In such cases interlocutory decrees or orders are made. See DECREES.

INTERLOCUTORY Judgments are such as are given in the middle of a cause, upon some plea, proceeding on default, which is only intermediate, and does not finally determine or complete the suit. But the interlocutory judgments most usually spoken of, are those incomplete judgments, whereby the right of the plaintiff is established, but the *quantum* of the damages sustained by him is not ascertained, which is the

province of a jury. In such a case, a writ of inquiry issues to the sheriff, who summons a jury, enquires of the damages, and returns to the court the inquiry so taken, whereupon the plaintiff's attorney taxes costs, and signs final judgment. See JUDGMENT.

INTERLOCUTORY Order, that which decides not the cause, but only settles some intervening matter relating to the cause.

As, where an order is made in chancery for the plaintiff to have an injunction to quit possession till the hearing of the cause; this order, not being final, is called interlocutory.

INTERLOPERS are properly those, who, without due authority, hinder the trade of a company, or corporation lawfully established, by dealing in the same way.

INTERLOPING, the intercepting or disturbing the traffic of a company; or the taking up a new trade, or the employment, to the prejudice of those who were brought up in it.

INTERLUCATION, in *Husbandry*, the thinning of a wood, or letting in light between, by lopping or cutting away boughs.

INTERLUDE, an entertainment exhibited on the theatre between the acts of a play, to amuse the spectators while the actors take breath, and shift their dress; or to give time for changing the scenes and decorations.

In the ancient tragedy, the chorus sung the interludes, to shew the intervals between the acts.

Interludes, among us, usually consist of songs, dances, feats of activity, concerts of music, &c.

Aristotle and Horace give it for a rule, that the interludes should consist of songs built on the principal parts of the drama; but since the chorus has been laid down, dancers, buffoons, &c. ordinarily furnish the interludes.

INTERMEDIATE, is usually understood of the space of time elapsed from any certain point to any other.

In *Chemistry*, those substances are called intermediate, by means of which, other substances, incapable of uniting together of themselves, may be united.

INTERMEWING, in *Falconry*, is a hawk's mewing, from the first change of her coat till the turn white.

INTERMEZZO. *Ital.* **INTERMEDE**, *Fr.*, a piece of music, a dance, or a short dramatic scene, generally between two performers of different sexes, exhibited between the acts of a serious opera, to vary the entertainment, and to relieve and enliven the audience, that may be too much oppressed and dispirited by tragic scenes of great interest.

The ancient Romans had satires performed between the acts of their regular comedies; and these were afterwards exhibited as farces at the end of pious pieces.

Tragicomedies had a very early admission on the stage at Bologna during the 17th century: as *Andromeda*, Tragicomedia, set by Girolamo Giacobbi, maestro di cappella of San Petronio, and founder of the Academy de' Filomati, in that city, was performed in 1610; and *Amor vuol Gioventù*, scherzo drammatico, at Viterbo, 1659. Musica di Giambattista Mariani, 1659. But the only real burlettas which we have met with are Girello, *Drama Burlesca*, set by the famous Pistocchi, 1673, which was represented at Venice by little figures of wax: I dos Diogeno, *dramma burlesca per musica*, and *Agripina in Baja*, Scherzo drammatico per musica, were both performed at Ferrara, 1687.

There are intermezzi, says Rousseau, that are true comic or burlesque dramas, which detach the audience from the interest of the principal piece, without taste or reason. As the dance in Italy is never analogous to the drama, they are obliged to admit it on the stage as an *intermezzo*; "but this

is not what I blame; on the contrary, I think it may be useful to efface, by an agreeable dance, the melancholy impressions left by the events of a grand serious opera; and I see plainly that the subject of this dance should have no connection with the piece; but what offends me, continues the citizen of Geneva, is that they destroy all the interest that has been excited, and render each act a new piece." We suppose he means that the ballet should be given at the end, not in the middle of the opera.

INTERMITTENT, a thing which ceases its action for some time; which time is called the *interval*.

INTERMITTENT, in *Medicine*, any animal motion or action, which ceases and returns at intervals. The period of cessation is termed the *interval*, or *intermission*.

Thus those fevers which, after continuing several hours, altogether go off, and again return at certain intervals, as of one, two, or three days, are called *intermittent fevers*, in contradistinction from those which go through their course with little variation, or with regular diminution and aggravation only; the former being called *continued*, the latter *remittent fevers*. See **FEVER** and **AGE**.

Various other disorders, besides the acute fevers just mentioned, put on the *intermittent form*; such as head-ache, especially the *bemicrania*, or head-ache of one side of the head, the *migrain*, and sometimes the *tic dououreux*; and pains, seated in various other parts of the body, as in the liver, bladder, uterus, &c. It is extraordinary, and does not easily admit of any explanation, that, in parts of the body, suffering severe organic disease, and actually much injured in their structure, the pain connected with this disorder sometimes becomes regularly *intermittent* with intervals of absolute freedom from the distress; while of course no variation can have occurred in the morbid structure. Such intermissions we have witnessed in cancerous and ulcerated conditions of the womb; and, in suppuration in the brain. But, indeed, it is equally difficult to account for the fact in all instances; and no speculations have yet enabled us to explain, why the vessels of any part, (as of the supra-orbital notch, in the case of *migrain*), or of the whole system, (as in *ague*), should take on an extraordinary action at regular but distant periods, and continue only their ordinary action in the intervals: whether the parts be actually diseased in structure or not, the periodical recurrence and cessation of increased vascular action is equally inexplicable. Dr. Darwin has ingeniously endeavoured to refer these periodical changes to the influence of our diurnal habits, in regard to activity and sleep, exhaustion of sensorial power and invigoration, and to the diurnal periods of heat and cold, light and darkness, &c. upon all the actions of our frame. That these circumstances greatly influence the operations of the animal body, cannot be doubted: and were all the periods of action and intermission *diurnal* only, we might admit the generalization as correct. But it is not easy to discover how the very frequent *intermissions* of disease, which continue for *tertiary* periods, that is, during an interval of forty-eight hours, and still more those which continue for *quartan* periods, of seventy-two hours, can be referred to this general law. See Darwin, *Zoonomia*, vol. i. sect. 36.

The bark of the cinchona, and some other bitter vegetable substances, it is well known, possess a considerable degree of power, when administered during the intermissions, for preventing the recurrence of diseases of this class. But a remedy has been added to the list of the *materia medica*, which seems to have a specific virtue of arresting all *intermittent* affections: we mean the *arsenic*, which had long been used as an empiric nostrum, under the appellation of the "tasteless *ague-drop*," but which was first prepared in a safe and ma-

nageable form by the late Dr. Fowler, of York, and is now introduced into the pharmacopoeia of the College of Physicians of London. This medicine has not only been administered with decided benefit in intermittent fevers; but also in the intermittent head-ache and *migrain*, with the most marked success. And we have found it, in more instances than one, speedily arrest the intermitting pain in diseased uterus, and other organic painful diseases. In a word, arsenic appears to have a specific remedial power over periodical disorders. But in cases of organic disease, its influence is of course confined to the periodic pains connected with them, and is not exerted upon the fixed and continued affection.

The term *intermittent* is also applied to the *pulse*, when, after an indefinite number of beats, it stops during the time of one pulsation, or loses a stroke. This is sometimes a formidable symptom, when connected with other signs of affection of the brain, or of the heart itself; but it is more commonly of minor import, being connected with indigestion, and a general irritability of the system, and is removable by correcting the state of the stomach and other organs concerned in the chylipoetic process. See **PULSE**.

INTERMITTING SPRINGS, in *Natural History*, or ebbing and flowing wells, are phenomena which attracted a great deal of attention in former times, and several works on natural philosophy contain explanations of the principles on which they might, by a proper application of the syphon, be made, by art, so as afterwards to be self-acting: it can scarcely be doubted but some of the intermitting springs were natural, or produced their ebbing and flowing or intermission, without the assistance of art, perhaps that on the N.W. side of Tideswell town in Derbyshire, which formerly existed and gave the name to the town, may have been of this number; and perhaps also Laywell Springs at Brixham, in Devonshire, may have been natural; but Mr. Farey, in his recent Report on Derbyshire, (vol. i. p. 288.) states the ebbing well at Barmoor, between Calfleton and Chapel-en-le-Frith, on the skirt of Peak forest, in Derbyshire, to occupy the site of an old stone-quarry, in the first limestone rock, and to be evidently the work of art; he also mentions an artificial well of this kind lately made in the parish of Chapel-en-le-Frith. See **SPRING**.

INTERNAL ANGLES, are all angles made by the sides of any right-lined figure within.

In a triangle, as KLM (*Plate VIII. Geometry, fig. 103.*) the angles L and M are particularly called *internal and opposite*, in respect of the external angle KLM, which is equal to them both. See **INTERNAL ANGLES**.

INTERNAL Angle, is also applied to the two angles formed between two parallels, by a line intersecting those parallels, on each side the intersecting line.

Such are the angles x and y , and z and s (*Plate VIII. Geometry, fig. 104.*) formed between the parallels OP and QR, on each side of the intersecting line ST.

The two internal angles are always equal to two right angles.

INTERNAL and Opposite Angles, are also applied to the two angles x and y , formed by a line cutting two parallels.

These are respectively equal to A and u, called the external and opposite angles.

INTERNAL Affection, Denomination, Ear, Modes, Orthography, Place, Sense. See the substantives.

INTERNAL Plans, in *Mining*, signify, according to M. Werner (*New Theory of Veins, Transl. p. 194.*), the internal drawings, or sections as they are called in this country, of the mines and the strata, or of rocks in which they occur. Sections of particular districts, formed into tablets in kind

with the principal rocks and minerals of such districts, have long been made by Mr. White Watson of Bakewell, in Derbyshire, Mr. Elias Hall of Castleton, Brown and Co. of Derby, and others, but it has justly been objected to all the tablets or sections of this kind which we have seen, that they represent some imaginary hill or mountain, instead of being in any way proportioned to, or made to represent, the actual strata and outline of any district. Now that mineral surveying, or the methods of obtaining a knowledge of the interior of stratified districts, as well as of ascertaining whether they are so stratified, has been fully explained in the Report to the Board of Agriculture on the County of Derby, by Mr. John Farey, senior, and illustrated by a survey of that interesting and difficult county, we hope that the making of accurate and natural representations or tablets of the interior, or sections of different districts, will be attempted. A very neat and interesting way of disposing a tablet of a gentleman's mineral strata in his estate, is in the front of his chimney-piece, instead of the flat or carved marble slab now generally used. Mr. William Milnes of the Butts in Ashover, in Derbyshire, has employed Mr. W. Watson to make him such a chimney-piece, which forms a very interesting object as well as a subject of contemplation to his friends and visitors.

INTERNOIDIUM, in *Anatomy*, the space between two articulations. It is only applied to the fingers, where it is employed in naming some of the muscles; at present it is used only in the extensors of the thumb, which are called extensor primi, and secundi internodii pollicis.

INTERNOBIUM, in *Botany*, the space that is between two knots, or joints, of the stalk of a plant; *e. gr.* of the stalk or straw of wheat, or other corn.

INTERNUS MALLEI, in *Anatomy*, one of the muscles of the ossicula auditus, called more commonly tensor tympani. See *EAA*.

INTEROSSEI, a number of small muscles of the hands and feet, so named from being situated in the intervals of the metacarpal and metatarsal bones.

The *interossei* of the hand are seven; *viz.* two for each of the three middle fingers, and one for the little finger. The abductors and the adductor of the thumb supply the places of the *interossei* in that member; and the adductor ossis metacarpi indicis holds the place of an internal *interosseus* muscle in the little finger. The *interossei* produce the lateral motions of the fingers to which they correspond; they may therefore be most conveniently arranged as abductors and adductors of their respective fingers. More commonly, however, they are divided into two classes, according as they are placed towards the palm or the back of the hand, and distinguished by the names of *interossei interni* priores or palmares, and *externi* posteriores or dorsales. In this distribution, the internal class contains four muscles, which are named by Albinus, 1, indicis prior, and 2, posterior; 3, prior annularis; 4, prior aricularis; the external has only three; *viz.* 1 and 2, prior et posterior digiti medii; 3, posterior annularis. Sometimes they are distinguished numerically, beginning from the thumb. The abductor indicis, or *seni-interosseus*, (see *ABDUCTOR*), forms the first external *interosseus* of Soemmerring; who therefore enumerates four external *interossei*. This anatomist makes only three internal *interossei*; the first, internal *interossei* of Albinus, being one of the heads of Soemmerring's first external *interosseus*. Both classes are called by some French writers *metacarpal-fus-phalangiens*.

Interossei of the fore-finger. The abductor (prior indicis of Albinus, one of the heads of the first external *interosseus* of Soemmerring and others) is attached to the radial flat

surface of the metacarpal bone of the fore-finger; it forms a tendon towards the finger, which is inserted, in common with that of the abductor indicis, into the radial side of the metacarpal end of the first phalanx of that finger, having also a slight connection to the extensor tendon; the radial artery dips into the palm of the hand between this muscle and the abductor indicis.

The adductor of the fore-finger (posterior indicis, Alb.) is placed towards the palm of the hand. It arises from the ulnar flat surface of the 2d metacarpal bone, and from the ligaments which unite that to the trapezoid bone. At the end of the metacarpus it forms a small flat tendon, passes over the articulation of the index and metacarpus, the side and back part of the first phalanx, the articulation between the first and second phalanges, and the dorsal surface of the 2d phalanx. On the middle of the latter bone, it meets at an acute angle with a corresponding tendon of the lumbricals, and the two tendons unite into a broader one, which is slightly contracted and inserted into the middle prominence of the back of the third phalanx. About the middle of the first phalanx, or rather sooner, it becomes united to the broad tendon of the extensor, from which it separates a little before the termination of that tendon.

This connection is formed by a thin and broad tendinous expansion, which closely covers the articulation of the index with the metacarpus.

Interossei of the middle finger. The abductor (prior digiti medii) is placed towards the back of the hand; it arises from the ulnar side of the second, and radial side of the third metacarpal bone; and has a middle tendon, in which two oblique rows of fibres terminate. The course of its tendon corresponds exactly to that of the preceding, and is united, at its termination, to that of the succeeding muscle.

The adductor of the middle finger (posterior medii digiti) is placed also towards the back of the hand, and has a similar form to the last muscle. It arises from the third and fourth metacarpal bones, and is inserted in the manner already described.

Interossei of the ring-finger. The abductor, (prior annularis,) placed towards the palm, is attached to the radial side of the fourth metacarpal bone, and to the ligaments which connect it to the carpus. It terminates in a tendon ending as already described. The adductor (posterior annularis) is placed towards the back of the hand, arises from the ulnar side of the fourth, and from the radial side of the fifth metacarpal bone, and has a middle tendon placed between two planes of fibres, and inserted like the preceding ones.

The *interossei* of the little finger. This finger has only an abductor (prior aricularis), which arises from the radial surface of the fifth metacarpal bone, and from the ligaments joining it to the carpus. Its tendon has a course and insertion like those of the former.

The expansions of the *interossei*, where their tendons begin to join those of the extensors, are connected by many fibres to the capsules of the joints formed between the metacarpal bones and the first phalanges: their aponeuroses are also strengthened by the tendons of the lumbricals. The relations of the *interossei* to the surrounding parts may be considered in a general view. On the sides they correspond to the metacarpal bones, and they are reciprocally in contact with each other. They are covered in front by the tendons of the flexor profundus, by the lumbricals, and, so far as the three first are concerned, by the abductor pollicis. They are retained, towards the end of the metacarpus, by the anterior transverse palmar ligament, at the level of which they

are all directed backwards. On the posterior surface the first interosseus is subcutaneous: the others are covered by thin aponeuroses attached to the corresponding metacarpal bones, separating the interossei from the extensor tendons, and in their intervals from the integuments. Their expanded tendons are placed between the phalanges and the skin.

These muscles seem to perform, as their primary use, the adduction and abduction of the fingers. They serve to fix the extensor tendons; which, not being covered by any fibrous sheaths, required this lateral support. They partake this office with the lumbricales; when the two interossei of any finger act together, the extensor tendon is drawn in the diagonal of their direction. If the fingers are extended, they will be fixed more firmly in this position; but if they are already bent, the flexion is increased by the action of the interossei, which exert themselves so much the more effectually, as their tendon falls perpendicularly in the moving part. From the course which the tendons pursue, along the sides to the backs of the fingers, they will have the effect of extending the middle and last joints. If the fingers are fixed, these muscles may bend the metacarpus to them.

The *interossei* of the foot hold the same relation to the metatarsus, as those of the hand do to the metacarpus; and are arranged into an internal and an external class, or a superior and an inferior; of which the former is placed towards the back, and the latter towards the sole of the foot. They are the adductors and abductors of the toes; and are seven in number, three internal, and four external. Of these, six belong to the three middle toes, and one to the little toe, their place being supplied, in the great toes, by its proper muscles.

The *internal interossei* are the adductors of the third, fourth, and fifth toes. They agree very nearly in their mode of origin, figure, course, termination, and action. They are small and tendinous at their commencement; grow gradually thicker and broader, then again decrease, and form long and flat tendons at the digital end of the metacarpus. They all pass forwards from the metatarsus towards the toes, and end at the tibial sides of the metacarpal extremities of their respective toes, near the terminations of the lumbricales. Their tendons are closely connected to the capsules of the first joints of the toes, to those of the lumbricales, and of the extensors. The first arises from the posterior part of the under surface of the third metatarsal bone on its tibial side: the second from the corresponding part of the fourth, and the third from that of the fifth metatarsal bone. The two latter are also connected to the sheath which contains the tendon of the peroneus longus.

The *external interossei* are 1 and 2, the adductor and abductor of the second toe, 3, the abductor of the third, and 4, the abductor of the fourth. The three latter resemble each other, and resemble also the external interossei of the hand, in having double origins: each of them has two heads, arising from the two contiguous metatarsal bones, tendinous at their commencement, uniting at acute angles in a middle tendon, which passes forwards to the toes. The tendons are thicker and broader than those of the internal interossei, connected in the same way to the capsules of the first joints, and inserted in the same manner, but on the opposite sides of the first phalanges. The abductor of the second toe has its larger origin from rather more than the posterior half of the third metatarsal bone, on its outer or peroneal surface; the smaller head comes from the opposed surface of the second bone. The abductor of the third toe has a larger origin from the fourth, and a smaller from the third bone; and the abductor of the fourth has the same relation in its origin to the fifth and fourth metatarsal bones. The adductor of the

second toe differs from the other external or superior interossei, in arising from one bone only: its origin is derived from more than the posterior half of the inner or tibial surface of the second metatarsal bone: its insertion is similar to that of the others.

The interossei of the foot have the following relations to the surrounding parts: On the back of the foot they are covered by the tendons of the two extensors, and by a very thin aponeurosis, which is sometimes scarcely sensible, and which is extended in the intervals of the metatarsal bones. In the sole they are in contact with the muscles of the great and of the little toe, with the tendons of the flexor longus digitorum and the lumbricales, and with the deep-seated plantar vessels. On their sides they correspond to each other, or to the metatarsal bones.

The motions produced by these muscles are analogous to those of the corresponding ones in the hand. In the first place they are adductors and abductors of their respective toes. They may act as flexors of the first phalanges through the means of their tendons affixed to these bones, more particularly when the first joints are already slightly bent; for they are then directed obliquely or perpendicularly to the moveable point, with which, in the extended state, they are parallel. By the portions, which they detach to the extensor tendons, they may assist the extension of the last phalanges; but it is necessary that the extensors should have previously acted in some degree, to carry the last phalanx upwards and backwards, and this motion is then increased by the interossei. They serve also, as in the hand, to fix the extensor tendons laterally.

INTEROSSEUS, an epithet of certain organs of the body, particularly in the fore-arm and leg, which are situated between two bones. The interosseous artery of the fore-arm is a branch of the ulnar, and is divided into an anterior and a posterior interosseous branch. In the leg, the peroneal artery is sometimes designated by this term. The interosseous ligaments are aponeurotic expansions attached to the opposed edges of the bones of the arm and leg, and filling up the intervals between these bones. See **ARTERY** and **EXTREMITIES**.

INTERPLEADER, *Bill of*, in *Law*, is where a person who owes a debt or rent to one of the parties in a chancery suit, but, till the determination of it, he knows not to which, desires that they may interplead, that he may be safe in the payment. In this last case it is usual to order the money to be paid into court, for the benefit of such of the parties to whom, upon hearing, the court shall decree it to be due. But this depends upon circumstances; and the plaintiff must also annex an affidavit to his bill, swearing that he does not collude with either of the parties.

INTERPOLATION, a term used by critics in speaking of ancient writings and manuscripts, in which some spurious additions or alterations have been since made.

To establish or ascertain an interpolation, P. Ruinart gives us the five following rules: 1. That the piece supposed to be interpolated appear to have all the antiquity it pretends to. 2. That there be good proofs that it has been interpolated. 3. That the supposed interpolations agree to the time of the interpolator. 4. That the interpolations do not touch the foundation of the work; and that they be not too frequent, nor entirely disfigure the piece. 5. That the restitution made, agree perfectly to the rest of the work.

Interpolations have occasioned several of the various readings in the New Testament. Michaelis, in his "Introduction to the New Testament," and also other writers, have suggested how these were introduced, and how they may be distinguished from the original text. *E. G.* If for a passage

that.

INTERPOLATION.

that is not absolutely necessary to the construction, various readings are found that differ materially from each other, we have reason to suspect its authenticity; and that all the readings are interpolations of transcribers, who have attempted by different methods to supply the seeming deficiency of the original. An interpolation is sometimes betrayed by the circumstance of its being delivered in the language of a later church. To this purpose Michaelis observes, that in the time of the apostles the word "Christ" was never used as the proper name of a person, but as an epithet expressive of the ministry of Jesus, and was frequently applied as synonymous to "Son of God." The expression, therefore, "Christ is the Son of God." (Acts, viii. 37) is a kind of tautology, and is almost as absurd as to say Christ is the Messiah, that is, the Anointed is the Anointed. But the word being used in later ages as a proper name, this impropriety was not perceived by the person who obtruded the passage on the text. If one or more words, that may be considered as an addition to a passage, are found only in MSS., but in none of the most ancient versions, nor in the quotations of the early fathers, we have reason to suspect an interpolation. Acts, viii. 39. $\alpha\pi\alpha\rho\iota\sigma\tau\alpha\iota$ [απὸ τοῦ ἁγίου πνεύματος ἔλαβεν δύναμιν] is an instance of this kind, where the words between the crotchets are probably spurious. Interpolations of considerable length are occasionally sometimes in the following manner: The owner of a MS. makes a note in the margin, either explanatory of some narrative in the text, or containing an account of some event that was handed down by tradition; which MS., being afterwards transcribed, the copyist writes text and notes without distinction in the body of his work. "I am persuaded," says Michaelis, "that John, v. 4, a very superfluous passage, and omitted in a very great number of MSS. has been introduced in this manner into our present text, and that this scholion was written originally not in Greek, but in some oriental language." The disputed passage in 1 John, v. 7. may probably be a specimen of this kind of interpolation. Its spuriousness has been shown by sir Isaac Newton, in a letter to Le Clerc, first published in London in 1754, and more correctly by Dr. Horley in 1785, from the author's origin al copy. (See his edition of Newton's Works, vol. v. p. 495—531.) This letter, says Dr. Marsh, is less known than it deserves, as the immortal author has displayed in it as much critical knowledge, as penetration in his mathematical inquiries. The question has been likewise examined, and with great impartiality, by Bengel, in his "Apparatus Criticus," p. 458—482. 2d ed; and the dispute has been satisfactorily terminated by the eminently learned Porson, in his "Letters to Travis," published in 1791. See *Various Readings*.

INTERPOLATION, in *Algebra*, is used for the finding an intermediate term of a series, its place in the series being given; and the method of doing this is called the *method of interpolations*.

When the algebraic equation of the series is given, the term required, whether it be a primary or intermediate term, may be found by the resolution of affected equations; but when this equation is not given, as it often happens, the value of the term sought must be exhibited by a converging series; or by the quadrature of curves.

When the first, second, and other successive differences of the terms of a series become at last equal, the interpolation of any term of such a series may be found by sir Isaac Newton's differential method.

The method of interpolation was first invented by Mr. Briggs, Savilian professor of Geometry at Oxford, and applied by him to the calculation of logarithms. His prin-

ciples were followed by Dr. Wallis, who made several ingenious applications of this theory; and by Reginald and Mouton, in France. Sir Isaac Newton, in lemma 5. lib. iii. Phil. Princip. Mathem. gave a most elegant solution of the problem for drawing a curve line through the extremities of any number of given ordinates; and in the subsequent proposition applied the solution of this problem to that of finding from certain observed places of a comet, the place of it at any given intermediate time. Dr. Waring, who adds, that a solution still more elegant, on some accounts, has been since discovered by Messrs. Nicholi and Stirling, has also resolved the same problem, and rendered it more general, without having recourse to finding the successive differences.

The theory of interpolation is of very extensive use, not only in pure analysis and geometry, but in various other subjects of mathematical inquiry and computation, and particularly in astronomy; we shall therefore endeavour to explain the principles upon which it is founded, and shew its application in a few cases to practical operations.

First, then, let $a, b, c, d, e, f, \&c.$ represent any series of similar quantities, and let the difference between the first and second, the second and third, the third and fourth, &c. terms, be taken; and these several remainders will form what is called the first order of difference; then again, let the differences of these differences be taken in the same way; and the differences of these last again the same, and so on, which will give the following result, observing, that for the convenience of exhibiting the operation, we have only retained the first remainders in each successive subtraction.

series	a	b	c	d	e	f	&c.
1st diff.		$a - b$					
2d diff.			$a - 2b + c$				
3d diff.				$a - 3b + 3c - d$			
4th diff.					$a - 4b + 6c - 4d + e$		
5th diff.						$a - 5b + 10c - 10d + 5e - f$	
6th diff.							$a - 6b + 15c - 20d + 15e - 6f + g$
					&c.	&c.	&c.

Now the co-efficients of these terms are respectively the same as those of the co-efficients of the binomial, and the order of their generation evidently follows the same law, and therefore we may conclude with equal certainty, that the n th difference of any series of quantities will be expressed by the formula

$$a - nb + \frac{n(n-1)}{1 \cdot 2} c - \frac{n(n-1)(n-2)}{1 \cdot 2 \cdot 3} d + \frac{n(n-1)(n-2)(n-3)}{1 \cdot 2 \cdot 3 \cdot 4} e - \&c.$$

Now it is obvious, that if the given quantities be such, that any order of their differences become equal to 0, that any one of those quantities may be accurately expressed in functions of the others; thus, for example, suppose the fourth difference to become zero, that is

$$a - 4b + 6c - 4d + e = 0$$

then will
$$e = \frac{-a + 4b + 4d - c}{6}$$

and it is obvious that any other of these quantities might be expressed in a similar manner; and therefore, if all those quantities but one be known, that one may be ascertained. Thus, by way of illustration, suppose we had the three squares $10^2 = 100$, $8^2 = 64$, and $7^2 = 49$, and the square of 9 was required; since the third differences of squares

$$\text{equal } 0, \text{ we should have } 9^2 = \frac{100 + 3 \cdot 64 - 49}{3} = 81, \text{ and}$$

INTERPOLATION.

the same is obviously true of any terms of which the differences vanish.

But if the differences do not vanish, then any intermediate term found by this method only approximate towards the true result, which is however sufficiently correct in a number of cases; thus, in finding any logarithm, of which those consecutive to it are given, the above formulæ may be successfully employed; for though, in fact, the differences of logarithm never become zero, yet their fourth differences are so small, that by considering them as 0, the error will not affect the truth of the result to 8 or 9 places of decimals.

Exam.—Given the logarithms of 101, 102, 104, 105, to find the logarithm of 103.

Here, calling the log. of 101 = a , of 102 = b , 103 = c , 104 = d , and 105 = e ; and considering the fourth differences of these logs = 0; we shall have from the formula

$$a - 4b + 6c - 4d + e = 0$$

$$c = \frac{4(b + d) - (a + e)}{6}$$

Hence the following computation :

$$\log. 101 = 2.0043334 = a$$

$$\log. 102 = 2.0086002 = b$$

$$\log. 104 = 2.0170333 = d$$

$$\log. 105 = 2.0211893 = e$$

$$\begin{array}{r} 4.0259335 = b + d \\ \hline 4 \end{array}$$

$$\begin{array}{r} 16.1023340 = 4(b + d) \\ \text{subtr.} \quad 4.0255107 = a + e \\ \hline 6)12.0778233 \end{array}$$

$$\log. 103 = 2.0128372 \text{ as required.}$$

This method of finding the intermediate logarithms between others that are known, though of little importance in the present state of the sciences, was of very essential service to the original computers; and to whom the invention of it is due, or more properly to Briggs alone, who seems to have been the first that entered upon the investigation of this theory.

This doctrine is applied with great success in various astronomical operations, and is the means of saving in many cases immense laborious calculations. Thus, for example, in finding the places of some of the planets, whose motion is not very rapid, it will be sufficiently accurate to find their places by calculation for every fourth or fifth day, and then by means of the method above described, their places for all the intermediate days may be found by interpolating between the known terms, which method will give a result much nearer the truth, than by proportional parts, because this supposes a uniformity both in motion and time, which is not correct.

Again, in computing the moon's place for any particular hour, supposing its place for every day at noon to be given, the method of interpolations may be applied with great success, the results having scarcely any sensible difference from those that arise from actual computation, and we may thus frequently avoid one of the most laborious of astronomical calculations.

By this means also, the place of a comet at any particular time may be ascertained, from observations made on it prior to, and subsequent to, that precise period, as also the times of the equinoxes and solstices, which are determined much

more accurately by this method than can be done by proportional parts, for in this, we are obliged to suppose that the sun's declinations increase and decrease proportionally to the distance of this body from the equinoctial point; which is evidently a false hypothesis. In fact, astronomy has derived more assistance from this theory than any other of the mathematical sciences, although it has been applied to other purposes with very great success; but in order to render its application thus general, a much more accurate and extended investigation of the theory than that which has been at present mentioned becomes necessary, and of which we propose to give a slight view in the subsequent part of this article.

The general problem to be resolved in all these cases is this. Having given two series of numbers, which correspond with one another, according to a certain law, and of which one may be called the series of roots, and the other the series of functions, to find an intermediate number, between two functions, which shall answer or correspond to a given intermediate number between two roots. This problem is treated of in all its generality by Newton, in his "Methodus Differentialis," and by Stirling in his "Tractatus de Summatione, &c.;" see also Lacaille's Astronomy, and a paper by Mayer in the Acta. Petrop. tom. ii. page 108; also an excellent memoir by Lalande, transmitted to the Academy of Sciences of Paris for 1761; in which he has shewn that in calculating the moon's place, and much more that of any other of the heavenly bodies, whose motions are more regular; it will always be sufficient to consider only the third differences, and in many cases only the second differences will be requisite, and sometimes only the first; in fact he has shewn how, and to what degree of accuracy, the method of interpolation may be employed in most cases. The same author has also a very complete article on this subject in the Encyclopédie Méthodique where, in explaining the nature of astronomical interpolation, he says, suppose a series of numbers 0, 1, 3, 6, 10, 15, 21, &c. of which the differences are unequal, but follow a certain law, being in fact in arithmetical progression as 1, 2, 3, 4, 5, 6, &c. so that the second differences are constant, and equal to unity. Now if we take the alternate terms of this series, as for instance 0, 3, 10, 21, &c. the first differences will be 3, 7, 17, &c. and the differences of these differences will be constant, and equal to 4; that is four times greater than before; because in doubling the interval, we have for the first difference the sum of 1 and 2, and in the other the sum of 3 and 4; hence it follows that the second difference increase in the ratio of the differences between 2 and 3, and 1 and 4; the increase, therefore, being equal to three times the first, this second difference will be equal to four times that; and if we took every third number, the second difference would be 9, and so on.

Thus, in general, the second differences increase as the square of the intervals of the numbers; and hence we have the following rule for supplying the intermediate terms of a series of numbers of which the law of their generation is uniform.

For example, let there be four numbers which may represent longitudes, observed at the interval of 12 hours each; and of which the three differences are 78, 223, and 366, so that their second differences will be constant, and equal to 144; according to the following tablet.

Hours	Nos.	1st Diff.	2d Diff.
0	0	78	
12	78	223	144
24	300	366	144
36	666		

Such

INTERPOLATION.
